Preface

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors-in-chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors-in-chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4,000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial co-producers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative—always helpful—than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of select articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April, 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors-in-chief occurred at their respective research centers—the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly two years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash,

Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Włodzimierz Wesołowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors-in-chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser

International Encyclopedia of the Social & Behavioral Sciences ISBN: 0-08-043076-7

Introduction

For several hundred years, encyclopedias have been a respected mode of publication. In them, authors judged to be experts attempt to present the best of learned knowledge and scientific evidence that they have to offer. The original Greek meaning of the word *encyclopedia* is typically translated into English as "general education." In today's language—and using the perspective offered in the master of all modern encyclopedic work—encyclopedias are "self-contained reference works" with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible.

Encyclopedias have a history dating to ancient times. For the contemporary Anglo-American world, the *Encyclopaedia Britannica*, whose first edition appeared in 1768–1771, is the hallmark of a general encyclopedia. In the German language, a similar role was played by the six-volume *Conversations-Lexicon* (1809) that was later transformed into *Der große Brockhaus*. Regarding compendia that are devoted to more limited aspects of knowledge, Western scholars often underscore the significance of the British *Cyclopedia* (1728) by Ephraim Chambers and the French *Encyclopédie* prepared subsequently by Diderot and d'Alembert (1751–1765). In line with its premier standing as a general encyclopedia, the *Encyclopaedia Britannica* contains an excellent entry on the history and nature of encyclopedias. For the present encyclopedia, the entry by Alan Sica (*Encyclopedias, Handbooks, and Dictionaries*) was invited to accomplish a similar feat. In that entry the reader will find much information about the role of encyclopedias and kindred publications in the evolution of the social and behavioral sciences.

Historically, like the evolution of the sciences themselves, the meaning of encyclopedias has changed and will continue to change, especially in light of the transformations in methods of representing scholarly knowledge occasioned by the rise of modern modes of information. Originally, for instance, there was no widely accepted differentiation between encyclopedias, handbooks, or dictionaries. In today's world, each has become a recognizable type in itself.

Encyclopedias are designed to offer comprehensive, well-organized, integrative, interthematic, and intensively cross-referenced presentations in depth. Dictionaries supply definitions of words and concepts without a serious effort at integration and depth. Handbooks, as a rule, identify the current frontiers of knowledge without a special commitment to comprehensiveness and the historical development of knowledge. At the same time, this differentiation among encyclopedias, dictionaries, and handbooks is dynamic and subject to overlap and variation.

When asked to become editors-in-chief of this work, we did not spend much time reading about the history of encyclopedias and their special function in the history of science. We relied instead on our general understanding of the concept of an encyclopedia. As we familiarized ourselves more and more with that concept and its historical evolution, however, our inclinations turned out to resemble closely what encyclopedia scholars have identified as the core of the encyclopedia concept.

In undertaking this enterprise, we assumed that scientific encyclopedias are meant to be comprehensive accounts of a given field with primary emphasis on catholicism and on truth-value of the arguments and the evidence. We also assumed that it is important to locate current knowledge in historical perspective. We wanted to treat this encyclopedia more as a repository of established knowledge than as a visionary attempt to predict the future. Moreover, we conceived of this encyclopedia as a way to highlight efforts at integration and reveal the dynamics of current thinking about a given topic. Therefore both disciplinary differentiation and transdisciplinary integration were in the forefront of our thinking. Finally, we were committed to showing the relevance of the social and behavioral sciences for questions of application and social policy. We thought that the time had come for the social and behavioral sciences to present themselves as contributors to the public good, beyond their role as intellectual partners in science and scholarship.

With these general perspectives in mind, we asked the contributors to prepare entries that were fair, comprehensive, and catholic in approach. While asking them to analyze current trends that seemed to shape future lines of inquiry, we did not suggest that they become speculative prognosticators. Rather, we were striving for:

(a) secure knowledge, realizing that security of knowledge is a dynamic and relative term
(b) knowledge with balance and comprehensiveness

(c) knowledge that is integrative rather than fragmented
(d) knowledge that places the evidence into historical and theoretical context
(e) knowledge that highlights connections between topics and fields
(f) knowledge that combines, where possible, theory and practice.

To convey these aims, we prepared the following statement of "guidelines for authors," reminding them at the same time that these were not a straitjacket, that there could be no single format for all entries, and that different topics and different authors would make for a diversity of types of entries:

To be of maximum educative value to readers, an entry should include the following ingredients:

- A clear *definition* of the concept, idea, topic, area of research, or subdiscipline that constitutes the title of the entry (e.g., the definition of *alienation* or *intelligence*).
- The *intellectual context* of its invention or rise as a problematic concept or area of study in the discipline or disciplines in which it has received attention. In other words, what considerations have made it *important* (e.g., in the case of alienation, the Marxian theory of capitalist organization of technology and work; in the case of intelligence, the institutional contexts such as schools in which psychometric assessment of intelligence evolved).
- *Changes in focus or emphasis* over time, including the names of the most important theorists and researchers in these transitions. This account should give the reader an idea of the *history* of the concept or topic (e.g., the transformation of alienation from a specific, technical term in Marxian theory into a general social-psychological concept important in industrial sociology, industrial psychology, and other subfields; or the enrichment of the concept of psychometric intelligence by methods and processes associated with cognitive and developmental psychology).
- *Emphases in current theory and research*. The author should trace major developments and empirical results, changes of direction of research, falling off of interest, as well as special salience in certain traditions (e.g., alienation in the analysis of the internalization of the labor process), or in certain regions of the world (e.g., alienation in sociology and political science in newly developing countries); or rejection of the concept of intelligence as an index of talent, as well as the differentiation of intelligence into its factual and procedural knowledge parts to reflect the impact of culture and cultural variation.
- *Methodological issues or problems* that are evident in research on the concept, topic, or area of study.
- *Probable future directions of theory and research*, insofar as the author can determine and is confident in predicting them.

Why a New Encyclopedia Now?

In the early 1990s Elsevier Science publishers began to plan an end-of-millennium publication of a completely new encyclopedia of the social sciences. The idea for such a publication had been in the air among some publishers for several years, but none had been ready to make a commitment, in large part because of the enormous investment required to carry out such a project.

Aside from financial questions, there are three sets of justifications for a new encyclopedia. The first is the passage of time. Two other encyclopedias covering similar ranges of subject matter appeared in the twentieth century: *Encyclopedia of the Social Sciences* (Seligman and Johnson, 1930–1935) and *International Encyclopedia of the Social Sciences* (Sills, 1968). If we invoke the logic of "one-encyclopedia-every-one-third-century," a new, beginning-of-century publication seems indicated.

The second justification has to do with quality control of knowledge. New modes of publication such as the Internet—with its tremendous increase in the quantity of publicly available information—are badly in need of better control of the quality of the knowledge produced. Encyclopedias are meant to be methods of quality control, offering some insurance against information that has not achieved a certain level of rational or empirical validity. The primary strategy for achieving good quality in an encyclopedia is a peer-based selection of experts as authors and a peer-review system for submissions.

The third and main motive for a new encyclopedia, however, must be a scientific one. Has there been sufficient growth of knowledge and new directions of research to justify it? On this score neither we nor any of our advisors nor the publishers have ever expressed doubt: the

answer is strong and positive. Early in our thinking about the encyclopedia we put down the following points as justifying a new stocktaking:

- the astonishing growth and specialization of knowledge since the 1960s
- the rapid development of interdisciplinary fields
- the expansion of interest in policy and applications
- the internationalization of research in response to the dynamics of globalism
- the impact of the computer and information revolutions on theory and practice
- the new web of connections between the social and behavioral sciences on the one side and the biological life sciences on the other.

We see no need to alter these assessments at this moment of publication of this encyclopedia. If anything, we are convinced that new developments in information technology require a special effort by the scientific community to make sure that its best knowledge and practice are available to as many segments of society as possible.

Planning for the Encyclopedia

We noted how important the peer-review system is for achieving a high level of quality—quality with regard to the topics to be included, the scientific experts selected as authors, and the evaluation of the text that experts produce. In the following paragraphs, we describe some steps that we took to achieve goals of comprehensiveness and fair coverage, but above all quality control. We begin with the planning phase.

Much of the planning for the new encyclopedia took place around and during three meetings.

- Smelser hosted the first meeting, initiated by Elsevier Science, at the Center for Advanced Study in the Behavioral Sciences, Stanford, California, October 14–15, 1995. The publisher had not yet decided finally whether to publish such an encyclopedia, and the purposes of the meeting were to sound out experienced social and behavioral scientists (mainly American) on the feasibility of the project, and—if it seemed feasible—to think about its organization.
- Some months later, Elsevier committed itself to the project, and, with Smelser's cooperation, organized a second planning meeting, attended mainly by European scholars, at the Swedish Collegium for Advanced Study in the Social Sciences in Uppsala, September 26–27, 1996. The Elsevier organizers also approached Smelser about assuming the editorship-in-chief just before the Uppsala meeting. He accepted this invitation soon after that meeting, and some months later Baltes was persuaded to join as co-editor-in-chief. The reasons for having co-editors were three. First, the scope and magnitude of the project made it nearly impossible for one person to manage it. Second, a team of chief editors could better cover the full spectrum of the behavioral and social sciences. Even though we overlapped in many ways, Baltes's expertise encompassed mainly the behavioral sciences, Smelser's the social sciences. Third, we needed international coverage. Everyone agreed that if the term "international" was to be taken seriously, there had to be co-editors from North America and Europe.
- The third planning meeting was held in Dölln/Berlin, July 16–18, 1997, with Baltes as host. That meeting brought in more advisory scholars from continental Europe and included a larger number of behavioral scientists to elaborate on the coverage of those sciences. Baltes and Smelser had been in continuous contact with one another after Baltes agreed to be co-editor, and after the Dölln meeting we completed the basics of the encyclopedia's organization.

During the later planning activities, Ursula M. Staudinger was a key consultant in helping us set up a data bank that facilitated recruiting international authors and monitoring other aspects of planning such as assuring substantive coverage and tracking the gender distribution of authors. She continued this role in the development of some sections, for example Ethics of Research and Applications.

The Intellectual Architecture of the Encyclopedia

In keeping with convention, this encyclopedia lists its entries in alphabetical order. Such a practice typically obscures any intellectual structure that has been built into the work. Behind the alphabetical ordering, however, lies a complex but definite architecture—the product of many

strategic decisions we made in the planning phases and throughout the development of the encyclopedia. In this section we make explicit these decisions and provide our rationale for them.

Scope of the Encyclopedia. At the second planning meeting, one question dominated the discussion: "Do we want to include the behavioral sciences and, if so, in what ways?" The 1935 and 1968 renditions of the encyclopedia had only "social" in their titles, and among the behavioral sciences only psychology was adequately represented. No final answers were generated at that meeting. When Baltes joined as the second editor-in-chief, we re-confronted the issue and decided on the full inclusion of the behavioral sciences. At the third meeting in Dölln/Berlin, we solidified and elaborated that decision. This meant including "Social and Behavioral" in the title of the encyclopedia. It also meant dividing psychology into three distinct sections—all other disciplines were granted only one—and including a number of behavioral fields bordering on the biological sciences: evolutionary science; genetics, behavior, and society; behavioral and cognitive neuroscience; psychiatry; and health.

The main reasons for these decisions were first, that the subject-matters of the social and behavioral sciences blend into one another; second, that both are driven principally by the norms of scientific inquiry; third, that great advances in knowledge had occurred in some of the biologically based behavioral sciences; and finally, that including both branches in our huge enterprise—bound to be regarded as canonical in some quarters—would counteract what we perceived as an unwelcome drifting apart of the social and the behavioral sciences over the past decades.

Indeed, we believe that a new and proper perspective in the social and behavioral sciences demands more explicit consideration of the biological and cultural "co-construction" of behavior and society than has been true in the past (Baltes and Singer 2001). Over the last decades the relations between the social and biological sciences have suffered from an unproductive measure of defensiveness, hostility, and territoriality—observable in many places but noticeable among social scientists. This has certainly been true with respect to the role of genetic factors in the production of culture and social differentiation. Therefore, we believe firmly that a new Encyclopedia of the Social and Behavioral Sciences must reflect a new and more open view on the interactions and transactions between genetic, brain, behavioral, social, and cultural factors and processes.

Biographical Entries. We may discern two significant modes in the history of presenting scientific knowledge: person-centered and idea-centered. As a general rule, the more developed a field, the more it appears to be guided by representations of concepts and methods rather than individuals. Nevertheless, there are exceptions. We cannot grasp the idea of relativity theory in physics without taking Einstein into account. And what is modern evolutionary theory without Darwin, historical materialism without Marx, or behaviorism without Skinner?

Regarding the role of individuals as producers and organizers of scientific knowledge, we had before us two different models. The 1935 rendition of the encyclopedia, in common with many early encyclopedias, contained many brief biographies of figures in the social sciences—more than 4,000 in its 15 volumes. The editorial board of the 1968 encyclopedia considered this number excessive, and decided on some 600 biographies of "major" figures. They reasoned that if more were included, many would go unread, and that it would be difficult to locate authors for many minor figures. The editors of the 1968 edition decided to include biographies of living persons on grounds that "readers should not be deprived of information about a man because he happened to live a long time" (Sills 1968, p. xxv). Still, the editors did not include anybody who had been born after 1890. Sills reported that one member of the editorial advisory board argued against *any* biographical entries, because "they are out of place in a topically and conceptually oriented reference work" (Sills 1968, p. xxv).

The issue of including biographical entries was debated at the first planning meeting in 1995. At that time, the consensus was that the new encyclopedia should not contain any. The main scientific arguments for eliminating biographies were that the representation of the social and behavioral sciences should be organized around knowledge rather than persons, and that biographical entries tend to be fraught with political and emotional contests around persons to be included and excluded, especially if living scholars are among the biographees. We were also aware of the argument that reviewers of encyclopedias—in part, because of the vastness of the reviewing task—tend to focus their critiques on the biographical section and fall to complaining that one or another of their favorite great minds was not included. And who

would want to set up an entire encyclopedia for such narrow and possibly parochial critical reactions?

The issue of biographies remained dormant for a time, but was re-raised by Baltes when he joined the editorial team. He argued that knowledge in the social and behavioral sciences cannot be grasped without appreciating the biographies of its founding figures. Furthermore, he argued that the mental representation of the learning student is helped by reference to personages and their clearly articulated views—in other words, we think not only in the abstract, but very much of distinctive people. Why should we make it more difficult than necessary to understand the social and behavioral sciences? In the end we compromised. There would be 150 biographical entries of greater length than those in the earlier encyclopedias. To assure historical distance, these would be limited to deceased scientists and scholars.

Restricting the number in this way created a new problem of inclusion: how to decide on the very small number of really towering figures in each discipline and tradition of thought? It was easy to identify Darwin, Boas, Malinowski, Freud, Wundt, James, Skinner, Marx, Durkheim, Weber, Marshall, Fischer, and Pearson, but where to go from there? To develop satisfactory answers to these questions, we appointed a section editor for biographies, Karl Ulrich Mayer, who together with us sought and relied on multiple sources of advice before coming to final decisions. We are aware of the residue of arbitrariness in these decisions, and acknowledge that any other group of editors would have produced an overlapping but different list from ours.

Because of the special significance of the biographies and likely conflict over their selection, we offer a brief account of how the selection process was carried out. We first had to select a kind of person who could be entrusted with the responsibility—a person with a broad and historical knowledge base as well as extensive contact across disciplines. We were also concerned about fairness and openness toward all disciplines. In Mayer we found a person who invested himself into generating a list of a maximum of 150 biographees. We are especially grateful for his special skills, knowledge, and practical vision in accomplishing this task.

We asked Mayer to consider the following criteria: 7–10 persons per discipline; only deceased people should be included; there should be evidence for intellectual influence into the present; people with visibility and impact beyond one discipline should be favored. We also suggested that the biographies should focus on the history of ideas more than on chronological accounts of their work. Finally, we asked that an effort be made to include figures who remain relevant for contemporary social and behavioral science.

Mayer carried out several lines of advice and consultation and bibliometric analyses:

- Consulting a number of other handbooks and encyclopedias and making informal inquires of as many colleagues as feasible.
- Asking all section editors to name and rank the five or ten most important names in the history of their disciplines or research traditions. Subsequently the biography section editor discussed these names, along with other possibilities, with all the other section editors.
- Submitting the consolidated list of 150 names arising from these processes to 24 additional expert consultants for review.
- Running citation checks in publications between 1973 and 1996 on all the tentatively selected and some nonselected biographees. A total of 350 individuals were considered in this citation analysis. In addition, the check attempted to determine whether there were high-citation individuals not included in the original pool of candidates.

The authors of biographic entries were given the following guidelines: to include: "(a) the briefest sketch of the major dates and events in the life of the biographee; (b) the major contours of the substantive contribution to knowledge of each biographee, including the intellectual contexts within which he or she worked; (c) most important, to assess the importance and relevance of the biographee's work for the contemporary social and behavioral sciences."

Table 1 (prepared by Mayer) offers an alphabetic listing of those 147 who were ultimately included as well as the disciplines that, according to the section editors' and additional reviewers' judgments, were influenced by each biographee. We call attention to the absence of many figures in the history of philosophy who might legitimately have a claim to be considered as precursors to the social and behavioral sciences. We leaned toward including those philosophers—e.g., Hume, Kant, and Rousseau—whose work coincided with the eighteenth-century beginnings of these sciences. We did make a few exceptions to this rule—Aristotle,

Table 1. *Biographees*

Macchiavelli, Bernoulli, Hobbes, Locke, Montesquieu—because of their powerful and enduring influence.

One person who is missing from Table 1 (because of author failure) is the French historian Fernand Braudel. In addition, we asked Mayer to include "near misses" in the table—the people who, under the procedures chosen, came closest to making the final list. Many of these are worthy, but could not be included. Some of these names may be included in subsequent on-line releases of the entire encyclopedia. We acknowledge the risk of peer bias and arbitrariness of judgment, but we can assure the reader that our editorial efforts were sincere and based on a high threshold for inclusion and extensive peer judgment.

We faced new decisions about biographees right up to the deadline for inclusion of entries into the encyclopedia (March 1, 2001). Two men died shortly before that date: the philosopher Willard van Orman Quine and the economist-psychologist Herbert Simon (who was able to prepare two entries for the encyclopedia before his death). Several section editors—and we ourselves—believed that they merited inclusion. However, considering the impending deadline, we concluded with regret that it was not possible to obtain the kind of biographies that Quine and Simon deserved. In our view, then, Braudel, Quine, and Simon should be on the list of biographees, but, for the reasons stated, are not.

Disciplines or Other Ways to Organize? In the end, of course, the encyclopedia was to be organized alphabetically. From which sources of knowledge would these entries spring? The first great European encyclopedias proceeded from a classification of the structure of knowledge based on *a priori* taxonomy, as developed for instance by Francis Bacon or Matthias Martini.

We judged the modern social and behavioral sciences to be less tied to an *a priori* conceptual order. The evolution of communities of science responded also to other questions, interests in particular problems, social relevance, as well as the priorities of funders of scientific research (see entries: *National Traditions in the Social Sciences*; *Science Funding*, *Asia*; *Science Funding*: *Europe*; *Science Funding*: *United States*; and several regional entries on *Infrastructure, Social/Behavioral Research*). As many entries in this encyclopedia demonstrate, the history of disciplines, research traditions, and learned societies is a dynamic, evolving, and multi-sided process (e.g., see entries *Paradigms in the Social Sciences*; *Disciplines*, *History of*, *in the Social Sciences*; *Intellectual Transfer in the Social Sciences*; *Universities*, *in the History of the Social Sciences*; *Anthropology*, *History of*; *Demography*, *History of*; *Developmental Sciences*, *History of*; *Economics*, *History of*; *Psychiatry*, *History of*; *Psychology*, *Overview*; *Sociology*, *History of*). Although we believed from the beginning that we needed a more or less systematic selection and classification of the behavioral and social sciences under which to select section editors and organize entries, we also realized that the actual practice of social and behavioral science demanded that we employ other criteria as well. To recognize this general point, however, did not carry us very far toward devising specific classificatory strategies.

One model was available: the 1968 *International Encyclopedia of the Social Sciences*. Its intellectual architecture was based mainly on disciplines, with some accommodation to other areas that were salient at that time. There were seven associate editors, one each for political science, anthropology, statistics, psychology, economics, sociology, and social thought, along with five special editors for biographies, applied psychology, economic development, experimental psychology, and econometrics. Inspection of that list, however, immediately revealed its inadequacy for a contemporary encyclopedic effort, given the vast array of new specialties within disciplines, the hybridization of knowledge, the permeability of disciplinary boundaries, and the mountain of interdisciplinary work in the last third of the twentieth century (Centre for Educational Research and Innovation 1972, Dogan and Pahre 1990, Klein 1990, Levine 1994).

The principal question was: to what degree should we rely on disciplines as bases for organizing entries? We knew that a strong case could be made for the disciplinary principle and an equally strong case could be made against it. The disciplines remain the primary basis for organizing departments and faculties in universities, as well as membership in noted academies. Disciplines have displayed remarkable institutional staying power. Future professionals receive their training in disciplinary settings and call themselves by disciplinary names. They find employment in discipline-based departments and faculties, and if they have not been certified in discipline-based training programs, they are often not employable. Together the training and employment systems form discrete labor markets, more or less sealed off from one another. The disciplinary principle is also mirrored in the organization of

professional associations, in their learned journals, and in publishers' academic lists. Governmental and foundation donors organize their giving in part under discipline-named programs and program officers. Honorary and fellowship societies also subdivide their activities along disciplinary lines. In a word, the disciplines persist as the life-blood of many vested interests in the social and behavioral sciences.

At the same time, much important work done in the social and behavioral sciences cannot be subsumed conveniently under disciplinary headings. Many intellectual, social, and personal forces draw scientists outside their disciplinary boundaries. A decade ago Smelser co-chaired a national committee on basic research in these sciences for the National Research Council. Its charge was to identify leading edges of research in the relevant sciences for the coming decade. After spirited debate, that committee decided *not* to use the disciplines as organizing principles, but, rather, to shape its report around some 30 topical areas of active research and significant promise (for example, memory, crime and violence, markets, modernization), most of which were interdisciplinary (Gerstein et al. 1988).

Given these complexities and uncertainties, it soon became apparent that we had to carve some creative middle position between the two alternatives. We wanted to reflect the organizing conceptual bases of the social and behavioral sciences, but we wanted to be sensitive to practices of sciences that are guided by topical, nondisciplinary, cross-disciplinary, transdisciplinary, and multidisciplinary marriages. This dual perspective on the organization of the encyclopedia developed as we progressed, and we now present an analytic recapitulation of how we arrived at the 39 sections that we used to recruit section editors and develop plans for entries.

The final result is presented in Table 2, which lists both the section titles and their editors, who in consultation with us were primarily responsible for identifying the entries specific to their sections. The table also gives the approximate number of entries allocated to each section—approximate because many entries had multiple allocations. Table 2 is not the table of contents of this encyclopedia, which is alphabetical, but the conceptual structure from which the vast majority of entries were derived.

We made some progress on conceptual organization at the first advisory meeting in 1996. We decided that some sections of the encyclopedia should be organized around disciplines (though we stopped short of identifying a definitive list), but there should be a supplementary list of sections as well. There should be, we decided, a number of "Social Science and . . ." sections, with the "ands" being areas such as law, education, health, communication, and public policy. This "and" principle took into account the fact that single disciplines do not encompass these areas, but all of them contain a great deal of social and behavioral science analysis. It was our way of recognizing the incompleteness and imperfections of the disciplines as comprehensive bases for organizing entries.

This first approximation created two further questions that were to preoccupy us. Which disciplines to include? What should be the bases *other* than disciplines for representing social and behavioral science work?

As for the disciplines, we had no problems about including anthropology, economics, political science, psychology, and sociology—recognized widely as "mainstream." But this set did not seem enough. For one thing, psychology presented an asymmetrical case—much larger by all measures than the others. In the end we subdivided psychology into three: Clinical and Applied Psychology; Cognitive Psychology and Cognitive Science; and Developmental, Social, Personality, and Motivational Psychology. This division represents areas of research acknowledged by most psychologists. However, other fields, such as Cognitive and Behavioral Neuroscience, have a strong affiliation with the discipline of psychology as well.

We then asked what other areas to include, either as additional disciplines or under some other heading. At this point we entered an arena of uncertainty, because some areas we wanted to include are not usually labeled as social or behavioral sciences, and many of them include other kinds of research. In the end we decided to err on the side of inclusiveness in considering disciplines. If a strong and reasonable (even if an incomplete) case could be made for considering an area to be a social or behavioral science discipline, we included it. (We were also aware that, from a political point of view, many scientists and scholars prefer their areas of work to be labeled as a discipline rather than something else.)

With this rationale in mind, we listed eight additional disciplines on the basis of their conceptual affinity to the social and behavioral sciences and the amount of social and behavioral science research carried on in them. Here, too, we acknowledge that our decisions reflect some arbitrariness, and that other scholars would create overlapping but different lists.

Table 2. *Sections, Section Editors, and Number of Articles (Original Targets in Parentheses)*

Overarching topics	Disciplines	Intersecting fields	Applications

	Clinical and Applied Psychology 139 (150) T. Wilson, USA	**Area and International Studies** 90 (137) M. Byrne McDonnell & C. Calhoun, USA	
	Cognitive Psychology and Cognitive Science 161 (184) W. Kintsch, USA		
	Developmental, Social, Personality, and Motivational Psychology 173 (174) N. Eisenberg, USA		
	Sociology 197 (204) R. Boudon, France		

These are the eight:

- Archaeology, most frequently considered a part of anthropology, but having an independent, coherent status
- Demography, most frequently organized as part of sociology, economics, and anthropology departments, but also possessing a kind of disciplinary integrity
- Education, a great deal of which involves social and behavioral scientific study
- Geography, research in a major part of which is of a social-science character
- History, sometimes classified in the humanities but as often in the social sciences, and clearly contributing centrally to knowledge in the social and behavioral sciences
- Law, whose subject-matter overlaps significantly with that of several of the social and behavioral sciences, with important though different linkages in Europe and North America
- Linguistics, spanning both the humanities and the social and behavioral sciences, but maintaining close links with the latter in cognitive science, psycholinguistics, sociolinguistics, and anthropology
- Philosophy, a subfield of which is the philosophy of the social sciences and whose work in the philosophy of mind, logic, metaphysics, epistemology, and ethics also pervades the social and behavioral sciences.

Even more difficult issues arose in connection with what should be in the "social/behavioral science and . . ." category. It became clear that not everything could be subsumed under the "and" rubric, because relations between the social and behavioral science disciplines and "other" areas are very diverse. After consultation with advisors and conversations between ourselves, we worked out the following ways to capture the complexity of work at the edges of the social and behavioral sciences.

Some subjects are relevant to all the social and behavioral sciences. We chose the term "overarching topics" to describe these subjects and identified four headings:

- Institutions and Infrastructure of the Social and Behavioral Sciences: universities, research academies, government structures, funding agencies, databases, etc.
- History of the Social and Behavioral Sciences
- Ethics of Research and Applications
- Biographies.

Various methodologies, methods, and research techniques also arch over many of the social and behavioral sciences. We chose three categories to capture them:

- Statistics, which infuses most of the social and behavioral sciences
- Mathematics and Computer Science, which does the same, but more selectively
- Logic of Inquiry and Research Design, including various nonstatistical methods of analysis (for example, comparative analysis, experimental methods, ethnography) and the whole range of methodological issues associated with the design, execution, and assessment of empirical research.

A third category evokes areas of research in which some work is in the social and behavioral sciences, but which also include other kinds of work. We called these "intersecting fields." We considered many candidates for this list, and after much consultation and deliberation we chose the following as the most apt:

- Evolutionary Sciences, which encompasses inquiry in psychology, anthropology, and sociology, as well as the geological and biological sciences
- Genetics, Behavior, and Society, a category that also bridges the biological and the behavioral and social sciences
- Behavioral and Cognitive Neuroscience, for which the same can be said, although it has equally strong ties to Psychology
- Psychiatry, which is partly biological and partly behavioral and social in orientation, but which also includes an applied therapeutic aspect
- Health, which includes mainly the medical and public health sciences, but in which much behavioral and social science work deals with conditions contributing to health and illness, health delivery systems, and public policy
- Gender Studies, which spread across most of the humanities and the social and behavioral sciences, as well as the biological sciences

- Religious Studies, which have theological and philosophical aspects but also include much social and behavioral science research
- Expressive Forms, many aspects of which are covered by research in the humanities, but also include the anthropology, psychology, and sociology of art, literature, and other cultural productions
- Environmental/Ecological Sciences, with links between the social and behavioral sciences and to the physical and biological sciences and policy studies
- Science and Technology Studies, which encompass the physical sciences, engineering, history, and the social and behavioral sciences
- Area and International Studies, some aspects of which are subsumed by the behavioral and social sciences, but which have an independent status as well.

We acknowledge some arbitrariness in calling one area a "discipline" and another an "intersecting field." Geography, for example, might qualify for either list, as might education, linguistics, and the behavioral and cognitive neurosciences. In the end we had to settle for ambiguity, because there is no unequivocally correct solution. Our ultimate justification was that our judgments were not unreasonable and that what mattered most was to guarantee coverage of all the relevant areas.

To complete the process of compilation, we identified several fields that also intersect with the social and behavioral sciences but are more aptly described as "applications" of knowledge to discrete problems:

- Organizational and Management Studies
- Media Studies and Commercial Applications
- Urban Studies and Planning
- Public Policy.

These 37 categories—representing overarching issues, methods, disciplines, intersecting fields, and applications—constitute our best effort to maximize coverage and to provide a basis for selecting section editors. Later, we decided to add two more sections to make the encyclopedia more timely and complete:

- Modern Cultural Concerns, intended to cover topics of contemporary preoccupation and debate—for example, affirmative action, transnationality, and multiculturalism; on some of these we envisioned two separate entries, one pro and one con; we believed such a section would capture some of the major concerns of civilization at the end of the second millennium.
- Integrative Issues and Concepts, meant to encompass topics, questions and gaps that remained after we divided up the social and behavioral sciences world the way we did.

We note that the number of categories (39) generated for the new encyclopedia is much larger than the number (12) for the 1968 edition. It is also nearly twice the number envisioned by the publishers and the scholars present at the first advisory meeting in 1995. We are unashamed of this expansion, acknowledging as it does the additional input provided by our extensive consultations as well as the accumulation, spread, and increased diversification of knowledge in the past 35 years.

Despite our efforts to maximize coverage, additional topics remained for which an argument for a distinct section could be made, but which we did not include as such. One example is "race and ethnic studies," which some might say is as important as "gender studies." Another suggestion is "time," a plausible way of grouping some research, but one we believe is not sufficiently precise analytically. Other categories having similar claims are "human development" and "gerontology" or "information science and "information technology." In the end we had to set an upper limit on number of sections, and in the case of omissions we made special efforts to assure adequate coverage within the designated categories.

Assembling Section Editors and Advisors. Even before Baltes agreed to be co-editor-in-chief, it had been arranged that he would spend the academic year 1997–98 as a residential Fellow of the Center for Advanced Study in the Behavioral Sciences. This coincidence proved to be a blessing. It was essential that we interact continuously during that year, because it was the period for finally consolidating the intellectual structure of the encyclopedia and designating and recruiting academic leaders.

We made each of the 39 categories a "section" of the encyclopedia. In the fall and winter of

1997 we identified, sought, persuaded, and recruited one person to be responsible for entries in each section (we included co-editors when a section editor requested one or when a section needed broader topical or international coverage). Knowing that these appointments were crucial to the coverage and quality of the encyclopedia, we were thorough in our search, exploiting our networks of advice in the social and behavioral sciences, and creating such networks when we did not already have them. A few additional section co-editors were added later, as evolving needs seemed to dictate.

During the same period we recruited 86 scholars to constitute an International Advisory Board for the encyclopedia. We wanted this group to be composed of the most distinguished senior social and behavioral scientists around the world. To identify them we sought advice through the same networks on which we relied to seek out section editors, and we also sought the opinions of section editors themselves as we appointed them. We called on individual members of the advisory board from time to time, and asked all of them to become involved in reviewing and making suggestions for all the entry lists. On a few occasions the advisors offered unsolicited advice, to which we also listened and responded with care.

Weighting the Sections and Entries. We realized that not every section merited the same number of entries. We devised a scheme to assign 200 entries to most of the disciplines and some of the intersecting fields, 150 or 100 to some other sections, and 50 entries to some of the smaller areas such as Religious Studies and Expressive Forms. In doing this we were simultaneously making qualitative judgments about the categories—once again with a degree of arbitrariness. We never thought that these numbers were fixed, they were meant to be approximations.

As a second weighting strategy we permitted section editors to vary the length of their entries between a minimum of 2,000 and a maximum of 5,000 words. We left these decisions mainly to section editors on grounds that they were the best judges of topical priority in their own areas, though we consulted with them from time to time. This flexibility produced some changes in the targeted number of entries per section, depending on section editors' different patterns of word-allocation. Also, inability to locate authors for some topics and author failures meant that the originally targeted numbers were seldom reached.

We employed one final method of weighting. We asked each section editor to classify every one of his or her entries as "core" or "noncore." The former were entries that, in the section editors' estimation, would create a recognizable gap in coverage if unwritten. The second were entries deemed important enough to merit original inclusion in the entry list, but less central to the discipline or field than the core items. As time went on, and especially when we reached the final stages of commissioning, we pressed section editors to give highest priority to signing and securing core entries.

Overlap and Redundancy. In pursuing all these classificatory and weighting strategies, our overriding aim was to capture the "state of the art" in the social and behavioral sciences with all their expanse and complexity. In the end—after several years of pondering, consulting, weighing, rejecting, including, reformulating, and coming to final decisions—we emerged reasonably satisfied that we had woven a seine that would catch almost all the fish swimming in the waters of the social and behavioral sciences.

In creating this structure, however, we discovered that other problems emerged as a result of our efforts to classify and select. Because our system captured so much of social and behavioral science work, we found we had captured too much. We had to contend continuously with overlap among the 39 sections and among the thousands of entries that filled the sections' lists.

Overlap is a problem because the history of development in the social and behavioral science disciplines and elsewhere has been uncontrolled. Any scientist in any discipline can, by choice, take up a topic or research theme, and many scholars from different disciplines take up the same topics or themes. This freedom generates both hybridization and overlapping of knowledge. Gender studies is a case in point. It infuses at least a dozen separate disciplines and other lines of inquiry. Race and ethnic relations is another illustration, as are legal studies, medical studies, urban studies, and gerontology.

We therefore faced many problems of potential overlap in the encyclopedia. To stay with the gender studies illustration, if we had asked all section editors simply to cover their fields, we would have found some identical and even more overlapping entries on gender in the sections on evolutionary science, genetics, anthropology, economics, geography, history, law, political

science, psychology, sociology, and religious studies, to say nothing of the section on gender studies itself.

In the course of our work the problem of overlap became as nettlesome as the problem of comprehensiveness of coverage. We attacked it in a number of ways:

(a) At the "master meeting" of virtually all the section editors April 2–4, 1998, at the Center for Advanced Study in the Behavioral Sciences, we reviewed all aspects of the architecture of the encyclopedia in collective meetings. In addition, much time and energy was spent in meetings of "clusters" of section editors in related fields and in one-on-one meetings among the section editors. The smaller meetings were devoted almost entirely to identifying potentially overlapping entries among different section editors as a way of minimizing redundancy. The scene was somewhat frantic, resembling a stock exchange, with dozens of "you-take-this-I'll-take-that" transactions transpiring simultaneously. Almost all section editors approached the process in a remarkably nonterritorial way, being as willing to give up entries as to take responsibility for them. Their cooperative spirit was facilitated by the knowledge that, in the end, the boundaries among sections would disappear into the alphabetical listing, and that readers would have no basis of knowing, except in a general way, which section editor was responsible for a given entry. The main concerns in these horse-trading meetings were to assure coverage and minimize overlap, but also to increase quality control by finding the best match between the interests and abilities of section editors and entries.

(b) We sent out lists of entries for each section to every entry-author, requesting them all to be aware of overlap and, if possible, to contact other authors and coordinate their entries.

(c) We asked section editors to be on the lookout for overlap within sections in assigning entries, in reading abstracts of entries (submitted by authors within a month after contract-signing), and in reviewing and approving final manuscripts submitted by their authors.

(d) As co-editors-in-chief we gave an overview reading to abstracts and final manuscripts. This was a way of reducing overlap among sections, which individual section editors, with access to only their own section entries, could not identify adequately.

(e) The editorial staff of Elsevier, which was responsible for the copy-editing phase for all manuscripts, was asked to be sensitive to repetition and overlapping during the copy-editing process.

(f) As co-editors-in-chief, we joined the Elsevier editorial staff in reviewing the titles of all entries in order to minimize overlap and ensure that the titling would maximize accessibility and facilitate searching by readers of the encyclopedia.

Minimizing overlap of content, however, was not enough. We also strove to guide readers to related entries by an elaborate system of cross-referencing entries to one another. We asked authors and section editors to enter their own suggestions for cross-referencing within sections at the entry-approval and proofreading stages.

As editors-in-chief we are in charge of supplying cross-references *across* sections.

Finally, it should be added that an inevitable residue of overlapping remains, despite all our efforts.

Author Recruitment. We kept a running account of the acceptance rate of authors asked to contribute. Our statistics on this topic are not perfect, because they are incomplete and because there were occasional changes in topics that the invited authors covered after consulting with the editors.

Despite these shortcomings, we offer the following two approximate data. First, the percentage of acceptances in the initial round of invitations was slightly more than 60%, with substantial variation among sections. This rate persisted in the next round of invitations. Second, nearly 90% of the authors who agreed to contribute wrote acceptable entries in time to be included in the printed version of this work. This means that the encyclopedia covers all but about 10% of the entries that we originally envisioned.

Quality Control. We made scientific and scholarly quality our primary and overriding concern throughout. There were two levels of quality control, the first resting with the section editors, the second with the editors-in-chief.

The main mechanisms for assuring quality, of course, were to select the best section editors we could, and to have the section editors create the best entry lists and recruit the best authors they could. To facilitate the latter, we reviewed the entry lists and authors ourselves and circulated the lists among selected members of our International Advisory Board and independent experts, asking for emendations.

Beyond these general guarantees, we asked section editors to review both abstracts and entry manuscripts, and to return them to authors for revisions when necessary. All manuscripts approved by section editors were then sent to the editors-in-chief for final review and approval.

We mention another mechanism of quality control if for no other reason than that it commanded so much of our attention. Early in the planning and recruitment process the editors-in-chief established a "one-author-per-entry" policy. Our reasoning was simple: we wanted each author to assume responsibility for his or her entry, and we wanted to prevent authors from agreeing to contribute but then assigning the work to an assistant and signing the entry as co-author. We may have been too cynical, but we were familiar enough with the practice to want to discourage it. As the signings began, however, we found that many potential authors wanted co-authors, some so strongly that they indicated they would not contribute if they could not have them. Their demands raised yet another issue of quality control—losing authors we wanted—and threatened to overwhelm us with requests for exceptions. In the end we eased the policy somewhat, permitting co-authors if both were recognized scholars or had a history of collaborating with one another. This policy proved satisfactory, but we continued to receive queries from section editors on the issue of co-authorship. We granted occasional exceptions when we found that authors, through lack of understanding of the policy, had invited co-authors without prior permission.

The ultimate level of quality control rested with us, the editors-in-chief. We reviewed all entries after the section editors cleared them. Both of us took a careful look at every manuscript ourselves before finally approving it. We read most of them in full. In addition, we used a variety of expert colleagues as readers. Baltes, for instance, had seven colleagues representing neuropsychology, psychiatry, psychology, education, cognitive science, linguistics, and law, who as a group read about 1,300 manuscripts and offered valuable suggestions for improvement. Smelser asked for occasional advice from others, and also employed an editorial assistant to go over all manuscripts for general readability. Together we asked section editors and authors for revisions of about 10% of the entries. This number varied considerably by sections. Elsevier assumed responsiblity for translating some articles into English and for copy-editing all manuscripts before production.

In one final and important facet of quality control, we recruited Dr. med. Julia Delius as scientific editorial assistant in Baltes's office in Berlin. She monitored the entire editorial process and reviewed—especially for Baltes—the formal aspects of the submitted entries. As her experience developed, she became a vital person in transmitting readers' comments to section editors and authors, later also assisting with cross-referencing and proof-reading. Her service was exceptional.

Representativeness of Authors. What about authors and their origins? Along with comprehensiveness, quality, and orderliness, we aspired to international and gender representativeness of authors in developing the encyclopedia. Of the four criteria, the last proved the most elusive. We were aware that research in many of the social and behavioral sciences is concentrated in North America, and if North America is combined with Western Europe, the pattern is one of outright dominance. We did not want this dominance to overwhelm the encyclopedia. We wanted representation, however modest in some cases, from other regions of the world. We were also aware that biases along gender and age lines are likely to work their way into any encyclopedic effort, unless active steps are taken to counteract them.

From the beginning the editors-in-chief were especially concerned with representativeness with respect to nation/region and gender. We dealt with these issues in three ways:

- We made efforts to assure that European scholars and women were represented among the section editors. In selecting editors, however, we confess that we found it extremely difficult to locate satisfactory candidates in regions outside North America and Europe, largely because the social and behavioral sciences are less developed in these areas and because many scholars there are less acquainted with general developments in their fields.
- We made similar efforts to assure representativeness among authors. At a certain moment, just after the section editors had submitted their semi-final lists of entries, along with two alternative authors for each entry, we went over every entry list and communicated to all authors about the regional and gender balance of their lists. In some cases we suggested finding alternative authors, and in others we suggested reversing first and second choices to achieve better balance, if quality would not be sacrificed. This process was not restricted to the initial phase of author selection. We strove throughout the writing process to increase the number of non-North American authors. Whenever a new entry

was added or we noticed that an entry was not yet assigned to an author, we attempted to strengthen international as well as gender representation. These interventions produced significant results in the relevant proportions.

- In reviewing regional balance, we sometimes noticed cases of underrepresentation of certain regions and countries and waged periodic campaigns with section editors to intensify their searching. We supplemented their efforts with our own inquiries. For example, we wrote to a large number of presidents of Eastern European academies to enlist their support in identifying candidates for authorship.

In reporting these efforts we acknowledge that there is no fixed and correct formula for representativeness and that no matter what is done, more could always be done. Nevertheless, we want to report to readers what we undertook.

Table 3 provides a summary of first authors by country and gender. About 58% of the authors are from North America, 35% from Europe, and 7% from other countries. Authors from 51 countries are represented; of these, however, 15 provided only one author. As to gender composition, 21% of the authors are women. We will not comment on the numbers we achieved, though we know that others will. In sharing the statistics with some colleagues, we received both applause and criticism, depending on the perspectives and standards of those who read them. We daresay that this will be the case generally.

Some Concluding Thoughts on Encyclopedias

As editors-in-chief thinking on this enormous enterprise at the moment of its birth, we offer of few reflections. We have invested both commitment and perspiration in its production, so we naturally hope that it will have as much impact and age as gracefully as its two forerunners,

Table 3. *Geographical Distribution of First Authors* (*Total 3842*)
Male: 3034 (79%), Female: 808 (21%)

10 Authors and More		Less than 10 Authors	
USA	2061	South Africa	9
Germany	431	Hungary	8

Note. Countries reflect first authors' affiliations and not their nationalities.

published in 1931–35 and 1968. Both of these captured and reflected well the scientific accomplishments of their times, and many contributions to their pages endure to this day. We hope that the editors of the next encyclopedia—sometime into the twenty-first century—will be able to say the same of ours.

In saying this, however, we must call attention to two evident, changing—and historically unique—contexts in which these volumes appear. The first is the remarkable character of the encyclopedia "industry" at the present time. In recent decades the number of new encyclopedias coming on the market has been increasing at a galloping rate, one that, moreover, shows no signs of slowing. We have no way of making an accurate count, but we discovered that Amazon.com lists nearly 6,000 encyclopedias for purchase, and the number reaches almost 10,000 for Barnesandnoble.com. We can gaze into the future and imagine the appearance of an encyclopedia of encyclopedias!

In some respects this explosion reflects the reality of market opportunities for publishers. More important, however, it expresses the evident impulse to consolidate knowledge that is growing at increasing rates in magnitude, diversity, specialization, and fragmentation.

Despite this integrative thrust, most of the new encyclopedias are themselves quite specialized, covering only delineated subparts of disciplines and topical areas of inquiry. Elsevier Science itself, for instance, has published multivolume encyclopedias on clinical psychology (one subfield among many in psychology) and higher education (a specialty within the study of education). To underscore this point further, we report discovering such unexpected and unlikely titles as the *Encyclopedia of Canadian Music, Encyclopedia of Celts, Panic Encyclopedia,* and *Alien Encyclopedia*. Handbooks also show a tendency to cover more limited ranges of knowledge.

We believe that we have marched against these trends. These volumes represent our continuous effort to assemble the whole range of knowledge—vast and complex as it is—of the social and behavioral sciences in one place. We hope to raise the consciousness and expand the knowledge of our readers, and—more important—to encourage them to link their work productively with that of others as the research enterprise of our sciences moves into the future.

The second changing context has to do with the current state of scientific knowledge and information technology. We express the wish for durability, but at the same time we wonder whether modern encyclopedias will be able to endure on the shelves in unaltered form. The dynamics of knowledge in the social and behavioral sciences are now radically telescoped, and will become more so. Research in these sciences is exploding, as is the knowledge it yields. Moreover, we live in a world of interdisciplinarity in which different lines of work mate and breed incessantly. We note especially but not exclusively the ferment at the boundaries between the biological and the behavioral and social sciences.

The implication of this dynamism is that it becomes increasingly mandatory for encyclopedias to be more open to revision and enrichment. We therefore welcome the decision of the publisher to produce an Internet version of this encyclopedia. We do not suggest that technology is the primary reason for reducing the half-life of encyclopedia knowledge, but we do know that technology will permit the scientific community to improve the scope, depth, quality, and timeliness of that knowledge. It will do so by allowing us to complete entries that were envisioned but not received, to fill in the gaps that we and others will inevitably notice, and above all to keep abreast of new knowledge and new applications as they materialize. The surest sign of success of our work may lie in its capacity to adapt. If this encyclopedia can be at the center of this process, we would be delighted.

Editors-in-Chief

Neil J. Smelser, *Center for Advanced Study in the Behavioral Sciences, Stanford, CA, USA*

Neil J. Smelser was, until 2001, director of the Center for Advanced Study in the Behavioral Sciences, Stanford, California. In 1994 he retired as University Professor of Sociology at the University of California, Berkeley, after 35 years of service in that university. His education includes B.A. and Ph.D. degrees from Harvard University, a B.A. from Oxford University, and graduation from the San Francisco Psychoanalytic Institute. His research interests are sociological theory, social change, economic sociology, collective behavior and social movements, sociology of education and psychoanalysis. He has been editor of the *American Sociological Review*. He is a member of the National Academy of Sciences, the American Philosophical Society, and the American Academy of Arts and Sciences. He has also served as vice president of the International Sociological Association (1990–94) and president of the American Sociological Association.

Paul B. Baltes, *Max Planck Institute for Human Development, Berlin, Germany*

Paul B. Baltes, a developmental and cognitive psychologist, is director of the Center for Lifespan Psychology at the Max Planck Institute for Human Development, Berlin, Germany. In addition to psychological-developmental work (with children, adolescents, adults, and the aged) on topics such as intelligence, memory, and personality, Baltes has pursued more broadly based scholarship in collaboration with researchers from other disciplines. Examples range from research on lifespan human development to the interdisciplinary study of human aging, the influence of historical-societal change on modern ontogeny, and the study of wisdom.

After receiving his doctorate in psychology (with minors in physiology and psychopathology) at the University of Saarbrücken in 1967, Baltes spent the first decade of his professional career in the United States before returning to Germany as a senior fellow of the Max Planck Society and institute director. Baltes has received many honors, among them the International Psychology Award of the American Psychological Association, The Aris Award of the European Societies of Prefessional Psychology, the German Psychology Award, honorary doctorates, and election to several academies (e.g., the Royal Swedish Academy of Sciences, the American Academy of Arts and Sciences, the Academia Europaea, at the German Academy of Scientists, Leopoldina. From 1996 until 2000, he chaired the Board of Directors of the USA Social Science Research Council.

Acknowledgments

Amin A 'Globalization: Geographical Aspects'
The author is very grateful to Mike Crang and Gordon MacLeod for their insightful comments on an earlier draft.

Baldessarini R J, Tondo L 'Bipolar Disorder (Including Hypomania and Mania)'
Supported, in part, by USPHS (NIH) Grant MH-47370, an award from the Bruce J. Anderson Foundation, and by the McLean Hospital Private Donors Neuropharmacology Research Fund and a Stanley Foundation International Mood Disorders Center award.

Banks J A 'Multicultural Education'
The author thanks these colleagues for their helpful comments on an earlier draft of this article: David Gillborn, Institute of Education, University of London; Gerd R. Hoff, Freie Universität Berlin; Kogila Adam Moodley, University of British Columbia; and Gary Partington, Edith Cowan University, Australia.

Basu A, Das Gupta M 'Family Systems and the Preferred Sex of Children'
The authors would like to thank Fred Arnold, Daniel Goodkind, Carolyn Makinson, and Ingrid Waldron for helpful suggestions. All errors and omissions remain the authors' responsibility.

Benedek D M, Ursano R J 'Military and Disaster Psychiatry'
The authors acknowledge the assistance of Harry C. Holloway, Ann E. Norwood, Thomas A. Grieger, Charles C. Engel, and Timothy J. Lacy in the preparation of this article.

Bijker W E 'Technology, Social Construction of'
The author wishes to thank Karin Bijsterveld, Anique Hommels, Sheila Jasanoff, and Trevor Pinch for their helpful comments.

Brainard D H 'Color Vision Theory'
The author would like to thank A. Poirson for useful discussions and contributions to an early version of the manuscript and P. Delahunt for providing Fig. 1.

Brinton R D, Nilsen J T 'Sex Hormones and their Brain Receptors'
This work was supported by grants from the National Institutes of Aging (PO1 AG1475: Project 2), and the Norris Foundation to RDB.

Bukowski W M, Rubin K H, Parker J G 'Social Competence: Childhood and Adolescence'
Work on this entry was supported by grants from the Social Sciences and Humanities Research Council of Canada and a grant from the Fonds pour la formation des chercheurs et pour l'aide à la recherche.

Carley K M 'Artificial Social Agents'
This work was supported in part by the Office of Naval Research ONR N00014-97-1-0037, ONR 1681-1-1001944 and by the National Science Foundation NSF IRI9633 662.

The author's work is currently supported by the National Cancer Institute (CA64710 and CA78995).

Casella G, Berger R L 'Estimation: Point and Interval'
Supported by National Science Foundation grant DMS-9971586.

Coburn D 'Medical Profession, The'
The author greatly appreciates the insightful comments of Lesley Biggs.

Corina D P 'Sign Language: Psychological and Neural Aspects'
This work was supported by Grant R29 DC03099 from NIDCD.

Currie G 'Methodological Individualism: Philosophical Aspects'
This article is dedicated to the memory of the author's teacher and friend John Watkins.

Eiser C 'Childhood Health'
This work was supported by the Cancer Research Campaign, London (CP1019/0401 and CP1019/0201).

Elder G H Jr. 'Life Course: Sociological Aspects'
The author acknowledges support by the National Institute of Mental Health (MH 43270, MH 51361, MH 57549), a contract with the US Army Research Institute, research support from the MacArthur Foundation Research Network on Successful Adolescent Development Among Youth in High-Risk Settings, a grant from the National Institute of Child Health and Human Development to the Carolina Population Center at the University of North Carolina at Chapel Hill (PO1-HD31921A), a Research Scientist Award (MH 00567), and a Spencer Foundation grant.

Fischer G 'Lifelong Learning and its Support with New Media: Cultural Concerns'
The author thanks the members of the Center for LifeLong Learning & Design (L3D) and the Institute of Cognitive Science at the University of

Colorado, who have made major contributions to the conceptual framework and systems described in this paper. The research was supported by the National Science Foundation, Grants REC-9631396 and IRI-9711951; Software Research Associates, Tokyo, Japan; and PFU, Tokyo, Japan.

Flor H 'Pain, Health Psychology of'
This research has been supported in part by the Deutsche Forschungsgemeinschaft.

Friedman H S 'Personality and Health'
This research was supported by a grant from the National Institute on Aging, AG08825.

Fryer D 'Unemployment and Mental Health'
The support of ESRC grant ROOO 231798 during some of the preparatory work for this article is acknowledged with gratitude.

Geyer F 'Alienation, Sociology of'
This text is partially based on the introduction to *Alienation, Ethnicity and Postmodernism* (Greenwood, Westport, CT, 1996) and on several articles published over the last decade in *Kybernetes*, the official journal of the World Organisation of Systems and Cybernetics, published by MCB University Press, Bradford, UK, with the approval of the publisher.

Geyer F 'Sociocybernetics'
This text is based on 'The Challenge of Sociocybernetics', published in *Kybernetes* (**24**(4): 6–32, 1995), the official journal of the World Organisation of Systems and Cybernetics, published by MCB University Press, Bradford, UK, with the approval of the publisher.

Gierveld J de Jong 'Adolescent Behavior: Demographic'
The data used in this contribution were derived from the Family and Fertility Surveys Project, which was carried out under the auspices of the UN ECE, Geneva. The analysis for this contribution formed part of NIDI project no. 41. The author thanks Aart Liefbroer and Edith Dourleijn for their assistance in preparing this article.

Gold I 'Perception: Philosophical Aspects'
The author is grateful to Jonathan Dancy, Martin Davies, Frank Jackson, Philip Pettit, and Daniel Stoljar for comments on earlier versions of the article.

Grusky D B 'Social Stratification'
Portions from an earlier article by D B Grusky on 'Social Stratification' in the *Encyclopedia of Sociology*, 2nd edn., edited by Edgar F. Borgatta and Rhonda J. V. Montgomery, 2000, are reprinted here with permission of

Macmillan Reference USA. Portions of this essay are also reprinted from D B Grusky's essay 'The past, present, and future of social inequality'. In *Social Stratification: Class, Race, and Gender in Sociological Perspective*, 2nd edn., edited by D Grusky, 2001, with permission of the Perseus Books Group.

Guillemard A-M 'Welfare'
The author expresses gratitude to Bruno Palier, whose unpublished dissertation and comparative research have been an inspiration for writing this article, which has been translated from French by Noal Mellott (CNRS, Paris, France).

Holahan C J, Moos R H 'Community Environmental Psychology'
Preparation of this manuscript was supported in part by the Department of Veterans Affairs Health Services Research and Development Service and by NIAAA Grants AA06699 and AA12718.

Iusem A N 'Linear and Nonlinear Programming'
Research for this work was partially supported by CNPq grant no. 301280/86 and Catedra Marcel Dassault, Centro de Modelamiento Matematico, Universidad de Chile.

Tanner M A, Jacobs R A 'Neural Networks and Related Statistical Latent Variable Models'
Jacobs R A was supported by NIH grant R29-MII54770. Tanner M A was supported by NIH grant RO1-CA35464.

Kaplan G A 'Socioeconomic Status and Health'
Research for this article was partially supported by a grant from the National Institutes of Health (National Institute of Child Health and Human Development, 1 P50 HD38986) and the University of Michigan Initiative on Inequalities in Health.

Kessler R C 'Comorbidity'
Preparation of this article was supported by the National Institute of Mental Health (Grants MH46376 and MH49098).

Kiewiet D R 'Voting: Retrospective/Prospective'
The author would like to thank Sam Kernell and Robert Sherman for their helpful comments.

Kinney D K 'Schizophrenia and Bipolar Disorder: Genetic Aspects'
The author gratefully acknowledges research assistance of Sharon Tramer, Paul Choquette, and Elizabeth Ralevski. Work on this article was supported in part by a grant from the NIMH (RO1 MH55611).

Laskey K B, Levitt T S 'Artificial Intelligence: Uncertainty'
The Bayesian networks in this article were produced using Netica. Thanks are due to Sara-Jane Farmer for assistance in locating bibliographic citations.

Laursen B 'Conflict and Socioemotional Development'
Support for the preparation of this article was provided by a grant to the author from the US National Institute of Child Health and Human Development (R29-HD33006). Special thanks are extended to Erika Hoff for insightful comments on an earlier draft.

Leventhal H 'Illness Behavior and Care Seeking'
Preparation of this article was supported by grant AG 03501.

Leventhal H 'Stressful Medical Procedures, Coping with'
Preparation of this article was supported by grant AG 03501. Special thanks to Carolyn Rabin for assisting with its preparation.

Leventhal T, Brooks-Gunn J 'Poverty and Child Development'
The authors would like to thank the NICHD Research Network on Child and Family Well-Being for their support. We are also grateful to the National Institute of Mental Health and Administration for Children Youth and Families, the Head Start Mental Health Research Consortium, and the MacArthur Networks on Family and Work and Economy and Work. Thanks also to Rebecca Fauth for assistance with this manuscript.

Levine R J 'Ethics for Biomedical Research Involving Humans: International Codes'
This work was supported in part by grant number PO1 MH/DA 56 826-01A1 from the National Institute of Mental Health and the National Institute on Drug Abuse.

Li M, Vitányi P 'Algorithmic Complexity'
Li M was supported in part by NSERC Research Grant OGP0046506, a CITO grant, and an NSERC Steacie Fellowship. Vitányi P was supported in part by the European Union through NeuroCOLT II ESPRIT Working Group and the QAIP Project.

Lounsbury M 'Institutional Investors'
The author would like to thank Hitoshi Mitsuhashi for his helpful comments and research assistance.

Martin R D 'Primates, Evolution of'
Permission to reproduce quote from *Primates: A Definition* (1986) granted by Cambridge University Press.

Mason W M 'Statistical Analysis: Multilevel Methods'
The assistance of V. K. Fu is gratefully acknowledged.

Massaro D W 'Speech Perception'
This work was supported in part by NSF CHALLENGE grant CDA-9726363, Public Health Service grant PHS R01 DC00236, National Science Foundation grant 23818, Intel Corporation, and the University of California Digital Media Innovation Program.

Monroe K R 'Altruism and Self-interest'
Parts of this article appeared in Monroe K R 1996 *The Heart of Altruism: Perceptions of a Common Humanity*, Princeton University Press, Princeton, NJ, reprinted with permission.

Morgenthaler S 'Robustness in Statistics'
The writing of this article was supported by a grant from the Swiss National Science Foundation.

Morris C N, Chiu C W F 'Experimental Design: Large-scale Social Experimentation'
The research was supported by NSF grant DMS-97-05156.

Oldenburg B 'Public Health as a Social Science'
The author would like to formally acknowledge the wonderful contribution made by Nicola Burton in commenting on the manuscript and assisting with its preparation.

Pedraza S 'Migration to the United States: Gender Aspects'
Parts of this article have previously appeared in the article 'Women and migration in the social consequences of gender' *Annual Review of Sociology* (1991) **17**: 303–25.

Polinsky A M, Shavell S 'Law: Economics of its Public Enforcement'
This entry is a condensed version of Polinsky A M, Shavell S 1998 'Public enforcement of law'. In: Newman P (ed.) *The New Palgrave Dictionary of Economics and The Law*. Macmillan, London, Vol. 3, pp. 178–88. The authors thank Macmillan Reference Ltd. for permission to reproduce parts of it here.

Poplack S 'Code Switching: Linguistic'
This research was supported by the Social Sciences and Humanities Research Council of Canada.

Posner M I, Rothbart M K 'Brain Development, Ontogenetic Neurobiology of'
This research was supported in part by NIMH grant R01-43361 and by a grant from the James S. McDonnell Foundation.

Radner R 'Bounded and Costly Rationality'
The author is grateful to Tony Marley for comments on earlier drafts of this article. The material in the article (except for Sect. 7) is for the most part a condensation of a much longer paper (Radner 2000). The author wishes to thank Oxford University Press for permission to use this material here.

Raichle M E 'Functional Brain Imaging'
The author wishes to acknowledge many years of generous support from NINDS, NILBI, The McDonnell Center for Studies of Higher Brain Function at Washington University, as well as The John D. and Katherine T. MacArthur Foundation and The Charles A. Dana Foundation.

Reisberg B 'Dementia: Overview'
This work was supported in part by USDHHS Grants AG03051 and AG0851 from the National Institutes of Health, by Grant 90AR2160 from the US DHHS Administration of Aging, and by the Zachary and Elizabeth M. Fisher Alzheimer's Disease Education and Resources Program of the New York University School of Medicine and the Fisher Center for Alzheimer's Disease Research Foundation.

Rock P 'Prison Life, Sociology of'
The author expresses gratitude to Tony Bottoms, Eamon Carrabine, Megan Comfort, Stephanie Hayman, and Richard Sparks for their help in the preparation of this article.

Rosenbaum P R 'Observational Studies: Overview'
This work is supported by a grant from the Methodology, Measurement and Statistics Program and the Statistics and Probability Program of the National Science Foundation.

Sarris V 'Köhler, Wolfgang (1887–1967)'
Many thanks to Mitchell G. Ash, Rudolf Bergius, Lothar Spillmann, and Michael Wertheimer for reading earlier versions of this article.

Schilling H 'Reformation and Confessionalization'
Translated by Lotz-Heumann U.

Schneider S H 'Environmental Surprise'
Modified from Schneider SH, Turner BL, Morehouse Garriga H 1998 'Imaginable surprise in global change science'. *The Journal of Risk Research* **1**(2): 165–85. The author thanks Kristin Kuntz-Duriseti for editorial help.

Schott F 'Instructional Design'
For valuable comments upon a draft of this article the author thanks Michael Hannafin, Glenn Snelbecker, and Michael Spector in the USA, as well as Jeroen van Merrienboer in The Netherlands.

Shanahan M J 'Historical Change and Human Development'
The author thanks Robert L. Burgess and Frank J. Sulloway for helpful comments.

Slavin R E, Hurley E A, Chamberlain A M 'Cooperative Learning in Schools'
This article is adapted from Slavin, 1996. It was written under funding from the Office of Educational Research and Improvement, US Department of Education (Grant No. OERI-R-D40005). However, any opinions expressed are those of the authors and do not necessarily represent OERI positions or policies.

Pellegrini A D, Smith P K 'Play and Development in Children'
Work on this article was partially supported with grants from the W. T. Grant Foundation and the Spender Foundation to A.D.P.

Stein B E, Wallace M T, Stanford T R 'Cross-modal (Multi-sensory) Integration'
The research was supported by NIH grants EY36916 and NS22543. The authors thank Nancy London for editorial assistance.

Trakman L E 'Contracts: Legal Perspectives'
The author wishes to thank Stewart Macaulay and John Yogis for commenting on preliminary drafts of this article.

Turk D C 'Chronic Pain: Models and Treatment Approaches'
Preparation of this manuscript was supported in part by grants from the National Institute of Arthritis and Musculoskeletal and Skin Diseases (AR44724) and the National Institute of Child Health and Human Development (HD33989).

Vaillant G E 'Defense Mechanisms'
This work is from the Department of Psychiatry, Brigham and Women's Hospital.

Vila J 'Stress and Cardiac Response'
The preparation of this article was partially supported by Research Grant PB97-0841 from the Spanish Ministry of Education and by the Research Group HUM-388 of the Junta de Andalucía.

Wahl H-W 'Adulthood: Dependency and Autonomy'
This article owes a great deal to Margret M. Baltes and her work on dependency and autonomy in adulthood and old age. Her death in January 1999 brought to an end her very unique and irreplaceable insights into these essential human issues.

Weinstein C E 'Learning to Learn'
The author acknowledges Thea Woodruff, Tammy Tomberlin, and Donwook Yang.

Williams R M 'Ethnic Conflicts'
Portions of this article have been adapted from a paper presented at the Earl and Edna Stice Lecture in Social Sciences, University of Washington, Seattle, October 1997.

Wills T A 'Adolescent Health and Health Behaviors'
Preparation of this article was supported in part by grant #CA81646 from the National Cancer Institute and a Research Scientist Development Award #DA00252 from the National Institute on Drug Abuse. Thanks to Meg Gerrard, Frederick X. Gibbons, Diane McKee, and James Sandy for comments on this work.

Zanutto E, Gelman A 'Large-scale Social Survey, Analysis of'
The authors wish to thank the National Science Foundation for research support.

A. A. J. Marley obtained his Ph.D. in Psychology at the University of Pennsylvania. He is currently professor and chair of the Department of Psychology at McGill University, where he has been since 1969. He has been president of the Society for Mathematical Psychology and editor and book review editor of the *Journal of Mathematical Psychology*. His research interests center on probabilistic models in the social and behavioral sciences.

Alberto Martinelli was born in 1940. He obtained his master's degree in economics from Bocconi University of Milan and his Ph.D. in sociology from the University of California at Berkeley. He is dean of the Faculty of Political Sciences and Professor of Political Science at the University of Milan. He also teaches sociology at Bocconi University of Milan and has taught at various universities, including Stanford and New York University.

Martinelli has written books and essays on sociological and political theory, complex organizations, entrepreneurship and management, higher education, interests groups and political parties, and international economic relations. Among his most recent books and essays in English are: *The New International Economy* (with H. Makler and N. J. Smelser; 1983); *Economic and Society: Overviews on Economy Sociology* (with N. J. Smelser; 1990); *International Markets and Global Firms* (1991); *The Handbook of Economic Sociology* (1994); and *Social Trends in Italy, 1960–1995* (1999).

Martinelli is currently president of the International Sociological Association. He has been a member of Italy's National Council of Science and Technology. He is on the editorial board of several scientific journals and a commentator for *Corriere della Sera*, the largest Italian newspaper.

Axel Honneth is Professor of Philosophy at the Institute for Social Research at the Johann Wolfgang Goethe University, Frankfurt. His books include *Human Nature and Social Action* (1988), *Critique of Power* (1991), *The Fragmented World of the Social* (1995), and *The Struggle for Recognition* (1997).

Bernard Comrie was born in England in 1947, and educated at the University of Cambridge, completing a B.A. in modern and medieval languages in 1968 and a Ph.D. in linguistics in 1972. From 1970 to 1974 he was a Junior Research Fellow at King's College, University of Cambridge. In 1974 he took up a position as University Lecturer in Linguistics at the University of Cambridge, which he held until 1978. In 1978 he moved to Los Angeles to accept a position as Associate Professor of Linguistics (from 1981, Professor of Linguistics) at the University of Southern California, where he continues to hold a courtesy appointment as Research Professor. In 1997 he was appointed to his present position as director of the Department of Linguistics at the Max Planck Institute for Evolutionary Anthropology in Leipzig; he took up this position in 1998. In 1999 he was appointed Honorary Professor of Linguistics at the University of Leipzig and elected a member of the Saxon Academy of Sciences.

His main interests are in the area of language universals and typology, though he is also interested in historical linguistics and linguistic fieldwork. He has held visiting positions in Australia, Russia, the Netherlands, Spain and Japan, and was chair of the Scientific Advisory Panel of the European Science Foundation Project on Language Typology. His publications include *Aspect* (Cambridge, 1976), *Language Universals and Linguistic Typology* (Oxford/Chicago, 1981, 1989), *The Languages of the Soviet Union* (Cambridge, 1981), *Tense* (Cambridge, 1985), and *The Russian Language in the Twentieth Century* (with Gerald Stone and Maria Polinsky, Oxford, 1996), some of which have been translated into Chinese, Italian, Japanese, Korean and Spanish. With Stephen Matthews and Maria Polinsky he was a consultant editor for *The Atlas of Languages: The Origin and Development of Languages Throughout the World* (London/New York, 1996), which has also appeared in Dutch, German, and Japanese editions.

Comrie is also editor of *The World's Major Languages* (London/New York, 1987) and *The Slavonic Languages* (with Greville G. Corbett, London 1993), and is managing editor of the journal *Studies in Language*.

Billie L. Turner II is the Higgins Professor of Environment and Society, Graduate School of Geography and George Perkins Marsh Institute, Clark University. He is an author or editor of nine books, over 125 journal articles/chapters, and 20 published reports dealing with nature or society relationships, ranging from ancient Maya agriculture and environment in Mexico and Central America, to contemporary agricultural change in the tropics, to global land-use change. Turner holds his Ph.D. (1974) from the University of Wisconsin–Madison and is a member of the National Academy of Sciences and the American Academy of Arts and Sciences.

Charles C. Ragin holds a joint appointment as Professor of Sociology and Professor of Political Science at Northwestern University. He is also appointed Professor of Sociology and Human Geography at the University of Oslo, Norway. His main interests are methodology, political sociology, and comparative-historical sociology, with a special focus on such topics as the welfare state, ethnic political mobilization, and international political economy. His book, *The Comparative Method: Moving Beyond Qualitative and Quantitative Strategies* (University of California Press, 1987), won the Stein Rokkan Prize of the International Social Science Council (UNESCO). Other books include *Issues and Alternatives in Comparative Social Research* (E. J. Brill, 1991), *What is a Case? Exploring the Foundations of Social Research* (Cambridge University Press, with Howard S. Becker, 1992), and *Constructing Social Research: The Unity and Diversity of Method* (Pine Forge Press, 1994). His recent research has focussed on austerity protests in Third World countries and the causes of welfare state expansion. His latest book is *Fuzzy-Set Social Science* (University of Chicago Press, 2000).

Craig Calhoun is president of the Social Science Research Council and Professor of Sociology and History at New York University. He received his doctorate from Oxford University and taught at the University of North Carolina, Chapel Hill from 1977 to 1996. At North Carolina he also served as dean of the Graduate School and was the founding director of the University Center for International Studies.

Calhoun's most recent books include *Nationalism* (University of Minnesota Press, 1997), *Neither Gods Nor Emperors: Students and the Struggle for Democracy in China* (University of California Press, 1995), and *Critical Social Theory: Culture, History and the Challenge of Difference* (Blackwell, 1995). He is also editor-in-chief of the forthcoming *Oxford Dictionary of the Social Sciences*.

David Alfred Martin is Professor Emeritus of Sociology in the University of London (LSE), Honorary Professor, Department of Religious Studies, Lancaster University, and International Research Fellow, Boston University. He was previously Scurlock Professor (1986–91) at Southern Methodist University, Dallas, Texas. He is author of some 14 books and editor of 10. Since 1983, Martin has been a non-stipendiary Anglican Priest, Guildford Cathedral. He has been resident of the International Conference of the Sociology of Religion 1975–83 and also an Academic Governor of the London School of Economics 1971–81.

David L. Featherman was appointed director and senior research scientist at the Institute for Social Research at the University of Michigan in 1994. He is also Professor of Sociology and of Psychology in the College of Literature, Science and the Arts. Prior to 1994, he served as president of the Social Science Research Council (SSRC) in New York City for six years. Featherman began his academic career in the Department of Sociology and Office of Population Research, in 1969–70, at Princeton University and for twenty-one years thereafter was on the faculty of the University of Wisconsin–Madison, where he chaired several departments and institutes and held the John Bascom Professorship in Sociology.

Featherman received his Ph.D. and master's degrees from the University of Michigan in sociology and social psychology. His research has spanned the multidisciplinary fields of demography, social psychology, human development, and gerontology. He has written or co-authored five books and dozens of published papers about socioeconomic inequality and social mobility in Western industrial nations, and between 1981 and 1987 he chaired the SSRC Committee on Comparative Stratification Research. Since the late 1980s, Featherman's publications on the sociology of the life course, aging, and life-span human development have included five volumes of a co-edited series, *Life-Span Development and Behavior*. His contributions to the latter field were acknowledged in 1990 with the Distinguished Career of Research Award of the American Sociological Association, Section on Aging and the Life Course.

Featherman is a fellow of the American Academy of Arts and Sciences, the American Association for the Advancement of Science, a 1978–79 fellow of the Center for Advanced Study in the Behavioral Sciences, and a former Guggenheim fellow. He serves on various national and international advisory boards and boards of trustees.

Eugénie Ladner Birch is professor and chair of the Department of City and Regional Planning at the University of Pennsylvania. She holds doctoral and master's degrees in urban planning from Columbia University and a bachelor of arts from Bryn Mawr College. After graduating from Bryn Mawr, she was a Fulbright fellow in the School of Architecture in the Universidad Central, Quito, Ecuador.

Birch has published widely in two fields, the history of planning and contemporary planning and housing. Her articles have appeared in such publications as the *Journal of Urban History*, *Journal of Planning Education and Research*, *Journal of the American Planning Association* and *Planning Magazine*. Her books include *The Unsheltered Woman: Housing in the Eighties* (Center for Urban Policy Research). She served as an associate editor of the *Encyclopedia of New York City*, edited by Kenneth T. Jackson.

Birch has lectured in the United States and abroad on city planning matters. In 1997, she was visiting scholar, Queens University, Kingston, Ontario; earlier in the year she delivered the Foreign Scholar lecture at the University of Hong Kong. In 1994, she was a visiting professor at the University of the Witwatersrand, Johannesburg, South Africa. In the past few years, she has given the Dublois Lecture at the University of New Orleans (1993), London School of Economics Lecture (1992), the plenary address at the national meeting of the American Planning Association (1990) and the Catherine Bauer Wurster Lecture at the University of California, Berkeley (1989).

Birch has served as president of the Association of Collegiate Schools of Planning (1995–1997). Between 1988 and 1993 she served as co-editor (with Peter D. Salins) of the *Journal of the American Planning Association*. She has also served as president of the Society of American City and Regional Planning History (1986–91). In 1994, the Association of Collegiate Schools of Planning gave her the Margarita McCoy Award.

She is currently engaged in research of the rise of downtown housing funded by the Fannie Mae Foundation.

Florian Holsboer was born in Germany in 1945. He studied both chemistry and medicine at the University of Munich and qualified in psychiatry in 1983. He has held professorships in psychiatry at the Universities of Mainz, Zurich, and Freiburg. In 1989 Holsboer was appointed director and scientific member of the Max Planck Institute of Psychiatry and honorary professor at the Medical Faculty of the Ludwig-Maximilians University of Munich.

Holsboer holds memberships in numerous scientific associations and advisory boards and has been editor of several academic journals. His main research interests lie in the fields of neuroendocrinology and psychopharmacology.

Franz Emanuel Weinert was, until his death in 2001, a co-director of the Max Planck Institute for Psychological Research and Research Professor at the Universities of Heidelberg and Munich. He received his Ph.D. from the University of Erlangen and his Habilitation from the University of Bonn. From 1968 until 1981 he worked as a professor and director of the Psychological Institute at the University of Heidelberg. For some years he served as a president of the German Psychological Association, as a vice president of the German Science Foundation, and as a vice president of the Max Planck Society. Among his many awards are honorary doctorates from the University of Würzburg and the Free University Berlin.

Ira Katznelson is Ruggles Professor of Political Science and History at Columbia University. He earned his B.A. from Columbia in 1966 and his Ph.D. from Cambridge in 1969. He was chair of the Department of Political Science, University of Chicago, from 1979 to 1982 and dean of the New School for Social Research between 1983 and 1989. His co-authored publications include *Black Men, White Cities, City Trenches: Urban Politics and the Patterning of Class in the United States* and *Working Class Formation*. His research interests lie in comparative politics and social history.

James L. McClelland is Professor of Psychology and Computer Science at Carnegie Mellon University and co-director of the Center for the Neural Basis of Cognition, a joint project of Carnegie Mellon and the University of Pittsburgh. Over his 20-year career he has contributed to both the experimental and theoretical literatures in a number of areas, most notably in the application of connectionist models to problems in perception, cognitive development, language learning, and the neurobiology of memory. He was a co-founder with David E. Rumelhart of the Parallel Distributed Processing Group.

McClelland received his Ph.D. in cognitive psychology from the University of Pennsylvania in 1975. He served on the faculty of the University of California, San Diego, before moving to Carnegie Mellon in 1984. He has served as senior editor of *Cognitive Science*, and is a past president of the Cognitive Science Society. Currently McClelland's work focuses on issues related to functional disorders of cognition resulting from damage to the brain and on the cognitive neuroscience of learning and memory.

James S. House is Professor of Sociology and director of the Survey Research Center at the Institute for Social Research at the University of Michigan, where he is also affiliated with the Department of Epidemiology. He received his Ph.D. in social psychology from the University of Michigan in 1972 and was on the faculty of Duke University from 1970–78. His research has focused on the role of psychosocial factors in the etiology of health and illness, initially on occupational stress and health, later on social relationships, social support, and health, and currently on the nature and explanation of socioeconomic differences in health and the relation of age to health.

House is an elected member of the Institute of Medicine of the National Academy of Sciences, an elected fellow of the American Academy of Arts and Sciences, has been a Guggenheim fellow and has served as chair of the Social Psychology Section of the American Sociological Association. He is a member of the editorial boards of the *Annual Review of Sociology*, *Journal of Health and Social Behavior, Social Psychology Quarterly*, *Work and Stress*, and *Journal of Behavioral Medicine*, a subcommittee chair for the Task Force on Behavioral Science Research at the National Institute of Mental Health, and a member of the Advisory Board for the Robert Wood Johnson Investigators in Health Policy Research Program.

Jan M. Hoem is director at the Max Planck Institute for Demographic Research and Professor of Demometry at Stockholm University. Previously, he directed the Socio-Demographic Research Unit in the Central Bureau of Norway and subsequently was Professor of Insurance Mathematics at the University of Copenhagen. In Stockholm he started and led Sweden's first research institute in modern demography, the Demography Unit (SUDA).

Trained as a statistician, Hoem has contributed substantially to the development and application of statistical methods for the analysis of event-history data. Much of his empirical work focuses on the unique Scandinavian pattern of cohabitation. He has investigated links between education, employment, family formation, childbearing, and family disruption. Several of his studies demonstrate effects of public policies on demographic behavior.

Joseph B. Kadane is Leonard J. Savage Professor of Statistics and Social Sciences at Carnegie Mellon University. He earned his B.A. in mathematics at Harvard (1962) and his Ph.D. in statistics at Stanford (1966).

For Kadane, statistics is an adventure in understanding how people make decisions and draw conclusions from data. His work has been both theoretical and applied and in fields as various as econometrics, political science, archaeology, law, psychophysics, environment, medicine, and computer science.

Kadane's applied projects include a study of how to prove age discrimination in court, working with physicists and colleague Chris Genovese on the application of Markov Chain Monte Carlo methods to the study of critical phenomena in Ising models in physics, and helping the Data Monitoring Committee of a set of clinical trials make coherent sequential plans.

On the theoretical side, Kadane is interested in Bayesian theory, both in its decision-theoretic foundations and in problems of elicitation (the process of determining probability distributions from background knowledge of investigators) and computation.

Jürgen Kocka has held the Chair for the History of the Industrial World at the Free University of Berlin since 1988. He has been a permanent fellow of the Wissenschaftskolleg zu Berlin (Institute for Advanced Study) since 1991. Since 2001, he has been the president of the Wissenschatfszentrum Berlin. He has published widely in the field of modern history, particularly social and economic history of the eighteenth to twentieth centuries. Kocka has also written on theoretical problems of history and the social sciences. His publications include: *Unternehmensverwaltung und Angestelltenschaft am Beispiel Siemens 1847–1914* (1969); *Facing Total War: German Society 1914–1918* (1984); *White Collar Workers in America 1890–1940* (1980); *Les employés en Allemagne 1850–1980* (1989); *Arbeitsverhältnisse und Arbeiterexistenzen. Grundlagen der Klassenbildung im 19. Jahrhundert* (1990); and *Vereinigungskrise: Zur Geschichte der Gegenwart* (1995).

Kocka studied history, political science and German literature in Marburg, Vienna, Chapel Hill (NC) and Berlin, receiving his M.A. in political science in 1965 (Chapel Hill) and his Ph.D. in history in 1968 (Free University of Berlin). In 1969/70 he was an ALCS fellow at the Charles Warren Center of Studies in American History, Harvard University. In 1988 he received an honorary doctorate from Erasmus University Rotterdam, and in 2000 from the University of Uppsala.

From 1973 to 1988, Kocka was a Professor of History at the University of Bielefeld where he also served as director of its Center for Interdisciplinary Research (1983–88). He is an honorary member of the Hungarian Academy of Science (since 1995). He was a visiting member of the Institute of Advanced Study at Princeton in 1975–76, a fellow of the Historisches Kolleg Munich in 1983–84, a fellow of the Wissenschaftskolleg zu Berlin in 1988–89, and a fellow at the Center for Advanced Study in the Behavioral Sciences in Stanford in 1994–95. Kocka is also a member of the Academia Europaea (since 1988) and of the Berlin-Brandenburgische Akademie der Wissenschaften (since 1993). In 1992 he received the Leibniz Prize of the Deutsche Forschungsgemeinschaft.

Jürgen Mittelstrass was born in 1936 in Germany. From 1956–60 he studied philosophy, German literature, and protestant theology at the universities of Bonn, Erlangen, Hamburg, and Oxford. He received his Ph.D. in philosophy from the University of Erlangen in 1961, and his Habilitation in 1968. Since 1970 Mittelstrass has been Professor of Philosophy and Philosophy of Science at the University of Constance, and from 1990 also director of the Center for Philosophy of Science.

He has been member of the German Science Council 1985–1990; member of the senate of the German Research Society 1992–1997; president of the General Society for Philosophy in Germany since 1997; member of the Berlin-Brandenburg Academy of Sciences (Berlin) and of the German Academy of Scientists, Leopoldina (Halle) and vice president of the Academia Europaea (London). In 1989 he received the Leibniz-Prize of the German Research Society; in 1992 the Arthur Burkhardt Prize; and in 1998 the Lorenz Oken Medal of the Society of German Scientists and Physicians.

His publications include: *Die Rettung der Phänomene* (1962), *Neuzeit und Aufklärung* (1970), *Die Möglichkeit von Wissenschaft* (1974), *Wissenschaft als Lebensform* (1982), *Der Flug der Eule* (1989), *Geist, Gehirn, Verhalten* (with M. Carrier, 1989), *Leonardo-Welt* (1992), *Die unzeitgemässe Universität* (1994), *Die Häuser des Wissens* (1998). He is also editor of *Enzyklopädie Philosophie und Wissenschaftstheorie*, 4 volumes.

Karl Ulrich Mayer was born in Germany in 1945. He is director of the Center for Sociology and the Study of the Life Course at the Max Planck Institute for Human Development in Berlin and Professor of Sociology at the Free University of Berlin. He received his B.A. in sociology at Gonzaga University, Spokane, Washington in 1966 and his M.A. in sociology at Fordham University, New York in 1967. In 1973, he became Dr. rer. soc. (social sciences) at the University of Constance. He completed his Habilitation in sociology at Mannheim University in 1977.

Mayer's research interests are social stratification and mobility, comparative social structure analysis, and sociology of the life course. He is a member of the German Science Council (Wissenschaftsrat), co-editor of the *Kölner Zeitschrift für Soziologie und Sozialpsychologie*, foreign honorary member of the American Academy of Arts and Sciences, member of the German Academy of Scientists, Leopoldina (Halle), of the Academia Europaea, and of the Berlin-Brandenburg Academy of Sciences.

Kenneth Prewitt, Director of the United States Census Bureau, came to government service after a distinguished career in higher education and private philanthropy. Most recently, he served as the president of the Social Science Research Council, a position he also held from 1979 to 1985. For 10 years, he was senior vice president of the Rockefeller Foundation, where his primary duties were the international Science-Based Development program involving activities in Asia, Africa, and Latin America. He taught for 15 years at the University of Chicago and, for shorter periods, at Stanford University (where he received his Ph.D.), Columbia University, Washington University, the University of Nairobi, and Makerere University (Uganda). He served for five years as the director of the National Opinion Research Center, based at the University of Chicago.

Prewitt is the author or co-author of a dozen books, and more than 50 contributions to professional journals and edited collections. Among his awards are a Guggenheim fellowship, an honorary degree from Southern Methodist University and a Distinguished Service Award from the New School for Social Research. He has been a fellow of the American Academy of Arts and Sciences, the Center for Advanced Study in the Behavioral Sciences, and the American Association for the Advancement of Science, and has been an officer or served on the Board of each of these organizations. He has also served on advisory boards to the World Bank, the World Health Organization, and UNESCO.

Lauren B. Edelman is Professor of Law and Sociology at the University of California, Berkeley. She received her B.A. from the University of Wisconsin–Madison and her M.A. and Ph.D. from Stanford. Edelman's research addresses the interplay between organizations and their legal environments, focusing on employers' responses and constructions of civil rights laws, workers' mobilization of their legal rights, and the internal legal cultures of work organizations. She was awarded a Guggenheim fellowship in 2000 for her work on the formation of civil rights laws in the workplace.

Marc Galanter is John and Rylla Bosshard Professor of Law and Professor of South Asian Studies at the University of Wisconsin–Madison. He studied philosophy and law at the University of Chicago and has since taught at Stanford, Chicago, Buffalo, and Columbia as well as at Wisconsin. He has been a Guggenheim fellow, a fellow of the National Endowment for the Humanities and a fellow of the Center for Advanced Study in the Behavioral Sciences. He is a former editor of the *Law and Society Review* and has served as president of the Law and Society Association. He is a member of the American Law Institute and the American Academy of Arts and Sciences. He has also served as advisor to the Ford Foundation on legal services and human rights programs in India.

Marcus W. Feldman is Professor of Biological Sciences at Stanford University. His research has made important contributions to evolutionary theory and population genetics. He is managing editor of *Theoretical Population Biology* and is on the editorial boards of *Genetics* and *Complexity*. He was a Guggenheim fellow in 1976 and a fellow of the Center for Advanced Study in the Behavioral Sciences in 1983–84. He is a member of the American Academy of Arts and Sciences.

Margaret W. Conkey is the Class of 1960 Professor of Anthropology and director of the Archaeological Research Facility at the University of California, Berkeley. She received her B.A. from Mt. Holyoke College, and her M.A. and Ph.D. degrees in anthropology from the University of Chicago. She has been carrying out research in anthropological archaeology for more than 30 years, with particular attention to understanding the social and cultural contexts within which prehistoric peoples, at the end of the Ice Age, produced a material and visual culture, such as cave art. Her current research in this regard, sponsored by the National Science Foundation and France-Berkeley Fund, is focused on an open-air regional survey in the French Midi-Pyrenées for recovering traces and patterns of prehistoric life 'between the caves.' Conkey has been active in shaping the field of gender and feminist archaeology as well.

Conkey's numerous publications include co-edited volumes on *The Uses of Style in Archaeology*, *Engendering Archaeology: Women and Prehistory*, and *Beyond Art: Pleistocene Image and Symbol*. Conkey is a fellow of the California Academy of Sciences, and is currently the chair of the Association for Feminist Anthropology of the American Anthropological Association.

Mary Byrne McDonnell had been the Program Director for East Asia and Indochina programs at the Social Science Research Council before her appointment as Executive Director in 1997. In that capacity she has been responsible to the president for the health and well-being of the Council's programs while continuing to develop programs in her areas of expertise including a new program on Human Capital. As a Program Director, McDonnell has served in various positions at the Council related to the Middle East, Southeast and East Asia beginning in 1984. She also spent 10 years as a journalist covering Asian and Middle Eastern affairs.

McDonnell received her Ph.D. in History from Columbia University with a focus on Southeast Asia and Arab Middle East. Her master's degrees are in international affairs and journalism from Columbia University's School of International and Public Affairs (SIPA). McDonnell has authored numerous articles on the subject of Southeast Asia, including 'The Cambodian Stalemate: America's Obstructionist Role in Indochina' in *World Policy Journal.*

McDonnell served as the chair of the Association of Asian Studies' Vietnam Studies Group. She is also a member of the Indochina Roundtable and the Council for Security Cooperation in the Asia Pacific.

Melvin Sabshin, M.D., recently retired from his position as medical director of the 41,000-member American Psychiatric Association (APA). As its chief executive, he was responsible for the day-to-day administration of a wide range of education, government relations, and service programs which seek to improve the quality and availability of psychiatric care. Currently Sabshin serves as Clinical Professor of Psychiatry in the Department of Psychiatry at the University of Maryland School of Medicine in Baltimore.

Sabshin was appointed APA medical director in 1974, after a broad career in psychiatric practice, medical education, and research. He served as Acting Dean of the University of Illinois College of Medicine in Chicago from 1973 until his APA appointment. He had served since 1961 as Professor and Head of the Department of Psychiatry at the school. In 1967, he was a fellow at the Center for Advanced Study in the Behavioral Sciences.

Sabshin received his B.S. degree from the University of Florida in 1944 and his M.D. degree from Tulane University School of Medicine in 1948. He interned at Charity Hospital of New Orleans, served a psychiatric residency at Tulane from 1949 until 1952, and held a Public Health Service Fellowship in Psychiatric Research from 1952–53.

Active in international affairs, Sabshin is a distinguished fellow of the Egyptian, Hong Kong, and Royal Australian and New Zealand Psychiatric Associations and an honorary fellow of the Royal College of Psychiatrists and the World Association for Social Psychiatry. He is a past member of the Board of the World Federation for Mental Health. From 1983–89 Sabshin served on the Executive Committee of the World Psychiatric Association. He is also past president of the American College of Psychiatrists.

The author of over 140 scientific reports, Sabshin is the co-author of five books that encompass multiple areas of psychiatry, including studies of normal behavior, clinical phenomena of depression and anxiety, and science versus ideology in psychiatry.

Michael Schudson is Professor of Communication and Adjunct Professor of Sociology at the University of California, San Diego where he has taught since 1980. He received his B.A. from Swarthmore College, Ph.D. from Harvard University in sociology, and he taught at the University of Chicago before assuming his present position.

He is the author or editor of seven books on the media, politics, and popular culture including *Discovering the News* (1978), *Advertising, the Uneasy Persuasion* (1984), *Watergate in American Memory* (1992), *The Power of News* (1995), and *The Good Citizen* (1998). He is the recipient of a MacArthur Foundation fellowship, a Guggenheim fellowship, and a residential fellowship at the Center for Advanced Study in the Behavioral Sciences. His present work concerns political culture, especially the history of American political culture and civic preparation.

Nancy Eisenberg received her B.A. from the University of Michigan and her M.A. and Ph.D. in psychology from the University of California, Berkeley. She is currently Regents' Professor of Psychology at Arizona State University. She has published over 200 books, chapters, and empirical journal articles on children's and adults' social, emotional, and moral development. She has been a recipient of five-year Research Scientist Development Awards from the National Institute of Health and the National Institutes of Mental Health and is currently funded by a Research Scientist Award from the National Institutes of Mental Health. She was president of the Western Psychological Association in 1996, has been associate editor of the *Merrill-Palmer Quarterly* and *Personality and Social Psychology Bulletin*, and is editor of the journal *Psychological Bulletin*. She also has been on the governing council of the American Psychological Association and the governing council and publications committee of the Society of Research in Child Development, and is a member of the US National Committee for the International Union of Psychological Science (a committee of the National Academy of Science). Her research interests are in the domain of social and emotional development, especially in children, including individual differences in emotionality and emotion-related regulation, empathy, prosocial behavior, and moral development.

Nelson W. Polsby is Heller Professor of Political Science at the University of California at Berkeley where he has taught American politics and government since 1967. He was educated at Johns Hopkins (B.A.), Brown and Yale (M.A., Ph.D.) and has taught at Wisconsin and Wesleyan as well as at Harvard, Columbia, Yale, the London School of Economics, Oxford, and Stanford on a visiting basis. He has held Guggenheim fellowships twice, fellowships at the Center for Advanced Study in the Behavioral Sciences twice, and a Brookings fellowship, among other honors, and is a fellow of the American Academy of Arts and Sciences, the American Association for the Advancement of Science, and the National Academy of Public Administration. He holds the Wilbur Cross Medal and the Yale Medal of Yale University, an honorary Litt.D. from the University of Liverpool, and an M.A. from Oxford where he was Olin Professor of American Government, 1997–98.

He is editor of the *Annual Review of Political Science* and a former managing editor of the *American Political Science Review.* His books include *Congress and the Presidency* (4th ed., 1986), *Political Innovation in America* (1984), *Consequences of Party Reform* (1983), *Community Power and Political Theory* (2nd ed., 1980), *Presidential Elections* (with Aaron Wildavsky, 10th ed., 2000), *Political Promises* (1974), *British Government and its Discontents* (with Geoffrey Smith, 1981), and *New Federalist Papers* (with Alan Brinkley and Kathleen Sullivan, 1997).

Orley Ashenfelter is Joseph Douglas Green 1895 Professor of Economics at Princeton University. His areas of specialization include labor economics, econometrics, and the analysis of arbitration and related dispute-settlement mechanisms. He has been director of the Industrial Relations Section at Princeton University, director of the Office of Evaluation of the US Department of Labor, a Guggenheim fellow, and the Benjamin Meeker Visiting Professor at the University of Bristol. He edited the *Handbook of Labor Economics* and is currently editor of the *American Economic Review*. His present research includes the evaluation of the effect of schooling on earnings and several empirical studies of the impact of various dispute resolution mechanisms.

Patrick Kirch is Class of 1954 Professor of Anthropology at the University of California, Berkeley. His recent publications include *On the Road of the Winds: An Archaeological History of the Pacific Islands before European Contact* (University of California Press, 2000) and *Historical Ecology in the Pacific Islands* (Yale University Press, 2000).

Kirch has been elected to the National Academy of Sciences and the American Academy of Arts and Sciences. He is an honorary member of the Prehistoric Society of Great Britain and Ireland and has been a fellow at the Center for Advanced Study in the Behavioral Sciences. In 1997 he was awarded the John J. Carty Award for the Advancement of Science by the National Academy of Sciences.

Paula England is Professor of Sociology, Research Associate of the Population Studies Center, and affiliate of the Women's Studies program at the University of Pennsylvania.

Her research focuses on gender and labor markets and on integrating sociological, economic, and feminist perspectives. She is the author of two books: *Households, Employment and Gender* (with George Farkas; Aldine,1986) and *Comparable Worth: Theories and Evidence* (Aldine, 1992), and editor of *Theory on Gender/Feminism on Theory* (Aldine,1993). She is also author of numerous articles on gender and labor markets published in anthologies and journals in the fields of sociology, women's studies, economics, and other fields. From 1994–96 she served as the editor of the *American Sociological Review*. She has testified as an expert witness in a number of sex, race, and age discrimination cases.

Peter Wagner is Professor of Social and Political Theory at the European University Institute in Florence, Italy, and Professor of Sociology and co-director of the Social Theory Centre at the University of Warwick, UK. His research currently focuses on issues of a social theory and political philosophy of contemporary Europe. It draws on earlier comparative research in the history of the social sciences, an attempt at formulating a 'sociology of modernity' and on work on key issues in contemporary social and political theory.

Before 1996, Wagner was a Senior Research Fellow at the Wissenschaftszentrum Berlin für Sozialforschung and taught at the Free University of Berlin. He also held visiting positions at the Ecole des Hautes Etudes en Sciences Sociales, Paris; the Centre National de la Recherche Scientifique, Paris; the Institute for Advanced Study, Princeton; the Swedish Collegium for Advanced Study in the Social Sciences, Uppsala; the University of California, Berkeley; and the University of Oxford. His publications include: *Le travail et la nation* (co-editor; 1999); *A Sociology of Modernity* (1994); *Der Raum des Gelehrten* (with Heidrun Friese; 1993); *Discourses on Society* (co-editor; 1991); and *Sozialwissenschaften und Staat* (1990).

Philip Pettit is Professor of Social and Political Theory at the Australian National University. Among his recent publications are: *Republicanism: A Theory of Freedom and Government* (Oxford University Press, 1997, 1999) and *The Common Mind: An Essay on Psychology, Society and Politics* (Oxford University Press, 1993, 1996). He is also the co-editor, with Robert Goodin, of *A Companion to Contemporary Political Philosophy* (Blackwell, 1993). He is a fellow both of the Academy of Humanities and of the Academy of Social Sciences in Australia and has held a number of distinguished visiting appointments in Cambridge, Oxford, London, and Paris. Since 1997 he has been a regular visiting professor of philosophy at Columbia University, New York. Pettit recently received an honorary D. Litt. from the National University of Ireland.

Ralf Schwarzer has been Professor of Psychology at the Free University Berlin since 1982. He also holds the position of Adjunct Professor at York University, Canada. His work focuses on educational psychology and health psychology. He was founding editor of *Anxiety, Stress, and Coping: An International Journal*. He is a past president of the European Health Psychology Association and fellow of the American Psychological Association. His research focus lies on coping with stress and illness, social support, self-efficacy, and health behavior change.

Raymond Boudon was born in 1934. He has been professor at the University of Bordeaux and member of the National Center for Scientific Research. Since 1967 he has been professor at the University of Paris – Sorbonne (Paris IV).

Boudon has been fellow at the Center for Advanced Study in the Behavioral Sciences, and invited professor notably at the University of Geneva, Harvard University, the University Bocconi of Bologna, Oxford University, the University of Chicago, and the University of Stockholm.

His published works include: *Education, Opportunity and Social Inequality* (Wiley, 1974); *The Logic of Social Action* (Routledge & Kegan Paul, 1981); *The Unintended Consequences of Social Action* (Macmillan, 1982); *Theories of Social Change: A Critical Appraisal* (Basil Blackwell/Polity, 1986); *The Analysis of Ideology* (Polity Press, 1989); *A Critical Dictionary of Sociology* (University of Chicago Press and Routledge, 1989) (with F. Bourricaud); *The Art of Self Persuasion* (Polity, 1994); *Le Juste et le Vrai; Etudes sur L'Objectivité des Valeurs et de la Connaissance* (Fayard, 1995); *Etudes sur les Sociologues Classiques* (PUF, 1998); *Le Sens des Valeurs* (PUF, 1999).

He is the editor of the *Année Sociologique* and of the series 'Sociologies' at the Presses Universitaires de France. He is member of the editorial board of the series *Theory and Decision* and *Epistémè*. He has been member of the editorial board of the *American Journal of Sociology*.

He is member of the Institut de France (Académie des Sciences morales et politiques), the Academia Europaea, the British Academy, and the American Academy of Arts and Sciences. He is also member of the Central European Academy of Art and Science and the International Academy of the Human Sciences of St Petersburg.

Richard A. Shweder is a cultural anthropologist and Professor of Human Development in the Committee on Human Development at the University of Chicago. He received his Ph.D. in social anthropology in the Department of Social Relations at Harvard University, taught at the University of Nairobi, and has been at the University of Chicago ever since.

He is author of *Thinking Through Cultures: Expeditions in Cultural Psychology* and the editor or co-editor of many volumes, including *Culture Theory: Essays on Mind, Self and Emotion*; *Metatheory in Social Science: Pluralisms and Subjectivities*; *Ethnography and Human Development*: *Meaning and Context in Social Inquiry*; *Cultural Psychology: Essays on Comparative Human Development*; and *Welcome to Middle Age! (And Other Cultural Fictions)*.

Shweder has been a visiting scholar at the Russell Sage Foundation, the recipient of a Guggenheim fellowship, and the winner of the American Association for the Advancement of Science Socio-Psychological Prize for his co-authored essay 'Does the Concept of the Person Vary Cross-Culturally?'. He is a member of the American Academy of Arts and Sciences and has served as president of the Society for Psychological Anthropology. He is currently co-chair of the Russell Sage Foundation/Social Science Research Council Workshop on Ethnic Customs, Assimilation and American Law and a member of the MacArthur Foundation's Research Network on Successful Midlife Development.

Richard F. Thompson is Keck Professor of Psychology and Biological Sciences at the University of Southern California and Director of the Program in Neural, Informational, and Behavioral Sciences (Neuroscience). He also holds appointments as Professor of Neurology, School of Medicine, and Senior Research Associate, School of Gerontology. Prior to this he was Bing Professor of Human Biology and Professor of Psychology at Stanford University, where he served as chair of the Human Biology Program from 1980–85. He received his B.A. degree at Reed College, his Ph.D. in psychobiology at the University of Wisconsin, and did postdoctoral research in the Laboratory of Neurophysiology at the University of Wisconsin and in the Laboratory of Neurophysiology at the University of Goteborg in Sweden.

His area of research and scholarly interest is the broad field of psychobiology with a focus on the neurobiological substrates of learning and memory. He has written several texts, edited several books, and published over 350 research papers. Honors include election to the National Academy of Sciences, the American Academy of Arts and Sciences and the Society of Experimental Psychologists; recipient of the Howard Crosby Warren Medal of the Society of Experimental Psychologists and the Distinguished Scientific Contribution Award of the American Psychological Association. He was also elected president of the Western Psychological Association, president of the American Psychological Society, and chair of the Psychonomic Society. He held a Research Scientist Career Award from the National Institute of Mental Health and was a fellow at the Center for Advanced Study in the Behavioral Sciences.

Thompson has been involved in a wide range of scientific-administrative activities at the national level, including the Assembly of Behavioral and Social Sciences of the National Research Council, a Presidential Task Panel on Research in Mental Health, chair of the Board of Scientific Affairs of the American Psychological Association, chair of the Committee on Animal Research and Experimentation of the American Psychological Association, member of the Commission on Behavioral and Social Sciences and Education of the National Research Council/National Academy of Sciences.

He served as chief editor of the journals *Physiological Psychology* and *Journal of Comparative and Physiological Psychology* and chief editor (and founder) of the journal *Behavioral Neuroscience* (1983–90). He is currently regional editor of the journals *Physiology and Behavior*, *Behavioral Brain Research*, associate editor of the *Annual Review of Neuroscience*, consulting editor for *Behavioral Neuroscience*, section editor, *NeuroReport*, and is on the editorial board of a number of other scientific journals. Thompson also has served on several research and training grant panels for the National Science Foundation and the National Institute of Mental Health, and committees of the National Research Council/National Academy of Sciences.

Richard M. Lerner is the Bergstrom Chair in Applied Developmental Science in the Eliot-Pearson Department of Child Development at Tufts University. A developmental psychologist, Lerner received his Ph.D. in 1971 from the City University of New York.

He has been a fellow at the Center for Advanced Study in the Behavioral Sciences and is a fellow of the American Association for the Advancement of Science, the American Psychological Association, the American Psychological Society, and the American Association of Applied and Preventive Psychology. Prior to joining Boston College, he was on the faculty and held administrative posts at Michigan State University and Pennsylvania State University. He has also held the Tyner Eminent Scholar Chair in Human Sciences at Florida State University.

Lerner is the author or editor of 40 books and more than 275 scholarly articles and chapters, including his 1995 book, *America's Youth in Crisis: Challenges and Options for Programs and Policies.* He edited Volume 1, on 'Theoretical models of human development' for the fifth edition of the *Handbook of Child Psychology*. He is known for his theory of, and research about, relations between lifespan human development and contextual or ecological change. He is the founding editor of the *Journal of Research on Adolescence* and of the new journal, *Applied Developmental Science*.

Robert A. Scott is associate director of the Center for Advanced Study in the Behavioral Sciences, a position he has held since 1983. He received his Ph.D. in sociology from Stanford University in 1960 and was on the research staff of the Russell Sage Foundation from 1966–83.

His research has focused on the sociology of deviancy with a particular interest in physical disability. He is the author or co-author of books on deviance and physical disability and the applications of social science knowledge to public policy and co-editor of two volumes of essays on social deviancy and mental health. He has also held visiting appointments at the London School of Economics in 1969 and 1972, has had a courtesy appointment in the program in Human Biology at Stanford from 1988–96, and taught occasional courses in the Program in Continuing Studies at Stanford from 1992 to the present. He is writing a book on the origins of Gothic cathedrals in medieval Europe.

Robert McCormick Adams was born in the USA in 1926. He received his Ph.B., A.M., and Ph.D. degrees from the University of Chicago and was a member of faculty there from 1955 to 1984, including two years as provost of the University. Thereafter he was for 10 years Secretary of the Smithsonian Institution as well as Homewood Professor at Johns Hopkins University. Since 1994 he has been based at the University of California, San Diego.

Adams has held visiting appointments at numerous institutions including Harvard, Berkeley and London. He is an invited member of many bodies including the American Philosophical Society and the National Academy of Science and is a fellow of the American Academy of Arts and Sciences. Adams has conducted field research in the Middle East and Mexico and is the author of more than 130 monographs, edited works, articles and reviews. His primary research interests are the environmental, agricultural and urban history of the Middle East, the history of technological and industrial innovations, and research institutions and policies.

Rüdiger Wehner is a professor at the Institute of Zoology, University of Zurich. In addition, he is a permanent fellow at the Berlin Wissenschafts Kolleg. His research has focused on the neurobiology of visually guided behavior with a particular emphasis on long distance navigation in ants. Wehner is the recipient of many prestigious honors and awards.

Sheila Jasanoff is Professor of Science and Public Policy at the Kennedy School of Government and the School of Public Health at Harvard University. Previously, she was Professor of Science Policy and Law and the founding chair of the Department of Science and Technology Studies at Cornell University.

Jasanoff's longstanding research interests center on the interaction of law, science, and politics. Specific areas of work include science and the courts; environmental regulation and risk management; comparative public policy; social studies of science and technology; and science and technology policy. She has published more than 60 articles and book chapters on these topics and has authored or edited several books, including *Controlling Chemicals: The Politics of Regulation in Europe and the United States* (with R. Brickman and T. Ilgen; 1985), *Risk Management and Political Culture* (1985), *The Fifth Branch: Science Advisers as Policymakers* (1990), and *Learning from Disaster: Risk Management After Bhopal* (edited; 1994). Jasanoff is a co-editor of the *Handbook of Science and Technology Studies* (1995). Her book *Science at the Bar: Law, Science and Technology in America* (1995) received the Don K. Price award for the best book on science and politics of the American Political Science Association, Section on Science, Technology, and Environmental Politics.

Jasanoff has taught at Yale University (1990–91), Boston University School of Law (1993), and Harvard University (1995), and has been a visiting scholar at Wolfson College and the Center for Socio-Legal Studies, Oxford University (1996, 1986). In 1996, she was a resident scholar at the Rockefeller Foundation's Bellagio Study and Conference Center. She is a fellow of the American Association for the Advancement of Science and recipient (1992) of the Distinguished Achievement Award of the Society for Risk Analysis.

Jasanoff holds an A.B. in mathematics from Harvard College (1964), an M.A. in linguistics from the University of Bonn (1966), a Ph.D. in linguistics from Harvard University (1973), and a J.D. from Harvard Law School (1976). She was admitted to the Massachusetts Bar in 1977. From 1976 to 1978 she was an associate with Bracken, Selig and Baram, an environmental law firm in Boston.

Stephen E. Fienberg is Maurice Falk University Professor of Statistics and Social Science and acting director of the Center for Automated Learning and Discovery at Carnegie Mellon University in Pittsburgh. He has served as dean of the College of Humanities and Social Sciences at Carnegie Mellon and as vice president for Academic Affairs at York University in Toronto.

He has published extensively on statistical methods for the analysis of categorical data, and on aspects of sample surveys and randomized experiments. His research interests include the use of statistics in public policy and the law, surveys and experiments, the role of statistical methods in census-taking, and confidentiality and statistical disclosure limitation.

Fienberg has served as president of the International Society for Bayesian Analysis and the Institute of Mathematical Statistics, and as vice president of the American Statistical Society. He has been coordinating and applications editor of the *Journal of the American Statistical Association* and a founding co-editor of *Chance Magazine*. He is a member of the National Academy of Sciences.

Susan Hanson, Professor of Geography at Clark University, is an urban geographer with interests in urban transportation, urban labor markets, and gender issues. Before earning her Ph.D. at Northwestern University (1973), she was a Peace Corps Volunteer in Kenya. She has been the editor of several academic journals including *The Annals of the Association of American Geographers* and *Economic Geography* and serves on the editorial boards of nine other journals. Her publications include *Ten Geographic Ideas that Changed the World* (Rutgers University Press, 1997), *Gender, Work, and Space* (with Geraldine Pratt; Routledge, 1995), *The Geography of Urban Transportation* (Guilford Press, first edition 1986; second edition 1995), and numerous journal articles and book chapters.

Hanson is a past president of the Association of American Geographers, a fellow of the American Association for the Advancement of Science, a former Guggenheim fellow, and a recipient of the Honors Award of the Association of American Geographers and of the Van Cleef Medal from the American Geographic Society. Hanson has served on many national and international committees in geography, transportation, and the social sciences.

G. Terence Wilson completed B.A. and B.A. (Hons) degrees at Witswatersrand University, Johannesburg, South Africa, before receiving a Ph.D. at the State University of New York at Stony Brook in 1971. He is currently Oscar K. Buros Professor of Psychology at Rutgers University, where he has served as Director of Clinical Training and specializes in training graduate students in clinical research and cognitive behavior therapy.

Wilson has co-authored a number of books, including *Behavior Therapy: Application and Outcome* (with K. D. O'Leary), *The Effects of Psychological Therapy* (with S. Rachman), and *Evaluation of Behavior Therapy: Issues, Evidence, and Research Strategies* (with A. E. Kazdin). He co-edited the *Annual Review of Behavior Therapy: Theory and Practice* (with C. M. Franks), and *Binge Eating: Nature, Assessment and Treatment* (with C. G. Fairburn).

A past president of the Association for Advancement of Behavior Therapy, his academic honors include fellowships at the Center for Advanced Study in the Behavioral Sciences at Stanford in 1976–77 and 1990–91; the Distinguished Scientific Contributions to Clinical Psychology award from Division 12 of the American Psychological Association (1994); and the Distinguished Contributions to Applied Scientific Psychology award from the American Association of Applied and Preventive Psychology (1995). He was a member of the American Psychiatric Association's Eating Disorders Work Group (which developed the diagnostic criteria for eating disorders in *DSM-IV* [1994]), and serves on the National Institute of Health's Task Force on the Prevention and Treatment of Obesity.

Thomas D. Cook is Professor of Sociology, Psychology, Education and Public Policy at Northwestern University. He has a B.A. from Oxford University and a Ph.D. from Stanford University. He was an academic visitor at the London School of Economics in 1973–74, a visiting scholar at the Russell Sage Foundation 1987–88, and a fellow at the Center for Advanced Study for Behavioral Sciences 1997–98. He has received the Myrdal Prize for Science of the American Evaluation Association, the Donald T. Campbell Prize for Innovative Methodology of the Policy Sciences Organization and the Distinguished Research Scholar Prize of Division 5 of the American Psychological Association. He is a trustee of the Russell Sage Foundation and serves on the Advisory Panel of the Joint Center for Poverty Research. He has also served on federal committees and scientific advisory boards dealing with child and adolescent development, preschools and school education, and the evaluation of social programs of many kinds.

Ulf Hannerz was born in 1942 in Sweden. He received his M.A. from the University of Indiana in 1966 and his Ph.D. from Stockholm University in 1969. He is Professor of Social Anthropology at Stockholm University, Sweden.

He is a member of the Royal Swedish Academy of Sciences and the American Academy of Arts and Sciences, a former chair of the European Association of Social Anthropologists, and a former editor of the journal *Ethnos*. For several years he served as a director of the Swedish Collegium for Advanced Study in the Social Sciences, Uppsala. He has taught at several American, European and Australian universities and has done local field research in the United States, West Africa, and the Caribbean. His current research is on globalization and transnational cultural processes, and his most recent project on news media foreign correspondents has involved interviews and observations in Europe, the United States, East Asia, the Middle East, and South Africa. Among his books are *Soulside* (1969), *Caymanian Politics* (1974), *Exploring the City* (1980), *Cultural Complexity* (1992), and *Transnational Connections* (1996). Several of these have appeared in French, Spanish, and Italian editions.

Walter Kintsch is Professor of Psychology and director of the Institute of Cognitive Science at the University of Colorado, Boulder. He started his career as an elementary school teacher in Austria and then studied psychology at the University of Vienna and the University of Kansas, where he received his Ph.D. in 1960. After a dissertation on animal learning, his research focused on mathematical psychology and verbal learning. He held positions at the University of Missouri and the University of California, Riverside, and moved to Colorado in 1968. At that time his work turned to the emergent field of text and discourse processing and to modeling the comprehension process.

He is a founding member and past chair of the Cognitive Science Society, past chair of the Psychonomic Society and past president of Division 3 of the American Psychological Association (APA). He received the Distinguished Scientific Contribution Award of APA in 1992.

Wendy Griswold received her M.A. in English from Duke University and her Ph.D. in sociology from Harvard University. She taught at the University of Chicago (Sociology and the Committee on History of Culture) from 1981 to 1997. At present she is Professor of the Humanities at Northwestern University. Her books include *Renaissance Revivals: City Comedy and Revenge Tragedy in the London Theatre 1576–1980* (Chicago, 1986); *Cultures and Societies in a Changing World* (Pine Forge, 1994); and *Bearing Witness: Readers, Writers, and the Novel in Nigeria* (Princeton University Press, 2000). She is currently working on the relationship between culture and place.

William Durham is chair of the Department of Anthropological Sciences and Bing Professor in Human Biology at Stanford University. He was awarded his Ph.D. from the University of Michigan in 1977. His research is concerned with the human ecology of tropical forest peoples, the patterns and processes of evolutionary change in cultural systems, and interactions of genetic and cultural change in human populations. His publications include *Scarcity and Survival in Central America* (Stanford, 1979) and *Coevolution: Genes, Culture and Human Diversity* (Stanford, 1991). He was a fellow at the Center for Advanced Study in the Behavioral Sciences in 1989–90. He has been an editor of the *Annual Review of Anthropology*.

A

Aboriginal Rights

1. *Aboriginal Rights*

Aboriginal rights commonly are understood to be the rights of the original peoples of a region that continue to exist notwithstanding the imposition of power over them by other peoples. The term came into common usage in the 1970s, but is likely to be superseded by the term 'Indigenous rights' which gained precedence in the 1990s. Here, the two terms are considered synonyms. While seemingly straightforward, the definition of Aboriginal rights is complex and contested. This article discusses the origin and development of the concept as well as the term, and the ambiguities associated with its contemporary usage as well as those concerning the definition of 'Aboriginal peoples.' It concludes with a brief account of the history of scholarship respecting Aboriginal rights, and alternatives to the concept of rights to understand and resolve relationships between Aboriginal peoples and states.

2. *Defining Aboriginal Rights*

The concept of Aboriginal rights has existed at least since the beginnings of the period of European colonization. It originated in the political and legal system of those who colonized and poses the question of what rights rest with the original population after colonization. In this context, the term used by the British was 'Native rights.' Aboriginal rights were seen to differ from one Aboriginal group to another. Practical considerations such as the ability to resist colonial rule played an important role in determining rights (Reynolds 1999). The rationale for their determination was inevitably ethnocentric reasoning, in which similarity to European religions, customs, or economies played a crucial role (Bennett 1978).

Since the Second World War, and especially since the United Nations Declaration on *The Granting of Independence to Colonial Countries and Peoples* in 1960 (United Nations 1960), the concept of Aboriginal rights has undergone a significant shift. In Africa and Asia, colonies once ruled by European powers became independent states. Here, 'Aboriginal (or Indigenous) rights' is no longer used to describe the rights of former colonized populations, but rather the rights of peoples who now form a small and relatively powerless fragment of the state's population, such as the hunting peoples in Botswana or the scheduled tribes in India. In Scandinavia, it is applied to the rights of the Sami, albeit as an aspect of customary rather than common law. 'Aboriginal rights' is also used in Latin America, including situations where Indigenous peoples form a majority of the population in a state but do not control the state's cultural, political, and legal organization, for example, the Maya in Guatemala.

Most commonly, in the postdecolonization period 'Aboriginal Rights' is used to describe the rights of Aboriginal peoples who form a minority of the population in states founded by settlers of European origin, especially in English-speaking states with common law traditions, such as Australia, Canada (while the term 'Aboriginal rights' generally excludes treaty rights' in Canadian usage, as used here, it includes 'treaty rights'), and New Zealand. In these countries, the definition of these rights, as in the past, has been determined largely from the perspective of the state's political and legal regime. The extent and nature of these rights, as so defined, has taken different forms at different times. At some moments, states have defined Aboriginal rights as transitory, pertaining to presumptions, such as 'backwardness,' which they assumed would eventually disappear. At other times, as in Australian, Canadian, and US policies up to the 1970s, states have taken an assimilationist perspective, asserting that the future of Aboriginal peoples rests with their full integration into the general population and, concomitantly, with the disappearance of any special status ascribed to them. At other moments, governments have seen Aboriginal rights as akin to rights of ethnic or cultural minorities. They have also sought to depict Aboriginal rights as arising out of unique circumstances and are thus not comparable, for example, to colonial relations described in United Nations Declarations.

By the 1990s, Aboriginal rights had come to be understood (within the dominant legal and political regimes of settler states) as substantial legal protection to pursue a traditional way of life free from state interference. In Australia, New Zealand, and Canada, Aboriginal rights are considered to include ownership to tracts of traditional lands. States may also accept a wider range of rights. For example, Canada recognizes that Aboriginal rights include religious traditions, the pursuit of economic activities such as hunting and fishing (even using contemporary technology), and governmental powers (but only those recognized

through formal agreements with the Crown). In Canada, the rights of Indigenous peoples receive protection through a clause in its 1982 Constitution (Hogg 1997). The Aboriginal people of New Zealand, the Maori, have their rights guaranteed by the 1840 Treaty of Waitangi (Orange 1987). In the United States, Aboriginal peoples' sovereignty as "domestic dependent nations" is protected through judicial interpretation of the Constitution (Wilkinson 1987). Other states which protect Aboriginal rights do so through the common law or, as in the Philippines, by legislation (*Philippine Natural Resources Law Journal* 1999). In every case, ultimate jurisdiction over Aboriginal rights rests with the state. For example, in the United States, Aboriginal rights are under the plenary authority of Congress.

Indigenous peoples, especially in states with common law traditions, have adopted the concept and often the term, 'Aboriginal rights,' to describe their relationship with the state. They have developed at least three approaches to defining the scope of these rights. Indigenous peoples who advance the first approach see Aboriginal rights largely as rights to pursue a way of life on their traditional territories and under self-government structures with minimal interference from the state, but within the context of existing state sovereignty and ultimate jurisdiction. By accepting state sovereignty, this orientation is closely analogous to international definitions of rights of ethnic and cultural minorities (e.g., United Nations 1979).

The second approach advanced by Indigenous peoples follows the one developed in the international arena for rights of colonized peoples. The work of the Working Group on Indigenous Populations of the United Nation's Sub-Commission on Prevention of Discrimination and Protection of Minorities of the Economic and Social Council has been of major import. One result is the 'The Draft Declaration on the Rights of Indigenous Peoples.' In language that echoes the 1960 Declaration, this Declaration states that: 'Indigenous peoples have the right to self-determination. By virtue of that right they freely determine their political status and freely pursue their economic, social and cultural development' (United Nations 1994).

All parties are keenly cognizant of the usage of the 'right of self-determination' in both Declarations. Some states seek to differentiate between the right to self-determination in the two cases. Specifically, they assert that unlike the Declaration on Colonized Peoples and the Covenants, self-determination in the Draft Declaration does not sanction the redrawing of state boundaries. That is, as the New Zealand statement of 7 December 1998 to the Working Group on the Draft Declaration states (United Nations 1998):

> … any right to self-determination included in this Declaration shall not be construed as authorising or encouraging any action which would dismember or impair, totally or in part, the territorial integrity or political unity of sovereign and independent States, possessed of a government representative of the whole people belonging to the territory, without distinction as to race, creed or colour.

At the same time, many Indigenous parties consider the expression of 'self-determination' in both Declarations identical and thus see their situation as mirroring that of colonized peoples under the 1960 Declaration. In effect, this view extends the purview of that Declaration to situations of internal colonialism.

The third approach adopted by Indigenous peoples suggests that, while incorporating aspects of ethnic and minority rights on the one hand and those of colonized peoples on the other, Aboriginal rights represent something different, especially in their expression. This view is grounded on the premise that Indigenous peoples have a right to self-determination identical to that of colonized peoples. However, the resolution of this situation is not through the redrawing of political borders. Rather, they advocate a reconfiguration of political relations within the existing state, but not, as with ethnic and minority rights, within existing state polity. Instead, reconfiguration necessitates changes in the political relationship from a situation where one party dominates the other to one based on a form of political 'mutuality' (e.g., Indian Brotherhood of the Northwest Territories 1977, Orange 1987). This view of Aboriginal rights is founded on the principle of 'sharing' between peoples and is often described as established through 'treaty relationships.' In some cases, as with certain treaties in Canada, the Indigenous party understands that such a treaty relationship was established by mutual agreement at the time the treaty was negotiated. Here, the objective is to oblige the state to honor those agreements. It is an approach to resolving issues of relationship that would not necessitate the creation of new states or the redrawing of existing political borders. Only if it proved impossible to reconfigure the state in such a manner would the Aboriginal right to self-determination be expressed as the right of colonized peoples to political independence from the existing state.

Is the term 'Aboriginal rights' transitional? Perhaps. In one view, it is similar to ethnic and minority cultural rights. From another perspective, Aboriginal rights, in principle, cannot be differentiated from the rights of colonized peoples as expressed in the 1960 United Nations Declaration. Aboriginal rights from these viewpoints will be salient only as long as the political relationship between Indigenous peoples and states remains unresolved, and thereafter will be equivalent to either rights of minority cultures or rights of colonized peoples. However, the third stream of thought provides a definition of Aboriginal rights which differentiates them from those of ethnic minorities or colonized peoples. This differentiation is

located not in the origin of the rights, but in their expression. Here, the concept of Aboriginal rights is unique. It serves as a conceptual framework to reconfigure political relations between Indigenous peoples and the states within which they find themselves that promotes rather than suppresses the fact that peoples with different cultures and histories live together and share the same political space. In this sense, the concept, if not the term, may find broader application to other political situations where multiple ethnonational communities exist within the same state.

3. *Defining 'Aboriginal'*

In common usage the term 'Aboriginal' as in 'Aboriginal peoples' refers to the original people of a territory and is used to contrast that population with those who came later, especially after the invasions and colonial expansions during the past 500 years. In certain countries, the term 'Aboriginal' has a specific legal definition. For example, 'Aboriginal people' in Canada is defined constitutionally as Indians, Inuit, and Metis (the latter includes the group of people descended from marriages between Indians and settlers). In other countries, 'Aboriginal' refers to specific groups, such as in Australia where it denotes the Aboriginal people of that continent only.

Terms for particular Aboriginal peoples, such as Cree or Navajo, generally denote national identity. However, the referent for the collective term 'Aboriginal' is not that obvious. The literature lists four possibilities. The first is national identity, that is, Aboriginal peoples are defined as a collectivity of nations of people. But which nations are included and on what basis are they differentiated from other nations? The second definition is the 'original' peoples of an area, that is, those who have lived in a territory since time immemorial, or at least for a long, long time. But, does this mean that it is appropriate to refer to the Germans, the English, and other such national groups as Aboriginal? The third is way of life. In this view, 'Aboriginal peoples' are those groups who practice and have certain cultural values that encompass a particular relationship to land, certain spiritual ties, and certain kinds of internal social relationships. The typical features of Aboriginal societies are idealized to include economic norms such as gathering and hunting as well as forms of cultivation that only intrude minimally on the environment, a sense of intimate ties through spiritual relations to the land and all living and nonliving things related to it, and political systems that promote harmony rather than division. The extent to which this is always a realistic portrayal of such groups is doubtful and raises questions: Should people not live up to these ideals or cease to live up to them, are they still Aboriginal? Equally, can groups, that in other respects could not qualify as Aboriginal, become so defined solely because they make conscious efforts to incorporate such 'Aboriginal' values and practices into their lives? The fourth perspective on 'Aboriginal' is political location. Accordingly, Aboriginal refers to those national groups that are original to an area, do not have state power, and are likely in a subordinate position within existing states. Were this the case, would the achievement of state power mean that these groups are no longer Aboriginal?

Such questions may remain unanswered for a long time, in part due to the complexity of the term itself. But more importantly, the term is contested because at present the description of who constitutes Aboriginal persons and peoples may well carry with it certain internationally recognized rights. For example, there are states such as China and India that would prefer to exclude from the definition peoples who have not been incorporated into settler states through colonial processes. A definition has been developed through the United Nations Working Group on Indigenous Peoples 'for the purposes of international action that may be taken affecting their [Indigenous populations] future existence.' It is the current consensus definition. How long it remains such will ultimately depend upon political processes such as those discussed above. This definition states (Cobo 1986):

> Indigenous communities, peoples and nations are those which, having a historical continuity with pre-invasion and pre-colonial societies that developed on their territories, consider themselves distinct from other sectors of the societies now prevailing in those territories, or parts of them. They form at present non-dominant sectors of society and are determined to preserve, develop and transmit to future generations their ancestral territories, and their ethnic identity, as the basis of their continued existence as peoples, in accordance with their own cultural patterns, social institutions and legal systems .... On an individual basis, an Indigenous person is one who belongs to these Indigenous populations through self-identification as Indigenous (group consciousness) and is recognized and accepted by these populations as one of its members (acceptance by the group).

Neither the total population identified as Aboriginal by this definition nor the total number of peoples included within it can be calculated with precision; however, both are large. For example, the 1997 Working Group included Aboriginal peoples' representatives from over 25 countries from all inhabited continents. The Aboriginal peoples of these countries alone represent a population of over 100 million people (Burger 1990).

4. *Scholarship on Aboriginal Rights*

Scholarship respecting Aboriginal peoples and their rights has played an important role in Western thought since the beginnings of European colonization. One

orientation, now discredited but of great historical importance, used ethnocentric reasoning that compared Aboriginal societies and their rights with those in Europe in order to advance Western economic, social, political, and legal thought as well as to justify imperialism. Important early exemplars of this approach included Locke, Hobbes, Adam Smith, Rousseau, and Blackstone. A second orientation that continues to the present began with such as sixteenth Century Spanish scholars Vittoria, Las Casas, and Sepulveda (Dickason 1984). This approach focuses on identifying the specific rights of Aboriginal peoples under the Law of Nations and international law. A third orientation, which developed in the period between the two World Wars, concentrated specifically on the rights of 'Native' peoples within colonial legal and political systems, especially in Africa and Asia. As illustrated in the work of British social Anthropologists, the dominant paradigm, functionalism, stressed that despite cultural differences, Aboriginal societies were rational and their rights should be protected in colonial law (e.g., Malinowski 1945). Still, this scholarship was in harmony with the dominant political philosophy of the time—Indirect Rule—and did not question the ultimate authority of colonial powers in these regions.

In the postdecolonization period, scholarship on Aboriginal rights has focused largely on the situation in settler states such as Canada, the United States, Australia, and New Zealand. Three strains of research predominate. The first developed from political and legal philosophy. It concerns the nature and extent of Aboriginal rights in the abstract, asking whether they are unique or an aspect of other kinds of rights. The second, also largely researched in political science and law, questions the extent to which the state can be reshaped to accommodate the legal, economic, and political rights of Aboriginal peoples in a manner consistent with democratic principles. The third stream, which includes research in anthropology, law, political science, and other social science disciplines, discusses the legitimacy of the assertion of Aboriginal rights as special rights within the state. This approach questions the extent to which cultural differences, human rights, or the history of colonialism form legitimate grounds for assertions concerning Aboriginal rights (see *Rights: Legal Aspects*). In recent years, the scope of research has broadened to include work on Aboriginal rights and relations in countries such as in Africa and Asia that are not settler states with European origins. These streams of research have led to a rethinking of: the history of settler states (e.g., Deloria and Lytle 1984, Reynolds 1983, Williams 1990); the position of Indigenous peoples in International law (e.g., Barsh 1986, Crawford 1988); and the nature of democratic institutions and citizenship (e.g., Kymlicka 1989, Tully 1995). It is also bringing to the fore conflicts between grounding Aboriginal rights as a universal human right and as a right based on cultural difference (e.g., Wilson 1997) (see *Fundamental Rights and Constitutional Guarantees*).

The relationship between Aboriginal peoples and states has been a central focus of scholarly knowledge in many Aboriginal societies. Recently, scholarship from the viewpoint of Aboriginal societies has come into the Western academic literature, contributing to all aspects of inquiry concerning Aboriginal rights. One significant dimension concerns how specific Aboriginal peoples understand their relationships to settlers, to settler states, and to other peoples in general (e.g., Treaty 7 et al 1996). Often, these discussions are framed on the basis of sharing or treaty making between peoples rather than rights of peoples. As such, they provide a useful alternative to rights-based discourse as a means to conceptualize and reform relationships between Aboriginal peoples and states (Asch 2001).

M. Asch

Absolutism, History of

The term 'absolutism' first came into use in the nineteenth century. It describes a form of rule and government which evolved in the early modern period and dominated seventeenth- and eighteenth-century Central and Western Europe (though not England) during the formation of modern states.

The term itself, much like the period during which it prevailed, is by no means sharply defined. It has been less accepted in France and England than in Germany, where it also led to problems in the later decades. Any attempt to define absolutism must begin with an explanation of what it was not, which was 'absolute' in the sense of unlimited power. Intensive research into modern European history has brought to light the complex and multitiered requirements and conditions needed for the development of an absolute monarchy. It also revealed the limits of an absolute sovereign and highlighted the differences between the claim and reality of such rule.

1. Terminology and Theory

In a historical context, absolutism is a relatively new word. The term was rarely used at the turn of the seventeenth and eighteenth centuries, gained popularity in the nineteenth, but did not really thrive until later. What is meant by absolutism is a specific type of monarchy, which played an important role in seventeenth- and eighteenth-century Europe, the reality of which, however, is only conditionally described by the word itself. Characteristics of an absolute monarchy include the concentration of state power on a monarch who is not encumbered by other persons or institutions, and who can enforce his or her sovereignty with the instruments of legislation, administration, taxation, and a standing army, and who is also the final arbiter of the courts. That is the ideal definition, though one must distinguish between theory and concrete practical limitations. Even an absolute despot was bound by divine right, the country's fundamental laws, customs of inheritance, representation of the state abroad, and the preservation of law domestically.

The jurist Jean Bodin (1530–96) first used the term *potestas absoluta*, meaning the highest sovereign, who, independent of any institutions, is subject to no laws. Jaques Benigne Bossuet (1624–1707) most adamantly supported the theory of 'divine right': especially in regard to Louis XIV, Bossuet wrote that God is the source of royal power, making it absolute and independent of any temporal control. In his book *Patriarcha: or the Natural Power of Kings*, Robert Filmer (1588–1653), influenced by the Civil War, postulated that all royal power derives from God and interpreted that to mean unlimited paternal authority. Thomas Hobbes (1588–1679), on the other hand, wrote that a sovereign's power derives from a social contract, the unlimited and irrevocable transferal of natural human rights to a higher authority for protection from the natural condition, which is a state of perpetual war of all against all.

In the late seventeenth century, discussions on limiting monarchic power, influenced especially by the English Revolution, began in earnest. The struggle for power between parliament and the king led to civil war, the abolition of the monarchy, and then its restoration. It culminated in the 'Glorious Revolution' of 1688/9 and an unwritten constitution, which called for a 'king in parliament.' In France, ruled by an absolute monarch, the political discussion on absolutism would remain theoretical for another century.

John Locke (1632–1704) was not so much interested in limiting absolute rule, which hadn't taken hold in England, as in eliminating it. Based on a social contract, which stipulates that the power of the state derives from the unanimous agreement of free and equal men (civil society), the consent of the governed and majority rule, Locke wrote that all forms of government are characterized by their exercise of power. Locke introduced the principle of separation of power with checks and balances. Montesquieu (1689–1755) confronted the reality of the *monarchie absolue* with the concept of *monarchie limitée*, citing it as the most moderate form of government. The sovereign remains the source of state and civil authority, though it is implemented by intermediaries (*pouvoirs intermédiares*): the aristocracy, the professional associations and guilds (as institutions), the high courts and city magistrates. State power is also kept in check by the separation of the legislative, executive, and the judiciary. 'When the law making and law enforcement powers are united in the same person,' wrote Montesquieu, 'there can be no liberty.' Montesquieu saw England as the country whose constitution guaranteed these liberties, though he also recognized the historical and political circumstances that led up to it.

The various forms of absolutist rule in Europe cannot be defined by a set of theories, nor can they be limited to specific periods. Eberhard Weis has distinguished between early, courtly, classical, and enlightened absolutism (Weis 1985). These differences describe a development in time, but in reality they were not clearly drawn. One cannot claim that 'classical absolutism' did nothing in the way of political reform, nor that 'enlightened absolutism' can be classified as especially progressive or modern.

2. *Politics*

What we have come to call absolutism was a form of government that developed along with the creation of modern territorial states in Europe. It gained in strength as the power of the states was centralized and intensified and the monarch's rule was legitimized with the aim of stabilizing peace and security within and among the states.

This policy led to religious peace and internal state formation. An early example of an absolute monarchy, or rather a monarchy with absolute claims, is that of Phillip II of Spain (1556–98). Convinced of the divine right of his reign and his responsibility toward God, Phillip II ruled over a huge conglomerate that had grown though inheritance, marriage, and conquest. This conglomerate was comprised of politically, socially, and culturally diverse countries and territories, which all kept their rights and institutions. They were held together by the Spanish crown and represented by the bearer of the crown, whose power was unlimited in principle, though often limited in practice and not met entirely without resistance.

In practice, absolute rule was realized by expanding and securing territory through treaties, alliances, war with other states, the possession of military potential—preferably a standing army (*miles perpetuus*)—and the financial means to support it. Financial and taxation policy, central to absolutist rule, became the impetus for employing a complex bureaucracy. The ostentatious presentation of the power vested in the monarch was characteristic of this policy, including the royal court and court ceremonies.

Absolutism can rightly be seen as the dominant political tendency in seventeenth- and eighteenth-century Europe. The period between the Peace of Westphalia (1648) and the Peace of the Pyrenees (1659) on the one hand, and the French Revolution (1789) on the other, can roughly be seen as the 'age of absolutism.' But absolutism did not flourish everywhere in Europe: The Republic of Venice, the Swiss Confederation, the Dutch Republic, the elected monarchy in Poland, or the many principalities and religious states of the Holy Empire were counterexamples. The only case in Europe where absolute despotism was introduced as law was Denmark in 1661.

Sweden's introduction in parliament (*Riksdag*) of an absolutist regimen in 1686 was replaced with the 'Age of Liberty,' an almost preparliamentary system, just 40 years later. In England, the Stuart dynasty's attempts at absolute despotism were thwarted by parliament. After the Civil War, the king's execution, and the abolition and resurrection of the monarchy, the end of the Glorious Revolution (1688/89) resulted in a parliamentary monarchy with a 'king in parliament.' During the same period, absolute despotism was enjoying its high point in France. Louis XIV was a model and ideal of absolutism and a royal court thronging around the monarch.

The dissimilar results of the two cases, both of which were precipitated by heavy fighting—between the crown and nobility in France, in England between the crown and parliament presenting the entire country—points to the importance of the differing historical political and social circumstances under which the rise, stall, and failure of absolutism occurred.

For a long time, historians predominantly dealt with absolutism only under the aspect of its importance in the development of the modern state. Absolute despotism was seen to have promoted the political, social, and economic development of Europe by strengthening the state, suppressing moves for independence by powerful nobles, establishing and ensuring religious hegemony, expanding the administration, supporting trade and early industry and eliminating the political influence of professional associations and guilds. This view underestimates the dependence of the monarchy on older local and regional institutions; institutions that protected not

only their corporate rights but also the rights of individuals. The numerous *pouvoirs intermédiares*, which, according to Montesquieu, placed boundaries on freedoms of the monarch, did forfeit some of their political significance under absolute despotism, but they remained constituent elements of the monarchy.

The encroachment on castes and corporate bodies, on the privileges of the aristocracy and the church, as well as their integration into the state, and the attempt in Germany to achieve independence from the constitution and high courts, comprised only a part of absolutist policies. The organization and presentation of despotic rule was more important. This included the creation of institutions and offices dependent on the monarch, the creation by monarchs of an administration subject only to them, to include the regional level, organizing the government and recruiting its staff—not only from the nobility, but also from the bourgeoisie—and the establishment of a civil servant nobility.

Finance and taxation posed the biggest problem for absolute monarchs, especially the collection and redistribution of taxes. This is where the contradictions and limits of absolutism can be seen most clearly. The tax privileges of the aristocracy were left untouched, income and spending not balanced. France could not do away with patronage and private tax collectors. Prussia developed a tightly controlled and vigorously pursued tax system, supported by the fusion of the military and provincial treasuries and the implementation of a tax administration on the municipal level, which, relative to the population, favored an oversized army, in sharp contrast to the rigorous frugality in other areas and the representational culture of the court.

Among the notable consequences of absolutist policy were the beginnings of planned trade and economic policies following the principles of mercantile theory (initially in France) or cameralism, which in Germany was developed into administrative theory and later into the academic science of public administration. The advance of early and preindustrial manufacturing disappointed early expectations. Lagging behind England, it nevertheless precipitated the economic development on the continent. In the long term, absolutism also had an elementary effect on day-to-day life through the increasing regulation by the state, the introduction of compulsory schooling, the church maintaining state tasks (e.g., the census, the declaration of state edicts via the pulpit). This was especially true in Protestant rural areas, where the church had a profound influence on people's behavior, preaching the virtues of hard work and obedience toward state authority. Obedience to the state, both directly and indirectly, became ubiquitous. The fact that this educational process was by no means linear or similarly successful everywhere, should not lead one to doubt its influence in general. To call it *Sozialdisziplinierung*, as Gerhard Oestreich did, is only correct if one does not see the state as strict enforcer of discipline, but rather in the sense of getting the public used to government regulation, recognizing its usefulness and growing demands on the state. Under absolutist rule, court proceedings were often decided against peasants and citizens, which frequently led to difficulties enforcing laws and regulations at the local level.

Patronizing the sciences, most spectacularly by naming academics to the royal academies of science, which themselves were founded not only in expectation of research, but to increase the cultural esteem of the royal house. The constant display of power and dignity, especially at the royal court, and at which France's Louis XII exceeded, was an exercise of power. That made Versailles, both symbolically and concretely, France's cultural center. It was not only a place to which all those looked who were seeking office and rank, decoration and pardon, or commissions and rewards, but it was also where one looked to confirm and strengthen one's national pride.

The exaggeration of the *monarchie absolue* could not last. The entire system of absolutism was in danger of becoming paralyzed, losing respect and approval if it lacked the ability to conform, develop, and reform within the boundaries of the social and economic situation, or if it lacked the political consciousness, as in France, where, after failed attempts in the second half of the eighteenth century, the monarchy proved unable to take the decisive step away from absolutism and toward a constitutional monarchy.

3. *Enlightened Absolutism*

The term 'enlightened absolutism' (*Aufgeklärter Absolutismus*, *despotisme éclair*) remains controversial. German historians, particularly, have used the term to distinguish a later period of absolutism in German-speaking Europe from classical absolutism that existed in France before the revolution of 1789 and which had prevented reform. According to this view, the governments of several of the German states, influenced by the Enlightenment, which began in the mid-eighteenth century, left the idea of classical absolutism behind them. They began the transition from absolute despotism to an administrative state and a reformed monarchy.

Examples of this phenomenon were seen in the Prussia of Frederick II (1740–86) as well as in Austria during the reign of Maria Theresia and Joseph II (1740–90). There was no solid foundation of theory to support enlightened despotism. It was simply the practice of enlightened monarchs directed by their understanding of the task to modernize the political, economic, and social circumstances of their countries, and to abandon hindering laws, institutions, and traditions. In achieving this goal, they often justified using an approach even more rigorous than under

classical despotism. For Frederick II, the monarchy was an office imposed on him by a social contract which could neither be taken from him, nor from which he could escape. He considered himself the highest servant of the state and saw it as his duty to act in the best interest and well-being of the state and his subjects, but also to decide what those interests were and what means would be used to achieve them. Frederick II also determined just how much influence the Enlightenment should have on Prussian politics. His absolutist regimen was underlined and reinforced by the paring down of the royal court, his personal command and control, and increasingly rigid adherence to a monarchic military and administrative state as well as state control of the professional associations, guilds, and mercantile policies.

Did 'enlightened absolutism' possess the ability to reform itself? Was the Enlightenment a practical philosophy, a rational way of thinking, an emancipating mentality—was it the motivating factor behind absolutist monarchies' reform policies? What did it accomplish?

Much of what is often ascribed to the Enlightenment—that is, the influence of the Enlightenment on the interpretations and actions of monarchs, their ministers, and councils—actually goes back to the earlier intentions and foundations of governments in the seventeenth century. It is also based on the concept that welfare, security, and happiness are the aim and duty of politics, which was anything but new. The justification and legitimization of reform policies, their scope and aims as well as their methods of execution, were new. The policies and their success depended more on the conditions in the states of the latter half of the eighteenth century than they did on energy, providence, and political savvy. It should be noted that enlightened reform was undertaken in states that, in the eyes of the reformers, were underdeveloped (i.e., Spain, Portugal, Naples), where reforms were extended and accelerated (Austria, Tuscany), or where the reforms had to be more systematic and thorough (Prussia). The suppression of the Jesuit Order (1773) helped invigorate reform policy in Catholic countries. In other countries, reorganization was brought on by the loss of territory (Galicia and Lodomeria to Austria after the first Polish division, Silesia to Prussia after the 1st Silesian War). In many other places, the improvement of trade and commerce drove politics, as did, when the monarch was weak, the vigor of leading ministers.

With variances in the different states, the reforms applied to criminal and procedural law and prisons as well as to the standardization and codification of civil law in the various regions. The Prussian code '*Landrecht*' (1794) demanded a state-controlled school system, increased agricultural efficiency, the influx and settlement of foreigners, administrative reform, and improvements in health care and care for the poor.

The introduction of Austria's 'Toleration Patent' under Joseph II (1782) was considered a good example of enlightened reform policy. His abridgement of the (Catholic) Church's influence, closing down of monasteries and convents and attempts to improve the education of priests were met with both approval and resistance. Disciplinary measures affecting the public's religious life (limiting the number of holidays and pilgrimages) led to opposition.

The military constitution and the interests of the nobility set limits to the state protection of the peasants against the encroachment by large landowners. The semiservitude of East-Elbe peasants, for example, was left untouched. This contrasts with Austria, where the nobility was even taxed. In general, one can say that in the period of 'enlightened absolutism' the privileges of the nobility remained intact. Full emancipation of peasants was achieved only in Sweden and Denmark, and late there as well.

The reform policies of 'enlightened absolutism' was entirely an authoritarian affair. The monarch and government were sure of their actions. In most cases, they did not seek the approval of the *pouvoirs intermédiares* or of their subjects, for whom they did look out, since a free 'public' was considered an important condition of enlightened, liberal policy.

Enlightened absolutism or 'reform absolutism,' as it is sometimes called (E. Hinrichs), was often more decisive than 'classic' absolutism could be. It met very little institutional resistance. Its problem was that it left untouched the structure of privileged society, which kept tight control of the measure, flexibility, and extent of reform, and even disrupted or ended it. The aristocracy might also, as was the case with Joseph II, drive reform forward with a hasty flood of laws. The attempt has been labeled 'revolution from above.' Joseph II had to retract many of his decrees before his death. His brother and successor, Leopold II (1790–2), Grand Duke of Tuscany, a model enlightened monarch and one of Joseph's critics, had to rescind even more reforms in light of unrest aimed at Joseph in the Netherlands and Hungary and the French Revolution.

Nowhere did enlightened absolutism lead directly to a constitutional monarchy. But since the reform path had already been taken and sustained despite much resistance—the counterreformation had begun even before the French Revolution—could they be expected to continue? Did reforms, in those countries where they were instituted, prevent a revolution or even make it unnecessary? Was reform perhaps prevented or blocked by the radicalization and expansion of the revolution?

That is certainly one of the reasons the drive toward revolutionary change was relatively weak in Germany. Many of the German states, including the religious ones, were ruled by moderate, enlightened governments already prepared to make reforms. The reform policies from 1800 to 1820 were made necessary by Napoleon's intervention in Germany. In many

respects the policies were directly linked to the reforms of enlightened absolutism and Bonapartism. With the exception of the most important German states, Austria and Prussia, the reforms resulted in an early form of constitutionalism in many states. The emerging restoration jammed up, but did not end, that process. The importance of the executive over the legislative in Germany, the 'constitutional monarchy' which can be characterized as 'state' or 'bureaucratic absolutism,' remained even after the 1848 revolution.

4. Current State of Research

The actuality of 'absolutism' research is based on the:

(a) difficulty depicting, in the era after World War I, the history of modern states as a continuous development;

(b) results of prodigious international research into the history of representative (class) and parliamentary institutions;

(c) discussion of 'early modern period' as a phase between the Middle Ages and modern times;

(d) analysis of the historical circumstances and meaning of absolutism in the creation of European states;

(e) interpretation of France's political *longue durée* and its structures;

(f) debate on enlightened or reform absolutism and its modernity.

The question has arisen, during the course of research and debate, of whether one can still speak about absolute monarchy, absolute rule, and an 'age of absolutism' or if one should differentiate further and include content-related terms. Recent research into the daily life, mentality, and behavioral history of the early modern period has shown how distant the world of that time is in which elements of the modern period developed. We must also reinforce comparative research, the various conditions under which absolutism thrived, was laid claim to or failed, and its consequences in the development of state and society, even today.

Academic Achievement: Cultural and Social Influences

The term 'school achievement' or 'academic achievement' encompasses many aspects of students' accomplishments in school, including progress in core academic subjects—mathematics, science, language, arts, and social studies, as well as in subjects that are emphasized less frequently in contemporary curricula, such as athletics, music and the arts, and commerce. Because of the emphasis placed on the core subjects, it is to the literature in the core subjects that reference is made most frequently in discussions of research and

philosophies of education. Little attention has been paid to achievements in personal and social spheres (Lewis 1995).

1. Obstacles to Discussion

Discussions of the influence of culture and social factors on academic achievement must deal with a complex and highly contentious area of research and social policy. The area is complex because many factors are involved and contentious because the discussion often relies on differences in the personal experience of the participants rather than on carefully conducted research. Unfortunately, these obstacles sometimes allow untrained advocates of many different positions in education to gain a ready audience among policy makers and the general public.

2. Special Problems

A good deal of attention is given in this article to methodological factors that pose special problems for research dealing with the influence of cultural and social factors on academic achievement. Emphasis has been placed on academic achievement rather than school achievement because the available information has been directed primarily at attempts to explain success in core academic subjects. Consequently, the first major section of this article deals with important methodological factors. The second section is concerned with interpretations of some of the most commonly obtained results and the final section is oriented toward policy issues that emerge in these areas of concern.

3. Cultural Factors in Education and Social Policy

A commonly asked question is why cultural factors, such as beliefs, attitudes, and practices which distinguish members of one culture from others should be of general interest. They are of interest primarily because of what can be learned about the researchers' own culture (Stevenson and Stigler 1992). By placing practices from one culture in juxtaposition with those of other cultures, everyday events suddenly demand attention and concern; events once considered to be novel or unique become commonplace. For example, five-year-olds in one culture may be able to solve mathematics problems that their peers in a second culture are able to solve only after several years of formal instruction. Proposing cultural factors to account for such a difference in academic achievement leads to new perceptions of the capabilities of kindergarten children and of how cultures differ in their efforts at explanation.

Another important contribution of comparative studies of academic achievement is to clarify the characteristics of different systems of education. What may be routine in terms of what is expected in one culture may be regarded as an exciting innovation by members of another culture. As a result of such discoveries, comparative studies of academic achievement have received increasing attention since the 1970s (Paris and Wellman 1998).

4. Comparative Studies

Led primarily by the International Association for the Evaluation of Educational Achievement (IEA), some of the most extensive studies of school achievement have taken place since the 1970s. These have included the First and Second International Mathematics Study, and more recently, the Third International Mathematics and Science Study (TIMSS) a project that involved over 500,000 students in 41 countries (Beaton et al. 1996, Martin et al. 1997). These studies provide a basis for discussing methodological issues involved in research on cultural factors related to academic achievement. Results have been similar in the three IEA studies and in other, smaller comparative studies: Western students were out-scored by students from many countries, especially those from East Asia, including Japan, Hong Kong, Singapore, and South Korea (Stevenson and Lee 1998). The only high scoring Western country was the Czech Republic.

The results were startling to the low-ranking cultures; they aroused a heightened concern for issues in education policy and education reform throughout the West. Policy makers have attempted to explain the performance of students in countries such as Germany and the United Kingdom, which had exerted leadership in research and application in mathematics and science for many years, and in countries such as the United States, where there have been large investments in education for many years.

4.1 Interpreting Differences

However, rather than focusing on Western weaknesses, it is more useful to go on to other, more productive discussions. Primary among these is a consideration of the successes and weaknesses of the explanations offered by different cultures in their efforts to clarify the bases of their students' low scores. Because many of the comparisons made in TIMSS involved Germany, Japan, and the United States, reference is made to these countries in discussing comparative studies. A review of the literature is likely to suggest explanations such as the following.

4.1.1 Common explanations.

(a) *Motivation*. Western students are involved less intensely in the achievement tests than are students in other cultures and are less likely to attend closely to the problems they are to solve.

(b) *Homework*. Western students are assigned less homework than are students in East Asian cultures, thereby depriving Western students of the extensive practice and review that are available in East Asia.

(c) *Time at school*. The school day and the school year are shorter in Western cultures, creating an unfair advantage to cultures that provide their students with greater opportunities to learn.

(d) *Heterogeneity of populations*. The population of many Western countries is assumed to be more diverse than those of East Asian cultures, resulting in a disproportionate representation of low-achieving students.

(e) *Divorce and poverty*. Many Western students lack harmonious and healthy psychological and social environments at home. As a result of parental disinterest and lack of support, Western students are less able to obtain pleasure and satisfaction from their experiences at school.

5. *Problems in Evaluation*

Advocates of particular viewpoints are able to continue to propose factors such as these as explanations of the differences in achievement precisely because the proposals are so difficult to evaluate. What measures serve as reliable indices of a culture's emphasis on mathematics and science? What evidence is there that home life is less healthy in Western than in other cultures? Does time devoted to clubs and extracurricular activities rather than to academic study provide a partial account for the longer school days found in some cultures? A search of the literature would reveal little firm data to support the usefulness of these measures as reliable explanations of differences in academic achievement.

5.1 *Designing Comparative Studies*

The main problem with these explanations of cultural differences in academic achievement is that they have not been subjected to careful scrutiny, especially in the area of methodology. It is useful, therefore, to discuss some of the methodological considerations that merit attention in comparative studies of academic achievement.

5.2 *Selection of Participants*

Common criteria are required for the selection of participants in comparative studies of different cultures, for comparisons across cultures are valid only if they are based on representative samples of the members of the cultures included in the research.

5.3 *Tests*

It is obviously unfair to test students with questions that cover information not yet discussed in their classroom lessons. One appropriate index of culture-fair materials can be obtained from analyses of the content of the participants' textbooks.

5.4 *Questionnaires*

Items which are not developed within the context of the cultures participating in the research run the risk of introducing bias into the interpretation of differences in academic learning. A problematic practice is the tendency to rely on questionnaires that have been constructed in Western or other cultures, translated and back-translated, and then adopted as the research instruments in a comparative study. Translation and back-translation may be helpful with relatively simple concepts but they are often inadequate as sources of information about the psychological and cultural variables in studies involving several different cultures. Creating instruments in different languages that are truly comparable in content and nuances of meaning is extremely difficult and requires the simultaneous participation of persons with high levels of skill in each of the languages as well as in the terminology of the social sciences.

5.5 *Interviews*

Questionnaires have an important role to play in the rapid collection of large amounts of data, but one-on-one structured interviews are likely to be a more fertile ground for obtaining insights into cultural phenomena. Large-scale studies seldom have the necessary time or funds to permit such interactions with more than a subsample of the population of participants included in the study, thereby limiting the range of respondents and number of topics that can be included.

5.6 *Ethnographies*

Ethnographies, like interviews, typically are conducted with subsamples of the groups being studied, but the ability to observe and to participate in daily activities reduces the possibilities of misunderstandings, low motivation, distractibility, and other problems that may accompany the use of methods where such participation is not possible.

6. Using Computers

The introduction of computers has made it possible to conduct new types of observational analyses. Although video cameras have been used effectively in educational settings for several decades, analysis of the videotapes continues to be cumbersome.

6.1 Computer Programs for Observational Records

Computers change the manner in which observational records can be taped and analyzed, thereby greatly extending the number and reliability of observations that can be included in a study. Rather than have a single observer compile a narrative or time-sampling record of activities, permanent records made under comparable conditions are readily available for detailed analyses. The combination of compact disks for recording video images, the attachment of translations of the audio portion, and the rapid location of images illustrating concepts and processes introduces vastly expanded opportunities for the creation of reliable observations of everyday behavior in social and academic settings (Stigler and Hiebert 1999).

6.2 Statistical Analyses

A second consequence of the use of powerful computers is in statistical analyses. In general, our knowledge of correlates of academic achievement was limited because of the impossibility of processing large amounts of data. It has become routine to consider sets of data that would have been impossible to handle with the computer and recording capabilities available only a few decades ago.

6.3 Choosing a Method

There is no consensus concerning the method that is most appropriate for studies of cultural and social variables. The most vigorous argument pits quantitative methods represented in tests and questionnaires against an opposing view that seeks more frequent collection of qualitative, descriptive information.

In the end, the appropriateness of each method depends on the types of research questions being asked. TIMSS adopted all of the methods: tests, questionnaires, interviews, ethnographies, and videotaped observations. The inclusion of so many methods was partially a response to criticisms that comparative studies had not yielded test items appropriate for evaluating achievement in different cultures nor had they offered more than superficial explanations of the bases of different levels of academic achievement. Although the integration of information obtained from the various methods remains a time-consuming task, the use of various methods vastly expands the possibilities for understanding the influence of social and cultural variables on students' achievement.

7. Culture and Policy

The ultimate purpose of research dealing with the influence of culture on academic achievement is to provide evidence for maintaining the *status quo*, for instituting new policies, or for modifying older ones. In realizing these purposes, policies are translated into action. Because of methodological problems and the resulting tentativeness of conclusions derived from research involving cultural and social phenomena, discussions of education policy often involve defenses of opposing views. Several examples illustrate some of the sources of disagreement.

7.1 Nature and Nurture

As in accounts for many psychological functions, explanations for successful achievement have tended to rely on both innate biological and acquired environmental variables (Friedman and Rogers 1998). Positions that emphasize the role of biology typically discuss innate differences among persons in attributes such as intelligence, personality, and motivation. In contrast, those that emphasize the influence of experience are more likely to consider the contributions of social status, home environments, and child-rearing practices. As research has progressed in studies of achievement, an interaction view of causality has been adopted. According to this view, the effects of innate and acquired factors are considered to be interactive, such that the influence exerted by each factor depends on the status of the second factor. For example, the low ability of slow learners may be compensated for by diligent study to produce average achievement, whereas neither factor alone may provide a sufficient explanation. Throughout East Asia, practices continue to be guided by the environmentalism contained in still influential Confucian principles. In contrast, Western explanations have tended to depend increasingly on innately determined factors in their interpretations of the bases of academic achievement.

7.2 Tracking

One of the most difficult dilemmas facing educators is the question of how classrooms should be organized. In some cultures it is believed that children should be separated into ability groups early in their education; members of other cultures believe this should occur later in the child's life. In Germany, for example, students attend general-purpose schools through the

fourth grade. Following this, the rapid learners who aspire to attend university are admitted to *Gymnasien*, academically oriented secondary schools with high standards. Arrangements are made for their slower learning peers to attend schools that provide a less demanding curriculum but offer opportunities to gain practical experience that will qualify them for employment after their graduation. In China and Japan, on the other hand, the separation of students into different tracks does not occur until the students enter high school. Behind these beliefs is the assumption that academic success is strongly dependent on the child's motivation and diligence, qualities that Germans believe can be gauged by the time children are 10 years old. Japan and China reject this assumption and suggest that it is impossible to evaluate the child's interest and potential for academic work until after the student has experienced the more demanding years of junior high school.

7.3 Education Standards

Another difficult decision that must be made by education authorities concerns the level of achievement for which the academic curricula are constructed and the manner in which academic performance is evaluated. To whom should education standards be addressed? Should officials who supervise the construction of the curriculum and of evaluation aim at average students or should the standards be more demanding and establish levels of performance toward which all students should aspire?

One argument against increasing standards demanded of all students is that they will experience heightened stress and anxiety, or in the worst case, resort to suicide. Studies provide little support for this argument. Students in high-achieving countries may complain about the need to work harder but they display little evidence of heightened stress. When asked about their reaction to high academic demands they point to the fact that all students are expected to improve, thus, it is a shared requirement for which they have the support of their families and of society. Western students, with more competing goals and weaker support for academic achievement, report more frequent stress related to their school work.

Other arguments are put forth against the adoption of standards that exceed the capabilities of low achievers. Even though members of many societies may decide to emphasize the education of the average child, they are faced with the problem of exceptionally high and low achievers. High achievers are of concern because if they are placed in special classes they gain the advantage of qualifying for prestigious programs and obtaining admission to schools with high standards, excellent teachers, and up-to-date facilities. Attention to low achievers is also required if all students are to attain their maximal potential. Research on learning and teaching practices in different cultures may offer suggestions for innovative solutions to this dilemma.

7.4 Attributions for Success

Highly significant differences appear among the choices of students in different cultures when they are asked to explain the sources of high levels of academic achievement. Students are asked to explain the most important sources of achievement—studying, natural ability, difficulty of the task, or luck. East Asian students are more likely to choose studying than are Western students and Western students are more likely to choose innate ability than are East Asian students. If the alternatives are modified to include studying, having a good teacher, home environment, or innate ability, the positive consequences of studying are again emphasized by East Asian students. Western students are more likely to choose 'having a good teacher.' Whether this is because the quality of teachers actually does differ to a greater degree in Western cultures than in East Asia or because Western students are unwilling to assume responsibility for their performance, nearly all variants of the attributions about which the questions are asked produce significant cultural effects.

8. Conclusion

It is clear that academic achievement is tied closely to social and cultural factors operating within each society. Relying both on indigenous beliefs, attitudes, and practices as well as those borrowed from other cultures, information is obtained in studies comparing different societies that is of local as well as more universal significance. Thus, the ultimate goal of attempting to understand antecedents and correlates of academic achievement requires familiarity with practices that lie both within and among cultures. It seems unlikely, however, that demands for high achievement will be met by a nation's schools until the bodies of research dealing with these phenomena are understood more thoroughly.

Study of practices that exist within cultures demonstrating high levels of academic achievement may be especially fruitful. This does not mean that differences among cultures are ignored; it does mean that broader consideration of successful practices may lead to advances in performance by children and youths at all levels of ability and from a much broader range of societies.

Academic Achievement Motivation, Development of

Over the years, psychologists have proposed many different components of academic motivation (see Weiner 1992 for full discussion of history of this field). Historically, this work began with efforts to understand and formalize the role of the basic need of achievement for human drive, the introduction of the idea of competence motivation, and early work on expectancies and social learning. Developmentalists such as Vaugh and Virginia Crandall, Battle, and Heckhausen translated these ideas into a developmental framework for studying the origins of individual differences in achievement motivation (e.g., Battle 1966, V C Crandall 1969, V J Crandall et al. 1962, Heckhausen 1968). Sarason and his colleagues elaborated the concept test anxiety, developed measures, and outlined a developmental theory to explain the origins of individual differences in this critical component of academic achievement motivation (e.g., Sarason et al. 1960, Hill and Sarason 1966).

Through this early period, the focus was on achievement motivation as a drive and need. With the cognitive revolution of the 1960s, researchers shifted to a much more cognitive view of motivation. Largely through the work of Weiner, attribution theory became the central organizing framework (see Weiner 1992). This article falls in this cognitive tradition.

Eccles et al. (1998) suggested that one could group these various components under three basic questions: Can I succeed at this task? Do I want to do this task? Why am I doing this task? Children who develop positive and/or productive answers to these questions are likely to engage their school work and to thrive in their school settings more than children who develop less positive and/or noneffectual answers.

1. Can I Succeed?

Eccles and her colleagues' expectancy—value model of achievement-related choices and engagement, (see Eccles et al. 1998) is depicted in Fig. 1. Expectancies and values are assumed to directly influence performance, persistence, and task choice . Expectancies and values are assumed to be influenced by task-specific beliefs such as perceptions of competence, perceptions of the difficulty of different task, and individuals' goals and self-schema. These social cognitive variables, in turn, are influenced by individuals' perceptions of other peoples' attitudes and expectations for them, by their own interpretations of their previous achievement outcomes, and by their affective memories of, or affective expectations about, similar tasks. Individuals' task-perceptions and interpretations of their past outcomes are assumed to be influenced by socializer's behavior and beliefs, by their own histories of success and failure, and by cultural milieu and unique historical events.

Bandura (1997) proposed a social cognitive model of motivated behavior that also emphasizes the role of perceptions of efficacy and human agency in determining individuals' achievement strivings. He defined self-efficacy as individuals' confidence in their ability to organize and execute a given course of action to solve a problem or accomplish a task. Bandura proposed that individuals' efficacy expectations (also called perceived self-efficacy) are determined by: previous performance (people who succeed will develop a stronger sense of personal efficacy than those who do not); vicarious learning (watching a model succeed on a task will improve one's own self-efficacy regarding the task); verbal encouragement by others, and the level of one's physiological reaction to a task or situation.

Bandura (1997) proposed specific development precursors of self-efficacy. First, through experiences controlling immediate situations and activities, infants learn that they can influence and control their environments. If adults do not provide infants with these experiences, they are not likely to develop as strong a sense of personal agency. Second, because self-efficacy requires the understanding that the self produced an

Figure 1
Model of Achievement Goals

action and an outcome, Bandura argued that a more mature sense of self-efficacy should not emerge until children have at least a rudimentary self-concept and can recognize that they are distinct individuals—which happens sometime during the second year of life. Through the preschool period, children are exposed to extensive performance information that should be crucial to their emerging sense of self-efficacy. However, just how useful such information is likely depends on the child's ability to integrate it across time, contexts, and domains. Since these cognitive capacities emerge gradually over the preschool and early elementary school years, young children's efficacy judgments should depend more on immediate and apparent outcomes than on a systematic analysis of their performance history in similar situations.

2. *The Development of Competence-related/ Efficacy Beliefs*

2.1 *Changes in Children's Understanding of Competence-related Beliefs*

Nicholls asked children questions about ability, intelligence, effort, and task difficulty, and how different levels of performance can occur when children exert similar effort (e.g., Nicholls 1990). He found four relatively distinct levels of reasoning: Level One (ages 5 to 6)—effort, ability, and performance are not clearly differentiated in terms of cause and effect; Level Two (ages 7 to 9)—effort is seen as the primary cause of performance outcomes; Level Three (ages 9 to 12)—children begin to differentiate ability and effort as causes of outcomes; Level Four—adolescents clearly differentiate ability and effort. They understand the notion of ability as capacity and believe that ability can limit the effects of additional effort on performance, that ability and effort are often related to each other in a compensatory manner, and, consequently, that a successful outcome that required a great deal of effort likely reflects limited ability.

2.2 *Change in the Mean Level of Children's Competence-related Beliefs*

Children's competence-related beliefs decline across the school years (see Eccles et al. 1998). To illustrate, in Nicholls (1979) most first graders (6 years old) ranked themselves near the top of the class in reading ability, and there was essentially no correlation between their ability ratings and their performance level.

In contrast, the 12-year-olds' ratings were more dispersed, and their correlation with school grades was 70 or higher. Expectancies for success also decrease during the elementary and secondary school years. In most laboratory-type studies, 4- and 5- year old children expect to do quite well on a specific task, even after repeatedly failing (Parsons and Ruble 1977). Across the elementary school years, the mean levels of children's expectancies for success both decline and become more sensitive to both success and failure experiences.

These studies suggest that most children begin elementary school with quite optimistic ability-related self-perceptions and expectations, and that these beliefs decline rather dramatically as the children get older. In part this drop reflects the initially high, and often unrealistic, expectations of kindergarten and first-grade children. Other changes also contribute to this decline—changes such as increased exposure to failure feedback, increased ability to integrate success and failure information across time to form expectations more closely linked with experience, increased ability to use social comparison information, and increased exposure to teachers' expectations.

Some of these changes are also linked to the transition into elementary school. Entrance into elementary school and then the transition from kindergarten to first grade introduces several systematic changes in children's social worlds. First, classes are age stratified, making within-age-ability social comparison much easier. Second, formal evaluations of competence by 'experts' begin. Third, formal ability grouping begins usually with reading group assignment. Fourth, peers have the opportunity to play a much more constant and salient role in children's lives. Each of these changes should impact children's motivation. Parents' expectations for, and perceptions of, their children's academic competence are also influenced by report card marks and standardized test scores given out during the early elementary school years, particularly for mathematics (Alexander and Entwisle 1988).

There are significant long-term consequences of children's experiences in the first grade, particularly experiences associated with ability grouping and within class differential teacher treatment. For example, teachers use a variety of information to assign first graders to reading groups including temperamental characteristics like interest and persistence, race, gender, and social class. Alexander, et al. (1993) demonstrated that differences in first-grade reading group placement and teacher-student interactions have a significant effect (after controlling for initial individual differences in competence) on motivation and achievement several years later. Furthermore, these effects are mediated by both differential instruction and the impact of ability-group placement on parents' and teachers' views of the children's abilities, talents, and motivation (Pallas et al. 1994).

3. *Theories Concerned With the Question 'Do I Want to Do This Task?'*

3.1 *Subjective Task Values*

Eccles et al. (1983) outlined four motivational components of subjective task value: attainment value, intrinsic value, utility value, and cost. Attainment value is the personal importance of doing well on the task. Intrinsic value is the enjoyment the individual gets from performing the activity, or the subjective interest the individual has in the subject. Utility value is how well a task relates to current and future goals, such as career goals. Finally, they conceptualized 'cost' in terms of the negative aspects of engaging in the task (e.g., performance anxiety and fear of both failure and success), as well as both the amount of effort that is needed to succeed and the lost opportunities resulting from making one choice rather than another.

Eccles and her colleagues have shown that ability self-concepts and performance expectancies predict performance in mathematics and English, whereas task values predict course plans and enrollment decisions in mathematics, physics, English, and involvement in sport activities even after controlling for prior performance levels (see Eccles et al. 1998). They have also shown that values predict career choices.

3.2 *Development of Subjective Task Values*

Eccles and their colleagues have documented that even young children distinguish between their competence beliefs and their task values. They have also shown that children's and adolescents' valuing of certain academic tasks and school subjects decline with age.

Although little developmental work has been done on this issue, it is likely that there are differences across age in which of the components of achievement values are most dominant motivators. Wigfield and Eccles (1992) suggested that interest is especially salient during the early elementary school grades. If so, then young children's choice of different activities may be most directly related to their interests. And if young children's interests shift as rapidly as their attention spans, it is likely they will try many different activities for a short time each before developing a more stable opinion regarding which activities they enjoy the most. As children get older the perceived utility and personal importance of different tasks likely become more salient, particularly as they develop more stable self-schema and long-range goals and plans.

A third important developmental question is how children's developing competence beliefs relate to their developing subjective task values? According to both the Eccles et al. model and Bandura's self-efficacy theory, ability self-concepts should influence the de-

velopment of task values. Mac Iver et al. (1991) found that changes in junior high school (ages 11–13) students' competence beliefs over a semester predicted changes in children's interests much more strongly than vice versa. Does the same causal ordering occur in younger children? Wigfield (1994) proposed that young children's competence and task-value beliefs are likely to be relatively independent of each other. This independence would mean that children might pursue some activities in which they are interested regardless of how good or bad they think they are at the activity. Over time, particularly in the achievement domain, children may begin to attach more value to activities on which they do well, for several reasons: first, through process associated with classical conditioning, the positive affect one experiences when one does well should become attached to the activities yielding success. Second, lowering the value one attaches to activities that one is having difficulty with is likely to be an effective way to maintain a positive global source of efficacy and self-esteem. Thus, at some point the two kinds of beliefs should become more positively related to one another.

3.3 Interest Theories

Closely related to the intrinsic interest component of subjective task value is the work on 'interest' (Renninger et al. 1992). Researchers in this tradition differentiate between individual and situational interest. Individual interest is a relatively stable evaluative orientation towards certain domains; situational interest is an emotional state aroused by specific features of an activity or a task. The research on individual interest has focused on its relation to the quality of learning. In general, there are significant but moderate relations between interest and text learning. More importantly, interest is more strongly and positively related to indicators of deep-level learning (e.g., recall of main ideas, coherence of recall, responding to deeper comprehension questions, representation of meaning) than to surface-level learning (e.g., responding to simple questions, verbatim representation of text). The research on situational interest has focused on the characteristics of academic tasks that create interest. Among others, the following text features arouse situational interest: personal relevance, novelty, and comprehensibility.

3.4 Developmental Changes in Interest

Several researchers have found that individual interest in different subject areas at school declines continuously during the school years. This is especially true for the natural sciences (see Eccles et al. 1978). These researchers have identified changes in the following instructional variables as contributing to these declines: clarity of presentation, monitoring of what happens in the classroom, supportive behavior, cognitively stimulating experiences, self-concept of the teacher [educator vs. scientist], and achievement pressure.

3.5 Intrinsic Motivation Theories

Over the last 25 years, studies have documented the debilitating effects of extrinsic incentives on the motivation to perform even inherently interesting activities (Deci and Ryan 1985). This has stimulated interest in intrinsic motivation. Deci and Ryan (1985) argue that intrinsic motivation is maintained only when actors feels competent and self-determined. Deci and Ryan (1985) also argue that the basic needs for competence and self-determination play a role in more extrinsically motivated behavior. Consider, for example, a student who consciously and without any external pressure selects a specific major because it will help him earn a lot of money. This student is guided by his basic needs for competence and self-determination but his choice of major is based on reasons totally extrinsic to the major itself. Finally, Deci and Ryan postulate that a basic need for interpersonal relatedness explains why people turn external goals into internal goals through internalization.

3.6 Developmental Changes in Intrinsic Motivation

Like interest and subjective task value intrinsic motivation declines over the school years (see Eccles et al. 1998), particularly during the early adolescent years (which coincide in many countries with the transition into upper-level educational institutions). Such changes lead to decreased school engagement. The possible origins of these declines have not been studied but are likely to be similar to the causes of declines in expectations, ability-related self-confidence and interest—namely, shifts in the nature of instruction across grade levels, cumulative experiences of failure, and increasing cognitive sophistication.

4. Why Am I Doing This?

The newest area of motivation is goal theory. This work focuses on why the children think they are engaging in particular achievement-related activities and what they hope to accomplish through their engagement. Several different approaches to goal theory have emerged. For instance, Schunk (1991) focuses on goals' proximity, specificity, and level of challenge and has shown that specific, proximal, and somewhat challenging goals promote both self-efficacy and improved performance. Other researchers have defined and investigated broader goal orientations.

Nicholls and his colleagues (Nicholls 1990) defined two major kinds of motivationally relevant goal patterns or orientations: ego-involved goals and task-involved goals. Individuals with ego-involved goals seek to maximize favorable evaluations of their competence and minimize negative evaluations of competence. Questions like 'Will I look smart?' and 'Can I outperform others?' reflect ego-involved goals. In contrast, with task-involved goals, individuals focus on mastering tasks and increasing their competence. Questions such as 'How can I do this task?' and 'What will I learn?' reflect task-involved goals. Dweck and her colleagues provide a complementary analysis distinguishing between performance goals (like ego-involved goals), and learning goals (like task-involved goals) (Dweck and Leggett 1988). Similarly, Ames (1992) distinguishes between the association of performance (like ego-involved) goals and mastery goals (like task-focused goals) with both performance and task choice. With ego-involved (or performance) goals, children try to outperform others, and are more likely to do tasks they know they can do. Task-involved (or mastery-oriented) children choose challenging tasks and are more concerned with their own progress than with outperforming others.

4.1 Development of Children's Goals

To date there has been surprisingly little empirical work on how children's goals develop. Nicholls (1990) documented that both task goals and ego goals are already developed by second graders. However, Nicholls also suggested that the ego-goal orientation becomes more prominent for many children as they get older, in part because of developmental changes in their conceptions of ability and, in part, because of systematic changes in school context. Dweck and her colleagues (Dweck and Leggett 1988) also predicted that performance goals should get more prominent as children go through school, because they develop a more 'entity' view of intelligence as they get older and children holding an entity view of intelligence are more likely to adopt performance goals.

It is also likely that the relation of goals to performance changes with age due to the changing meaning of ability and effort. In a series of studies looking at how competitive and noncompetitive conditions, and task and ego-focused conditions, influence pre- and elementary-school-aged children's interests, motivation, and self-evaluations, Butler (e.g., 1990) identified several developmental changes. First, competition decreased children's subsequent interest in a task only among children who had also developed a social-comparative sense of ability. Competition also increased older, but not younger, children's tendency to engage in social comparison. Second, although children of all ages engaged in social comparison, younger children seemed to be doing so more for task mastery reasons, whereas older children did so to assess their abilities. Third, whereas, 5, 7, and 10 year-old children's self-evaluations were quite accurate under mastery conditions, under competitive conditions 5- and 7-year-olds inflated their performance self-evaluations more than 10-year-olds.

5. The Development of Motivational Problems

5.1 Test Anxiety

Performance anxiety has been an important topic in motivational research from early on. In one of the first longitudinal studies, Hill and Sarason (1966) found that test anxiety both increases across the elementary and junior high school years and becomes more negatively related to subsequent grades and test scores. They also found that highly anxious children's achievement test scores were up to two years behind those of their low anxious peers and that girls' anxiety scores were higher than boys'. Finally, they found that test anxiety was a serious problem for many children.

High anxiety emerges when parents have overly high expectations and put too much pressure on their children (Wigfield and Eccles 1989). Anxiety continues to develop in school as children face more frequent evaluation, social comparison, and (for some) experiences of failure; to the extent that schools emphasize these characteristics, anxiety become a problem for more children as they get older.

5.2 Anxiety Intervention Programs

Earlier intervention programs emphasized the emotionality aspect of anxiety and focused on various relaxation and desensitization techniques. Although these programs did succeed in reducing anxiety, they did not always lead to improved performance, and the studies had serious methodological flaws. Anxiety intervention programs linked to the worry aspect of anxiety focus on changing the negative, self-deprecating thoughts of anxious individuals and replacing them with more positive, task-focused thoughts. These programs have been more successful both in lowering anxiety and improving performance.

5.3 Learned Helplessness

Dweck and her colleagues initiated an extensive field of research on academic learned helplessness. They defined learned helplessness 'as a state when an individual perceives the termination of failure to be independent of his responses' (Dweck and Goetz 1978, p. 157). They documented several differences between helpless and more mastery-oriented children's respon-

ses to failure. When confronted by difficulty (or failure), mastery-oriented children persist, stay focused on the task, and sometimes even use more sophisticated strategies. In contrast, helpless children's performance deteriorates, they ruminate about their difficulties, often begin to attribute their failures to lack of ability. Further, helpless children adopt an 'entity' view that their intelligence is fixed, whereas mastery-oriented children adopt an incremental view of intelligence.

In one of the few developmental studies of learned helpless behavior, Rholes et al. (1980) found that younger children did not show the same decrements in performance in response to failure as some older children do. However, Dweck and her colleagues' recent work (Burhans and Dweck 1995) suggests that some young (5- and 6-year-old) children respond quite negatively to failure feedback, judging themselves to be bad people. These rather troubling findings show that negative responses to failure can develop quite early on.

What produces learned helplessness in children? Dweck and Goetz (1978) proposed that it depends on the kinds of feedback children receive from parents and teachers about their achievement outcomes, in particular whether children receive feedback that their failures are due to lack of ability. In Hokoda and Fincham (1995), mothers of helpless third-grade children (in comparison to mothers of mastery-oriented children) gave fewer positive affective comments to their children, were more likely to respond to their children's lack of confidence in their ability by telling them to quit, were less responsive to their children's bids for help, and did not focus them on mastery goals.

5.4 *Alleviating Learned Helplessness*

There are numerous studies designed to alleviate learned helplessness by changing attributions for success and failure so that learned helpless people learn to attribute failure to lack of effort rather than to lack of ability (see Fosterling 1985). Various training techniques (including operant conditioning and providing specific attributional feedback) have been used successfully in changing children's failure attributions from lack of ability to lack of effort, improving their task persistence, and performance.

Self-efficacy training can also alleviate learned helplessness. Schunk and his colleagues (Schunk 1994) have studied how to improve low-achieving children's academic performance through skill training, enhancement of self-efficacy, attribution retraining, and training children how to set goals. A number of findings have emerged from this work. First, the training increases both children's performance and their sense of self-efficacy. Second, attributing children's success to ability has a stronger impact on their self-efficacy than does either effort feedback, or ability and effort feedback. Third, training children to set proximal, specific, and somewhat challenging goals enhances their self-efficacy and performance. Fourth, training that emphasizes process goals (analogous to task or learning goals) increases self-efficacy and skills. Finally, combining strategy training, goal emphases, and feedback to show children how various strategies relate to their performance has a strong effect on subsequent self-efficacy and skill development.

6. *Summary*

In this article, a basic model of achievement motivation was presented and discussed. Developmental origins of individual differences in students' confidence in their ability to succeed, their desire to succeed, and their goals for achievement were summarized. To a large extent individual differences in achievement motivation are accounted for by these three beliefs. Most importantly, lack of confidence in one's ability to succeed and extrinsic (rather than intrinsic) motivation are directly related to the two major motivational problems in the academic achievement domain: test anxiety and learned helplessness. Specific interventions for these two motivational problems were discussed. Future research needs to focus on interconnections among the various aspects of achievement motivation. For example, how is confidence in one's ability to master academic tasks related to individuals' desire to master these tasks and to the extent to which the individual is intrinsically motivated to work towards mastery? More work is also needed on the impact of families, schools, and peers on the development of confidence, interest, and intrinsic motivation. Exactly how can parents and teachers support the development of high interest and high intrinsic motivation to work hard to master academic tasks? Finally, we need to know a lot more about the motivational factors that underlie ethnic and gender group differences in academic achievement patterns.

J. S. Eccles and A. Wigfield

Academy and Society in the United States: Cultural Concerns

Over the past half-century, the American research university system has become the finest in the world. (Rosovsky 1990). Whether we measure relative standing by scientific discoveries of major importance rewarded by Nobel Prizes, the balance of intellectual migration as assessed by flows of students to American universities from abroad, or estimates of the impact of scholarly papers through citation counts, there can be little doubt that the best private and public American research universities dominate the upper tier of the world's educational institutions.

The best of American universities remain part of one societal institution where an open, free exchange of ideas is still possible and where the content of unpopular ideas is still protected reasonably well from political influence and formal sanctions. They are places that create opportunities for social mobility. They are also places where the biases and presuppositions of students and faculty are challenged; they encourage fundamental critical reasoning skills; they provide fertile soil for the development of new scholarly ideas and scientific and technological discovery; and they remain places that, at their best,

combine research, teaching, and a commitment to civic responsibility.

Throughout this period of American ascendancy, which we will define as the period from the end of World War II to the present, the educational system has undergone profound changes that reflect dynamics in the broader society. This essay is about the dynamic tensions in the relationship between the academy and the larger society and some of their consequences. These dynamic and reciprocal relations have transformed both the academy and society in ways that have benefited both, but not without creating structural strain in universities and at times in the larger society. Universities have always been places in which creative tensions have sparked change and advance. Today, the tensions are found as much with other institutions as within the academy's own borders.

Not only is the academy embedded deeply in American society but the reciprocal interactions between it and the larger culture create forces that may alter the traditional structures and normative codes of conduct associated with the great research universities. In short, the historical quasi-independence of universities from the larger cultural context during the period from their formation in the 1870s to the Second World War has been replaced by a close linkage between universities and colleges and the nation's other institutions.

The most noteworthy linkages that have had a transforming effect on the academy of the past decade have emerged from the changing relations between government, industry, and universities. Consider only a few of the extraordinarily positive outcomes of the linkages that have grown stronger over the past 50 years and some of the derivative consequences of those linkages that have posed problems for universities. Since the creation of the National Science Foundation and the National Institutes of Health in the late 1940s and early 1950s, the federal government has created the fuel that has propelled small universities into large producers of scientific and technical knowledge. This has transformed universities in a positive way. However, that linkage with government has simultaneously introduced inordinate levels of bureaucracy at universities that accompany an inordinate number of government regulations and compliance requirements that increase costs and, at times, operate to undermine some of the academy's traditional values. The impact of these features of change has done more than anything else to move universities from ecclesiastical models of organization to bureaucratic organizational forms.

Similarly, relationships with industry have enabled universities to bring knowledge more directly to the marketplace, have led to new medical treatments and new technologies of value to the larger society, and consequently have opened new streams of revenue to universities. Yet these new linkages have also created significant tensions within the academy about the norms that should govern research and about the ownership of intellectual property.

1. *Dynamic Change in the Academy*

1.1 *The Rise of Meritocracy*

Perhaps the greatest demographic shift in the American academy in the last 50 years is the increased realization of the ideal of meritocracy among the student and faculty populations. Today, the campuses of American universities and colleges mirror the faces of the nation and in many cases the faces of the peoples of the world. This heterogeneity is a recent phenomenon. In the 1950s, students at elite universities and colleges of the United States were predominantly white and Christian. In a typical class at an Ivy League institution, the diverse faces of both American society and the world were largely absent. Today, students from minority backgrounds often represent from 30 to 40 percent of the student population. Students from other nations frequently outnumber American graduate students in top quality Ph.D. programs. Increased campus diversity has led to student demands for changes in the curriculum, often linked to identity politics. Campus efforts by students to have faculty and courses related to their own ethnic or racial identities, and to create new departments of ethnic studies, have produced tensions at universities that reflect tensions in the larger society.

Efforts by universities and colleges to become more diverse in both their student and faculty populations had led to substantial controversy over the method of classification and selection of students for admissions and faculty members for appointments. Issues such as whether undergraduate admissions officers can or should take racial identity (along with other factors) into account when considering applicants for admission have become questions of substantial public and legal debate and have led to controversial state and federal policies (Bowen and Bok 1997).

The American 'revolutions' in areas of race, ethnicity, gender, and religion have had a transforming impact on the organization of the academy. Doors of opportunity have opened to groups which, as late as the 1960s, could only dream of higher education and the possibilities of the economic and social rewards attainable through this traditional avenue of social mobility. The impact of these changes has also been seen in the changing demographic profile of professors. For example, fields that had been largely closed to women and minorities have now been opened to them.

1.2 *The Changing Size, Complexity, and Composition of the Academy*

The American system of higher education has grown rapidly over the past 50 years and continues to expand.

According to the National Center for Educational Statistics, the number of institutions of higher education rose from 2,000 to 3,595 between 1960 and 1990. The number of full-time students grew from about 400,000 to 6.5 million, the percentage of women undergraduates moved from 37 to 51 percent, and the percentage of students from designated minority backgrounds increased from 12 to 28 percent. The number of doctoral degrees awarded annually increased from about 10,000 to 38,000 and the total number of faculty members grew from roughly 281,000 to close to 987,000 (Kerman 1997). There are now more than 300 universities offering a substantial number of PhD degrees. About 60 of these are considered major institutions.

1.3 Organizational Consequences of Growth and Complexity

Even if the names of the great educational institutions are the same today as 50 years ago, the institutions themselves are vastly different from what they were in the mid-twentieth century. For example, Columbia University had an operating budget of $57 million for 15 schools in 1959; 42 years later, that annual operating budget (for the same number of schools), which doubled about every 10 years, stood at approximately $2 billion (source: Columbia University Operating Plan and Capital Budget 2001–02). The pattern of growth and increased complexity has been the same in most other distinguished research universities. Not only has the size of these budgets grown. The distribution of revenues and expenses has shifted markedly during the period. Today, the set of health science schools and research institutes represent as much as half or more of the total expense budget of many research universities. The increases in federal funding for biomedical research and in physician practice plan revenues represent the two fastest growing sectors of the university budget. The budget of the traditional core of universities—the arts and sciences disciplines and undergraduate colleges—represents a smaller proportion of the total budget.

The patterns of change experienced by research universities over the past half-century have led to substantial convergence between the public and private universities. The public research universities, which are major contributors to the research base of the nation and are more likely than in the past to share preeminence with their sister private institutions, receive an increasing share of government funding. Less than 20 percent of the operating budgets of major state institutions come from state allocations, although they benefit greatly by capital investments by the states in the infrastructure needed for modern scientific and engineering research. Similarly, the private universities, which have long depended on the kindness of their alumni and friends, also receive large portions of their budgets from state and federal research agencies. In short, the private universities are becoming more public and the publics are becoming more private.

1.4 Consequences for the Growth of Knowledge

Increased size and complexity of universities has produced a set of positive and negative consequences for the growth of knowledge. Many of the great research universities, imitating industrial organizations, have become highly decentralized budgetary entities. It remains unclear whether the financial and budgetary organization act as fetters on the development of new ideas and knowledge systems. Universities may well be migrating, without the appropriate awareness of potential unintended negative consequences, toward becoming large 'holding companies', without any substantial unifying central core or force. Research universities at the beginning of the twenty-first century often resemble states in which central authority is weak and baronies (the schools), each looking out for its own interests, strong. In short, larger institutional priorities that require fund-raising rarely trump local priorities. Unifying features of research universities (the 'uni' in universities) may represent endangered species that are at risk of extinction at many universities, despite some recent efforts to reverse this trend.

Some counter-forces within the academy are operating against this pattern of extreme decentralization of authority. These may be found in the emergent and dynamic intellectual interests within the university faculties for studying research problems that intrinsically require expertise from multiple schools and disciplines. These forces are organic and are growing from within the belly of the university. The current budgetary and organizational model conflicts increasingly with the way knowledge is growing. Faculty members are finding the most interesting and challenging problems, such as understanding global climate change or understanding human genomics, at the interstices among departments and schools of the university. They are even experimenting with forming new multidisciplinary groups (virtual departments) and trying to find ways of collaborating across the barriers of disciplinary 'foreign languages.'

Free intellectual trade among departments and schools is often impeded in precisely those areas where the pressure toward multidisciplinary collaboration is greatest. The successful nineteenth-century structures for organizing the research university along departmental and disciplinary lines continue to fulfill important functions and will endure for the foreseeable future. But in the twenty-first century, they also represent limits on unusual and productive teaching and research collaborations that link people with different angles of vision born out of their disciplinary training. Deans, who oversee self-contained budgetary

schools, often place disincentives on multischool collaborations in teaching or research that have negative consequences on their own bottom line. Ironically, those bureaucratic and organizational structures that enhance the efficiencies and capabilities within schools tend to impede the ability of universities to maximize the use of talented faculty who are less committed to an organizational straight-jacket and who want to participate in scholarship without borders.

The growth in complexity and in organizational structure has produced tensions within the academy over issues of governance and decision-making. When universities were more like colleges, they could organize decision-making as faculty members and administrators as if they were 'a company of equals.' This is no longer possible. Yet, the culture of the academy resists the idea of a division of corporate responsibility, and rightly so for matters of curricula, hiring, and promotion. Faculty, who may like decentralized control of budgets and decentralized authority, have problems with corporate decision-making models. In prosperous times for higher education, when endowments are growing, when general inflation is low, when demand for educational programs is high, and when the budgets of national supporters of basic and applied research are growing rapidly, the structural problems of decision-making at universities are muted and fade into the background. However, when the economy of the university is at risk, as happens periodically, it is increasingly difficult to make hard choices among competing programmatic alternatives, to limit new initiatives, and to eliminate academic programs that are either moribund or no longer major academic priorities.

Decentralized control and lack of clarity about criteria add further complication to the task of making and carrying out tough choices in periods of limited growth for universities, especially when coupled with the question of legitimacy of the right of academic administrators (who are themselves professors) to make decisions about retrenchment as well as growth.

1.5 'Corporatizing' of the University Presidency

The organizational structure of the academy and its continual need for life-supporting resources necessary for maintaining excellence, has had an effect on the voice of leadership at these institutions. The chief executive officers of these institutions, whether presidents or chancellors, are spending increasing amounts of time on resource acquisition—whether by cultivating prospective donors, lobbying elected officials or leaders of key federal agencies with budgetary control over resources, or seeking positive publicity for their institutions. This often involves heroic effort by leaders who are expected to meet resource targets in much the same way as their corporate counterparts are expected to provide positive earnings reports each quarter. The division of intellectual labor at universities has, as a consequence, become more sharply divided. The provosts are the chief academic officers. While they have far lower profiles than the presidents and share academic policymaking with them, they and the deans have as much to do with the academic quality and strategic planning for the university as the presidents.

The need for resources has also placed enormous pressure on academic leaders to remain silent on matters of public interest and consequence, rather than take a public position on controversial issues which might resonate negatively with external audiences capable of influencing the allocation of resources to universities. These economic concerns may have done more to muzzle university presidents than any other factor. If an outspoken president of a major research university takes a public position with which a public official is in vehement disagreement, there is the risk that the stream of resources to the university will be jeopardized. Consequently, research universities, despite their impact on societal welfare, have become institutions without a strong public voice. They are less often attached to large corporations or foundations through memberships on boards of trustees and their presidents are less often appointed to lead large national commissions with mandates for inquiries into areas of national interest.

This is not to say that, in the mythical golden past, university presidents were unconstrained in formulating public positions and public policy. President Harper of the University of Chicago surely must have thought about whether his public positions would offend John D. Rockefeller, the chief benefactor of the University of Chicago during the later part of the nineteenth and early part of the twentieth century. The historical record would likely show that President Elliot of Harvard was not a totally independent agent and often had to consider the consequences of his public positions on Harvard's efforts to attract private donors. Nonetheless, the complexity of the task of gathering resources and the implications of differences of opinion between university presidents and external supporters increase the probability that sitting university presidents of the great research institutions will not speak strongly.

Although Elliot, Harper and their colleagues were undoubtedly influenced by the values of 'friends' of the university, the fact is that their constituencies—the folks that they had to be careful not to offend—were a much more homogeneous group of people. Thus the synaptic potential for offense was less varied and less complex. With the growth in diversity among the alumni of research universities, as well as within student bodies and faculty, and of external political leadership at all levels of government, there are more opportunities for a university president to offend a powerful group, no matter what position is taken.

These 'kings' continue to find that they are faced with a conflict of interest as a result of their dual role: as an individual member of the institution and as leader of the same institution. This is perhaps one reason why presidents of major research universities relinquish their office more quickly than in the past.

Universities, then, face an ironic and unintended outcome of the positive role that they have played in increasing the changing face of American society. The achievements of diversity in the academy and throughout American society have produced various groups occupying positions of wealth, power, and influence. The positive effects of these developments have simultaneously produced the unintended effect of muting voices at the very institutions that most value diversity. This may also be why highly intelligent university leaders (who often have strong private opinions on all manner of important societal issues) often appear to students and other external audiences as corporate bureaucrats rather than as people with ideas and opinions.

2. *Resources Matter: The Larger Picture*

While it plainly is not the only factor that determines institutional success, the existence of plentiful resources that can be applied toward that end remains a key ingredient to success. The amount of research university endowments grew at a rapid pace during the 1980s and 1990s —a period of unprecedented wealth creation in the United States. In the year 2000, Harvard University's endowment was roughly $19 billion compared with approximately $371 million in 1960; Yale's endowment today is roughly $10 billion; Princeton's about $8 billion; Columbia's and Chicago's slightly above and below $4 billion respectively. While most other universities have not experienced the same level of absolute growth as these, increased donations and the law of compound interest have contributed to a growing inequality of wealth among private research universities. Improved rates of interest and of return on endowments are apt to exacerbate rather than attenuate these inequalities over time, especially since about 85 percent of growth in endowments can be attributed to the appreciated value of endowments through investments, rather than to a rise in the number of gifts to the endowment.

Since prominence or prestige, whether national rankings of academic departments or the quality of professional schools, is strongly correlated with universities' levels of endowment, this growing inequality is cause for growing concern. How could the widening gap in resources influence the distribution of quality among American research universities? Will the academy become like baseball where fewer and fewer clubs can truly play in the competitive game or have a shot at winning a championship on opening day? Finally, what effects would reducing the number of distinguished universities have on the output of these universities—and with what consequences for the larger society?

3. *Resources Matter: Competitive vs. Cooperative Strategies of Growth*

Throughout much of their history, American research universities have been engaged in intense competition to establish their preeminence. Those at the top of the research pyramid continue to compete fiercely for the students with the greatest potential and for faculty members whose achievements will bring credit to the institution. Today, the most prominent faculty members are highly mobile, identifying themselves more often with their professional discipline or specialty than with their home institution, and act increasingly as academic free agents. The market for those who bring quality and prestige to a department or institution, the academic stars, has driven the cost of maintaining preeminence in many fields to staggering levels.

Competition has, for the most part, proved to be a productive force for American higher education. The top universities have had to provide the resources needed to permit the development of creative science, technology and scholarship, as well as clinical research. Students, faculty, and the larger society have benefited from periodic revolutions in the technical means and modes of scientific and scholarly production that have been financed by universities through private and public monies. Those research universities that have fared well in the competition are today's most distinguished institutions of higher learning. They also have had the largest impact on the growth of knowledge and have been the most successful in obtaining external resources to continue their missions. At these universities, there is now a technological imperative which justifies, in part, the continual quest for resources. Falling from the ranks of the most distinguished only multiplies the cost of trying to reclaim that territory, so that institutions are loath to retreat from the competition, even for short periods of time. The cost of quality, in short, continues to spiral upwards.

At what point will rising costs become dysfunctional for the system of higher education? Will there be sufficient resources, even at the most well endowed institutions, to continue in this mode of intense institutional competition, without cutting down on their range of activities? There are signs that leaders of leading research universities are seriously beginning to consider encouraging the number of cooperative efforts and joint ventures that represent enhancements for each of the institutions. One early effort is the creative sharing of books, journals, and data among libraries; another, the sharing of instructional cost

associated with teaching esoteric foreign languages; and, a third, experimenting with joint Ph.D. programs. Also, law schools, business schools, science, and engineering programs at major American universities are forming joint degree programs with major institutions in the United Kingdom, Europe, and Asia. These joint ventures permit universities to gain enormous additional strength and quality at minimal additional costs. Finally, joint ventures are already underway for the creation of new forms of learning, course content and on-line degree programs through the exploitation of new digital technologies. Although it is unlikely that the American academic community will witness full-scale mergers in the foreseeable future, it is probable that we will see a more balanced mix between competitive and cooperative strategies of growth over the next several decades.

4. The Dynamic Interaction between the Worlds of Government, Industry, and Research Universities

In his manifesto, *Science: The Endless Frontier*, Vannevar Bush (1945) outlined for President Harry Truman a scenario for American preeminence in post-World War II science and technology. Using taxpayer dollars, the government would support basic and applied research through newly created agencies (the National Science Foundation and the National Institutes of Health) and would create a mechanism for training an elite group of younger scientists and engineers who would gain advanced training in the laboratories of the nation's best academic scientists and engineers (Cole et al. 1994).

Over the past half-century since the creation of this partnership, we have seen the greatest growth in scientific and technological knowledge since seventeenth century England and arguably the greatest period of expansion in scientific knowledge in history. This partnership turned into a great American success story. It transformed the American research university and may represent the most significant example, along with the GI Bill, of how the larger society has influenced change in the academy.

While still largely in place, the partnership has become far more complex over the past 20 years, than in the immediate post-war period. For example, in 1982 the Bayh–Dole Act assigned intellectual property rights for discoveries emerging from federally funded research to the universities concerned, thus creating incentives for the translation of discoveries into useful products by bringing them to the market more rapidly and for developing technology transfer mechanisms. These incentives have worked, as universities have generated a new revenue stream to support its research and teaching mission through intellectual property licensing agreements with pharmaceutical companies or through the creation of small incubator companies. The Bayh–Dole Act was one factor that heightened awareness within universities of the value of the knowledge they created. Consequently, who 'owns' intellectual property becomes an important matter for discussion and policymaking within the research university. These new commercial activities at universities have produced normative dilemmas about free access to and utilization of knowledge.

Potential revenues from intellectual property have begun to redefine the relationship between universities and industry, as well as those within universities and closer institutional ties are clearly being established. Major companies are investing substantial research dollars in genome and other biomedical projects, in exchange for limited or exclusive rights to the intellectual property resulting from those research efforts. There are many examples of university-based discoveries that have contributed to improved treatment of disease and illness. The fruits of this increased interaction can be easily documented. However, potential problems from these closer ties are also becoming clear. The traditional normative code of science and academic research enjoined scientists and scholars to choose problems and create works without consideration of personal financial gain. This normative code may have represented an ideal never fully approximated in practice, but it was internalized and did guide behavior.

Today, the boundaries between pure academic research and work that is intended to bring significant financial returns to the scholar (often resulting from work that will also benefit the larger society) have become blurred. Increasingly, scientists are starting their own companies with the goal of bridging the divide between pure science and technological products. In short, there is increasing tension at universities between the value placed on open communication of scientific results and the proprietary impulses that lead scientists and engineers to consider the market value of discoveries that could lead universities and individuals to withhold knowledge from the public domain.

Many salient questions can be asked about these new relationships. At what point are members of the academy more often absent than present at their universities—people used to create prestige without attending to students or colleagues? Will the desire to reap the considerable rewards that could be gained from the sale of intellectual property lead to institutional blindness about conflicts of interest? Will tenure decisions be affected by the value of a scientist's patents as opposed to his scholarship? Will professors have their most talented graduate and postdoctoral students work on problems most likely to lead to patents and licenses, rather than the scientifically most significant problem for the field?

The boundaries between university and commercial ventures are apt to become even more complex in light of the extraordinary biological discoveries that will be

made in the twenty-first century. Universities will continue to try to separate potential conflicts between research and for-profit businesses. However, there will be substantial pressure to alter the normative code of inquiry so that faculty members and universities can take advantage of the changing market value of their intellectual property.

Universities, and the society in which they are embedded, are also being transformed by the revolution in new digital media communications. Hundreds of millions of people around the world are now users of the Internet. They use it to access information and, with increasing frequency, for electronic commerce. In due course, these new media technologies will be widely used for educational purposes. Higher education at many levels is apt to be affected profoundly by the development of new digital media. In fact, some prognosticators claim that the new media will make brick and mortar universities obsolete. That is unlikely, and it is very unlikely that the new digital media will undermine the quality of the best American colleges and universities or replace the functions that they fulfill. The new digital media technology does have, however, great potential to bring ideas and electronic courses of leading scholars and scientists to people around the world who would not otherwise be able to access this information or courses on demand regardless of place or time.

In short, the new digital media will revolutionize the distribution of knowledge, just as electronic books and courses will revolutionize the mode of academic production. Today, about 90 percent of all scholarly monographs sell fewer than 800 copies (half of which were purchased by libraries). Tomorrow, the same authors of high quality monographs and research studies will be able to reach audiences of 8,000 or 80,000 or more on the Internet. Realizing that the education market is huge in the United States and around the world, entrepreneurs are creating for-profit educational businesses. Few of these educational experiments are yet of high quality and fewer still profitable, but the revolutionary change has just begun.

Under pressure to explore new revenue sources and to defend itself against private internet educational companies threatening to compete with universities for virtual space and students, research universities face a 'prisoner's dilemma.' In the absence of good information about what their competitors are intending to do, should they move rapidly and at great expense, to occupy the high end educational space on the web and act as a first mover, or should they wait and examine the evolving terrain while creating for themselves high quality educational content and technological knowledge tools which facilitate the use of these materials by their own students, faculty, and alumni?

The new digital technologies are less likely to make profound changes in the research process at universities. While digital media will help scholars in their search for information published in electronic journals, and they may foster institutional collaborations, they are unlikely to substitute for close interaction found in laboratory collaborations or for the interpersonal associations so critical to the creative process. The technology is thus far more important for the distribution of knowledge than for its production.

Changes in the means of academic production of knowledge will put new pressure on traditional relationships between faculty members and their universities. For example, questions are already surfacing about ownership of intellectual property. Who should own the works that are created in digital form by members of the faculty? What are the rights and responsibilities of faculty members in the process of creating new digital course content? Should full-time faculty members be permitted to create courses for new digital businesses? Where do conflicts of commitment begin and end for members of a university's faculty? If there is income generated by universities from the sale of courses or other forms of knowledge and information, how should the faculty and the university share in the distribution of those revenues? What are appropriate and inappropriate uses of the University's name when used by faculty members creating new digital products for other institutions? Clearly, the introduction of these new digital media will require new definitions of the traditional relationships and roles of faculty, students, technology experts, and university administrative leaders.

Many of these attributes of the American academy result from its dynamic connection to the nation's other institutions. The academy has responded to the changing needs of the larger society and it has done much to influence social change and rapid economic growth in America. Correlatively, exogenous movements in the broader society create challenges for the academic world. There is little reason to believe that this dynamic interaction and its attendant tensions will change in the decades to come.

Acceptance and Change, Psychology of

When intervening, applied psychology is always oriented toward change procedures in one sense of the term 'change.' It is one thing, however, to try to change a particular piece of psychological content; it is another to change the very meaning and purpose of change efforts themselves. This distinction has been addressed in many different ways in the various traditions in psychology: first-order change versus second-order change, changes in form versus function, changes in content versus changes in context, and several others. The terms 'acceptance' and 'change' can be added to the list of distinctions oriented toward the same basic issue. This article seeks to differentiate 'acceptance' and 'change,' to define different kinds of acceptance, and to discuss what is known about the relative value of these two classes of approaches in given settings.

1. *Change*

The ordinary approach to difficult psychological content (e.g., troublesome thoughts, unpleasant bodily sensations, negative feelings, ineffective overt behavior) is to target these events for deliberate change. Change efforts of this kind are 'first-order.' That is, they are designed to reduce the frequency of difficult psychological content, to alter its intensity or other aspects of its form, or change the events that give rise to such content.

Most intervention procedures from across the many psychological traditions (behavioral, humanistic, psychodynamic, cognitive, and biological) are change-oriented in this sense. The targets, rationales, and techniques may differ, but the strategy is the same. For example, systematic desensitization may seek to reduce anxiety directed toward given stimuli, while cognitive restructuring may seek to alter irrational thoughts, but at a higher level of abstraction both procedures are designed to alter the form, frequency, or situational sensitivity of difficult psychological content.

2. *Acceptance*

Acceptance can also be conceptualized as a kind of change, but it is of a different variety: it is second-order change, metachange, or contextual change. According to the *Oxford English Dictionary*, etymologically 'acceptance' comes from a Latin root that means 'to take in' or 'to receive what is offered.' There are four primary dictionary definitions of the term, each of which have parallels in psychology:

(a) To receive willingly or with consent;

(b) To receive as sufficient or adequate, hence, to admit;

(c) To take upon oneself, to undertake as a responsibility;

(d) To receive with favor.

The first sense of the term refers in psychology to a deliberate openness, mindfulness, or psychological embracing of experience. Perhaps most emphasized originally in the humanistic traditions (but also in each of the other main traditions), this kind of *active, embracing acceptance* involves deliberate actions taken to heighten contact with psychological content, or to remove the barriers to such contact. Meditative procedures, body work, or experiential procedures, exemplify this kind of acceptance.

The second sense of the term in psychology refers to an acknowledgement of psychological events. This kind of *passive, acknowledging acceptance* involves the dissolution of barriers to admitting to states of affairs. For example, working to convince a patient of the presence of an illness or psychological disorder, or of the need to change, or working to help a grieving person to admit the permanence of death, exemplify this kind of acceptance.

The third sense of the term in psychology refers to *taking responsibility* for events, past, present, or future. Self-control, self-management, or consciousness raising exemplify this kind of acceptance. The fourth sense of the term in psychology refers to *affirmation* or *approval.*

So defined, passive acceptance and responsibility are components of virtually all psychological (and many physical) change procedures. Most healthcare interventions are based on an initial acknowledgement of the need for intervention (e.g., the drug addict must first admit to an addiction; the cancer patient must first admit to having cancer). In most problem areas (though not all, e.g., times when a 'positive halo' is helpful), a failure to acknowledge difficulty leads to ineffective remediation of that difficulty. For example, a hospitalized psychotic person who fails to admit to the need for treatment is likely not to comply with medication regimen and is thus more likely to be rehospitalized. Similarly, in all procedures that require the patient's active participation, accepting responsibility is key to follow-through and to eventual success.

Conversely, the fourth sense of the term (approval) rarely applies to healthcare interventions. It needs to be mentioned, however, because patients often have a hard time distinguishing other types of acceptance from approval. For example, an abused person may have a hard time accepting the fact of abuse in the quite reasonable sense that the perpetrator's actions should not be condoned.

Active acceptance is not a component of many psychological or physical change procedures, though there is increasing evidence of its utility, particularly with severe, chronic, or treatment-resistant problems. Thus, this is the kind of acceptance that most requires analysis and the kind that seems most innovative. Except as noted, in the remainder of this article, 'acceptance' refers to active acceptance.

3. *Domains of Acceptance and Change*

There are several domains of acceptance and change, psychologically speaking. We can break these down into personal domains on the one hand—including personal history, private events, overt behavior, and self—and social or situational domains on the other. Active acceptance is not appropriate in all of these domains.

3.1 *Personal History*

Humans are historical organisms and when looking at their problems it is the most natural thing for people to imagine that if their history had been different then their problems would have been different. In some sense, this is literally true, but since time and the human nervous system always goes 'forward,' in the sense that what comes after includes the change from what went before, it is not possible to change a history. All that can be done is to build a history from here.

A person who has been raped, for example, may imagine that it would be better not to have been raped. Unable to accomplish this, the person may try to repress the incident, pretend that it did not happen, or even pretend that it happened to someone else. The trauma literature shows, however, that these avoidant coping strategies are extremely destructive and lie at the very core of trauma (Follette et al. 1998) (see *Post-traumatic Stress Disorder*). Conversely, acceptance of one's personal history (not in the sense of approval) seems clearly necessary and healthy.

3.2 *Private Events*

A second area is that of private events, such as emotions, thoughts, behavioral predispositions, and bodily sensations. Here, the picture is more complex. Some private events surely can be changed deliberately, and it might be quite useful to do so. For example, a person might feel weak or ill, and by going to a doctor discover the source of these difficulties and ideally have them treated successfully. Minor anxieties may be readily replaced by relaxation. If emotions and thoughts repeatedly persist in the face of competently conducted change techniques, however, it may be time to give acceptance strategies a try. Furthermore, psychologically produced private events very often do not respond well to first-order change efforts, both because they are produced by extensive histories and because change efforts might paradoxically increase them (see Hayes et al. 1996 for a review).

A number of studies have demonstrated, for instance, that when subjects are asked to suppress a thought they later show an increase in this suppressed thought when compared to subjects who are not given suppression instructions (Wegner and Pennebaker 1993). More recent literature shows similar effects for some kinds of emotions and bodily sensations. For example, attempts to suppress feelings of physical pain tend to increase the length of time pain persists and to lower the threshold for pain (Cioffi and Holloway 1993).

The culture can be very supportive of first-order change practices in this area, sometimes to the point of repression. For example, it is not uncommon for a person facing the sadness associated with a death in family to be told to think about something else, to 'get on with life,' to focus on the positive things, to take a tranquilizer, or to otherwise avoid the sadness that naturally comes with the death of a loved one. Thus, it is not surprising that most patients who seek help with a psychological problem will cast that problem in terms of supposedly needed changes in emotions, thoughts, or other private events.

3.3 *Overt Behavior*

Most often, but not always, deliberate change efforts are useful and reasonable in the overt behavioral domain. Except in the sense of admission or responsibility, there is no reason to 'accept' maladaptive behavior (which in this context, would probably mean approval).

3.4 *Sense of Self*

The fourth area is the area of self. If we limit the senses of 'self' that are relevant here to those that involve knowing by the person involved, there are three senses of self to examine: self as the content of knowing, as the process of knowing, and as the context of knowing.

3.4.1 The conceptualized self. Patients invariably have a story about their problems and the sources of those problems. If this story is accepted by the client as the literal truth, it must be defended, even if it is unworkable. 'I am a mess because of my childhood' will be defended even though no other childhood will ever occur. 'I am not living because I am too anxious' will lead to efforts to change anxiety even if such efforts have always been essentially unsuccessful. Thus, acceptance of a conceptualized self, held

as a literal belief, is rarely desirable. If the story is negative, accepting it is tantamount to adopting a negative point of view that, furthermore, is to be defended. If the story is positive, facts that do not fit the tale must be distorted.

3.4.2 Self as a process of knowing. Self as the process of knowing is necessary for humans to live a civilized life. Our socialization about what to do in life situations is tied to the process of verbal knowing. For example, a person who is alexithymic will not know how to describe behavioral predispositions in emotional terms. Thus, active acceptance seems very appropriate in the area of the ongoing process self-knowledge. In most conditions, it is desirable to 'know thyself.'

3.4.3 Self as context. The final aspect of self is consciousness *per se*—that is, knowing from a consistent locus or perspective. Active acceptance is clearly beneficial here. Any attempt to disrupt continuity of consciousness (e.g., through dissociation) is almost universally harmful (Hayes et al. 1996).

3.5 Social and Situational Domains

Social and situational domains present some of the same complexities in personal domains. When we are considering the domains relevant to other persons, we can consider the acceptance of other's personal history, private events, overt behavior, or sense of self.

Once again, acceptance of others' personal history seems to be the only reasonable course available, since history is not changeable except by addition to what is. Acceptance of others' overt behavior is sometimes called for, but often change is equally appropriate. Acceptance is called for when the efforts to change overt behavior of others undermines other features of the relationship that are important, or when the behavior itself is relatively unimportant. For example, it may not be worth the effort it would take to prevent a spouse from leaving underwear on the bathroom floor. But it is also possible to err on the other side of this issue when the behaviors are not trivial. For example, a spouse may be unwilling to face the possibility of rejection and may fail to request changes in a loved one. Often this avoidance is in the name of the relationship, but in fact it contributes to a dishonest relationship.

In the area of situations, first-order change efforts are usually called for unless the situation is unchangeable. A person dealing with an assuredly fatal disease, or with the permanent disability of a child, is dealing with an unchangeable situation, and acceptance is the only reasonable course of action.

4. When Acceptance is Useful

Acceptance seems called for when one of five things occurs. First, *the process of change contradicts the outcome*. For example, if a person tries to earn self-acceptance by change, a paradox is created. Somebody may believe that he or she will be an acceptable person when they change, but the very fact that the person needs to change reconfirms the fact that they are not acceptable now.

The second instance when acceptance is called for is when *change efforts leads to a distortion, or unhealthy avoidance of, the direct functions of events*. For example, a person with a difficult childhood may insist that their childhood was always a happy one, even if it means that they cannot recall the events of their childhood clearly.

A third situation in which acceptance is called for is one in which *social change efforts disrupts the social relation or devalues the other*. Repeatedly trying to get a spouse to change a minor habit, for example, may create an aversive atmosphere that undermines the relationship itself.

A fourth situation is one in which the *outcome ultimately cannot be rule governed*. Deliberately trying to be spontaneous is doomed to failure because spontaneity does not occur by following rules, and deliberate change efforts are always efforts in rule following at their core.

The final situation has already been mentioned: *the event is unchangeable*.

5. Methods of Acceptance

Acceptance methods have always existed in psychology, but they have been largely embraced by relatively nonempirical traditions (e.g., gestalt, humanistic, and psychoanalytic traditions). Little actual data on their impact was collected until behavioral and cognitive psychologists began to explore them as well. In the modern era these more empirical forms of psychology have attempted to work out when and for whom acceptance or change methods would be most effective (see Hayes et al. 1994 for a collection of such authors). Many of these procedures have now been empirically supported, at least to a degree. Among many others, these include:

Interoceptive exposure. Deliberately creating contact with feared bodily states is among the more effective methods with several forms of anxiety disorders (Barlow et al. 1989).

Eastern traditions, such as mindfulness meditation. Mindfulness meditation is known to be helpful in several areas, such as in the acceptance of urges in substance abuse as a component of relapse prevention (Marlatt 1994) (see *Relapse Prevention Training*), the acceptance of emotions in personality disorders (Linehan 1993), or the acceptance of chronic pain (Kabat-

Zinn 1991). Mindfulness is at its essence an active acceptance procedure because it is designed to remove the barriers to direct contact with psychological events.

Social acceptance. Jacobson and his colleagues (Koener et al. 1994) have improved success in behavioral marital therapy by working on acceptance of the idiosyncrasies of marital partners as a route to increased marital satisfaction.

Cognitive defusion. Acceptance and commitment therapy (Hayes et al. 1999) is a procedure designed to increase emotional acceptance in part by undermining cognitive fusion with literal evaluations.

Emotional exposure. Emotion-focused therapy (Greenberg et al. 1993) is an experiential approach that has shown good results with couples and various psychological problems by increasing emotional exposure and acceptance (see *Experiential Psychotherapy*).

6. Conclusion

An anxious, depressed, angry, or confused individual usually thinks that these states need to be changed before a healthy and successful life can be lived. A growing body of evidence suggests otherwise. In the context of psychological acceptance, fearsome content is changed functionally, even if no change occurs in its form or its frequency. When one deliberately embraces difficult psychological content, one has transformed its function from that of an event that can cause avoidance, to that of an event that causes observation and openness. The paradox is that as one gives up on trying to be different one immediately becomes different in a very profound way. Stated another way, active acceptance is one of the most radical change strategies in the psychological intervention armamentarium.

Access: Geographical

1. Definition and Meaning

Access in a geographical context is the quality of having interaction with, or passage to, a particular good, service, facility, or other phenomenon that exists in the spatiotemporal world. For example, access may be based on measuring the distance or travel time between where residents live (housing units) and the facilities they need (e.g., medical facilities, shops, workplaces). Access is also a relative concept that varies according to the level of opportunity afforded at the destination. Assessments of access (or lack of access) are made meaningful by comparing access in one zone (or for one type of individual) with access in (or for) another. If goods are spatially specific, geographical access typically involves one or more origins and one or more destinations and the distance between them.

1.1 Alternative Definitions

While the above definition of access is common, there are other concepts of access that should be identified. One emerging view is that the notion of access must be redefined for the information age, whereby transactions take place in virtual as opposed to physical space or some hybrid form (NCGIA 1998). Part of this interest relates to the notion of varying levels of access to information technologies and how this variation effects matters of equity in a wide variety of ways. But there is also an attempt to understand how information technology has changed accessibility patterns by changing the geographic locations of people and the built environment that sustains them. If infor-

mation technologies affect patterns of land use, for example, such technologies indirectly affect accessibility patterns that are determined by land use configurations. Another complexity is that access does not have to be viewed as a positive phenomenon. Access to goods can also be negative, as in the case of environmentally hazardous areas, dilapidated buildings, or other services and facilities considered to have an excessive number of negative externalities. When these negative costs associated with access are analyzed, the issue is one of environmental justice, and whether there are discriminatory patterns of negative access along racial or economic lines. Studies have shown that access to negative conditions in the environment is often higher among low-income groups (Bowen et. al. 1995).

Some views of access are not based on distances between two or more locations in space, but may instead be based on social factors, cultural barriers, or ineffective design. For example, there may be barriers to access based on whether or not an individual possesses a certain subjectively defined level of 'citizenship' (Staeheli and Thompson 1997). In addition to exclusionary practices that prohibit certain groups from 'free' access to a given good, there may be problems inherent to the good, service or place itself. For example, public parks may or may not be designed appropriately to deter crime by incorporating defensible space techniques, which in turn may significantly impact access to that space.

1.2 Spatial Equity and Access

Access defined on the basis of spatial distributions invokes the concept of spatial equity. The issue is one of who has access to a particular good or service and who does not, and whether there is any pattern to these varying levels of access. Spatial equity can be defined as equality, in which everyone receives the same public benefit (i.e., access), regardless of socioeconomic status, willingness to pay, or other criteria. Alternatively, access equity may vary according to indicators such as poverty, race, or the nature of the service being provided.

In a distance-based analysis, the purpose of research on access might address the question of whether access to a particular good is discriminatory. Such inquiries might entail, more specifically, an examination of the extent to which there is a spatial pattern to varying levels of access, and whether that spatial pattern varies according to spatially-defined socioeconomic groups (Talen 1998). For example, do people of color have to travel further to gain access to public goods than others?

Over the past several decades, researchers have examined patterns of accessibility to certain services and the spatial relationship between service deprivation and area deprivation (Knox 1978, Pacione 1989). Geographers have explored regional and local variations in access to, among other things, recreational amenities, secondary education, public playgrounds, and child care (see Talen 1998).

In addition to exposing differentials in accessibility, there is the quest to discover why certain patterns of access exist. Factors implicated include urban form, organizational rules, citizen contacts, politics, and race. Until recently, spatial inequity has been explained predominantly by the notion of unpatterned inequality (Mladenka 1980). This is the idea that although there is inequality in people's access to services and facilities, there is no evidence that there is a clear discriminatory pattern to it. In the absence of patterned inequality, some argue, it is difficult to attach blame to those responsible for the existing distributional pattern. Current critiques of this theory (Miranda and Tunyavong 1994) focus on the failure to take the political process properly into account, and the problem of variable definition.

1.3 Normative Views of Access

Interrelated to equity considerations, the concept of access has taken on a normative role. Specifically, access and its aggregate, accessibility, are increasingly seen as important criteria of well-designed urban environments. The promotion of access through planning and design is seen as a way of counter balancing the decentralizing forces of metropolitan expansion. Access to facilities, goods and services in a spatial sense is what differentiates urban sprawl from compact city form. In short, some urban forms inherently have better access: development patterns that are low-density and scattered necessarily diminish accessibility because facilities tend to be far apart and land uses are segregated (Ewing 1997). For locally oriented populations, accessibility to urban services is crucial because distance is not elastic (Wekerle 1985). This is particularly true for populations who rely on modes of transport other than the automobile (e.g., the elderly and the poor).

Current models of normative urban pattern give geographical access a prominent and defining role, and access is viewed as having a direct impact on quality of life. Physical proximity defines access, and it retains importance despite the increase in nonspatial forms of interaction occurring via virtual networks. Most importantly, access can be improved through design. Kevin Lynch (1981) made this connection early on, and held 'access' as a key component of his theory of ideal urban form. His view of access was highly qualitative, since he viewed it as integral to the 'sensuous' quality and symbolic legibility of place. In this same genre, New Urbanists have developed a specific town planning manifesto based on enhancing access at the level of region (by promoting a variety of transportation alternatives), metropolis (by promoting compact urban form), and neighborhood (by promoting mixed uses and housing density).

2. The Measurement of Access

The majority of studies of geographic access assume that access is a positive phenomenon, and that access is based in part on some measurement of distance in space. If access is being considered as something desirable, the impediments to access—friction or blockage of the opportunity to interact or the right to enter—must be factored in. Right of entry assumes that a transaction must occur between the consumer and the good, service, or facility. More important in terms of definitions of access is that these transactions have a cost associated with them. Geographical interest in access therefore is often focused on these transaction costs. The interest is often methodological—how can these transaction costs be measured? Empirical investigations—who pays a higher transaction cost for access and why—invoke the issue of spatial equity discussed above.

2.1 Factors Affecting the Measure of Access

There are five classes of factors affecting the measure of access. The first two are simply the spatial locations of points of origin and points of destination. Usually the points of origin refer to housing locations, and points of destination involve entities that can be spatially referenced, such as schools or places of employment.

The third factor is the travel route and its distance between an origin(s) and destination(s). This involves not only the distance between two or more points, but the qualities of the route and the mode of travel that occurs on that route. Factors that effect the route include topography, design speed, number of lanes of traffic, and mode. For pedestrian access, perceived safety, sidewalk quality, and traffic volumes are important factors. Measuring the distance along a route can be based on the shortest distance between destination and origin, or can be more complex and involve a variety of spatial networks.

Another factor affecting the measurement of access has to do with the attributes of the individuals who seek access. Characteristics of individuals are usually derived using the characteristics of a given spatial unit, such as a census block (the degree of disaggregation of the spatial unit varies widely). Factors that might affect access include socioeconomic status, age, gender, and employment status. Certain assumptions can be made about the attractiveness or relevance of travel to certain facilities (and the likely mode of travel) based on these characteristics. The frictional effect of the available travel mode is also likely to be predicated on the characteristics of residents. For example, lack of bus service may adversely impact access for low-income individuals but have only a marginal effect on higher income groups.

A final class of factors involves the destination(s), specifically the amount, type, and quality of a given destination (e.g., facility). These attributes determine the attractiveness of a destination for consumers, and therefore affects how access to it is measured.

2.2 Types of Measures

Accessibility is measured in a variety of ways, and there can be significant variation in the resulting measurement depending on which method is used. Traditional measures assess the 'cumulative opportunities' of a given location (Handy and Niemeier 1997). There can be counts of the number of facilities within a given spatial unit or range, or measures based on average travel cost and minimum distance. Alternatively, a gravity potential measure can be used in which facilities are weighted by their size (or other characteristic) and adjusted for the frictional effect of distance. Another type of accessibility measure is based on random utility theory and measures access on the basis of the desirability or utility of a set of destination choices for an individual (Handy and Niemeier 1997).

Finally, accessibility measures can be based on individual rather than place access (see Hanson and Schwab 1987, Kwan 1999). This approach, which uses travel diaries to determine destination choices and linkages between them in an individual's daily pattern of movement, has two important advantages. First, multipurpose trips can be factored in and therefore interdependencies in trip destinations can be taken into account. Second, individual space–time constraints can be included in the evaluation of differences in personal accessibility.

Accidents, Normal

Normal Accident Theory (NAT) applies to complex and tightly coupled systems such as nuclear power plants, aircraft, the air transport system with weather information, traffic control and airfields, chemical plants, weapon systems, marine transport, banking and financial systems, hospitals, and medical equipment (Perrow 1984, 1999). It asserts that in systems that humans design, build and run, nothing can be perfect. Every part of the system is subject to failure; the design can be faulty, as can the equipment, the procedures, the operators, the supplies, and the environment. Since nothing is perfect, humans build in safeguards, such as redundancies, buffers, and alarms that tell operators to take corrective action. But occasionally two or more failures, perhaps quite small ones, can interact in ways that could not be anticipated by designers, procedures, or training. These unexpected interactions of failures can defeat the safeguards, mystify operators, and if the system is also 'tightly coupled' thus allowing failures to cascade, it can bring down a part or all of system. The vulnerability to unexpected interactions that defeat safety systems is an inherent part of highly complex systems; they cannot avoid this. The accident, then, is in a sense 'normal' for the system, even though it may be quite rare, because it is an inescapable part of the system.

Not all systems are complexly interactive, and thus subject to this sort of failure; indeed, most avoid interactive complexity if they can, and over time become more 'linear,' by design. (The jet engine is less complex and more linear than the piston engine.) And not all complexly interactive systems are tightly coupled; by design or just through adaptive evolution they become loosely coupled. (The air traffic control system was more tightly coupled until separation rules and narrow routes or lanes were technically feasible, decoupling the system somewhat.) If the system has a lot of parts that are linked in a 'linear' fashion the chances of unanticipated interactions are remote. An assembly line is a linear system, wherein a failure in the middle of the line will not interact unexpectedly with a

Complex systems	*Linear systems*
Proximity	Spatial segregation
Common-mode connections	Dedicated connections
Interconnected subsystems	Segregated subsystems
Limited substitutions	Easy substitutions
Feedback loops	Few feedback loops
Multiple and interacting controls	Single purpose, segregated controls
Indirect information	Direct information
Limited understanding	Extensive understanding
Tight coupling	*Loose coupling*
Delays in processing not possible	Processing delays possible
Invariant sequences	Order of sequences can be changed
Only one method to achieve goal	Alternative methods available
Little slack possible in supplies, equipment, personnel	Slack in resources possible
Buffers and redundancies are designed-in, deliberate	Buffers and redundancies fortuitously available
Substitutions of supplies, equipment, personnel limited and designed-in	Substitutions fortuitously available

Characterstics of the two major variables, complexity and coupling

Figure 2
Interaction/coupling chart showing which systems are most vulnerable to system accidents

failure near the end, whereas a chemical plant will use waste heat from one part of the process to provide heat to a previous or later part of the process. A dam is a linear system; a failure in one part is comprehensible and though it may be one that is not correctable, making an accident inevitable, the system characteristics are not the cause of the failure; a component simply failed. But a dam is tightly coupled, so the component failure cannot be isolated and it precipitates the failure of other components. A university is an example of a complexly interactive system that is not tightly coupled. Substitutes can be found for an absent teacher, another dean for an absent dean, or to retract or delay a mistaken decision, the sequencing of courses is quite loose and there are alternative paths for mastering the material. Unexpected interactions are valued in a university, less so in the more linear vocational school, and not at all in the business school teaching typing. Figure 1 summarizes some of the characteristics of the two major variables, complexity and coupling.

NAT has a strong normative content. It emerged from an analysis of the accident at the Three Mile Island nuclear power plant in Pennsylvania in 1979. Much of the radioactive core melted and the plant came close to breaching containment and causing a disastrous escape of radioactivity. The catastrophic potential of that accident, fortunately not realized, prompted inquiry. It appeared that elites in society were causing more and more risky systems with catastrophic potential to be built, and just trying harder was not going to be sufficient to prevent catastrophes. Though people at all levels in the company running the Three Mile Island plant did not appear to have tried very hard to prevent accidents, the more alarming possibility was that even if they had, an accident was eventually inevitable, and thus a catastrophe was possible. Other systems that had catastrophic potential were also found to be both complexly interactive and tightly coupled. Figure 2 arrays these two variables in a manner that suggests which systems are most vulnerable to system accidents. The catastrophic potential of those in the upper right cell is evident. The policy implications of this analysis is that some systems have such extensive catastrophic potential (killing hundreds with one blow, or contaminating large amounts of the land and living things on it), that they should be abandoned, scaled back sharply to reduce the potential, or completely redesigned to be more linear in their interactions and more loosely coupled to prevent the spread of failures.

Normal Accidents reviews accidents in a number of systems. The Three Mile Island (TMI) accident was the result of four failures, three of which had happened before (the fourth was a failure of a newly installed safety device), all four of which would have been handled easily if they had occurred separately, but could not when all four interacted in unforseen ways. The system sent correct, but misleading, indications to the operators, and they behaved as they had been trained to do, which made the situation worse. Over half of the core melted down, and had it not been for the insight of a fresh arrival some two hours into the accident, all of the core could have melted, causing a breach of containment and extensive radioactive releases. Several other nuclear power plant accidents appear to have been system accidents, as opposed to the much more common component failure accidents, but were close calls rather than proceeding as far as that at TMI. Several chemical plant accidents, aircraft accidents, and marine accidents are detailed that also fit the definition, and though there were deaths and damages, they were not catastrophic. In such linear systems as mining, manufacturing, and dams the common pattern is not system accidents but preventable component failure accidents.

One of the implications of the theory concerns the organizational dilemma of centralization versus decentralization. Some processes still need highly complex interactions to make them work, or the interactions are introduced for efficiency reasons; tight coupling may be required to ensure the most economical operation and the highest throughput speed. The CANDO nuclear reactors in Canada are reportedly more forgiving and safer, but they are far less efficient than the 'race horse' models the USA adopted from the nuclear navy. The navy design did not require huge outputs with continuous, long-term 'base load' operation, and was smaller and safer; the electric power plant scaled up the design to an unsafe level to achieve economies of scale.

Tight coupling, despite its associated economies, requires centralized decision making; processes are fast and invariant, and only the top levels of the system have a complete view of the system state. But complex interactions with uncertainty call for decentralized decision making; only the lower-level operators can comprehend unexpected interactions of sometimes quite small failures. It is difficult, and perhaps impossible, to have a system that is at the same time centralized and decentralized. Given the proclivities of designers and managers to favor centralization of power over its decentralization, it was a fairly consistent finding that risky systems erred on the centralization side and neglected the advantages of decentralization, but it was also clear that immediate, centralized responses to failures had their advantages. No clear solution to the dilemma, beyond massive redesign and accompanying inefficiencies, was apparent.

A few noteworthy accidents since the 1984 publication of *Normal Accidents* have received wide publicity: the Challenger space shuttle, the devastating Bhopal (India) accident in Union Carbide's chemical plant, the Chernobyl nuclear power plant explosion in the former USSR, and the Exxon Valdez oil tanker accident in Alaska. (These are reviewed in the Afterword in a later edition of *Normal Accidents* (Perrow 1999).) None of these were truly system accidents; rather, large mistakes were made by designers, management, and workers in all cases, and all were clearly avoidable. But the Bhopal accident, with anywhere from 4,000 to 10,000 deaths, prompted an important extension of Normal Accident Theory. Hundreds of chemical plants with the catastrophic potential of Bhopal have existed for decades, but there has been only one Bhopal. This suggests that it is very hard to have a catastrophe, and the reason is, in a sense, akin to the dynamics of system accidents. In a system accident everything must come together in just the right way to produce a serious accident; that is why they are so rare. We have had vapor clouds with the explosive potential to wipe out whole suburbs, as in the case of a Florida suburb, but it was night and no cars or trucks were about to provide the spark. Other vapor clouds have exploded with devastating consequences, but in lightly populated rural areas, where only a few people were killed. The explosion of the Flixborough chemical plant in England in 1974 devastated the plant and part of the nearby town, but as it was a Saturday few workers were in the plant and most of the townspeople were away shopping.

Warnings are important. There was none when the Vaiont dam in Italy failed and 3,000 people died; there was a few hours warning when the Grand Teton dam failed in the USA and only a few perished. Eighteen months after Bhopal another Union Carbide plant in West Virginia, USA, had a similar accident, but not as much of the gas was released, the gas was somewhat less toxic, and few citizens were about (though some 100 were treated at hospitals). (Shortly before the accident the plant had been inspected by the Occupational and Safety and Health Administration and declared to be very safe; after the accident they returned and found it to be 'an accident waiting happen' and fined Union Carbide.) Such is the role of retrospective judgment in the accident investigations Perrow 1999.)

To have a catastrophe, then, requires a combination of such things as: a large volume of toxic or explosive material, the right wind direction or presence of a spark, a population nearby in permeable dwellings who have no warning and do not know about the toxic character of the substance, and insufficient emergency efforts from the plant. Absent any one of these conditions and the accident need not be a catastrophe. The US government, after the Union Carbide Bhopal and West Virginia accidents, calculated that there had been 17 releases in the US with the catastrophic potential of Bhopal in 20 years, but the rest of the conditions that obtained at Bhopal were not present (Shabecoff 1989). The difficulty of killing hundreds or thousands in one go may be an important reason why elites continue to populate the earth with risky systems.

A number of developments appear to have increased the number of these 'risky systems' and this may account for the attention the scheme has received. Disasters caused by humans have been with us for centuries, of course, but while many systems started out in the complex and coupled quadrant, almost all have found ways to increase their linearity and/or their loose coupling, avoiding disasters. We may find such ways to make nuclear power plants highly reliable in time, for example. But the number of risky systems has increased, their scale has increased; so has the concentration of populations adjacent to them; and in the USA more of them are in privatized systems with competitive demands to run them hotter, faster, bigger, and with more toxic and explosive ingredients, and to operate them in increasingly hostile environments. Recent entries might be global financial markets, genetic engineering, depleted uranium, and missile defenses in outer space, along with others that are only now being recognized as possibilities, such as hospital procedures, medical equipment, terrorism, and of course, software failures.

NAT distinguishes system accidents, inevitable (and thus 'normal') but rare, from the vastly more frequent component failure accidents. These could be prevented. Why do component failure accidents nevertheless occur even in systems with catastrophic potential? Three factors stand out: the role of production pressures, the role of accident investigations that are far from disinterested, and the 'socialization of risk' to the general public. The quintessential system accident occurs in the absence of production pressures; no one did anything seriously wrong, including designers, managers, and operators. The accident is

rooted in system characteristics. But the opportunities for small failures that can interact greatly increases if there are production pressures that increase the chances of small failures. These appear to be increasing in many systems, and not just in complex/tightly coupled ones, as a result of global competition, privatization, deregulated markets, and the failure of government regulatory efforts to keep up with the increase in risky systems. Accidents have been rising in petrochemical plants, for example, apparently because their growth has not included growth of unionized employees. Instead, work is contracted out to non-union contractors with inexperienced, poorly trained and poorly paid employees, and they do the most risky work at turnaround and maintenance times. The fatalities in the contractor firms are not included in safety statistics of the industry, but counted elsewhere (Kochan et al. 1994).

A second reason preventable accidents are not prevented in risky systems is the 'interested' nature of the investigations. Operators—those at the lowest level, though this includes airline pilots and officers on the bridge of ships—are generally the first to be blamed, though occasionally there is a thorough investigation that moves the blame up to the management and the design levels. If operators can be blamed then the system just needs new or better trained operators, not a thorough overhaul to change the environment in which operators are forced to work. Operators were blamed at TMI for cutting back on high pressure injection, but they were trained to do that; the possibility that 'steam voids' could send misleading information and there could be a zirconium–water interaction was not conceived by designers; indeed, the adviser to the senior official overseeing the recovery effort, the Governor of Pennsylvania, was told it would not happen. Furthermore, if conditions A and B are found to be present after the accident, these conditions are blamed for it. No one investigates those plants that had conditions A and B but did not have an accident, suggesting that while A and B may be necessary for an accident, they are sufficient; unrecognized condition C may be necessary and even sufficient, but is not noted and rectified.

A third reason for increases in accidents may be the 'socialization of risk.' A large reinsurance company found that it was making more money out of arbitraging the insurance premium it was collecting from many nations: making money by transferring the funds in the currency the premium was paid in to other currencies that were slightly more valuable. They enlarged the size of the financial staff doing the trading and cut the size of their property inspectors. The inspectors, lacking time to investigate and make adequate ratings of risk on a particular property, were encouraged to sign up overly risky properties in order to increase the volume of premiums available for arbitraging. More losses with risky properties occurred, but the losses were more than covered by the gains made in cross-national funds transfers. The public at large had to bear the cost of more fires and explosions ('socializing' the risk). Insurance companies have in the past promoted safe practices because of their own interest in not paying out claims; now some appear to make more on investing and arbitraging premiums than they do by promoting safety. Open financial markets, and the speed and ease of converting funds, appear to interact unexpectedly with plant safety.

Normal Accident Theory arose out of analyzing complex organizations and the interactions of organizations within sectors (Perrow 1986). Recent scholarship has expanded and tightened the organizational aspects of the theory of normal accidents. Scott Sagan analyzed accidents and near misses in the United States' nuclear defense system, and pointed to two aspects of NAT that needed emphasis and expansion: limited or bounded rationality, and the role of group interests (Sagan 1993).

Because risky systems encounter much uncertainty in their internal operations and their environments, they are particularly prone to the cognitive limits on rationality first explored by Herbert Simon, and elaborated by James March and others into a 'garbage can' model of organizations, where a stream of solutions and problems connect in a nearly random fashion under conditions of frequent exit and entry of personnel and difficult timing problems (March and Olsen 1979). Sagan highlights the occasions for such dynamics to produce unexpected failures that interact in virtually incomprehensible ways.

The second feature that deserved more emphasis was the role of group interests, in this case within and among the many organizations that constitute the nuclear defense system. These interests determined that training was ineffective, learning from accidents often did not occur, and lessons drawn could be counterproductive. Safety as a goal lost out to group interests, production pressures, and 'macho' values. In effect, Sagan added an additional reason as to why accidents in complex/coupled systems were inevitable. The organizational properties of bounded rationality and group interests are magnified in risky systems making normal safety efforts less effective.

A somewhat competing theory of accidents in high-risk systems, called High Reliability Theory, emphasizes training, learning from experience, and the implanting of safety goals at all levels (Roberts 1990, La Porte and Consolini 1991, Roberts 1993). Sagan systematically runs the accidents and near misses he found in the nuclear defense system by both Normal Accident Theory and High Reliability Theory and finds the latter to be wanting. Sagan has also developed NAT by exploring the curious association of system accidents with redundancies and safety devices, arguing that redundancies may do more harm than good (Sagan 1996).

NAT touched on social-psychological processes and

cognitive limits, but this important aspect of accidents was not as developed as much as the structural aspects. Building on the important work of Karl Weick, whose analysis of the Tenerife air transport disaster is a classic (Weick 1993), Scott Snook examines a friendly fire accident wherein two helicopters full of UN peacekeeping officials were shot down by two US fighters over northern Iran in 1991 (Snook 2000). The weather was clear, the helicopters were flying an announced flight plan, there had been no enemy action in the area for a year, and the fighters challenged the helicopters over radio and flew by them once for a preliminary inspection. A great many small mistakes and faulty cognitive models, combined with substantial organizational mismatches and larger system dynamics caused the accident, and the hundreds of remedial steps taken afterwards were largely irrelevant. In over 1,000 sorties, one had gone amiss. The beauty of Snooks' analysis is that he links the individual, group, and system levels systematically, using cognitive, garbage can, and NAT tools, showing how each contributes to an understanding of the other, and how all three are needed. It is hard to get the micro and the macro to be friends, but he has done it.

Lee Clarke carried the garbage can metaphor of organizational analysis further and looked at the response of a number of public and private organizations to the contamination by dioxins of a 18-story government building in Binghamton, NY (Clarke 1989). Organizations fought unproductively over the cause of the accident, the definition of risk involved, the assignment of responsibility, and control of the cleanup. While the accident was a simple component failure accident, the complexity of the organizational interactions of those who could claim a stake in the system paralleled the notion of interactive complexity, and their sometimes tight coupling led to a cascade of failures to deal with it satisfactorily. An organizational 'field' can have a system accident, as well as an organization. Clarke followed this up with an analysis of another important organizational topic related to disasters (Clarke 1999). When confronted with the need to justify risky activities for which there is no experience—evacuating Long Island in New York in the event of nuclear power plant meltdown; protecting US citizens from an all-out nuclear war; protecting sensitive waterways from massive oil spills—organizations produce 'fantasy documents' based on quite unrealistic assumptions and extrapolations from minor incidents. With help from the scientific community and organizational techniques to co-opt their own personnel, they gain acceptance from regulators, politicians, and the public to launch the uncontrollable. It is in the normative spirit of *Normal Accidents*.

Widespead remediation apparently saved us from having a world-wide normal accident when the year 2000 rolled around and many computers and embedded chips in systems might have failed, bringing about interactive errors and disasters. But even while extensive remediation saved us, something else was apparent: the world is not as tightly coupled as many of us thought. Though there were many 'Y2K' failures, they were isolated, and the failures of one small system (cash machines, credit card systems, numerous power plants, traffic lights and so on) did not interact in a catastrophic way with other failed systems. A few failures here and there need not interact in unexpected ways, especially if everyone is alert and watching for failures, as the world clearly was as a result of all the publicity and extensive testing and remediation. It was a very reassuring event for those who worry about the potential for widespread normal accidents.

One lesson is that NAT is appropriate for single systems (a nuclear plant, an airplane, or chemical plant, or part of world-wide financial transactions, or feedlots and live-stock feeding practices) that are hard-wired and thus tightly coupled. But these single systems may be loosely coupled to other systems. It is even possible that instead of hard-wired *grids* we may have a more 'organic' form of dense *webs* of relationships that overlap, parallel, and are redundant with each other, that dissolve and reform continuously, and present many alternative pathways to any goal. We may find, then, undersigned and even in some cases unanticipated alternatives to systems that failed, or pathways between and within systems that can be used. The grid view, closest to NAT, is an engineering view; the web is a sociological view. While the sociological view has been used by NAT theorists to challenge the optimism of engineers and elites about the safety of the risky systems they promulgate, a sociological view can also challenge NAT pessimists about the resiliency of large system (Perrow 1999).

Nevertheless, the policy implications of NAT are not likely to be challenged significantly by the 'web' view. While we have wrung a good bit of the accident potential out of a number of systems, such as air transport, the expansion of air travel guarantees catastrophic accidents on a monthly basis, most of them preventable but some inherent in the system. Chemical and nuclear plant accidents seem bound to increase, since we neither try hard enough to prevent them nor reduce the complexity and coupling that make some accidents 'normal' or inevitable. New threats from genetic engineering and computer crashes in an increasingly interactive world can be anticipated. Lee Clarke's work on fantasy documents shows how difficult it is to extrapolate from experience when we have new or immensely enlarged risky systems, and how tempting it is to draw ridiculous parallels in order to deceive us about safety (Clarke and Perrow 1996, Clarke 1999).

It is also important to realize how easily unwarranted fears can be stimulated when risky systems proliferate (Mazur 1998). Formulating public policy when risky systems proliferate, fears abound, production pressures increase, and the costs of accidents can be 'socialized' rather than borne by the systems, is

daunting. We can always try harder to be safe, of course, and should; even civil aviation has seen its accident rate fall, and commercial air travel is safer than being at home, and about as safe as anything risky can be. But for other systems—nuclear plants, nuclear and biological weapons, chemical plants, water transport, genetic engineering—there can be policy attention to internalizing the costs of accidents, making risk taking expensive for the system; downsizing operations (at some cost to efficiency); decoupling them (there is no engineering need for spent fuel rod storage pools to sit on top of nuclear power plants, ready to go off like radioactive sparklers with a power failure or plant malfunction); moving them away from high-population areas; and even shutting some down. The risks systems to operators may be bearable; those to users and innocent bystanders less so; those to future generations least of all.

NAT was an important first step for expanding the study of accidents from a 'operator error,' single failure, better safety, and more redundancy viewpoint that prevailed at the time *Normal Accidents* was published. It questioned all these and challenged the role of engineers, managers, and the elites that propagate risky systems. It has helped stimulate a vast literature on group processes, communications, cognition, training, downsizing, and centralization/decentralization in risky systems. Several new journals have appeared around these themes, and promising empirical studies are appearing, including one that operationalizes effectively complexity and coupling for chemical plants and supports and even extends NAT (Wolf and Berniker 1999). But we have yet to look at the other side of systems: their resiliency, not in the engineering sense of backups or redundancies, but in the sociological sense of a 'web-like' interdependency with multiple paths discovered by operators (even customers) but not planned by engineers. NAT, by conceptualizing a system and emphasizing systems terms such as interdependency and coupling and incomprehensibility, and above all, the role of uncertainty, should help us see this other, more positive side.

Accountability: Political

Political accountability is the principle that governmental decision-makers in a democracy ought to be answerable to the people for their actions. The modern doctrine owes its origins to the development of institutions of representative democracy in the eighteenth century. Popular election of public officials and relatively short terms of office were intended to give the electorate the opportunity to hold their representatives to account for their behavior in office. Those whose behavior was found wanting could be punished by their constituents at the next election. Thus, the concept of accountability implies more than merely the tacit consent of the governed. It implies both

mechanisms for the active monitoring of public officials and the means for enforcing public expectations.

1. Accountability and Responsibility

When the doctrines and institutions of representative democracy were originally developed, the term most commonly used to capture what we now mean by accountability was 'responsibility.' As the editor of a standard edition of *The Federalist Papers* notes, '[r]esponsibility is a new word that received its classic definition in the ratification debate [over the proposed Constitution of 1787] and, especially, in the pages of *The Federalist*. Although the term had appeared sporadically in eighteenth-century British politics, it was in America in the 1780s that it achieved its lasting political prominence' (Hamilton et al. 1999, p. xxii). In *The Federalist*, however, 'responsibility' carried several meanings, only one of which is synonymous with 'accountability.' The virtual replacement of the broader term by the narrower one in modern political discourse is indicative of powerful trends in democratic thought.

In his essays on the presidency Alexander Hamilton described responsibility as equivalent to accountability. A plural executive, he argued, tends 'to conceal faults and destroy responsibility' because the people do not know whom to blame for misconduct or poor stewardship of the affairs of state. Hamilton contrasted England, where the king was legally 'unaccountable for his administration' with 'a republic where every magistrate ought to be personally responsible for his behavior in office.' The American president was responsible (i.e., accountable) to the people through the electoral process and, in serious cases of misconduct, through impeachment, conviction, and removal (Hamilton et al. 1999, pp. 395–97).

Yet *The Federalist* also includes a somewhat broader and more subtle understanding of responsibility. 'Responsibility', James Madison wrote in an essay on the proposed Congress, 'in order to be reasonable, must be limited to objects within the power of the responsible party, and in order to be effectual, must relate to operations of that power, of which a ready and proper judgment can be formed by the constituents.' Here Madison distinguished governmental measures 'which have singly an immediate and sensible operation' from others that depend 'on a succession of well-chosen and well-connected measures, which have a gradual and perhaps unobserved operation.' A 'reasonable' understanding of governmental responsibility would recognize the value of legislators exercising their discretion and judgment in promoting the long-term well being of the country. Put differently, legislators act responsibly when they behave in this way, despite the fact that their constituents may not recognize the value of their acts, at least for some time (Hamilton et al. 1999, pp. 351–2).

Hamilton and Madison each followed these discussions with powerful statements that when the people push for prejudiced, irresponsible, or unjust measures, their elected officials have a 'duty' to resist the popular desires until reason can regain its hold on the people (Hamilton et al. 1999, pp. 352, 400). Public officials have a responsibility at times to act against public opinion in the interest of the public good. This notion of responsibility goes well beyond accountability, at least as commonly understood. As one modern commentator notes, responsibility in this broader sense 'is concerned with results.' The responsible public official 'takes care that the results are correct 'and 'good for many. Such responsibility is the most interesting kind because it goes beyond questions of accountability and obligation in any simple meaning' (Blitz 1998). It follows that responsibility as accountability may at times conflict with responsibility in the broader sense of acting to promote the good of many.

2. The Accountability of Elected Officials

Under the first constitution of the USA, the Articles of Confederation (1781–1788), the delegates to the Congress were appointed by the state legislatures for one-year terms. Under Article V, each state retained the authority 'to recall its delegates, or any of them, at any time within the year.' Thus, the nation's legislators were entirely accountable to those who appointed them. Under the Constitution of 1787, however, neither the popularly elected members of the House of Representatives with their two-year terms nor the members of the Senate, elected by the state legislatures for six-year terms, were recallable between elections. Here the Constitution's framers sacrificed some amount of accountability in order to promote the independent judgment and the collective deliberation of legislators. Secure in office for either two or six years, lawmakers could act for the public good as they came to understand it without the fear that unpopular actions would result in their immediate dismissal. Because of the difference in the length of terms, this principle was expected to apply with much greater force to senators than to representatives.

As early as the First Congress (1789–1791) under the new Constitution, some in the House and Senate sought to remedy what they took to be deficiencies in the accountability of national lawmakers. Members of the House, for example, proposed an amendment to the Constitution that would guarantee the right of the people 'to instruct their representatives', thereby binding them to a certain course of action. Representative Elbridge Gerry of Massachusetts argued that it was 'absurd to the last degree' to say that 'sovereignty resides in the people' but to deny the right of the people 'to instruct and control their Representatives.' But others, such as Representative Thomas Hartley of Pennsylvania, argued that 'the great end of

meeting [in a legislature] is to consult for the common good' and thus to transcend 'local or partial view[s].' The proposed amendment was defeated by a 4–1 margin.

In the new Senate the proponents of greater accountability argued that under a proper understanding of the Constitution senators were already obliged to follow instructions from the state legislatures that appointed them. Indeed, from the very beginning some of these legislatures instructed their senators as to how to vote on specific bills. Although this practice continued for some decades, there was no way for state legislatures to enforce compliance with their instructions. At best they could refuse to reappoint a senator when his term expired. The adoption in 1913 of the direct popular election of senators (Seventeenth Amendment) effectively ended any issue of accountability to state legislatures, while it also promoted the accountability of senators to the people of their states.

It was in the 1960s and 1970s that public pressure to make Congress more accountable for its behavior reached its peak. The institution responded with a variety of 'government in the sunshine' reforms, including: (a) the opening up of nearly all committee meetings to public scrutiny; (b) the televising of floor debates in the House and Senate; and (c) new requirements that most votes in committee and on the floor be recorded and made available to the public. Although these changes have been popular, some members of the institution as well as some scholars have questioned whether greater accountability has been good for legislative deliberation within Congress. In the early 1980s, for example, after a decade of conducting its mark-up (bill drafting) sessions in public, the tax-writing House Ways and Means Committee returned to closed sessions. Committee members had become convinced that greater accountability to constituents and interest groups had made it increasingly difficult for the members to take actions that imposed costs on their supporters, however conducive such measures might be to the broader public good. In the language of *The Federalist*, these legislators promoted responsible behavior, even if this came at the cost of some direct accountability.

3. *The Accountability of the Bureaucracy*

The issue of political accountability is not limited to elected officials. Modern democratic states are characterized by large bureaucracies whose members have no direct electoral link to the populace. How are these thousands of individuals, whose actions directly affect the citizenry in a myriad of ways, held to account for what they do? In the USA President Andrew Jackson (1829–37) and Senator Daniel Webster engaged in a classic debate on this issue. Jackson's position was that the president himself was 'responsible for the entire action of the executive department.' Executive officials, 'mere instrument[s] of the Chief Magistrate in the execution of the laws', were accountable to the nation for their behavior through the combination of their subservience to the president and his direct accountability to the people. The president, Jackson maintained, is 'accountable at the bar of public opinion for every act of his Administration.' Webster, by contrast, decried this 'undefined, undefinable, ideal responsibility to the public judgment.' Executive branch officials were not primarily 'the President's agents' but 'agents of the laws.' It was the law that 'define[d] and limit[ed] official authority', that 'assign[ed] particular duties to particular public servants', and that 'define[d] those duties.' And it is Congress, of course, that makes the law.

In practice the movement for a more accountable bureaucracy has traveled down these two distinct paths. One path is the enhancement of presidential control of the bureaucracy through (a) the centralization of executive branch budget making; (b) White House clearance of legislative proposals; and (c) the development of personnel policies to increase the influence of the president's appointees over career civil servants. The other is the formalization of Congress's oversight function, stemming from the Legislative Reorganization Act of 1946 which required that 'each standing committee exercise continuous watchfulness of the execution [of the laws] by the administrative agencies.' One of the ironies of this movement to enhance governmental accountability is that even as Congress has formalized and expanded its oversight activities, it has increasingly delegated policy-making responsibilities to the executive branch. Scholars have argued that the members of legislative institutions have strong political incentives to create new bureaucracies and empower them to make the controversial policy decisions. The bureaucrats 'make the hard choices' and the lawmakers 'disclaim any responsibility for harm done' (Schoenbrod 1993, p. 8, Fiorina 1989, pp. 40–7). When constituents complain, lawmakers eagerly intervene on their behalf with the bureaucrats. In this way Congress undermines genuine democratic accountability while giving the appearance of increasing bureaucratic accountability.

4. *Accountability and Other Goals*

The modern movement for greater political accountability has led to such reforms as requirements that governmental agencies do their business in public, that the public have access to government information, and that the public be given formal opportunities to testify or comment on proposed administrative rules and regulations. More than ever before modern democratic governments are open to the scrutiny of the media, of interest groups, and of the broader public. The tendency throughout has been to view and pursue accountability as an end in itself, as an

unmitigated good. Yet while accountability is necessary to ensure that democratic government is faithful to the interests of those it serves, it is also in some tension with other conditions and values of sound governance, such as the exercise of informed discretion by decision-makers and the promotion of sound deliberation about common ends.

Action Planning, Psychology of

1. Basic Concepts

1.1 Action

The concept of action refers to *the intended behavior of an agent*. Different prototypical types of actions can be distinguished: 'goal-directed action' aims at the attainment of an end state (such as repairing a bicycle), and to a great extent is under cognitive control. 'Intuitive actions' are more or less spontaneously performed without much conscious thought and awareness (e.g., many acts in face-to-face social interaction). In experience- (or process-) oriented actions' it is the performance process itself, and not the end state, that is important (such as skiing or dancing), and they may produce the experience of 'flow' (Csikszentmihalyi 1990). 'Acts committed in the heat of passion' are not under full cognitive control, but seem to erupt in states of strong affective pressures (as is the case in many violent crimes). Finally, there are long-term 'projects' (such as constructing a house or achieving an academic degree) which are composed of many consecutive actions of various forms. These types of actions seem to correspond to social prototypes, in the sense that cultural concepts of them exist. However, pure forms of action prototypes are rarely observed because most actions in real life contain elements of several prototypes. In this article, we concentrate on *goal-directed action of human individuals* since the features of 'planning' are most important and clear in this context.

Most researchers in the field of action consider it as characteristically human; therefore, basic assumptions about the human nature have led to different concepts of action, with different authors and schools emphasizing different aspects. Some emphasize the commonsense nature of an action (Heider 1967); others conceive it as an ex-post interpretation of behavior (Lenk 1978); still others concentrate on its logical nature (Smedslund 1997) or emphasize its symbolic meaning in a cultural context (Boesch 1991). Approaches that discuss action from a motivational and a regulation perspective have received the most attention in the field and have elicited the most empirical work. Both approaches refer to goal-directed action, seeing it as events in a systemic context and emphasize its cognitive, if not rational, nature. The motivational approach addresses the problem of how a person decides, among the many possibilities, on a *specific goal or action*, and how, once chosen, an action is maintained and *carried through* (Heckhausen 1991). The regulation approach concentrates on the question of *how* the attainment of a given goal is achieved (Cranach et al. 1982, Hacker 1998). Starting with these two approaches, we add the notion that individual action tends also to be socially steered and controlled.

As a summary, we define action as the behavior of an individual human agent (or actor) which is directed and (at least partly) consciously aspired, wanted, planned, and steered in order to achieve a specific goal.

1.2 Planning

In order to attain a goal, an actor needs energy, so the mind–body system can be set in motion. He or she also

needs direction, or steering, towards the intended end-state. We therefore distinguish between *energizing processes* and *steering processes*. Mental processes can serve either one, or both, functions. Thus, we distinguish between 'decision' and 'resolve' (William James' 'fiat'). The first refers to the choice between alternatives and has a steering function, whereas the second energizes the action as an initiating command.

In a broad sense, the term 'planning' is used with regard to all mental activities that serve action steering (e.g. Miller et al. 1960). For example, this is the way the term 'plan' is used in the method of 'plan–analysis' in psychotherapy (Caspar 1995). In this case, planning contains elements of goals *and* elements of the means to attain the goals. In the context of action-regulation theory and some related approaches, planning is used in a narrower sense and is seen as one part of a more or less ordered action steering cycle composed of anticipatory cognitive representations of the operations, steps, rules, and procedures of goal attainment. Planning therefore is the *program of the course of action*.

2. Planning as 'Steering'

2.1 Expectancy Theories of Behavior

The basic idea that an action should be executed if its expected results are of high value and if the action appears to be a likely mean to realize them was formulated by Blaise Pascal and David Bernoulli in the seventeenth and eighteenth centuries. However, its psychological formulation is based on Kurt Lewin's (1951) field theory. It has been further developed by John W. Atkinson, Heinz Heckhausen and many others (see Heckhausen 1991). The expectancy theories of motivation, which are one of the most influential branches of motivation theory, have been differentiated in many details and have led to a great variety of experimental studies. Their assumptions explain how people choose a specific action among several possibilities: (a) in the course of their life, people develop (and adopt) values that may be formulated as goals; (b) certain situations contain hints ('incentives') about the possibility of realizing a goal through an action; (c) the incentive is related to a certain *expectancy* that the goal can be attained; and (d) if the value-based incentive and the expectancy are strong enough, an *intention* is formed to realize the action (in a suitable situation). For example, if a person values energy saving and believes that insulating windows helps to achieve this goal, he or she should be inclined to install better windows in his or her house. This normally means that some other possible personal goals may have to be sacrificed.

On the basis of expectancy and value assumptions, the 'theory of planned behavior' (Ajzen 1991), which is a development of the 'theory of reasoned action' by Marty Fishbein and Icek Ajzen, tries to explain the influence of attitudes on behavior. Value and expectancy produce an *attitude* with regard to a specific behavior. However, even a positive attitude is normally not enough to elicit an action. The attitude becomes an *intention* to act, when two other conditions are satisfied: first, the person must hold a normative belief which conforms to the action, and he or she must be motivated to comply to that norm ('*subjective norm*'). Second, the person must perceive that he or she can in fact execute the action and is able to reach the goal ('*perceived behavior control*'). In our example, the house-owner knows that insulated windows conform to the standards of the neighborhood, and that he or she has enough money, time, organizational talent, and persistence to realize this project.

Figure 1
The hierarchical–sequential organization of the action

2.2 Action Regulation Theory

The decision to purchase new windows is only the beginning of the action. The house-owner must now decide what kind of windows to choose, which contractor to commission with the job, and when and how to install the new windows. A host of complicated cognitive operations and their execution (not to speak of their emotional aspects and the necessary volitional acts) are required. These processes are treated by *the action regulation theory* (for a more comprehensive description, see Frese and Zapf 1994) that has been developed in the context of work psychology (e.g., Hacker 1998) and in social psychology (Cranach et al. 1982). Psychological action theory is based on assumptions from *activity theory*, developed by Russian psychologists (e.g., S. L. Rubinstein and A. L. Leontjew) combined with a *cybernetic approach* (e.g., Miller et al. 1960).

Actions are seen as goal-directed *units of work activity* that are consciously and voluntarily steered. Actions are hierarchically and sequentially organized. The hierarchical organization refers to the nested units of goals, subgoals, and subsubgoals of an action. In order to attain a goal, the related subgoals must be attained before the agent can proceed to the next superordinate unit (the sequential characteristic of action) (Fig. 1). The model includes information transfer from lower to higher levels of action, but also

on the horizontal axis, and therefore represents a weak form of hierarchy. In order to facilitate the application of the model, various authors have introduced the concept of *levels of regulation* which contains the notion of a quasistandardized hierarchy. Units on a given level are assumed to have certain features in common. In his original model, Hacker (1998) proposed the 'intellectual,' the 'perceptive conceptual,' and the 'sensorimotor' levels of action regulation, each level having different functions and qualities. All levels of action regulation include steering activities together with the actual action execution. Higher-level processes are more comprehensive and more likely to require conscious monitoring of the operations whereas lower-level processes are more likely to become automatic.

The sequential dimension of an action has been further differentiated, and cyclical regulation processes have been described. On each level, successful action requires a prototypical cycle of regulatory functions: A cycle starts with either *goal determination* or *situational orientation*; the latter contains the two components of *orientation about the environment* and *orientation about the agent's own state*. After a goal has been determined, the *development of an action plan* follows. These components are integrated into a relatively stable cognitive representation, known as the *operative representation system* (Miller et al.'s 'image'), which directs the *execution*. Action execution is constantly monitored with regards to deviations from plans and goal attainment (*execution control*). The regulatory cycle is accomplished with the *consumption of the result* and a *final evaluation of the action*. If we return to our example: after deciding to install new windows (goal determination), our agent seeks information about the prices of different windows on the market, possible contractors, as well as his or her own budget (*orientation about environment and own state*). He or she must then decide what windows to purchase and which contractor to entrust with the work. The next step requires that the details of the procedure to replace the old windows must be worked out (*plan development*). Execution of the work follows according to the plan in several steps, each consisting of a number of sub- and subsubtasks, which must be worked through in a specific sequential order (first, take out the old windows before installing the new ones). It has been found that actions which follow an ideal cyclical order tend to be more successful.

3. *Planning in the Narrower Sense*

Besides the general notion of behavior regulation and steering of behavior, planning can also be considered as the anticipatory, cognitive construction of the action and its steps, that is, the cognitive *development of the action program*. Steering in its prototypical form includes planning in this sense as one of the important regulatory activities. Planning in the narrower sense is basically a behavior stream that is imagined and thought, but not executed. Planning consists of conditions, possible executions, and possible outcomes of an action (Dörner 1990). As conditions can vary, several plans can be made with regard to one outcome. Planning can start at the status quo (when I cover furniture before installing the windows), but also start from the end state (when will the contractor come) and be recursive. Backwards planning has been found to be less frequent, but more effective in certain types of problem solving. (Dörner 1990).

Planning seems to have obvious benefits. It could therefore be assumed that human actors normally carefully plan ahead before acting. However, individuals and groups often do not do so or they show satisfying tendencies (Simon 1957), in that they elaborate only very rudimentary action plans. In spite of this, they somehow reach their goals. In this context, the following questions are important: what is the advantage of planning, and when is planning necessary?

(a) The possibility of elaborating a complete plan before acting depends very much on the information available. If the situation is very clear from the beginning and complete information is available, the elaboration of a complete plan or action program is possible. If the situation is dynamic and new information is acquired during the action, *conditional planning* or *rolling planning* is more indicated.

(b) *Different kinds of tasks require different amounts of planning*. For example, in sports, a 5,000 m race requires a lot of strategic and adaptive planning from all of the competitors. In contrast, the execution of a pole-vault requires that the essential activities are automated to a high degree in order to lead to a smooth and successful execution. The essential parts of the activity must therefore be trained and practiced in order not to require planning; conscious monitoring could even disturb the perfect execution.

(c) *Automation of behavior execution*, which involves the absence of conscious and detailed planning, is normal when an action is frequently executed. This is especially true for the lower levels of regulation. An obvious example of this is talking, where we may plan on a general level what to say, but the details of composing the sentences, and even more so the phonological production, are highly automated and not consciously controlled. However, conscious monitoring of normally automated parts (the so-called 'emergency function of consciousness') will often be resumed if difficulties arise—for example, we perceive and correct speech slips. Automatic actions have been characterized as situation-specific, integrating different operations, requiring less feedback and fewer decisions and leading to more parsimonious movements (Semmer and Frese 1985).

(d) For many situations *preformed plans exist*, even on a societal level. For example, there exists a widely

shared general sequence of action steps, a 'script' (Schank and Abelson 1977), of how to eat in a restaurant, containing a general plan that can be specified and adapted for a specific situation. If 'scripts' exist, planning effort is reduced. People also tend to establish *personal scripts by planning on stock, for example they imagine or fantasize about situations* and behaviors during activities that do not demand their full attention (for example, they may plan the installation of the windows during a bus ride).

(e) There is great variation in the individual inclination and capability to plan. Personality dimensions like 'action versus state orientation' (Kuhl and Beckmann 1994) or 'action styles' like planfulness (Frese et al. 1987) are important indicators of the amount of planning done by individuals.

Taking all these complications into account, there is still a lot of evidence that planning is strongly related to successful action. Studies of experts (Ericsson and Lehmann 1996) and very successful workers ('superworkers') show that *intellectual penetration* of the task (Hacker 1996) and the development of more complete operative image systems that serve as a more complete basis for planning are crucial for expert performance. In addition, the study of thought processes during computer-simulation tasks (Dörner 1990) and of the action-related communication of successful teams (Tschan and von Cranach 1996) lead to similar conclusions.

4. *Inefficient Planning and Planning Mistakes*

Even if, generally speaking, planning is a necessary prerequisite to many actions and leads to more successful goal attainment, planning can be inefficient or may even fail.

Besides the planning inefficiencies that may occur if the informational basis is too small or if the planning is based on false assumptions or contains illogical or wrong 'if–then' relations, planning that is too detailed or too general may be inefficient. Too detailed planning, often done to reduce insecurity, may lead the person to get stuck and hinder execution. Another disadvantage is the concentration on details and specific aspects of a more complex task and the neglect of other important aspects. Plans that are too general may fail to include important specifications and conditions to their execution or they may be incomplete in other respects, and are therefore difficult to carry out (Dörner 1990). In dealing with complex, dynamic and non-transparent situations, typical planning inefficiencies include the misjudgment of the importance of certain information, which narrows down the searching space and misses valuable information, the neglect of side-effects of planned actions, and the failure to perceive possible delayed effects which may produce unforeseen, unwanted secondary results.

Error research distinguishes between slips (errors in action execution) and mistakes (errors in the intention). The latter include planning mistakes. Mistakes of steering activities have been conceptualized in a hierarchical model which corresponds to the levels of regulation described above (Reason 1990; for another important classification, see Frese and Zapf 1994). The model distinguishes *knowledge-based* regulation, where new plans are elaborated. Failures in the elaboration of correct plans on this level include limitations of workspace, limitations of handling complexity, and numerous biases, e.g., illusory correlation, halo effect, and confirmation bias. On the *rule-based* level, people faced with a new situation choose from a 'pool of available plans' or rules and apply them to a new situation. Mistakes on this level include the misapplication of a good rule or plan to a new situation and the application of a wrong plan to a specific situation. Reason (1990) summarizes the main mechanisms that produce errors as *similarity matching* (looking for and applying something that is already known) and *frequency gambling* (using knowledge which has already been frequently used) (see also Kahnemann et al. 1982).

Action Theory: Psychological

Action theory is not a formalized and unitary theory agreed upon by the scientific community, but rather a unique perspective, narrative or paradigm. Although this perspective varied in saliency during the history of psychology, it has been in existence since the very beginning of psychology in the nineteenth century both in Europe and North America. In Germany, Brentano, a teacher of Freud's, focused 1874 on intentionality as a basic feature of consciousness leading to the concept of 'acts of consciousness.' Ten years later, Dilthey distinguished between an explanation of nature and an understanding of the mind/soul, a dichotomy, which paved the way for the ongoing discourse on the dichotomy of explanation and understanding. In 1920 Stern criticized the mainstream psychology of his time because it neglected *intentionality* and also *cultural change* as a created framework for human development. In Paris, Janet wrote his dissertation about '*Automatisme*' in 1889. This was the beginning of an elaborated action theoretical system of neuroses (Schwartz 1951). In North America James developed a sophisticated theory of action at the end of the nineteenth century that anticipated a remarkable amount of action theory concepts (Barbalet 1997). Münsterberg, a disciple of Wundt, proposed action as the basic unit of psychology instead of sensations at the turn of the century. These early traditions were overruled by the neopositivistic logic of explanation expounded by the Vienna circle in philosophy and behaviorism in psychology. They were taken up in philosophy by Wittgenstein's 'language games' that are different in natural science and the humanities. In psychology action theory terms have increased in importance again during the 1960s to the 1990s.

In fact, in recent times human action (or aspects of it) is taken as a framework for analysis and/or research in many branches of psychology. This is true for 'basic science': in theories of motivation (e.g., Gollwitzer 1990), problem solving (e.g., Dörner and Kaminski 1988), ontogenetic development (e.g., Oppenheimer and Valsiner 1991), social psychology (von Cranach 1991), and particularly in cultural psychology (Boesch 1991). And it is true for 'applied domains': in clinical psychology (Schwartz 1951), educational psychology (Bruner 1996), organizational psychology or psychology of work (Hacker 1986), and sport-psychology (Kaminski 1982). Under an action theory perspective the boundaries between these domains become fuzzy. Cultural psychology, for instance, becomes an integrated enterprise, which is developmental as well as cognitive, affective, and motivational (cf. Boesch 1991; Cole 1990).

Beyond this diversity of action based theories in psychology, human action is also focused upon in other human sciences. It is particularly reflected upon in philosophy (Lenk 1984), and has a long tradition in sociology (Parsons 1937/1968, Weber 1904) and anthropology (Shweder 1990).

Finally, a 'second tradition' exists, basically equivalent to action theories, and with partly the same roots in Janet's work (Eckensberger 1995): the Russian activity theory in the tradition of Vygotsky, Luria, Leontiev, its most famous representatives. In the US this framework is particularly elaborated and applied by Cole, Rogoff, Valsiner, Wertsch; in Germany by Holzkamp.

1. *Attributes of Actions*

Considering the breadth of action theoretical frameworks, it is not surprising that the issues studied are not identical and that the terminology is not coherent or fully agreed upon by different authors or traditions.

1.1 *Action as an Analytical Unit*

From an analytical perspective it appears necessary to note that: To act does not mean to behave (although some authors consider actions as a particular subtype

of behavior); To speak of an action instead of behavior implies the following features:

(a) *Intentionality*: Broadly speaking, it means that sentences, symbols, but also mental states refer to something in the world (Searle 1980). Intentionality therefore occurs, if a subject (called *agency*) refers to the world. Agencies refer to the world by *acting* with reference to the world, by *experiencing* it (they think, feel, perceive, imagine, etc.) and by speaking about it: The latter is called '*speech act*.' An intentional state thus implies a particular content and a psychic mode (a subject can think that it rains, wish that it rains, *claim* that it rains, etc., where rain is the content, thinking, wishing, and claiming are modes). The intent of the action is the intentional state of an action; the intended consequence or goal is content. This implies what is also called 'futurity' (Barbalet 1997) or future orientation of an action. Although some try to explain actions by interpreting these intentions as causes of actions there is agreement at present that actions cannot epistemologically be explained by (efficient material) causes, but have to be understood in terms of their reasons (cf. Habermas 1984; von Wright 1971). This leads to serious problems, if psychology is understood as a natural science, which basically interprets events in terms of causes. It follows that aections are not necessarily observable from the outside. If they are, one also uses the term '*doing*' (Groeben 1986). However, allowing something to happen as well as refraining from doing something are also actions (von Wright 1971).

(b) *Control over the action*: It is assumed that action involves the free choice to do something (A or B), to let something happen, or to refrain from doing something. This condition is strongly related to the (subjective perception) of free will. Although the control aspect is sometimes also expanded to include the intended effects of an action, these two aspects should be distinguished, because the effects of an action can be beyond the control of the agency, although the decision to act itself was controlled.

(c) The *basic structure* of an action which aims at some effect (to bring something about) is the following: Analytically, it is assumed that the means applied to carry out an action follow rationally from the intentions, i.e., they can be justified or made plausible by the agency. They are chosen on the basis of finality (in order to reach a goal). If they are applied, the result is some change, and this change leads causally to some consequences. Those consequences of actions that represent the goal are intended, others are unintended. To let fresh air into a room (intended goal) one opens the window (does something), after having opened the window it is open (result) and lets fresh air in (intended), but the room may become cold (unintended).

(d) So actions in principle are *conscious activities* of an *agency*. The agency can reflect upon (a) their actions as well as (b) upon themself as an agency. This is why Eckensberger (1979) proposed interpreting action theories as a 'theory family' based upon the self-reflective subject or agency. This position is related to the basic issue of whether or not homo sapiens has a special position in nature, because this species is the only one that can decide not to follow natural laws. Once more this poses a serious problem for psychology as a natural science.

(e) There are *different types of actions*: (i) If directed at the physical/material world, and aimed at bringing about some *effect* (also 'letting things happen': von Wright 1971) or suppressing some effect, they are called 'instrumental actions'; (ii) But if actions are directed at the social world, i.e., at another agency B, they cannot (causally) 'bring something about' in B, but have to be coordinated with B's intentions. Therefore, agency B's intentions have to be understood (interpreted by agency A). This presupposes a communicative attitude (Habermas 1984). This type of action is consequently called a 'communicative action.' If this orientation not only implies understanding B, but also respecting B's intentions, this is clearly a moral action. If B's intentions are simply used for A's benefit it is a strategic action (Habermas 1984). Interestingly, in non-Western philosophies/religions (Hinduism, Buddhism, Confucianism) this 'adaptive attitude' and respect for the 'non-A' is extended to include the plant and animal world. So one may distinguish between two action types which aim at A's control of the environment (instrumental and strategic), and two action types which aim at harmonizing A with the environment (communicative and adaptive actions).

Although an agency is in principle considered autonomous, actions are not arbitrary but follow rules (of prudence as well as of social/cultural conventions and/or expectations). This tension between autonomy and heteronomy is basic to all action theories that also focus on the social/cultural context of actions (cf. Parsons 1937/1968). One tries to resolve this tension, however, by assuming that cultural rules and their alternation are also man-made, although the implied intentionality of cultural rules/norms may 'get lost' in time. In principle within this theoretical frame an action links the actor and his/her environment (see James 1897/1956), and cultures are considered intentional worlds (Shweder 1990) or action fields (Eckensberger 1995, Boesch 1991).

1.2 Actions as Empirical Units

The most recent and comprehensive review of action related to research in (developmental) psychology is given by Brandtstädter (1998):

1.2.1 Hierarchy of goals. There is considerable agreement among researchers that empirically actions do not just have one goal but many. They can

be seen as forming a chain or a hierarchy. To read an article may have the goal of understanding a particular problem and may be considered an action. Reading individual characters on paper may be taken as subactions or elements of an action (called 'actemes' by Boesch (1991)). Yet, reading the article can also be embedded in a larger set of goals (e.g., passing an examination), and may even be part of overarching far-reaching goals like becoming famous (called 'fantasms' by Boesch (1991)). These hierarchies are particularly elaborated in the application of action theory to work and sport settings (i.e., in instrumental contexts). But they are also relevant to communicative actions.

The fact that actions are meaningful to an agency implies that it is exactly this meaning which has to be identified empirically. This calls for hermeneutic methods, because actions have to be interpreted. Harré (1977) calls for an ethogenic approach (ethogenics literally mean 'meaning-giving'). This does not just refer to the dichotomy between qualitative and quantitative methods in psychology, but is a basic methodical feature derived from the theoretical model of an action (it should be noted, however, that no science can do without interpretation).

Beyond the structural aspects of actions, the course of actions is particularly relevant in empirical contexts. This is divided into action phases The number and features of these action phases differ, however: while, e.g., Boesch (1991) distinguishes three action phases (beginning phase, its course, and end) others, e.g., Heckhausen (see Gollwitzer 1990), propose four phases (a predecision phase, a preactional phase, the action phase (doing), and a postaction phase). Here, the decision to act plays an important role (Heckhausen uses the metaphor of crossing the Rubicon). In all these phases there is interplay between cognitive, affective, and energetic aspects of action.

Affects determine the 'valence' of a goal (and therefore of the environment in general), but as actions have more than one goal, goals are also 'polyvalent' (Boesch 1991). Additionally, affects also evaluate the course of an action (dealing with barriers, impediments during the action) and its end (was the action successful or not). These impediments basically increase consciousness, and thus, regulatory processes are of special interest in empirical research. They are basically coping processes dealing with occurring affects (external or primary control, actional, or secondary control). From a systematic point of view regarding these regulatory processes as 'secondary actions' is attractive because they are in fact 'action oriented actions' (Eckensberger 1995).

All questions relating to an agency are of particular empirical interest. First, the consciousness of actions is discussed differently. While some authors claim that consciousness is a necessary aspect of an action (which also implies the methodical possibility of asking actors about their actions), others claim that only the potential self-reflectivity of an agency (and a specific action) is crucial (Eckensberger 1979). This not only implies that a self-reflective action may be a rare event (during a day) but also that actions can turn into automatisms, etc. yet still remain actions. This calls for the analysis of the development of actions. Development therefore is a genuine and crucial dimension in many action theories (as microprocess or actual genesis, as ontogenesis, and as social/cultural change). Second, the development of the agency is a focus of research. Here, studies on self-development become relevant. Of particular interest in this context is the agency's perception of being able to act (called action potential or communicative competency) as a triggering or incitement condition for agency development. Third, the development of agency can itself be considered an action, as a project of identity development which has a goal and which may fail (Brandtstädter 1998). Eckensberger (1995), therefore, proposed calling these identity projects, which have agency related action structures, 'tertiary actions.'

The structural components distinguished above (intentions, finality, causality, etc.) have also become rather central empirical research topic. In fact, the expanding research on '*theory of mind*' (cf. Bartsch and Wellman 1995), and scripts (Nelson 1981) can be interpreted systematically as a program aiming at the questions of whether or not, and at what age, children can think in terms of action structures (distinguish between causal and intentional states, etc.). This strategy has also been applied to the development of moral judgments by Eckensberger and Reinshagen (1980), when analyzing arguments used in moral dilemmas in terms of action structures. Thus, most research programs on social cognition can be (re)interpreted in terms of action theory. Since the action links an agency with the (social and nonsocial) environment (see above), the action is the overlap between the internal and external action field. The internal action field is formed during ontogenetic experiences in the sense that actions are internalized as operations (in Piagetian sense) and normative rules (Turiel 1998) or categories, which for instance develop from (action bound) taskonomies to (generalized) taxonomies. These developments as well as control theories, individual rule systems (logic, understanding of morality, law, conventions) and ideas of the self as agency constitute the internal action field. The external action field, which is understood as culture, provides opportunities and constraints for actions, but it also attributes value to actions. Rituals as a cultural proffer of organized action clusters and myths (as complements of fantasms on the cultural level) are just as important as personal processes of construction (active production of order in the Piagetian sense). Like actions (the action field) can also have different levels of comprehensiveness and be organized hierarchically. According to Boesch (1991), for instance, the external action field of culture can be subdivided

into action spheres (like occupation or family) and action domains (like the office or kitchen). Both, the internal and external action field acquire their affective meaning (valence) via actions.

2. Action Theory as Opportunity for Developing an Integrated Psychological Theory

The uniqueness of the action theory approach to humans not only poses problems for the definition of psychology as a natural science, but also entails the possibility of developing an integrated theory, which not only interrelates different developmental dimensions (actual genesis, ontogenesis, and cultural change, see above) but also resolves most of the 'classical splits' in psychology (Overton 1998), like body/mind, nature/culture, cognition/affects.

The physiological bases for actions as well as the phylogenetic emergence of 'self-reflectivity' in nature can both be understood as 'enabling conditions' for human actions (Harré 1977). Cognitions and affects are integral parts of human actions and their development.

Action, Collective

Collective action is the means individuals use to pursue and achieve their values when individual action is not possible or likely to fail. Collective action theory is studied in all the social sciences: In economics, it is the theory of public goods and of collective choice (Stevens 1993); in political science, it is called 'public choice' (Mueller 1989); in sociology, it is linked to rational choice, collective behavior, and social movement theory. When markets fail because of imperfect competition, externalities, transaction costs, collective goods provision, and some other reasons, institutions and organizations—governments, political parties, corporations, universities, churches, kinship, social movements, etc.—structure collective action and allocate resources through nonmarket methods. Among these institutions have been conventions, ethical codes, morality, and norms which contribute to efficiency and welfare in social transactions (Arrow 1974). In the broadest sense, collective action theory seeks to explain the origins, evolution, and varieties of nonmarket institutions.

Most collective action is undertaken by organizations that initiate, coordinate, control, and reward individuals' participation in a joint enterprise. In a narrow sense, the theory of collective action deals with the noncoerced, voluntary provision of collective goods, the groups and organizations that provide them, participation and contribution in their pursuit, and contentious actions against targets that resist collective goods attainment. The groups and organizations are interest groups, civic associations, advocacy groups, dissidents, social movements, insurgents, and more transitory social formations such as crowds.

Collective and mass phenomena which result from many individuals pursuing personal goals in spatial and temporal proximity, as in a migration, a baby boom, or the fluctuations of public opinion, have been viewed as aggregations of individual choices and beliefs. Nevertheless, when there are strong externalities and when individuals choose strategically, collective action theory provides powerful insights about aggregation dynamics. Schelling (1978) has shown that housing choices in a mixed-race residential neighborhood can lead to more extreme patterns of racial segregation than the racial preferences of the majority of people in both groups. Similarly Boudon (1982) showed how French higher education reforms meant to increase the opportunities for working-class youth led to the perverse effect of increasing it for affluent youth. Unanticipated consequences, positive and negative bandwagons, unstable equilibria, critical mass, and threshold effects are common consequences of collective actions and central to the theory (Marwell and Oliver 1993).

1. *Collective Behavior*

Collective behavior refers to fads, panics, crazes, hostile crowds, riots, cults, moral panics, cargo cults, witch-hunts, Ghost Dance, and the like. The conventional explanation assumed a variety of social psychological and psychodynamic processes such as consciousness of kind, herd instinct, imitation, contagion, and regression. Observers were struck by the spontaneity and volatility, the emotional-expressive and transitory character of such behaviors in contrast to normatively structured everyday routines. Collective behavior was thought to result from extreme deprivation and threat perception in extraordinary situations when norms and expectations fail to guide action. The best known theorist in this tradition was LeBon ([1895] 1960), who postulated three 'laws' of crowd behavior: mental unity, loss of rational and moral faculties, and hero worship.

The problems with LeBon's and kindred theories of collective behavior is their highly selective character and disregard for alternative explanations. For the same episodes of crowd behavior in the French Revolution that LeBon described, Rude (1959) showed that they were atypical of crowds and many could be explained as purposive action without assuming unproven social psychological processes. Later theorists showed that uniform behavior and mental unity are due to selective convergence of predisposed participants, and that much variance of behavior occurs, ranging from engagement by hardcore activists to standing around by curious bystanders. Rather than amorality, emergent norms structure crowd behavior. Irrational crowd behavior results from the n-person, single game, prisoner's Dilemma aspect of some collective behavior, as in panics of escape (Turner and Killian 1987, Brown 1965).

Because of these shortcomings in the conventional view, collective behavior has been explained with collective action theory, even violent, destructive and bizarre collective behavior, such as lynch mobs, riots, and the witch-hunts of early modern Europe. Southern US lynch mobs in 1880–1920 were structured, ritualized, and predictable (Tolnay and Beck 1995). To be sure, some collective behavior manifests a lot of emotion, we-feeling, hate, fears, violence, and unusual beliefs, yet participants do respond to the benefits and

costs of actions, as they do in other situations. Charismatic leaders are not needed to organize collective behavior. Schelling (1978) has demonstrated how convergence and coordinated behavior by strangers comes about without prior leadership, organization and communication. Tilly (1978) has studied culturally learned and maintained repertoires of collective action of ordinary people against elites and the state. Because of empirical findings and explanations based on rational choice, collective behavior has been gradually integrated with collective actions theory.

Other theories are also being pursued. For Melucci (1996), emotions and identity seeking in small groups eclipses rationality and strategic interaction. Smelser (1963) defines collective behavior as mobilization on the basis of generalized beliefs which redefine social action. Unlike ordinary beliefs, generalized beliefs are about the existence of extraordinary forces, threats, conspiracies, wish fulfillment, utopian expectations, and their extraordinary consequences for adherents. Yet much institutionalized behavior, e.g., miracles in organized religion, the born again Christian conversion, have similar attributes, and the beliefs that inspire political crowds and movements tend to express conventional principles of popular justice, authority, solidarity, and equity (Rude 1959, Tilly 1978). Some political ideologies like xenophobic nationalism, the racist ideology of Nazis against Jews, and religious beliefs like the heresy of witchcraft in early modern Europe, as well as lesser moral panics, are full of threats and conspiracies, and instigate violent, cruel, and fatal actions against thousands of innocent people. Such belief systems and resulting collective actions have been explained with reference to elite manipulation and framing of mass opinion through the communications media, social control of citizens and repression of regime opponents, and conformity to the majority and one's peers (Oberschall 1993, Jenkins 1998). The most notorious genocides including the Holocaust were well planned and thoroughly organized by regime elites fully in command of the state apparatus, the military, the agents of social control, and the citizenry (Fein 1993).

2. *Interest Groups*

Interest groups, labor unions, professional and voluntary associations were assumed to form automatically from the common interest shared among a category of persons in reaction to deprivation and blocked goal attainment (Truman 1958). In the pathbreaking *Logic of Collective Action* where he applied the theory of public goods to public affairs, Olson (1965) argued that although individuals have a common interest in a collective good, each has a separate, individual interest of contributing as little as possible and often nothing to group formation and collective good attainment, i.e., enjoy the benefit and let others pay the cost. Because collective goods possess jointness of supply—if they are provided at all, they must be provided to contributors and non-contributors alike—collective action is subject to free-rider tendencies. Because many public, cultural, and social issues center on collective goods—pollution free environment, social and political reforms such as non-discrimination in employment and the right to abortion, humanitarian causes, charities, listener supported music stations—Olson's deduction that many collective goods will not be provided voluntarily and some only in suboptimal amount has far ranging implications.

Olson's conclusions applied strictly only to large groups of potential beneficiaries. In small groups, especially when one member has a large interest and obtains a large share, the collective good will be provided by such an interested person, though in suboptimal amount, while the others free-ride. This put the accent on patrons and sponsors in collective good provision, and the exploitation of the great by the freeriding small in alliances and coalitions. In an intermediate size population composed of a federation of small groups, a very important category in real world situations and applications, there is some likelihood of contributions to collective good attainment. In large populations, free-rider tendencies dominate. To overcome them, and because voluntary associations do not have the means to coerce contributions as the state can coerce its citizens to pay taxes, groups and leaders induce participation and contribution by offering selective incentives: these are individual benefits that non-contributors do not get, from leadership in the group to travel and insurance discounts, many other material and financial benefits, and some non-material solidarity incentives and social standing.

Free-rider tendencies are especially strong when the collective good is fixed in supply and diminishes as the size of the beneficiaries grows, i.e., freeriders actually diminish the amount of collective good available to contributors, as is the case with tax cheaters in a locality. For many non-market issues (humanitarian, social reform, environmental), the collective good is not subject to crowding, e.g., lower air pollution benefits all regardless of their numbers. Olson showed how the properties of the collective good, and not the psychological disposition and attitudes of individuals, explain differences in relationship between beneficiaries and contributors, recruitment and exclusion strategies of the group, and applied these insights to labor unions and labor laws.

Olson's theory was designed for economic interest groups though much of his model is broadly applicable. Because the accent is on obstacles to collective good attainment and on freeriding, one expects fewer voluntary associations than are actually observed in

democratic countries with freedom of association (Hirschman 1982). His conclusions were based on several assumptions: individuals don't think strategically and don't influence one another's decisions to contribute; only primary beneficiaries have an interest in contributing, and not humanitarians, ideologues, and identity seekers; the beneficiary population is composed of isolated individuals lacking a group and network structure; the production function of resources to collective good is linear and without thresholds, and the good itself continuous and divisible, not lumpy and indivisible; selective incentives are material, and not moral, ideological, and social; potential contributors and beneficiaries differ only in their interest in the collective good—their utility function—and not on many other variables that make for variation in the cost of contribution and the expected benefit.

Collective action theorists have modified and relaxed these assumptions to suit particular topics and applications in political science, sociology, and other disciplines. In particular the theory was restated as an iterated, open ended, N-person prisoner's Dilemma (PD) and integrated with the vast theoretical and experimental PD literature (Hardin 1982, Lichbach 1995). A major empirical test confirmed some parts of Olson's theory (Walker 1983). Walker studied over 500 voluntary associations concerned with national public policy. Citizen groups promoting social reform, environmental and ideological causes were frequently sponsored and maintained by patrons and sponsors, most often foundations, corporate philanthropy, and government agencies in search of a citizen constituency. Many had few material selective incentives to offer members, unlike professional and occupational interest groups, and made instead moral appeals to a conscience constituency who were not primary beneficiaries of the collective good. New communications technologies—direct mail, WATTS long distance telephone lines (and most recently email and the Internet), coupled with postal rates and tax laws favorable to nonprofits, have greatly reduced the costs of organizing and of communication with members and the public (Zald and McCarthy 1987).

A further advance has come from Ostrom (1990, 1998) and her associates' integration of collective action theory with empirical findings from case studies all over the world of member-managed common-pool resources (CPRs). CPRs such as fisheries, irrigation systems and shared groundwater basins, common pastures and forests, share a 'tragedy of the commons' PD, yet can under some circumstances be exploited and managed by beneficiaries in limited fashion without degrading or exhausting the CPR. Thus there is an alternative between privatization of the CPR and surrendering control to the state. Humans create and learn rules and norms, and adapt them to solving their problems. They learn to trust each other and abide by reciprocity norms when their actions are monitored and when compliance influences their reputations. Thus a PD is transformed into an assurance game. Trust, reciprocity, reputation, positive feedback in face to face groups, and a long time horizon make for contingent cooperation that overcomes social dilemmas (PDs) and free-riding. Much research is advancing collective action theory along these lines.

3. *Social Movements*

Social movements consist of groups, organizations, and people who advocate and promote a cause or issue and associated collective goods. They confront opponents, who are frequently governments and privileged groups. They use a mixture of institutional and unconventional means of confrontation, at times even coercive and violent means. In recent decades a large variety of movements have been studied: nationalist, ethnic, separatist, anticolonial, peace, democracy, human rights, environmental, ethnic minority, civil rights, women's rights and feminist, animal rights, labor, peasant, student, for and against abortion, temperance, antismoking, religious revival, religious fundamentalist, and so on. Many social, political, and cultural changes have resulted in part from social movements, even when they have failed in the short term. Olson's work, a reinterpretation of the Nazi movement based on new historical scholarship, and the social turmoil and explosion of popular participation in protests in the 1960s stimulated a reconceptualization of social movement theory.

Olson's assumptions were modified to suit the social contexts of collective action while adhering to the core of Olson's thinking. Sociologists embedded participation in social networks and groups. Moral, social, and ideological incentives were added to the material selective incentives, which put the accent on nonbeneficiary contributors and a conscience constituency. Seeking and fulfilling an identity through protest was added. Between spontaneous, unstructured crowds and social movement organization loosely structured collective action was discovered (a variety of the federated group). Participation became variable with a division of labor between activists, part-timers, supportive conscience constituency, and a sympathetic by-stander public. Issues were socially constructed through framing; varieties of contentious actions by challengers against opponents were studied, some of which were learned and culturally transmitted in protest repertoires. The trigger mechanism provided by small groups of activists and dissidents for large-scale collective action diffusion was discovered. Production functions for collective goods became nonlinear as well as linear, depending on the character of the collective good and the tactic of confrontation. Just as important, there was an outpouring of empirical research based on observation, social surveys of participants, case studies and comparative studies

from history, the testimony of movement leaders and rank-and-file participants, news coverage, systematic content analysis of news media, video documentaries, and much else, from a growing number of countries and especially the USA and Western Europe, with many researchers and writers using the same terminology, concepts, viewpoints, hypotheses, and methods (Diani and Eyerman 1992). Although some maintained that the Europeans adhered to 'new social movement theory' (Dalton and Kuechler 1990) and the US sociologists to 'resource mobilization' (Zald and McCarthy 1987), the difference was a matter of emphasis and only slight theoretical import. These and other labels obscure the fundamental unity and coherence of collective action theory.

Social movement theory operates at two levels simultaneously, the micro and the macro, both of which have a static and a dynamic dimension (Obserschall 1993). At the macro level, there are four conditions for initiation and continuance of social movements: (a) discontent, when institutionalized relief fails; (b) beliefs and values that filter, frame, and transform discontent into grievances calling for action (Snow et al. 1986); (c) capacity to act collectively, or mobilization (Gamson 1975, Tilly 1978); (d) opportunity for successful challenge, or political opportunity. Some analysts have emphasized one or another of these dimensions, as Gurr (1970) did with relative deprivation, a grievance variable; Zald and McCarthy (1987) did with social movement organizations, a mobilization variable; and McAdam (1982) and Tarrow (1993) did with political process. In actual studies, these and other theorists address all four dimensions. Many case studies and comparative studies of social movements can be accomodated within this four-dimensional approach, though causal theories of discontent, grievance, ideology, mobilizing capacity, and political opportunity are still incomplete.

At the micro level, the decision to participate in collective action is based on the value of the collective good to beneficiary multiplied by the probability of attainment, a subjective estimate. This term and selective incentives constitute the expected benefit. On the cost side there are opportunity costs and costs of participation, including expected costs of arrest, injury, blacklisting, and the like. Participation is chosen when net benefit is positive (Klandermans 1997, Oberschall 1993, Opp 1989). Because probability of attainment and some costs are a function of the expected number of participants, there is strong feedback among individual decisions. Dramatic shifts in net benefit can occur in a short time, which precipitates cascades of joining, or negative bandwagons. Empirical research, and in particular survey research based on participants' responses compared to nonparticipants, confirms the micro model for a variety of social movements and several countries (Klandermans 1997).

The dynamic theory of challenger–target confrontations, though richly dealt within case studies, lacks a developed theory. McAdam (1983) has demonstrated innovation, learning, and adaptation by both challengers and targets in confrontation sequences. Oberschall (1993) has shown that social control in contentious confrontations gives rise to new issues and grievances, e.g., police brutality, that mobilize new participants, and that news media coverage of protests can make for rapid protest diffusion by signaling focal points and issues for convergence and providing vicarious expectations of participant numbers. Confrontation dynamics show promise for analysis with game theory and simulation (Marwell and Oliver 1993) but much remains to be done.

4. *Norms and Institutions*

Together with the new institutional economics (North 1990) transaction cost theory (Williamson 1975) cooperation theory (Axelrod 1984), and public choice, rational choice/rational actor theory in sociology seeks to explain norms, institutions, group formation, social organization, and other products of collective action, from elementary principles. The most ambitious effort to date is Coleman (1990). The elementary units of analysis are actors, resources, interests, and control. From these both systems of exchange and authority relations and structures are constructed, based on the right to control resources and other actors' actions, e.g., a norm to which the actors conform. The demand for norms arises when actors create externalities for one another, yet a market in rights of control cannot be easily established. The realization of norms occurs when social relationships among actors enable them to share the benefits and costs of sanctioning. Among system properties discussed by Coleman are agency, social capital, and trust. Slowly evolved and inherited institutions such as kinship and the family (Ben-Porath 1980) and village communities (Popkin 1979) can be understood with these theories. Ascriptive relationships, as in kinship, are instances of specialization by identity, when individuals transact only with the same person or small groups in bilateral monopoly. This mode of transacting enables huge asymmetric investments in other human beings, as with raising children by parents, that are not expected to be paid back for a long time. To break out of kin encapsulation with limited opportunities for specialization, kin groups forge horizontal alliances through marriage and build political leadership through these networks. A perverse aggregate consequence, under conditions of extreme resource scarcity and competition, discovered by Banfield (1958) in a South Italian district, is 'amoral familism'—an instance of PD—which impedes community wide civic organization and leadership, and hinders social change. There is no civic culture. Among

other topics studied are sharing groups (Lindenberg 1982), state formation (Levi 1988) and varieties of religious organization and behavior (Iannaccone 1988).

The major social inventions of modernity for Coleman are roles, offices, and corporate actors—from the colonial trade joint stock companies and chartered towns to the modern corporation, labor unions, and professional associations—which are resistant to people mortality and turnover and allow investment in and transacting with a corporate venture and between corporate actors, not just specific persons. Corporate actors create entirely new opportunities for social change as well as problems of governance, agency, and asymmetries of power. They generate hitherto unknown modes of impersonal trust based on certified skills and professional ethics codes. These and other related topics on the evolution of institutions, based on rational choice and collective action theory, are published in *Rationality and Society* and similar journals. Together with advances in the other social sciences, in evolutionary biology, and in cognitive and evolutionary psychology, collective action theory is becoming a part of an integrated and comprehensive social science with a wide reach.

Action, Theories of Social

1. The Interpretive Theory of Social Action

Social action has become an important topic in sociological theory under the influence of the great German sociologist Max Weber. To him, 'social action, which includes both failure to act and passive acquiescence, may be oriented to the past, present, or expected future behavior of others' (Weber 1922, p. I). To Weber, explaining a social phenomenon means analyzing it as the effect of individual actions. He says explicitly in a letter addressed the year of his death to a friend, the marginalist economist Rolf Liefmann: 'sociology too must be strictly individualistic as far as its methodology is concerned' (Mommsen 1965, p. 44). The 'too' means that sociology should, according to Weber, follow the same principle as economics, a principle later christened 'methodological individualism' by Joseph Schumpeter, and later popularized by Friedrich Hayek and Karl Popper. This principle states simply that any *collective* phenomenon is the outcome of *individual* actions, attitudes, beliefs, etc. To methodological individualists, as Weber, a crucial step in any sociological analysis is to determine the causes of individual actions. Weber introduces then a crucial second postulate: that the causes of any action lie in the meaning to the actor of his action. Thus, the cause responsible for the fact that I look on my right and my left before crossing a street is that I want to avoid the risk of being hit by a car. To the operation aiming at retrieving the meaning to the actor of his action, Weber gives a name: *Verstehen*, to understand. Given the importance of the *Verstehen* postulate, Weber calls the style of sociology resting upon these two postulates 'comprehensive' sociology. To Weber, by contrast with notably Dilthey, the notion of 'comprehension' characterizes exclusively individual actions, attitudes or beliefs.

Weber (1922) has proposed in famous pages of his posthumous work *Economy and Society* a distinction between four main types of actions. Actions can be inspired by instrumental rationality (*Zweckrationalität*): when an actor does X because he perceives X as an adequate way of reaching a goal G. They result from axiological rationality (*Wertrationalität*) when an actor does X because X is congruent with some value he endorses. Actions are 'traditional' (*traditionell*) when they are oriented to the fact that such actions have been regularly performed in the past, and are perceived as recommended by virtue of that fact. Finally, an action is 'affective' (*affektuell*) when it is inspired by some feeling or generally emotional state of the subject.

2. The Functional Theory of Social Action

An important contribution to the theory of social action is Parsons' *The Structure of Social Action* (1937), a work where the American sociologist attempts to combine some seminal ideas on social action developed by Weber, Durkheim, Pareto, and Alfred Marshall. Parsons devotes much attention to the point that, to Weber, action is defined as oriented to the behavior 'of others.' He is notably concerned by the idea that social actors are embedded in systems of social roles. To him, roles rather than individuals should be considered as the atoms of sociological analysis. This shift from individuals to roles was inspired to Parsons by his wish of combining the Weberian with the Durkheimian tradition, individual actions with social structures. The most popular aspect of Parsons' theory is his typology of the 'pattern variables.' These 'pattern variables' are a set of four binary attributes by which all roles can in principle be characterized. Thus, the role of a bank clerk is 'specific' in the sense where his relation to his customers is limited to well-defined goals, by contrast with the role of, say, 'mother,' that is 'diffuse.' The role of mother is 'ascribed,' while the role of clerk is 'achieved.' The former is 'particularistic' in the sense where it deals with specific individuals; the latter is 'universalistic': the clerk is supposed to apply the same rules indistinctly to all customers. Ralf Dahrendorf (1968) saw in the Parsonian theory a definition of the *homo sociologicus* and a proper basis for making sociology a well-defined discipline, resting on a well-defined set of postulates. While economics sees the *homo oeconomicus* as moved by his interests and as able of determining rationally the best ways of satisfying them, the Parsonian *homo sociologicus*was described as moved, not only by interests, but by the norms and values attached to his various roles. Merton (1949) developed ideas close to Parsons's, insisting on the norms and values attached to roles but also on the ambiguities and incompatibilities generated by the various roles an individual is embedded in. It must be recognized, though, that the idea according to which the parsonian *homo sociologicus* would guarantee to sociology foundations as solid as the *homo oeconomicus*to economics has never gained recognition. More precisely, while most sociologists accept the idea

that norms, beside interests should be taken into account in the explanation of action, they doubt that the parsonian *homo sociologicus* can be expressed in a form able to generate deductive theories as precise and powerful as the *homo oeconomicus*.

The skepticism toward the Parsonian theory of action that appeared in the 1960s results not only from this theoretical consideration but also from conjunctural circumstances. In the 1960s, the so-called 'functional' theory, a general and vague label that covered then the sociology with a Parsonian inspiration, became strongly attacked. Critical sociologists objected to 'functionalism' in that it would contribute to legitimate the existing social institutions, while the main objective of sociology should be to criticize them. To this unfair objection another, equally unfair, was added: that functionalism would not be scientifically fruitful. Functionalism provides a useful theoretical framework to develop a sociological theory of stratification, of the legitimacy of institutions, and of other social phenomena. But it is true that it did not succeed in providing a theoretical basis from which sociological research could develop cumulatively. By contrast with the *homo oeconomicus*, the *homo sociologicus* of the functionalist tradition failed to generate a well-identified research tradition.

3. *The Utilitarian Theory of Social Action*

Neither critical theory nor other more recent sociological movements, as ethnomethodology or phenomenology, succeeded in providing a solid basis for a theoretical consensus among sociologists. The 'balkanized' character of sociological theory incited some sociologists to propose to identify the *homo sociologicus* with the *homo oeconomicus*. This proposal was motivated by the fact that the model of the *homo oeconomicus* had actually been applied successfully to several kinds of problems belonging traditionally to the jurisdiction of sociology. Thus, the so-called 'theory of opportunities' rests upon the postulate that criminal behavior can be analyzed as a maximizing behavior. The economist G. Tullock (1974) had shown that differential data about crime could notably be accounted for by a theory close to the theory of behavior used by neoclassical economists. G. Becker, another economist, proposed to analyze social discrimination along the same line. In *Accounting for Tastes*, Becker (1996) analyzes addiction as resulting from cost-benefit considerations and claims that the 'rational choice model,' namely the model of man proposed by neoclassical economists, is the only theory able to unify the social sciences. This general idea had been developed by J. Coleman (1990) in his *Foundations of Social Theory*.

The idea of explaining social action by the 'utilitarian' (in Bentham's sense) postulates is not new. Classical sociologists use it occasionally. Thus, in his *The Old Regime and the French Revolution*, Tocqueville ([1856] 1986) explains that the underdevelopment of French agriculture at the end of the eighteenth century, at a time when British agriculture knows a phase of quick modernization, is the effect of landlords' absenteeism. As to the latter, it results from the fact that the French landlords were better off socially when they bought a royal office than when they stayed on their land. The French centralization meant that many royal offices were available and brought prestige, power, and influence to those who filled them. In Britain by contrast, a good way of increasing one's influence was to appear as an innovative gentleman farmer and by so doing getting local and eventually national political responsibilities. So, Tocqueville's landowners make their decisions on the basis of a cost-benefit analysis, along the line of the 'rational choice model.' The social outcome is different in the two contexts because the parameters of the two contexts are different. But Tocqueville uses this model exclusively on subjects where it seems to account for historical facts.

The utilitarian postulates defended by rational choice modelists were not only occasionally used by Tocqueville, they had also been treated as universally valid by some theorists, notably Marx and Nietzsche and their followers. To Marx, and still more to Marxians, individual actions and beliefs should be analyzed as motivated by class interests, even though the final role of his interests can remain unrecognized by the actor himself ('false consciousness'). To Nietzsche, and still more to Nietzscheans, individual actions and beliefs should be analyzed as motivated by their positive psychological consequences on the actor himself. Thus, to Nietzsche, the Christian faith developed originally among the lower classes because of the psychological benefits they could derive from endorsing a faith that promised Paradise to the weak and the poor. In his *Essays in the Sociology of Religion*, Weber (1920–1) is critical toward such theories: 'my psychological or social interests can draw my attention on an idea, a value or a theory; I can have a positive or a negative prejudice toward them. But I will endorse them only if I think they are valid, not only because they serve my interests.' Weber's position has the advantage of making useless the controversial 'false consciousness' theory. As rightly stressed by Nisbet (1966), the ideas of 'false consciousness' in the Marxian sense (the concept itself being due to F. Mehring) and of 'rationalization' in the Freudian sense have become commonplace; they postulate highly conjectural psychological mechanisms, though.

The utilitarian approach proposed by rational choice theorists owes little to this Marxian–Nietzschean tradition. The motivation of 'rational choice theorists' resides rather in the fact that the postulates used by neoclassical economics explain many social phenomena of interest to sociologists. Moreover, they make possible the use of the math-

ematical language in sociological theory building. Above all, they provide final explanations without black boxes.

While the 'rational choice' approach is important and can be effectively used on many subjects, its claim to be the theoretical ground on which sociology could be unified is unjustified. Its limits are more and more clearly recognized by economists. Thus, Bruno Frey (1997) has shown that under some circumstances people are more willing to accept unpalatable but collectively beneficial outcomes than they are to accept outcomes for which they receive compensation.

Generally, a host of social phenomena appear as resistant to any analysis of the 'rational choice' type as the example of the so-called 'voting paradox' suggests. As in a national election a single vote has a practically zero influence on the outcome, why should a 'rational' voter vote?

Ferejohn and Fiorina (1974) have proposed considering the paradox of voting as similar in its structure to Pascal's bet: as the issue of the existence of God is crucial, even if the probability that God exists is supposed close to zero, I have an interest in betting that He exists. Pascal's argument is relevant in the analysis of attitudes toward risk. Thus, it explains why it is not necessary to force people to take an insurance against fire: the cost of the insurance is small and the importance to me of the damages being compensated in the case my house would burn is great, so that I would normally subscribe. That the same argument can be realistically used in the case of voting behavior is more controversial, notably because actual voters often show a very limited interest in the election.

Overbye (1995) has offered an alternative theory: people would vote because nonvoting would be negatively regarded, so that nonvoting would entail a cost. But, rational people should see that any individual vote fails to influence the outcome of an election; why then should they consider nonvoting as bad?

Another theory claims that people vote because they estimate in a biased fashion the probability of their vote being pivotal. The bias must be so powerful, however, that such an assumption appears as *ad hoc*.

Another theory, also resting on the 'rational choice model,' submits that people vote because they like to vote. In that case, the cost of voting being negative, the paradox disappears. Simple as it is, the theory introduces the controversial assumption that voters would be victims of their 'false consciousness,' since they do not see that they just like to vote and believe that they vote for some higher reasons. Moreover, this theory does not explain why the turnout is variable from one election to another.

Actually, no theory using the basic postulates of the 'rational choice model' appears as convincing. The good explanation is that people vote because they believe that democracy is a good regime, that elections are a basic institution of democracy, and that one should vote as long as one has the impression that a policy or a candidate are better than alternative ones. This is an example of what Weber has called 'axiological rationality.'

4. *The Cognitive Theory of Social Action*

The theory of action characteristic of neoclassical economics and used by 'rational choice' theorists was made more flexible by H. Simon. His study of decisions within organizations convinced him that decision-makers take 'satisficing' rather than 'optimizing' decisions: because of the costs of information, stopping a deliberation process as soon as one has discovered a 'satisfying' decision can be more rational than exploring further the field of possible decisions. A chess player could in principle determine the best next move. Actually, this would entail a huge number of computations. So, he will use rather rules of thumb. H. Simon qualified this type of rationality as 'bounded.' His contributions stress the crucial point that social action includes an essential cognitive dimension and invite sociologists to drop the postulate of neoclassical economics (used for instance in game theory) according to which social actors would be fully informed when they take their decisions.

Experimental cognitive psychology has also contributed to the sociological theory of action. It has shown that ordinary knowledge is often 'biased,' as in the case where respondents are confronted with a situation where they have to estimate the probabilities of alternative events. Thus, in an experiment, subjects are invited to guess the outcome of a heads-and-tails game with a biased coin, where heads and tails have a probability of coming out, respectively, of 0.8 and 0.2 and where the subjects are informed about it. The experiment reveals that most people guess 'heads' and 'tails,' respectively, with probabilities of 0.8 and 0.2. Now, by so doing, they are worse off than if they would predict 'heads' all the time, since they would then win on average eight times out of 10, while with their preferred strategy the probability of winning is $(0.8 \times 0.8) + (0.2 \times 0.2) = 0.68$. Rather than talking of 'biases' in such cases, it is perhaps more illuminating to make the assumption that, when people are faced with problem solving situations, they try to build a *theory*, satisfying to their eyes, but depending of course of their cognitive resources. In that case, people use the theory that, since they are asked to predict a sequence of events 'heads' or 'tails,' a good strategy is to use the law governing the actual sequence generated by the experimenter. So, while wrong, their answer may be analyzed as understandable, since inspired by a theory which in other situations would be valid. False scientific theories also generally result from *understandable* systems of reasons. Priestley did not believe in the phlogiston theory because he was affected by some cognitive 'bias,' but because strong

reasons convinced him of the existence of the phlogiston.

Fillieule (1996) has rightly contended that the theory of sociological action should take seriously the meaning of the notion of rationality as defined not only by neoclassical economics but by the philosophy of science as well. In the vocabulary of the philosophy of science, an actor is 'rational' when he endorses a theory because he sees it as grounded on strong reasons. Durkheim (1912) maintains in his *Elementary Forms of Religious Life* that scientific knowledge and ordinary knowledge differ from one another in degree rather than nature. Even religious and magical beliefs as well as the actions generated by these beliefs should be analyzed in the same fashion as scientific beliefs: primitive Australians have strong reasons to believe what they believe. One can call this type of rationality, evoked by Durkheim as well as by philosophers of science, 'cognitive rationality.'

Applications of this notion are easily found. In the early phase of the industrial revolution in Britain, the Luddites destroyed their machines because they thought that machines destroy human work and generate unemployment. Their action was grounded on a belief and the belief on a theory. They endorsed the theory because it is grounded on strong reasons: a machine is effectively designed and built with the purpose of increasing productivity by substituting mechanical for human work. So, other things equal, when a machine is introduced in a factory, it destroys effectively some amount of human work. But other things are not equal: in an economic system as a whole, human work is needed to conceive, build, maintain, and modernize the new machine, so that on the whole the new machine can create more work than it destroys. Whether this is actually the case is an entirely empirical question. But, at a local level, the workers have strong reasons to believe that the introduction of new machines are a threat to employment.

Taking 'cognitive' rationality into account, beside the instrumental type of rationality used in the 'rational choice model,' is essential to a realistic theory of social action. As stressed by Weber as well as Durkheim, beliefs are a normal ingredient of social action. Now, beliefs cannot generally be explained by the 'rational choice model': I generally do not believe that X is true because believing so serves my interests, but because I have strong reasons for so believing. The dominant status in contemporary sociology of the instrumental-utilitarian conception of rationality incorporated in the 'rational choice model' has the effect that the powerful intuition of classical sociologists according to which, first, explaining beliefs should be a main concern in the sociological theory of action and, second, beliefs should be analyzed as endorsed by social actors because they have strong reasons for endorsing them, appears actually as neglected.

Normative and axiological beliefs, beside representational beliefs, are also a crucial ingredient of social action. Weber's distinction between instrumental and axiological rationality introduces the crucial idea that normative beliefs *cannot always* be analyzed as the product of instrumental rationality nor *a fortiori* by the contemporary 'rational choice model,' which considers exclusively instrumental rationality. Boudon (1998) has submitted that a fruitful interpretation of the notion of 'axiological rationality' would be to consider that axiological beliefs are legitimated in the mind of actors because the latter see them as grounded on strong reasons. Axiological rationality would then be a variant, dealing with prescriptive rather than descriptive beliefs, of the 'cognitive' type of rationality.

Axiological rationality is responsible notably for the evaluations people bear on situations they are not involved in. The 'rational choice model' cannot for instance account for the opinions of people on a topic such as death penalty, because most people are obviously not personally concerned with the issue. They have strong convictions on the subject, though. Should we consider these convictions as irrational since the 'rational choice model' is unable to account for them, or decide rather to follow and elaborate on the classical sociological theory of rationality?

Activity Theory: Psychological

1. Introduction: Activity, Action, Operation

Psychology has traditionally distinguished various classes of behaviors, e.g., reflexes, affective responses, and goal-oriented activities. The special nature of goal-oriented activities is clearest when they are contrasted with the behavior of human beings who are not, or not yet, able to orient their activities to goals, i.e., mentally retarded people or those with major injuries to the frontal lobes of the brain. Those activities that are not organized towards goals are typically characterized as trial and error, impulsively and unreflectively driven, without direction and orientation, and without examination of the consequences of alternatives. Goal-oriented selection of programs, known or yet to be developed, is lacking. The particular steps of activity are not oriented towards goal implementation. They are neither *integrated parts* of linear sequences of steps nor *subordinated parts* of a hierarchical plan. Hence they are all perceived to be of equal importance for goal implementation. Furthermore, there is no anticipating comparison between the given state and a desired goal state. Finally, a prospective evaluation of consequences is lacking (see also *Action Planning, Psychology of*). There are distinctions to be drawn among the concepts of activity, action, and operation.

Activities are motivated and regulated by higher-order goals and are realized through actions that are themselves relatively independent components of each activity.

Actions differ from each other with respect to their specific goals. Actions may themselves be decomposed into their subordinate components, the operations. Operations are described as subordinate because they do not have goals of their own. Operations can be taken to be movement patterns or, in the case of mental activities, elementary cognitive operations.

The concept of a psychology of activities has been, since the mid-twentieth century, central to the tradition especially of Russian and German psychology. There are many points of agreements with, but also important differences between, the orientations of the leading research groups, particularly those of Leontjev (1979)—a student of Vygotski—Rubinstein (1961), and Tomaszewski (1981). The philosophical foundations of Marxism, the psychological findings of Lewin (1926), the psychophysiological results of Bernstein (1967), the neuropsychological results of Luria (1973), and suggestions of cybernetics, particularly of Systems Theory, have all contributed to the development of this concept. The basic idea of this concept is that activity cannot adequately be researched in stimulus–response terms. The elements or 'building blocks' of even primitive and unchallenging real-life activities are not just responses or reactions, but goal-oriented actions (Hacker 1985a, 1985b). Goal orientation, however, does not mean a strictly top-down planned activity (von Cranach et al. 1982). Instead, goal-oriented real-life activity is 'opportunistically' organized, which means that people are trying to accomplish goals by a kind of 'muddling through' with some planned episodes. A modern review from the very special point of view of linking cognition and motivation to behavior was presented by Gollwitzer and Bargh (1996), and a more general review was written by Frese and Sabini (1985).

The concept of goal-oriented activities and actions is a relational one that relates at least five components:

(a) the anticipated and desired result, represented as the goal;

(b) the objects of the activities (e.g., raw materials), which typically have their own laws governing how they can be transformed from a given state into the desired one;

(c) transformations of the physical or social world (e.g., nailing), requiring the expenditure of energy and the use of information (i.e., the *actual change* of the objects without which there would be only an unimplemented intention);

(d) the acting person, with her/his ability to have an impact on, and attitudes toward, the processes; these processes, in turn, act back on the person; and

(e) the means needed for, and the contextual conditions of, the activities.

This relational framework offers a guideline for task and activity analysis, especially the analysis of the

knowledge base which is necessary in order to implement a task.

2. Sequential and Hierarchical Organization of Activity

There are good theoretical reasons to describe the structure of the mental processes and representations regulating activity as being simultaneously sequentially (or cyclically) and hierarchically organized.

The sequential organization of activity control is a cyclical one in-as-much as the steps or stages of activity may be described in terms of control loops. An example of such a description is the Test–Operate–Test–Exit (TOTE) model (Miller et al. 1960). We will come back to these 'stages of control' in a less abstract manner in Sect. 4.

The concept of the hierarchical organization can help to explain the different levels of consciousness of the mental processes and representations that regulate activities. One can distinguish between (a) processes that one is normally not able to process consciously (breathing, e.g., while speaking), (b) processes that one is able to regulate consciously, but is not obliged to have in consciousness (e.g., formulating complete sentences while speaking), and (c) processes that have to be represented in consciousness (e.g., complex inferences).

The hierarchy of these levels means that 'higher' or conscious ('controlled') levels include and determine 'lower' ('automated') ones (Fig. 1).

Since the cyclically organized phases (e.g., in terms of TOTE units) are simultaneously hierarchically nested one in another, action control will be simultaneously organized sequentially and hierarchically.

Following this model of action control, a few characteristics will follow:

(a) superordinate levels of control with higher consciousness and a broader range of impact *include* subordinate ones;

Figure 1
Hierarchic organization of the cyclical control loop (TOTE) units

(b) superordinate levels *determine* subordinate ones;

(c) superordinate levels *delegate* details, thus saving mental capacity;

(d) subordinate levels obtain a *relative autonomy* and the possibility of a bottom-up impact on higher ones (von Cranach et al. 1982).

Following the above hierarchical organization, the regulation of movements or motor operations is a dependent component of the superior goal-oriented actions. There are several consequences of this approach, as follows.

First the *meaning of a task* for the subject/actor will determine the structure of the operations involved, as was shown by neuropsychological case studies (Luria 1973). The outstanding Russian physiologist Bernstein (1967, p. 70) more generally stressed, 'What kind of motor response will be analyzed..., only the meaning of the task and the anticipation... of the result are the invariant parameters which determine a fixed program or a program reorganized during implementation that both step by step will govern the sensory corrections.' The temporal and spatial parameters of the motor response do not offer the inevitable invariant parameters since several variations of a motor response may have the same result.

Following Bernstein's (1967) cited notion along with the meaning of the task, the *anticipated result* of an action is regulating the accomplishment of the action. This anticipation will become the goal in-as-much as it will be combined with the intention to implement the anticipated result. Generalizing this line of thinking on the goal-directed anticipative control of motor operations as components of actions, von Weizsäcker (1947, p. 139) stressed, 'In a motor response the effect will not be determined necessarily by its components, but mainly the motor process will be governed by its effect.'

3. Control of Activity by Goals and Other Mental (or Memory) Representations

Activity and actions are controlled by anticipations, i.e., the goals, which may form a hierarchy of super- and subordinate (or partial) goals. Goals are anticipations of the future results; motivationally, they are intentions to achieve these results by the person's own effort; from the point of view of memory they are the desired values, to be stored until the goal is completely achieved; emotionally, they are the starting points of specific task-inherent emotions (perception of success, failure, or flow), and from a personality point of view, goals and goal achievement are measures for self-assessment. Strings or hierarchies of goals are often reorganized into plans. Within a plan, the individual partial goal becomes a dependent component—a means—of a superordinate goal. For this reason, the sequence of individual goals is rationalized, and measures for goal achievement are integrated. For the

correspondences and differences within the conceptualization of goals in action regulation, see, for instance, Broadbent (1985), Kuhl and Atkinson (1986), and Locke (1991).

Furthermore, actions are controlled and led by mental representations of the conditions of action execution (e.g., the options of the machinery used). Action-guiding mental representations are a specific (e.g., response-compatible) type of mental representation. Some of these mental representations are not conscious ones (for further aspects, see *Action Planning, Psychology of*).

4. Stages of Control

Five stages are needed to describe the mental regulation of goal oriented activities (Tomasczewski 1981): (a) goal setting, i.e., redefinition of the task as the individual's goal, derived from his/her motives; (b) orientation towards the conditions of execution in the environment and in the actor's memory representations; (c) construction, or reproduction, of sequences of subgoals and the necessary measures; (d) decisions among particular versions of execution, if there is freedom to choose (autonomy); and (e) control of the execution by comparing the immediate results with the stored goals and possibly the plans. This control-loop shows the above-mentioned cyclical structure of action regulation. Functional units have to be represented in working memory, at least for the duration of execution: these units consist of goals, measures (programs), and the feedback or comparison processes just mentioned (Hacker 1985a, 1985b). Relationships between action theory and control theory are mentioned by Carver and Scheier (1990), among others.

From a motivational point of view, Heckhausen (1980) developed a sophisticated model of the sequential stages of goal-oriented activity, the Rubicon model. The main idea is that the action-preparing steps or stages show some different mental features in comparison with the action-accomplishing steps. The crucial transition from preparation to accomplishment is the specific decision actually to start the implementation ('to cross the Rubicon').

The above mentioned mental or memory representations are inevitable for the control of activity. All phases of activity are guided by them. It is useful to classify these representations into three types: (a) the goals or desired values; (b) the representations of the conditions of implementation; and (c) the representations of actions themselves, i.e. of the required patterns of operations, transforming the given state into the desired one.

The goal as the essential kind of internal representation, i.e., the anticipated result of the action, is the indispensable invariant regulator of every goal-directed process.

Goals are relatively stable memory representations that act as the necessary desired values during the implementation of an action. In the feedback processes mentioned, the actual state attained is compared with the goal as the required state.

5. Complete vs. Partialized Activity

As has been pointed out, activity will normally include, from a sequential or control loop point of view, preparation (goal setting, plan development, decision making), organization (co-ordination with other persons), execution of the intention, and checking the results in comparison with the stored goals. Checking, thus, produces the feedback closing the circle of the control loop or TOTE unit (Hacker 1986).

Correspondingly, from a hierarchical point of view, the regulating processes and representations of these phases, e.g., automated or intellectually controlled ones, are operating simultaneously at the aforementioned different levels of consciousness. The approach of 'complete vs. partialized (work) activity' enters here. This approach was launched as an ethical impulse by the German humanist philosopher Albert Schweitzer, discussing Western industrial culture (Schweitzer 1971). One can designate those activities as 'complete' that not only include routinized execution operations but also offer the opportunity for preparatory cognitive steps (e.g., goal development, decision making on the action programs), for checking the results, and for co-operation in terms of participating in the organization. Hence these 'complete' or 'holistic' activities are complete from the point of view of both the hierarchy of regulation levels and the cyclical control units. These sequentially (or cyclically) and hierarchically complete activities will offer the crucial option of learning, as opposed to the loss of skills and abilities in simple and narrow activities. Incomplete activities are sometimes called partialized activities.

6. Decision Latitude and Intrinsic Motivation

Decision latitude or autonomy is the most important variable of complete activity. Complete activity offers the decision latitude which is necessary for self-set goals, which are the prerequisite of comprehensive cognitive requirements of a task, and of intrinsic task motivation, i.e., motivation by a challenging task content ('task challenge').

Starting from the approach of decision latitude, Frese (1987) proposed a Theory of Control and Complexity of activity. He argued that one should distinguish among control over one's activity, complexity of activity, and complicatedness of activity: control here is defined in terms of the possibility to decide on the goals of activities and on the kind of goal attainment. Sometimes the amount of control is called decision latitude. Complexity refers to decision necessities, and complicatedness to those decision necessi-

ties that are difficult to control and socially and technologically unnecessary. Control should be enhanced, complexity should be optimized, and complicatedness should be reduced—in as much as working activities are concerned. Control should be increased at the expense of the other features because it has positive long-term consequences on performance, impairment, and well-being. The clearest finding of the Frese studies was that control has a moderating effect on the relationship between stressors and psychosomatic complaints at work: for the same amount of stressors given, complaints are lower with higher control.

7. *Activity Theory and Errors*

Activity theorists define errors as the nonattainment of an activity goal. The comparison of the activity outcome with the goal determines whether the goal has been achieved or whether further actions have to be accomplished. If an unintended outcome occurs, an error will be given. Consequently, a definition of an error based on Activity Theories integrates three aspects: (a) errors will only appear in goal-directed actions; (b) an error implies the nonattainment of the goal; (c) an error should have been potentially avoidable (Frese and Zapf 1991). Frese and Zapf (1991) developed an error taxonomy based on a version of Action Theory. This taxonomy and other comparable ones are inevitable in the examination of causes of errors and faults as a prerequisite of error prevention. Error prevention became an inevitable concern in modern technologies, e.g., the control rooms of nuclear power plants.

8. *Future Development*

Psychological theories are often short-term fashions, which are just launched and then soon pass away. Action Theories—there is still no 'one' Action Theory—seem to be an integrative long-term approach which is still developing especially with the development of subapproaches. Action Theories are still more a heuristic broad-range framework than final theories. Just this, however, might be their future advantage. The integrative power of Action Theories will bridge some inter-related gaps: the gap between cognition and action, the gap between cognition and motivation, and even the gap between basic and applied approaches—the last by fostering a dialogue between general (cognitive, motivational) psychology and the 'applied' disciplines (Hacker 1993). Perhaps its most challenging contribution might be to promote a reintegration of the breaking-off disciplines of psychology.

Actor Network Theory

The term 'actor network theory' (ANT) combines two words usually considered as opposites: actor and network. It is reminiscent of the old, traditional tensions at the heart of the social sciences, such as those between agency and structure or micro- and macro-analysis. Yet, ANT, also known as the sociology of translation, is not just another attempt to show the artificial or dialectical nature of these classical oppositions. On the contrary, its purpose is to show how they are constructed and to provide tools for analyzing that process. One of the core assumptions of ANT is that what the social sciences usually call 'society' is an ongoing achievement. ANT is an attempt to provide analytical tools for explaining the very process by which society is constantly reconfigured. What distinguishes it from other constructivist approaches is its explanation of society in the making, in which science and technology play a key part.

This article starts by presenting the contribution of ANT to science and technology studies and then shows how this approach enables us to renew the analysis of certain classical problems in social theory.

1. Technosciences Revisited by ANT: Sociotechnical Networks

Spawned in the 1970s by the sociology of scientific knowledge, science studies strives, on the basis of empirical research, to explain the process in which scientific facts and technical artifacts are produced, and hence to understand how their validity and efficacy are established and how they are diffused. It follows two main approaches. The first has remained faithful to the project aimed at providing a social explanation for scientific and technical content (Collins 1985). The second, illustrated by ANT, has denied this possibility and embarked on a long-term undertaking to redefine the very object of social science.

For the promoters of ANT, the social explanation of scientific facts and technical artifacts is a dead end. 'Providing a social explanation means that someone is able to replace some object pertaining to nature by another pertaining to society' (Latour 2000). A scientific fact is thus assumed to be shaped by interests, ideologies, and so on, and a technological artifact crystallizes and reifies social relations of domination or power. Now, as research on scientific practices in laboratories and the design of technical artifacts shows, this conception, in which nature is dissolved in society, is no more convincing than the more traditional and cautious one in which the two are totally separate.

1.1 From World to Words

Let us enter a laboratory to observe the researchers and technicians at work. The laboratory is an artificial setting in which experiments are organized. The objects on which these experiments are performed, such as electrons, neutrinos, or genes, have been put in a situation in which they are expected to react or prove recalcitrant. It is the possibility of producing a discrepancy between what an entity is said to do and what it actually does that motivates the researcher to perform the experiment. This raises the question of the mysterious adequacy between words and things, between what one says about things and what they are.

To this classic philosophical question, ANT offers an original answer based on the notion of inscription (Latour and Woolgar 1986). Inscriptions are the photos, maps, graphs, diagrams, films, acoustic or electric recordings, direct visual observations noted in a laboratory logbook, illustrations, 3-D models, sound spectrums, ultrasound pictures, or X-rays as arranged and filtered by means of geometric techniques. All these inscriptions are produced by instruments. Researchers' work consists of setting up experiments so that the entities they are studying can be made 'to write' in the form of these inscriptions, and then of combining, comparing, and interpreting them. Through these successive translations researchers end up able to make statements about the entities under experimentation.

Inscription is two-sided. On the one hand it relates to an entity (e.g., an electron, gene, or neutrino) and, on the other, through combination with other traces or inscriptions, relates to propositions that have been tested by colleagues. Instead of positing a separation between words and things, ANT tracks the proliferation of traces and inscriptions produced in the laboratory, which articulate words and things. The analysis of this articulation leads to the two complementary concepts of a network and circulation.

Circulation should be understood in a traditional sense. The map drawn up by a geologist, based on readings in the field; the photos used to follow the trajectories identified by detectors in a particle accelerator; the multicolored strips stacked on a chrom-

atograph; the tables of social mobility drawn up by sociologists; the articles and books written by researchers: all these circulate from one laboratory to the next, from the research center to the production unit, and from the laboratory to the expert committee which passes it on to a policy maker. When a researcher receives an article written by a colleague, it is the genes, particles, and proteins manipulated by that colleague in her or his own laboratory that are present on the researcher's desk in the form of tables, diagrams, and statements based on the inscriptions provided by instruments. Similarly, when political decision makers read a report that asserts that diesel exhaust fumes are responsible for urban pollution and global warming, they have before them the vehicles and atmospheric layers that cause that warming. We thus move away from classical epistemology, which opposes the world of statements, on the one hand, and that supposedly 'other' world (more or less real) of the things to which the statements refer and which, in a sense, constitutes the context of those statements, on the other. Referents do not lie outside the world of statements; they circulate with them and with the inscriptions from which they are derived.

By circulating, inscriptions articulate a network qualified as sociotechnical because of its hybrid nature (Latour 1987). The sociotechnical network to which the statement 'the hole in the ozone layer is growing' belongs, includes all the laboratories working directly or indirectly on the subject, eco-movements, governments that meet for international summits, the chemical industries concerned, and the parliaments that pass laws, as well as the chemical substances and the reactions they produce, and the atmospheric layers concerned. The statement 'the ozone layer is disappearing due to the use of aerosols' binds all these elements, both human and nonhuman. At certain points in these networks we find translation centers, which capitalize on all the inscriptions and statements. Inscriptions are information and consequently those centers are able to act at a distance on elements without bringing them in for good. But inscriptions can also be accumulated and combined: new unexpected connections are produced that explain why the translation centers are endowed with the capacity for strategic and calculated action; they can conceive of certain states of the world (e.g., without a hole in the ozone layer), and identify and mobilize the elements with which to interact to produce the desired state. Such strategic action is possible only because the sociotechnical network exists. Action and network are thus two sides of the same reality; hence, the notion of an actor network.

1.2 Black-boxing Collective Action

Technology can be analyzed in the same way. The social explanation of technological artifacts raises the same difficulties as that of scientific facts. Once again, it is by jettisoning the idea of a society defined *a priori*, and replacing it by sociotechnical networks that ANT avoids the choice between sociological reductionism, on one hand, and positing a great divide between techniques and societies, on the other.

Consider a common artifact such as the automobile. Its phenomenal success is probably due to the fact that it enables users to extend the range and variety of actions they can successfully undertake, freeing them to travel about without having to rely on anyone else. Thus, autonomous users endowed with the capacity to decide where they want to go, and to move about as and when they wish, are 'inscribed' in the technical artifact itself, the automobile (Akrich 1992). Paradoxically, the driver's autonomy stems from the fact that the functioning of the automobile depends on its being but one element within a large sociotechnical network. To function, it needs a road infrastructure with maintenance services, motorway operating companies, the automobile manufacturing industry, a network of garages and fuel distributors, specific taxes, driving schools, traffic rules, traffic police, roadworthiness testing centers, laws, etc. An automobile is thus at the center of a web of relations linking heterogeneous entities, a network that can be qualified as sociotechnical since it consists of humans and nonhumans (Callon et al. 1986).

This network is active, which again justifies the term actor network. Each of the human and nonhuman elements comprising it participates in a collective action, which the user must mobilize every time he or she takes the wheel of his or her automobile. In a sense the driver then merges with the network that defines what he or she is (a driver-choosing-a-destination-and-an-itinerary) and what he or she can do. When the driver turns the ignition key of a Nissan to go meet a friend on holiday at Lake Geneva, the driver not only starts up the engine, but also triggers a perfectly coordinated collective action. This action involves: the oil companies that refined the oil, distributed the petrol, and set up petrol stations; the engineers who designed the cylinders and valves; the machines and operators who assembled the vehicle; the workers who laid the concrete for the roads; the steel that withstands heat; the rubber of the tires that grip the wet road; the traffic lights that regulate the traffic flow, and so on. We could take each element of the sociotechnical network to show that, human or nonhuman, it contributes in its own way to getting the vehicle on the road. This contribution, which was progressively framed during the establishment of the sociotechnical network, is not reducible to a purely instrumental dimension. In its studies of technological innovation, ANT stresses the ability of each entity, especially nonhuman ones, to act and interact in a specific way with other humans or nonhumans. The automobile—and this is what defines it as a technical artifact—makes it possible, in a place and at a point in time, to

use a large number of heterogeneous elements that silently and invisibly participate in the driver's transportation. We may call these elements 'actants,' a term borrowed from semiotics, which highlights the active nature of the entities comprising the network. We could also say that this collective action has been black-boxed in the form of an artifact—here, an automobile. When it moves, it is the whole network that moves.

Sometimes, however, black boxes burst open. Thus, the role of these actants becomes explicitly visible when failures or incidents occur: petrol transporters go on strike; war breaks out in the Middle East; a road collapses; taxes increase the price of petrol in a way considered unacceptable; environmental standards curb the use of internal combustion engines; a driver's concentration flags; alloys tear because they are not resistant enough to corrosion; automobile bodies rip open on impact. At these times, the collective action becomes visible and all the actants who contributed to the individual and voluntary action of the driver are unveiled (Jasanoff 1994, Wynne 1988). But it is during the historical constitution of these sociotechnical networks, that is, during the conception, development, and diffusion of new technical artifacts, that all the negotiations and adjustments between human and nonhuman actants, preceding the black-boxing, most clearly appear. And it is to such processes of constitution that ANT directs its attention (Law 1987).

In the cases of both science and technology, the notion of sociotechnical networks is at the heart of the analysis. ANT has put a considerable effort into analyzing the process of construction and extension of these networks. Concepts such as 'translation,' '*interessement*' (a term borrowed from French) and 'the spokesperson' have been developed to explain the progressive constitution of these heterogeneous assemblages (Callon 1986). To account for either scientific facts or technical artifacts ANT refuses to resort to a purely social explanation, for ANT replaces the purity of scientific facts and technical artifacts with a hybrid reality composed of successive translations. These networks can be characterized by their length, stability, and degree of heterogeneity (Callon 1992; Bowker and Star 1999). This viewpoint necessarily challenges traditional conceptions of the social, an issue we shall now examine.

2. *Making up Hybrid Collectives*

For ANT, society must be composed, made up, constituted, established, maintained, and assembled. There is nothing new about this assertion, as such; it is shared by many constructionist currents. But ANT differs from these approaches in the role it assigns to nonhumans in the composition of society. In the traditional view, nonhumans are obviously present, but their presence resembles that of furniture in a bourgeois home. At best, when these nonhumans take the form of technical artifacts, they are necessary for the daily life they facilitate; at worst, when they are present in the form of statements referring to entities such as genes, quarks, or black holes, they constitute elements of context, a frame for action. To the extent that they are treated as lying outside the social collective or as instrumentalized by it, nonhumans are in a subordinate position. Similarly, when the topic of analysis is institutions, organization, or rules and procedures, social analysts assume that these meta-individual realities are human creations, like the technical artifacts that supplement daily life. The social sciences are founded on this great divide between humans and nonhumans, this ontological asymmetry that draws a line between the social and the nonsocial.

However, the past two decades of science and technology studies have caused this division to be called into question. Moreover, as we have seen, in the laboratory nonhumans act and, because they can act, they can be made to write and the researcher can become their spokesperson. Similarly, technical artifacts can be analyzed as devices that at some point capitalize on a multitude of actants, always temporarily. Society is constructed out of the activities of humans and nonhumans who remain equally active and have been translated, associated, and linked to one another in configurations that remain temporary and evolving. Thus, the notion of a society made of humans is replaced by that of a collective made of humans and nonhumans (Latour 1993). This reversal has numerous consequences. We shall stick to a single example, that of the distinction between macro and micro levels, which has been replaced by framed and connected localities.

Does a micro level exist? The answer seems obvious. When our motorist takes to task another motorist who refused him right of way, or when he receives a traffic fine, he enters into interactions with other perfectly identifiable individual actors. Generally speaking nothing else than interactions between individuals has ever been observed. Yet it seems difficult to simply bracket off realities like institutions or organizations that obviously shape and constrain the behavior of individual agents, even when they are considered as the unintentional outcome of the aggregation of numerous individual actions. To avoid this objection (and the usual solutions that describe action as simultaneously structuring and structured), ANT introduces the notion of locality, defined as both framed and connected.

Interactions, like those between motorists arguing with each other after an accident, or between them and the traffic policeman who arrives on the scene, take place in a frame that holds them. In other words, there are no interactions without framing to contain them. The mode of framing studied by ANT extends that analyzed by Goffman, by emphasizing the active part

played by nonhumans who prevent untimely overflowing. The motorists and traffic officers are assisted, in developing their argument about how the accident occurred, by the nonhumans surrounding them. Without the presence of the intersection, the traffic lights that were not respected, the traffic rules that prohibit certain behaviors, the solid lines that 'materialize' lanes, and without the vehicles themselves that prescribe and authorize certain activities, the interaction would be impossible, for the actors could give no meaning to the event and, above all, could not properly circumscribe and qualify the incident itself.

This framing which constrains interactions by avoiding overflowing is also simultaneously a connecting device. It defines a place (that of the interaction) and at the same time connects it to other places (where similar or dissimilar accidents have taken place, where the policemen go to write up reports, or where these reports land up, etc.). All the elements that participate in the interaction and frame it establish such connections for themselves. The motorist could, for example, invoke a manufacturing defect, the negligence of a maintenance mechanic, a problem with the traffic signals, the bad state of the road, the traffic officer's lack of training, etc. Suddenly the circle of actants concerned has become substantially bigger. Through the activities of the traffic officer, the automobile, and the infrastructure which all together frame interactions and their implications, other localities are associated with those of the accident: the multiple sites in which automobile manufacturers, the networks of garage owners, road maintenance services, and police training schools act. Instead of microstructures, there are now locally framed interactions; instead of macrostructures, there are connected localities, because framing is also connecting.

With this approach it is possible to avoid the burdensome hypothesis of different levels, while explaining the creation of asymmetries, i.e., of power relations, between localities. The more a place is connected to other places through science and technology, the greater its capacity for mobilization. The translation centers where inscriptions and statements converge provide access to a large number of distant and heterogeneous entities. The technical artifacts present in these far-off places ensure the distant delegation of the action decided in the translation center. On the basis of the reports and results of experiments it receives, a government can, for example, decide to limit CO_2 emissions from cars to a certain level. As a translation center it is in a position to establish this connection between the functioning of engines and the state of pollution or global warming. It sees entities and relations that no one else can see or assemble. But the application of this decision implies, among other things, the setting up of pollution-control centers and the mobilization of traffic officers to check that the tests have been performed, and if necessary to fine motorists, on the basis of a law passed by parliament. Thus, the action decided by the translation center mobilizes a large number of human and nonhuman entities who actively participate in this collective and distributed action. Just as the motorist sets in motion a whole sociotechnical network by turning the ignition key, so the minister for the environment sets in motion an elaborately constructed and adjusted network by deciding to fight pollution. The fact that a single place can have access to other places and act on them, that it can be a translation center *and* a center for distant action—in short, that it is able to sum up entire sociotechnical networks—explains the asymmetry that the distinction between different levels was supposed to account for.

3. *ANT : An Open Building Site*

ANT is an open building site, not a finished and closed construction (Law and Hassard 1999). It is itself more an inspirational frame than a constraining theoretical system (Star and Griesemer 1989, Singleton and Michael 1993, Star 1991, Lee and Brown 1994, Mol and Law 1994. Moreover, many points remain controversial. Its analysis of agency (and, in particular, the symmetry it postulates between humans and nonhumans) has been strongly criticized (Collins and Yearley 1992). For ANT this principle of symmetry is not a metaphysical assertion but a methodological choice which facilitates the empirical study of the different modalities of agency, from strategic to machine-like action. In all cases, agency is considered to be distributed and the forms it takes are linked to the configuration of sociotechnical networks. The opposition between structure and agency is thus overcome. In the 1990s, researchers inspired by ANT have moved into new fields such as organization studies (Law 1994) and the study of the formation of subjectivity or the construction of the person (Law 1992). After including nonhumans in the collective, ANT strives to analyze how socialized things participate, particularly through animate bodies, in the creation of subjectivities (Akrich and Berg, in press).

In parallel with work on the role of the hard sciences and technology in the construction of collectives, ANT also analyses the contribution of social science to the creation of society. It notes that the social sciences are no more content with just offering an analysis of a supposed society than the natural sciences are content just to describe a supposed nature. This point has been made in detail for economics. If we consider an extended definition of economics, including accounting, marketing, management science, etc., it is possible to study how a social science (here, economics) helps to format markets and economic agents such that organized modern markets are embedded in economics (Callon 1998). This approach, extended to the other social sciences such as sociology, psychology, anthropology, or political science, should

facilitate better understanding of the process through which society tends to think of itself as distinct from its environment, and that of its internal differentiation. It is by refusing to countenance, on a methodological level, the great divides postulated by the sciences (both natural and social), that ANT is in a position to explain, on a theoretical level, the role of the sciences in their construction and evolution.

Adaptation, Fitness, and Evolution

The adaptation, or adaptedness, of organisms to their environments is a central concept in evolutionary biology. It is both a striking phenomenon demanding explanation and an essential feature of the mechanisms underlying the patterns of evolutionary stasis and change alike. The organism–environment interaction which the adaptation concept embodies is the causal driver of the process of evolution by natural selection. Its nature, role in the evolutionary concept structure, and limitations must all be understood if a clear view of evolution is to be possible. In particular, adaptation's distinctness from and relation to the concept of fitness must be seen clearly. Only thus can evolution by natural selection, a central and perhaps the only 'natural law' peculiar to the life sciences (Rosenberg 2000, Watt 2000), be properly understood.

1. Adaptation's Identity and its Distinction from Fitness

If no concept is more central to evolution by natural selection than adaptation, then also none has been more debated. All the basic features of its definition are found in the work of Darwin, but progress in unfolding its full scope and implications continues to be made even at present.

Biological evolution, as distinct from cultural evolution (though often interwoven with it; e.g., Cavalli-Sforza and Feldman 1983), is manifested as change in the genetic composition of populations over time. Therefore, some genetic terminology is needed at the

outset. A 'gene' is a functionally coherent sequence of bases in nucleic acid, usually DNA except for some viruses, determining or influencing some biological structure and/or function. An 'allele' is one possible sequence of a gene, determining one alternative state of gene action. Many organisms, including most animals, carry two copies of each gene (and are thus termed 'diploid'). 'Genotype' refers to the whole heritable composition of a creature, whether viewed gene-by-gene (e.g., carrying two copies of the same allele, hence a 'homozygote,' or one copy each of two different alleles, hence a 'heterozygote') or more broadly up to the whole 'genome' which includes all genes. 'Phenotype' refers to the expressed structure and function of the organism as it develops via interactions of its genotype with the environment in which development takes place. Present understanding of the complexities of the evolutionary process requires this terminology to avoid ambiguity and confusion.

1.1 Basic Definitions of Adaptation

As a general concept, adaptation or adaptedness is best defined as an extent or degree of matching or suitedness between the heritable features (heritable functional phenotypes) of organisms and the environments in which they occur. It finds direct expression in the effectiveness with which organisms perform their characteristic biological tasks—osmoregulation, locomotion, capturing food, evading predators, etc.—in their environments. As such, its states are in principle quantitatively measurable, or at least orderable, rather than only qualitatively organized.

This general definition is exemplified in many parts of Darwin's writing, notably in the Introduction to his *Origin of Species* (1859) where a woodpecker appears as an exemplar 'with its feet, tail, beak, and tongue, so admirably adapted to catch insects under the bark of trees.' Here, the phenotypic states of these morphological characters, modified as compared to simpler and more general forms found in other birds, are related to their functional performance consequences in acquiring food resources which other birds, lacking those specific adaptive phenotypic states, cannot reach.

Adaptation also refers to the process of successively descended, modified phenotypes becoming more suited, 'better adapted,' to particular environments under the action of natural selection on variation in those phenotypes. Palaeontology provides strong evidence for such local improvement in adaptedness over time, as in the escalation of predator and prey attack and defense morphologies in marine invertebrates (Vermeij 1987). Recently, real-time experiments have shown such adaptive improvement directly, in the evolution of a bacterial stock in novel culture conditions over periods of 10^4 generations: a stock at an early stage in the process, if samples are frozen for later reactivation, is found to be inferior in performance to its own, manifestly better adapted, descendants sampled from late in the history of the stock (Lenski and Travisano 1994).

The historical nature of this successive evolutionary refinement of adaptive state has led to much debate over when a phenotypic feature may be termed 'an' adaptation and when not, i.e., how far it has been specifically selected for its current state of function in its environment. If, as stated above, states of adaptation differ quantitatively, then any viable phenotype represents *some* level of adaptation, and this debate loses urgency. Further, calling a phenotype 'an' adaptation only if it is the best available at a given time (as advocated by, e.g., Reeve and Sherman 1993) would require continuous redefinition as newer alternatives arise, and seems to offer no compensating advantage.

1.2 Elaborations of the Basic Concept

Gould and Vrba (1982) extended and refined definitions of adaptation in useful ways. In their terminology, 'aptation' describes the primary, historically unmodified relation of suitedness between phenotype and environment—that of any newly arisen variant, positive or negative in its functional effects. They regarded 'adaptation,' in this context, as the successive refinement of phenotypic suitedness by selection of newer variants, and coined the term 'exaptation' for the co-opting of a phenotypic feature by selection for a new function, as in the modification of skull-jaw joint bones toward the ossicles of vertebrate ears (e.g., Romer 1955). The exaptation/adaptation distinction poses problems of discrimination (how much change under a new selection pressure is needed before a phenotype of *ex*aptive origin is recognizable as presently *ad*aptive? Reeve and Sherman 1993), and also emphasizes that we are dealing with quantitative scales of variation, not alternate qualitative categories. Often the Gould–Vrba terms are not used unless the distinctions are pertinent to the issue at hand, and otherwise 'adaptation' is used as a generally inclusive term.

Another important augmentation of the adaptation concept is the work of Laland et al. (1996, 1999) in modeling 'niche construction.' This term refers to the active modification of environments by organisms in ways favorable to their own function, as emphasized by Lewontin (1983). It occurs in very diverse ways in different groups: for example, bacteria may release protease enzyme catalysts into their surroundings to aid foraging upon potential food items, while among multicellular animals beaver lodges and dams are a classic and dramatic example of such activities (quite aside from the obvious and often environmentally destructive capabilities of humans in this direction). Evolutionary models incorporating niche-construc-

tive feedbacks on organism–environment interactions may have very distinct properties from those not including such active forms of adaptation (Laland et al. 1996, 1999).

1.3 The Distinction Between Adaptation and Fitness

Alternative states of adaptation are the causes of evolutionary changes through their differences in organism–environment interaction and hence habitat-specific performances of these phenotypes. The performances of differently adaptive phenotypes, minute by minute or day by day, cumulatively affect how long they live, and how much they reproduce while alive. In short, adaptive differences among phenotypes alter their demographic parameters: survivorship ($= l_x$ of demography, where x denotes intervals of time) and male mating success or female fecundity ($= m_x$ of demography). These parameters are components of what, since the advent of mathematical population genetics, has been termed 'fitness' or 'Darwinian fitness' (though Darwin did not use the word in this way): the reproductive success of whole populations or of specific genotypes. Adaptation and fitness, then, are serially related concepts, but are in no sense the same.

In evolutionary genetics, fitness is usually measured as the net reproductive rate or replacement rate of organisms, whether an average value for a whole population or more narrow average values specific to carriers of particular genotypes. It is defined in 'absolute' terms as $R = \Sigma l_x m_x$ (e.g., Roughgarden 1979) under simple demographic conditions of non-overlapping generations and homogeneous reproductive periods (as, e.g., in annual plants or many insects). For complex demography in age-structured populations, the closest equivalent expression is λ (the leading eigenvalue of the demographic 'Leslie matrix'), a number which expresses complex interactions of age-specific survivorships and fecundities (e.g., Charlesworth 1994, McGraw and Caswell 1996). If either R or λ, as appropriate, is compared among genotypes by taking the ratio of each value to that of a chosen standard genotype, there result 'relative' genotypic fitnesses, wose value for the standard genotype is 1. Most evolutionary-genetic models use relative fitnesses for symbolic or numeric convenience.

It is essential to recognize that usage of the terms adaptation and fitness has changed dramatically since Darwin. He, Wallace, and other early evolutionists used 'fitness' as a synonym for 'adaptation,' and by 'survival' they often referred not to the demographer's life-cycle variable l_x but to 'persistence over long time periods.' Spencer's phrase 'survival of the fittest,' translated, thus meant 'the persistence through time of the best adapted.' Darwin had (necessarily) a clear view of the concept which an evolutionary geneticist now denotes by 'Darwinian fitness,' but he represented it by one version or another of a stock phrase (for which he had no summary term): '… the best chance of surviving and of procreating …' in the *Origin of Species* (1859). Failure to recognize these usage changes, and thus blurring of the sharp distinction between adaptation as cause and fitness as within-generation result, has led to no small confusion in later literature, including fallacious claims of an alleged circularity of evolutionary reasoning.

2. The Roles of Adaptation and of Fitness in Darwin's Argument for Natural Selection

From the inceptions of both Darwin's and Wallace's ideas of natural selection, differences in adaptation among heritable variants played the central, causal role in the process. Darwin formalized his argument in Chapter 4 of the *Origin*, especially in its first paragraph and its concluding summary, in such a way that it can be cast as a verbal theorem—as Depew and Weber (1995) make clear by judicious editing of Darwin's summary. Here it may be reformulated in modern terms.

To begin the argument, there are three points 'given' by direct observation: (a) organisms vary in phenotype; (b) some of the variants are heritable; and (c) some of these heritable variants are differently able to perform their biological functions in a given specific habitat, i.e., some are better adapted than others to that habitat. Then, Darwin's Postulate is that the better adapted, hence better performing variants in a habitat will survive and/or reproduce more effectively over their life cycles, i.e., have higher fitness, than other variants. Demography shows that greater reproduction of variants will cause their maintenance or increase of frequency in successive generations of a population. One may thus conclude that when the Postulate holds, the best adapted heritable phenotypes will persist and/or increase in frequency over time, thus realizing evolution by natural selection. This completes Darwin's Theorem.

The distinction between differences in diverse adaptive performances minute by minute or day by day in organisms' experience, and the resulting, cumulative appearance of fitness differences among them over their whole life spans is quite simply the difference between cause and effect. Its recognition is essential to keep straight the logic of natural selection, and to organize empirical studies of the process (Feder and Watt 1992, Watt 1994). The causal basis, in natural organism–environment interactions, of adaptive performance differences among genetic variants, and the transformation rules which translate those performance differences into fitness consequences, are now subjects of active and increasingly diverse study by evolutionary biologists.

3. *Alternatives to Adaptation in Evolution*

Adaptation is not ubiquitous, and natural selection is not all-powerful. 'Darwin's Theorem,' as summarized above, is not only empirically testable, but indeed may not hold in some well-defined circumstances. Two principal sources of limitation on the scope of adaptation are now considered.

3.1 *Neutrality*

As Darwin said in Chapter 4 of the *Origin*, 'Variations neither useful nor injurious would not be affected by natural selection …' The modern concept of neutrality (Kimura 1983, Gillespie 1991), which he thus described, is the null hypothesis for testing all causal evolutionary hypotheses. It occurs at each of the recursive stages of natural selection, as recognized by Feder and Watt (1992).

First, at the **genotype → phenotype** stage, genetic variants may differ in sequence but not in resulting function. For example, the 'degeneracy' of the genetic code often means that differences in DNA base sequence lead only to the same amino acid's insertion into a given position of a protein molecule. Alternatively, at least at some positions in proteins, substitution for one amino acid residue by a similar one, e.g., valine by isoleucine, may have little effect on the protein's function.

Next, at the **phenotype → performance** stage, functional differences among variants may not lead to performance differences among them, as other phenotypic mechanisms constrain or suppress their potential effects. For example, in the physiological reaction pathway used by bacteria to digest milk sugar (lactose), a twofold range of natural genetic variation in a phenotypic parameter (the V_{max}/K_m ratio) is observed for each of the protein catalysts, or enzymes, catalyzing the first two reactions. When these variants' resulting performances were measured under steady-state growth conditions, variants of the first enzyme in the pathway showed sizeable, reproducible differences, but no such effects were seen among variants of the second enzyme despite the similar size of their phenotypic differences—due to system constraints related to the position of the reactions in the pathway, analyzable by the theory of physiological organization (Watt and Dean 2000).

At the stage of **performance → fitness,** performance differences may not lead to corresponding fitness differences, e.g., if improved performance has less fitness impact above a threshold value of habitat conditions. For example, performance differences among feeding phenotypes (bill sizes and geometries) of Darwin's finches have minimal fitness impact when food is abundant in wet seasons, but have much more impact when food is scarce in dry seasons (Grant 1986).

Finally, at the stage of **fitness → genotype**, which completes the natural-selective recursion, small population size can allow random genetic drift to override fitness differences, as in the loss from small mouse populations of developmental mutant alleles ('t-system' variants) which should be in frequency equilibrium between haploid, gametic selection favoring them and their recessive lethality at the diploid, developing-phenotypic stage of the life cycle (Lewontin and Dunn 1960).

Because the usual statistical null hypothesis is that no treatment effect exists between groups compared, any adaptive hypothesis of difference between heritable phenotypes is *ipso facto* tested against neutrality by statistical testing.

Further, there is a subtler neutral hypothesis, that of association or 'hitchhiking': variants seeming to differ in fitness at a gene under study may be functionally neutral but genetically linked to an unobserved gene whose variants are the real targets of selection. But, 'hitchhiking' predicts that fitness differences seen among variants will not follow from any functional differences among them, so it is rejected when prediction from function to fitness is accurate and successful.

Indeed, where substantive adaptive difference exists among genetic variants in natural populations, neutral null hypotheses may be rejected under test at each of these levels, from phenotypic function to its predictable fitness consequences and the persistence or increase of the favored genotypes. This has been done, for example, for natural variants of an energy-processing enzyme in the 'sulfur' butterflies, *Colias* (Watt 1992). The explicit test of adaptive hypotheses against neutral nulls gives much of its rigor to such experimental study of natural selection in the wild (Endler 1986).

3.2 *Constraint*

Gould (e.g., 1980, 1989) has emphasized that many features of organisms may not result from natural selection at all but rather from various forms of constraint due to unbreakable geometric or physical properties of the universe at large or of the materials from which organisms are constructed, or other, more local biological limitations or conflicts of action.

Geometric or topological constraints may take a major hand in the form or function of organisms, e.g., in snail shells' form (Gould 1989) or in the fractional-power scaling of metabolic processes with body mass (West et al. 1997).

Selection among phenotypic alternatives at one time may entail diverse predispositions or constraints at later times. In one such case, the tetrapodal nature of all land-dwelling vertebrate animals (the bipedality of birds, kangaroos, and hominid primates is secondary) follows from the historical constraint that their ancestors, certain sarcopterygian fish, swam with two pairs

of oar-like ventral fins having enough structural strength *ab initio* that they could be exaptively modified into early legs (e.g., Gould 1980, Cowen 1995). In a more pervasive case, the evolved rules of diploid, neo-Mendelian genetics constrain many evolutionary paths. For example, if a heterozygous genotype is the best adapted, hence most fit, in a population, it can rise to high frequency in that population but cannot be the only genotype present because it does not 'breed true.'

Conflicts among different aspects of natural selection may constrain the precision of adaptation in diverse ways. As a case in point, adjustment of insects' thermoregulatory phenotypes may be held short of maximal or 'optimal' matching to average conditions in cold, but highly variable, habitats, because such 'averagely optimized' phenotypes would overheat drastically in uncommon but recurrent warm conditions (Kingsolver and Watt 1984). This illustrates the general point that environmental variance may sharply constrain adaptation to environmental means.

4. *Misdefinitions of Adaptation or Misconceptions of its Role*

Many misdefinitions of adaptation err by confusing it with fitness in one fashion or another. Much of this may originate in the usage changes, discussed earlier, between the early Darwinians and the rise of evolutionary genetics, such that 'fitness' ceased to be a synonym of adaptation and came to mean instead the 'best chance of surviving and of procreating' (e.g., Darwin 1859, p. 63). This entirely distinct concept is, as noted above, the cumulative demographic effect of adaptation. Some writers on evolutionary topics have been confused by inattention to these usage changes, but others have erred through conscious disregard or blurring of the adaptation–fitness distinction.

For example, Michod, despite early recognition of the separate nature of adaptation and fitness and of their antecedent–consequent relationship (Bernstein et al. 1983), has recently (Michod 1999) sought to collapse these concepts into different 'senses' of the single term 'fitness' to be used in different contexts to refer to both 'adaptive attributes' and their consequences in reproductive success. Authors may choose terminology for their own uses within some limits, but this usage is at best an ill-advised source of confusion, and at worst a mistaken conflation of distinct concepts.

A more subtle misconception was asserted by Lewontin (1983) in the course of an otherwise important argument for studying 'niche construction' (cf. above; Laland et al. 1996, 1999). Arguing that Darwin's adaptation concept implies 'passiveness' on the part of adapting organisms, he criticized it for allegedly implying that adaptation is like 'filing a key to fit a pre-existing lock.' But no such passivity is really in evidence. In Darwin's example already mentioned, the woodpecker's feeding 'strategy' actively transforms its environment compared to that experienced by more generally feeding birds, using a resource that its more generalized relatives do not even perceive. Further, Darwin's discussions (1859, Chap. 4) of co-adaptive mutualism between flowers and pollinators also show the active, indeed constructive nature of many adaptations. Pollinators not only obtain resource rewards from plants and spread their pollen during their foraging, but in so supporting the reproduction of their food sources, they increase their own future resource bases. Niche construction is therefore *an important form of* adaptation, not distinct from it or opposed to it.

Lewontin has also mis-stated the role of adaptation in the evolutionary process, arguing that 'three propositions'—variation, heritability, and differential reproduction—alone were sufficient to explain natural selection, and that the adaptation concept was gratuitously introduced into the argument by Darwin for sociological reasons (e.g., 1984). This claim is wrong, and has been extensively critiqued (e.g., Hodge 1987, Brandon 1990, Watt 1994, Depew and Weber 1995). Adaptation is the one element which distinguishes natural selection from artificial selection or from sexual selection alike. Without it, Lewontin's three propositions are sufficient only to define 'arbitrary' selection, wherein we do not know the cause of any differential reproduction of heritable variants. But the adaptive cause is, indeed, central to evolutionary change resulting from natural selection.

5. *Adaptationism and its Drawbacks*

Rose and Lauder (1996) identify adaptationism as '… a style of research … in which all features of organisms are viewed *a priori* as optimal features produced by natural selection specifically for current function.' Some, e.g., Parker and Maynard Smith (1990) or Reeve and Sherman (1993), hail the assumption of adaptiveness as a virtue, while others, e.g. Gould and Lewontin (1979), have attacked it as a vice. The question is: is it helpful, or legitimate, to assume that adaptation is ubiquitous?

First, is it true that adaptiveness is often assumed in practice? The usual null hypothesis in statistical testing is that there is no 'treatment effect.' Thus, any statistical test of adaptive difference among character states assumes *ab initio* that there is *no* such difference, i.e., that the character states in question are *neutral*. Only if this null hypothesis can be rejected according to standard decision rules is an effect recognized. All the null models of population genetics itself, beginning with the single-gene Hardy–Weinberg distribution, start with neutral assumptions. Tests of the population-genetic consequences of putatively adaptive differences in phenotypic mechanisms may or may not find departure from neutrality, but it is the routine 'starting point.'

Mayr (1988), among others, argues for testing all possible adaptive explanations for phenotypes before considering the 'unprovable' explanation of chance, i.e., neutral, origins. But this argument depends on a historicist approach to evolutionary studies. If one can instead analyze a phenotype by testing among neutrality, constraint, or adaptation with present-day experiments, historicism is no longer entailed. Even fossil structures unrepresented in living descendants can often be studied functionally by various means (Hickman 1988). A historical approach may sometimes be indispensable, but it is not the only one available to evolutionary biology.

As Gould (1980) observed, assuming the ubiquity of adaptation has a strong tendency to discourage attention to structural or constrained alternative explanations of phenotypes. It is not enough merely to test one specifically adaptive hypothesis about some phenotype against neutrality; one should consider all feasible alternative hypotheses, including the constraint-based one that a phenotype does make a non-neutral difference to performance and thence fitness, but does so in a particular way because no other is feasible or possible, rather than because it is 'optimized.'

Indeed, the strongest objection to adaptationism may be that attempting to use the optimal adaptedness of a phenotypic feature as a null hypothesis (an alternative sometimes suggested by adherents of this view) runs the serious risk of falling victim to 'the perils of preconception.' How can a scientist making such an attempt know that phenotypic function has been correctly identified, or that an appropriate adaptive hypothesis has been arrived at, to begin with (cf. Gordon 1992)?

As an illustrative cautionary tale, the behavior of certain 'laterally basking' butterflies in orienting their wings perpendicular to sunlight was at first guessed to be an adaptation to minimize their casting of shadows, hence to avoid predators' attention. More careful consideration shows that it does not do so! Parallel orientation of the closed wings to the solar beam gives true minimization of shadow. It was instead shown experimentally, with appropriate testing against neutral null hypotheses, that the perpendicular orientation behavior is adaptive, but in relation to thermoregulatory absorption of sunlight (Watt 1968).

Some users of adaptationist approaches do recognize these concerns, and construct optimizing models for test only within the confines of possible constraints or other alternative explanations (e.g., Houston and McNamara 1999). Nonetheless, the intellectual hazards of assuming adaptiveness of phenotypes seem to many to outweigh the possible advantages. Certainly, studies of adaptive mechanisms in diverse organisms have been executed successfully, achieving results which are both rigorous and generalizable, without this assumption (e.g. Lauder 1996, Watt and Dean 2000).

6. *The Future Study of Adaptation*

In brief, it is clear that mechanistic approaches to the study of adaptation in the wild are increasing in diversity, rigor, and effectiveness. Application of biomechanical approaches to the function of morphological adaptations (Lauder 1996), or of molecular approaches to study of adaptation in metabolism and physiology (Watt and Dean 2000), allow specific results to be obtained with much precision. At the same time, philosophical ground-clearing may reduce misunderstanding of adaptation or misapplication of the concept, and lead to greater effectiveness of specific work as well as greater possibilities for general insight (Brandon 1990, Lloyd 1994, Watt 2000). There has often been a tension between the use of well-studied 'model' systems which can maximize experimental power and the fascination with diversity which drives the study of evolution for many workers. Both have value for the study of adaptation, and the tension may be eased by the interplay of comparative and phylogenetic studies (Larson and Losos 1996) with genetics-based experimental or manipulative study of organism–environment interactions and their demographic consequences in the wild. This synergism of diverse empirical and intellectual approaches holds great promise for the widening study of adaptation as a central feature of evolution by natural selection.

W. B. Watt

Adaptive Preferences: Philosophical Aspects

'Adaptive preferences' refer to a process of preference change, whereby people's preferences are altered, positively or negatively, by the set of feasible options among which they have to choose. In the negative case ('unreachable grapes are probably sour anyway'), people value options less highly *ex post* of realizing that they are not feasible anyway than they valued those options *ex ante* of that realization. In the positive case ('forbidden fruit is sweeter'), they value more highly things *ex post* of realizing that they are beyond their grasp than they did *ex ante* of that realization.

Adaptive preferences of either sort threaten to violate normative canons of rational choice and undercut welfare theorems built around them (Elster 1983, Chap. 3). People's getting what they want makes them unambiguously better off, just so long as those preferences constitute fixed, independent standards of assessment. Where people alter their preferences in response to whatever they get (or did not get or could or could not get), just because that is what got (or did

not get or could or could not get), satisfying people's *ex ante* preferences does not necessarily make them better off *post hoc*. While adaptive preferences do not alter people's choice behavior, they do alter their evaluation of their chosen option relative to other infeasible ones, in that way affecting people's subjective welfare. Adaptive preferences also skew people's behavior in investigating new possibilities, making them more or less prone to being manipulated by inculcating misperceptions of what is or is not within the feasible set.

1. *Preference, Choice, and Welfare*

In the standard model of rational choice, normative decision theory prescribes that agents first produce a complete and consistent ranking over all conceivable options, then map the 'feasible set' onto that ranking, and finally choose the highest-ranked alternative (or pick among equal-highest ranked alternatives) that fall within the feasible set. Thus, microeconomic representations of consumer choice start by sketching 'indifference curves' representing the agent's preferences, then superimpose a 'budget line' (or 'production possibility frontier') on that, and finally identify where the budget line intersects the highest indifference curve as the rational choice.

When people proceed in this way, they maximize their subjective welfare (defined, tautologically, in terms of reaching the highest preference plateau they can), given their budget constraints. When groups of such individuals interact in free, perfectly competitive markets, the exchanges that they make similarly maximize the collective welfare of all concerned (defined in terms of Pareto-optimality: no one can be made better off without someone being made worse off).

1.1 *Preferences as Fixed, Independent Standards*

For those welfare conclusions to emerge, however, it is crucial that people's preferences form a fixed, independent standard of assessment. Suppose that people's preferences were not fixed but instead fluctuated randomly and with great frequency, so much so that we could be virtually certain that their preferences would have changed by the time the goods they have chosen were actually delivered. In the case of consumers so fickle as that, we have no reason to think that respecting their original preferences and delivering to them the goods they have chosen will leave them (individually or collectively) better off than any other course of action.

Suppose instead that people's preferences were not independent of ('exogenous to') the system that is supposed to be satisfying them. Suppose, for example, that people were infinitely adaptable and agreeable, thinking (like Dr Pangloss) that whatever happens is for the best and whatever they are allocated is *ipso facto* what they most want. Or suppose that people were infinitely impressionable, thinking that they most want whatever producers' advertising tells them they want (Gintis 1972). Where preferences are shaped in such ways by the same processes that are supposed to satisfy them, we once again have no reason to think that respecting people's original preferences will leave them (individually or collectively) better off than any other course of action. Presumably such adaptive or impressionable consumers could and would adjust their preferences in such a way that they would like equally well anything else they were allocated (Sunstein 1993).

1.2 *Relaxing that Requirement*

To insist that people's preferences never change is asking too much. Clearly, people's preferences do change all the time, at least at the margins. Respecting their expressed preferences still seems the most likely way to maximize their welfare, individually and collectively, just so long as those preference changes are not too large or too frequent.

So too is it too much to insist that people's preferences never change in ways endogenous to the process that is supposed to be satisfying them. Satisfying one preference causes yet another to come to the fore. The more experience people have of a certain good, the more they tend to like (or dislike) it, in part simply because they have more information about it, and in part because they have more 'consumption capital' that interacts with the good to enhance people's enjoyment (or otherwise) of that good (Stigler and Becker 1977, Becker 1996). More generally, people's preferences are socially inculcated and culturally transmitted, with the same underlying processes generating a demand for certain cultural forms and individual traits while at the same time ensuring a supply of them (Bowles 1998). Radical economists are rightly suspicious of such processes. But, again, so long as the causal processes shaping preferences operate at sufficient distance from the processes satisfying them—and especially if preferences, once formed, tend to be relatively impervious to subsequent influence by those same forces (Lerner 1972)—then perhaps we might still suppose that respecting people's expressed preferences is the most likely way to maximize their welfare, individually and collectively.

2. *Adapting Preferences to Possibilities*

People's altering their preferences in response to their perceived possibilities similarly threatens to prevent preferences from functioning as fixed, independent standards of the sort which could reliably ground welfare judgments.

People who get what they want are better off in consequence; but people who want what they get, just because that is what they got, are not unambiguously better off. They would have been happy (perhaps equally happy, if we can talk in such cardinal-utility terms) with whatever they got.

By the same token, people who can get what they want are better off (better off, that is, than they would be if they could not get what they wanted). But people who want what they can get, just because that is what they can get, are not unambiguously better off. They would have been happy (perhaps equally happy) with whatever they could get. Conversely, people who do not want what they can get, just because that is what they can get, would have been unhappy (perhaps equally unhappy) with whatever they could get. Preferences that adapt in either of these ways, either positively or negatively to possibilities, thus seem to undercut the status of preferences as the sorts of fixed, independent standards which can reliably ground welfare judgments.

2.1 Intentional Adaptation

In general, adaptability is something to be desired. It helps us to be individually well-adjusted and evolutionarily fit as a species. Adapting our future choices in light of past experiences is the essence of learning. Adapting our choices to what we expect others to do is the essence of strategic rationality (see *Game Theory*).

On some accounts, adapting your preferences to your possibilities might be desirable in some of the same ways. Stoics, Buddhists, and others have long advised that the best way to maximize your happiness is to restrain your desires, confining them to what you already have or can easily get (Kolm 1979). Theorists of self-control sometimes describe that process in terms of a game of strategy, whereby one's 'higher self' adaptively responds to the anticipated reactions of the 'base self' (Elster 1979, Chap. 2, Schelling 1984). Athletic trainers and social reformers, in contrast, often advise us to set our aspirations just beyond what realistically we believe we can obtain.

Those are cases of preferences that are intentionally adaptive. There, the individuals concerned deliberately and self-consciously attempt to alter their own preferences in certain directions. Intentionally adaptive preferences are in that respect akin to other instances of deliberate, self-conscious preference formation: people's striving to overcome unwanted addictions, build their character, or cultivate their tastes. It is unobjectionable for people to try to shape or reshape their own preferences in these or any of various other ways.

Preferences which are adapted unintentionally to possibilities are potentially more problematic, precisely because they can claim no warrant in the agent's will. Individuals who find themselves unself-consciously adapting their preferences to their circumstances are being controlled by their environment rather than controlling it. They no longer fully qualify as 'sovereign artificers' choosing their own way in the world. They no longer qualify fully as external sources of value, independent assessors of the worth of alternative states of the world.

2.2 The Irrelevance of Adaptation to Choice

Suppose people judge the feasible set correctly. What they think is impossible really is impossible, and what they think is possible really is possible. Suppose furthermore that the feasible set is given exogenously, and the agents themselves can do nothing to alter its contents.

In that case, there is no reason to think that the adaptiveness of people's preferences to their possibilities does anything to alter their choices. If people's preferences are positively adaptive, they will prefer options more strongly if they are in their feasible set than they would have preferred those same options if they were not in their feasible set; and conversely if people's preferences are negatively adaptive. Adaptation of either sort changes the relative ranking of options in the feasible set to options outside the feasible set. But neither sort of adaptation changes the relative rankings of options all of which are within the feasible set.

Adaptive preferences, in effect, just introduce a constant inflator (in the case of positive adaptation: deflator, in the case of negative adaptation) which applies equally to all options in the feasible set. Since all options in the feasible set are marked up (or down) by the same multiplier, feasible options' rankings relative to one another remains unaltered. And since choice can only be among feasible options, which option is in fact chosen is unaltered by either form of adaptation of preferences to possibilities.

2.3 Adaptation and Subjective Welfare

Even if adaptive preferences do not cause people to do (i.e., choose) differently, they nonetheless cause people to feel differently about their choices. People who positively adapt preferences to possibilities will think themselves fortunate to have been able to choose from a good set of options. People who negatively adapt preferences to possibilities will think themselves unfortunate to have been forced to choose from a bad set of options. Each group thinks as it does, not because of anything to do with the content of the set of options, but merely because those were the options that were indeed available to them.

Expressed in terms smacking of cardinal utilities, we might put the point this way. Suppose people were asked to put a cash value on various sets of options,

without being told which among them is possible and which is not. Upon being told which were possible and which were not, positively adaptive people would increase the value they attribute to those sets which are feasible and they would decrease the value they attribute to those sets that are infeasible. Negatively adaptive people would do the opposite.

Expressed in terms of merely ordinal utility rankings, the same point might be put this way. Suppose people were asked to rank order various sets of options, without being told which among them is possible and which is not. Upon being told which were possible and which were not, those sets of options which are indeed feasible would rise in the rankings of positively adaptive people and those sets of options which are not feasible would fall in their ranking. The opposite would be true among negatively adaptive people.

Differential evaluations of possible and impossible options can never directly manifest themselves in revealed choices, since there is never any opportunity actually to choose between possible and impossible options. But those differential evaluations might manifest themselves behaviorally in more indirect ways. Positively adaptive preferences tend to make people generally more content with their world, negatively adaptive ones make people generally more discontent with it.

People who are discontent tend, in turn, to be unhappy in themselves and unforthcoming in cooperative endeavors, and content people conversely. Adaptive preferences, by contributing to those more general personal dispositions, can thus have an indirect effect on individual and collective welfare, even if they do nothing to alter people's actual choices.

3. *Adaptive Preferences with Nonfixed Possibilities*

The conclusion that adaptive preferences make no difference to people's actual choice depends on the assumptions that possibilities are known and that they cannot be altered. Where either of those assumptions fails to be met, adaptive preferences really can make a difference, not just to how people feel about their choices, but to how they actually choose.

3.1 *Altering the Feasible Set*

Suppose that there is something that people, individually or collectively, can do to alter the possibilities before them. Suppose that they can invest in research and development into some new technology, for example.

It is assumed conventionally that rational choosers ought always prefer expanding their feasible set. There is substantial variability over time in the information upon which an individual's choices are based and the circumstances in which they are made—as well as, of course, variability over time in the individual's preferences themselves. Owing to variability in all those dimensions, the same individual might rationally choose different options at different times and the availability of different options is itself valuable in consequence (Arrow and Fisher 1974).

Those arguments for valuing the expansion of the feasible set are made independently of any consideration of how preferences might vary with past choices or future possibilities. Suppose, now, that people's preferences are strongly and positively endogenous, with previous experience leading us to seek yet more experiences of the same sort in future. That removes at least one of the reasons for valuing a range of options wider than merely continuing along the same path. (Other reasons may however remain: varying circumstances or information may mean that, in future, we will need to pursue some different path to secure the same sort of experience.)

Preferences that adapt to possibilities complicate the story still further. People with positively adaptive preferences tend, by definition, to be relatively more satisfied with their existing set of options than they would be were their preferences nonadaptive. That fact would make them relatively less anxious to seek out some new options than they would if their preferences were nonadaptive. People with negatively adaptive preferences represent the converse case: being relatively more dissatisfied with their existing options, they would be inclined to invest relatively more heavily in the search for new options (even if they would also tend to downgrade those new options, in turn, immediately upon their being discovered and added to the feasible set).

But of course the possibility of discovering new possibilities is itself one of the many possibility before people. People with positively adaptive preferences are inclined to mark up the value of the possibility of discovering new possibilities, just because it is possible. Those with negatively adaptive preferences are inclined to mark down its value for the same reason.

That latter set of considerations tends to push people in the opposite direction from the first. People with positively adaptive preferences would value new possibilities less (because they are not presently possible), but they would value the possibility of discovering new possibilities more (because that possibility is itself presently possible); and people with negatively adaptive preferences conversely. The joint effect of those two opposing tendencies might be to leave people of both inclinations roughly 'adaptively neutral' with respect to the search for new options. Alternatively, people might simply learn to differentiate between their appreciation of having and of using possibilities to discover new possibilities.

Less subtly, and more straightforwardly, people with positively adaptive preferences might adopt the

simple rule of thumb that, 'Possibilities are good, and more possibilities are better.' They would be led by that rule to seek out new possibilities, not because there is anything wrong with their present possibilities and not because presently impossible options hold any particular allure, but merely because possibilities themselves are what is to be maximized. What people with negatively adaptive preferences want is not the converse (to minimize possibilities): instead, what they want is to make possible the presently impossible (even knowing that they will downgrade the value of those options immediately upon their becoming possible). In practice, that might amount to much the same, a rule of maximizing possibilities being broadly desirable from either positively or negative adaptive perspectives.

The differences between positively and negatively adaptive preferences is more clear cut when it comes to restricting rather than expanding the feasible set. People whose preferences are positively adaptive value relatively highly their existing options and would be reluctant to see any reduction in them. People whose preferences are negatively adaptive attach relatively more value to options that they do not have; and they would be relatively more indifferent to reductions in their existing options, which they value less highly (in the paradoxical limiting case, watching with indifference as their feasible set is extinguished altogether).

3.2 Uncertainty Concerning the Feasible Set

Suppose, next, that people do not know with complete confidence what is within the feasible set. There are some things that are certainly inside that set, and some other things that are certainly outside it. But there are various other things that may be inside or out.

People with positively adaptive preferences will mark up the value of things that might be possible, compared to that which they know with confidence to be impossible. They do not mark up the value of 'maybe possible' options as much as they mark up the value of options that they know with confidence to be possible, to be sure. But the sheer fact that those options are somewhere in the penumbra of the feasible set makes them relatively more attractive to people with positively adaptive preferences than they otherwise would have been. People with negatively adaptive preferences will display the converse pattern, marking down the value of things in the penumbra of the feasible set.

Here again, the fact that it is possible that something is possible is itself a possibility, and people with positively adaptive preferences should respond positively (and those with negative adaptives ones negatively) to that possibility as any other. But there is surely something mad about applying a double inflator (or deflator) to merely possible possibilities. If it is good that something is possible, then what is good is that it is possible tout court. It is not doubly good that it merely possibly possible. It is not so much the possibility as such but the optionality—the eligibility for choice—that positively adpative preferences value (and negatively adaptive ones disvalue).

4. Manipulating Perceptions of the Feasible Set

Advertisers and other 'hidden persuaders' famously attempt to manipulate people's choices by shaping their perceptions of the relative desirability of various options before them. Shaping people's preferences is one fairly direct way to shape their choices. Much the same effect can also be produced indirectly, by shaping their perceptions of the feasible set.

Perceptions of what is possible, jointly with our preferences, determine our choices. That which is impossible is rightly regarded as beyond the bounds of rational choice. But our information about what is or is not possible for them to do is rarely perfect, and shaping people's perceptions of the possibilities and impossibilities facing them is one effective way of manipulating their choices (Goodin 1982, Chap. 7).

That trick works to shape the choices of rational choosers, quite generally, since all rational agents choose merely from among the options they perceive to be open to them. Some people, however, adapt not just their choices to their possibilities but also their preferences to their possibilities; and that makes them more (in the case of positively adpative preferences) or less (in the case of negatively adaptive ones) easily prey to that trick.

People whose preferences are positively adaptive inflate the value of options perceived to be in their feasible set, relative to ones that are not. If they are persuaded that something is not possible anyway, then by virtue of that very fact the value of that option falls in their estimation. Because of that, in turn, they will suffer less regret at not being able to pursue that option, they will be less inclined to search for ways to make that option possible after all, and so on. And because of that, there is less risk of them discovering that their perception of that option as being impossible is in fact in error.

People with negatively adaptive preferences constitute the converse case, valuing particularly highly options they perceive as impossible. Regretting and resenting their impossibility as they do, such people are more likely to seek ways of rendering those options possible. That makes it more likely for them to discover that their perception of the option's impossibility is in error, thus exposing the manipulative fraud.

Additive Factor Models

Sternberg's (1969) Additive Factor Method is one of the major ways of analyzing response times. The goal is to learn about mental processes and how they are organized. To use it, the experimenter manipulates experimental variables called factors (e.g., brightness, discriminability), while a person performs a task (e.g., naming a digit). The person executes processes such as perceiving and deciding (processes are actions, not processors). Assume the processes are executed one after the other, in series, each process stopping before its successor starts. The time to complete the task, the response time, is the sum of the durations of the individual processes. A factor selectively influences a process if changing the factor changes the duration of that process, leaving durations of the other processes unchanged. If the combined effect on mean response time of changing two factors together is the sum of the effects of changing them separately, the factors are called additive factors. In early applications, experimental results were interpreted as follows. (a) If two factors are additive, each factor selectively influences a different process. (b) If two factors are not additive, at least one process is influenced by both factors. This entry discusses the validity and current use of the method for response times, extensions to other measures such as accuracy and evoked potentials, and extensions to operations other than addition.

A common strategy in science is to isolate components by taking an object apart. Obviously, processing in the human brain cannot be studied this way, so methods are needed for analyzing the intact system. The main method of this type for response times is the Additive Factor Method.

1. Response Time and Serial Processes

Shwartz et al. (1977) provide an illustrative example. An arrow pointing rightward or leftward was presented. Response was with a button on the right or left. The experimenter manipulated three factors. First was intensity: in some trials the arrow was bright, in others, dim. Second was similarity: the arrow pointed distinctly rightward or leftward, or indistinctly. Third was compatibility: for some participants, the arrow pointed toward the correct response button, for others, away. In an analysis of variance, the factors had additive effects on mean response time (RT). The authors concluded that the mental processes required for the task were executed in series, and that each factor selectively influenced a different process.

1.1 Selective Influence

Intuitively, a factor selectively influences a process when changing the level of the factor changes only that process, leaving other processes unchanged. It is implicitly assumed that changing the level of the factor also leaves the arrangement of the processes unchanged.

For processes in series, the mean RT is the sum of the means of the individual process durations (whether or not processes communicate or their durations are stochastically independent). A factor selectively influencing a process may change its mean duration. It leaves the marginal distributions of other processes unchanged, and hence leaves their means unchanged. Therefore, if two factors selectively influence two different processes, the change in RT they produce when combined is the sum of the changes they produce individually.

Measures other than mean RT require stronger assumptions. A common assumption is that process durations are stochastically independent, that is, the joint distribution of the process durations is the product of their marginal distributions. Then a factor

selectively influences a process if changing the level of the factor changes the marginal distribution of the process, does not change the marginal distribution of any other process, and leaves process durations independent.

1.2 Response Time Cumulative Distribution Functions

The mean gives only part of the response time information. The summation test (Ashby and Townsend 1980, Roberts and Sternberg 1992) examines distribution functions. Consider a task requiring process a followed by process b. Suppose when the level of a factor changes from 1 to 2, the duration of process a changes from random variable A_1 to random variable A_2. Likewise, suppose when the level of another factor changes from 1 to 2, the duration of process b changes from random variable B_1 to random variable B_2. When the first factor is at level i and the second factor is at level j, denote the condition as (i, j) and the response time as T_{ij}. Then,

$$T_{ij} = A_i + B_j; \quad i, j = 1, 2$$

so

$$T_{11} + T_{22} = A_1 + B_1 + A_2 + B_2 = T_{12} + T_{21} \qquad (1)$$

Ashby and Townsend (1980), assuming stochastic independence, proved that the distributions of $(T_{11} + T_{22})$ and $(T_{12} + T_{21})$ are the same.

Roberts and Sternberg (1992) developed an innovative test of this. For a given participant, every response time in condition (1, 1) is paired with every response time in condition (2, 2). (That is, the Cartesian product of the set of response times in condition (1, 1) and the set of response times in condition (2, 2) is formed.) Every such pair of response times is added. The empirical cumulative distribution of these sums is an estimate of the cumulative distribution of the composite random variable $(T_{11} + T_{22})$. Similarly, the cumulative distribution of the composite random variable $(T_{12} + T_{21})$ is estimated. These two estimates are predicted to be close, and were found to be remarkably close in a number of experiments analyzed by Roberts and Sternberg (1992).

1.3 Counterexamples

It might seem at first that if two factors have additive effects on RT, then processing occurs in two disjoint time intervals, each factor changing the duration of a different time interval. The conclusion does not follow. Counterexamples include a dynamic system model of Townsend and Ashby (1983) and (approximately) McClelland's (1979) cascade model.

Despite the counterexamples, there are conditions under which additive effects of factors on response time imply the existence of random variables whose sum is the response time, and such that changing the level of one of the factors changes only one of the random variables in the sum (see below). It is natural to say the random variables are the durations of processes in series, but the mechanism producing the random variables is not implied.

With inductive reasoning, one can say an empirical finding of additive factors supports the statement that the factors selectively influence processes in series. For strong support, evidence for additivity in many circumstances is needed. Additivity must occur at all levels of the factors said to be additive, and at all levels of other factors also. The statistical power must be high.

If factors are not additive, it is tempting to conclude that they do not selectively influence different processes. If (a) processes are serial and (b) each factor selectively influences a different process, then the factors will indeed have additive effects on mean RT. But an interaction may indicate that the processes are not serial. If the task requires completion of parallel processes, the RT is the maximum of the process durations, not the sum (Sternberg 1969, Townsend and Ashby 1983). Factors selectively influencing parallel processes will have interactive effects on RT (see *Network Models of Tasks*).

2. Other Measures and Process Arrangements

Using experimental factors selectively to influence mental processes was so successful for RT (e.g., Sanders 1980) that it was extended to other dependent measures. Three will be discussed: accuracy, evoked potentials, and rate.

2.1 Accuracy: Log Probability Correct

Call a process correct if its output is right for its given input. Suppose the probability of a correct response for the task is the product of the probabilities that each individual process is correct. This assumption is plausible for serial processes, and for other arrangements also. (Stochastic independence is stronger, requiring multiplicative rules for all outcomes, correct and incorrect.) Then the log of the probability of a correct response is the sum of the logs of the probabilities that the individual processes are correct. Hence, factors selectively influencing different processes will have additive effects on log percent correct (Schweickert 1985).

If the probability P of a correct response is large, a test can be based on the fact that for large P, $\log_e P$ is approximately equal to $1 - P$, the error probability. Then additivity for log probability correct implies

approximate additivity for error probability. Schwartz et al. (1977), in the arrow identification experiment described above, found additive effects of the three factors on error probability.

Another test, not requiring large P, can be based on a log linear model. Predictions of this log linear model agree well with the observations of Schwartz et al. (1977), see Schweickert (1985).

2.2 Accuracy: Probability Correct and Multinomial Processing Trees

Serial processes are not the only possibility, as Townsend (1972) emphasized. Sometimes a correct response can be made in one of two mutually exclusive ways. For example, in an immediate serial recall experiment, after a list of words is presented, suppose each word can be correctly recalled via a speech-like representation (articulatory loop) or via a semantic representation, but not both. The probability of correctly recalling a word is the probability of correct recall via the articulatory loop plus the probability of correct recall via the semantic representation. Then two factors selectively influencing the two ways of producing a correct response will have additive effects on probability correct.

In a relevant experiment by Poirier and Saint-Aubin (1995), participants sometimes repeated an irrelevant word aloud during list presentation. Suppose then the articulatory loop is not as likely to lead to a correct response. Sometimes the words in a list were from the same semantic category, sometimes from different categories. Suppose with different categories the semantic representation is not as likely to lead to a correct response. The factors of repeating aloud and semantic similarity had additive effects, supporting the interpretation of mutually exclusive ways to respond correctly.

Recall of a word can be represented as a multinomial processing tree. Processing starts at the root node. Each branch represents the outcome of a process, correct or incorrect. Terminal nodes represent responses, correct or incorrect. Additivity is predicted by a tree with one path leading from the root to a correct response via the speech-like representation and another path via the semantic representation. If, instead, a path leads to a correct response using both representations, the result would be an interaction (Schweickert 1993).

2.3 Evoked Potentials and Parallel Processes: The Additive Amplitude Method

During mental processing neurons change electric fields and the changes in potential (voltage) can be measured at points on the scalp. The potential measured at any point in space is the sum of the potentials reaching that point from all sources, the basis of what Kounios calls the Additive Amplitude Method. Consider two mental processes executing simultaneously. If each of two factors selectively influences a different process, their combined effect on potential will be the sum of their individual effects, at every point at which potential is measured, throughout the duration of the processing.

Kounios and Holcomb (1992) presented sentences such as 'NO DOGS ARE FURNITURE.' Participants responded with the truth value. Sometimes the subject and predicate were related, sometimes not. Sometimes the subject was an exemplar and the predicate a category, sometimes the reverse. The two factors had additive effects on potential at each electrode site, throughout the interval from 300 to 500 ms after the predicate was presented. A brief interpretation is that the potential in this interval reflects two different parallel processes having synchronized neural firing, one for semantics and one for hierarchy.

2.4 Rates and Timers: The Multiplicative Factors Method

Roberts (1987) considered sequences of responses, such as repeated lever presses, controlled by an internal timer which emits pulses at the rate r per second. The pulses are sent to a filter permitting a fraction f of the pulses to be sent to another filter, which permits a fraction g of the pulses to be sent to the responder. Responses are made at the rate rfg. Suppose one factor changes the fraction of pulses sent on by the first filter, and another factor changes the fraction of pulses sent on by the second filter. The factors will have multiplicative effects on rate.

Roberts (1987) gives example data from Clark (1958). Rats pressed a lever for food. Different groups received different variable interval reward schedules, and rats were tested at different times after feeding. Reward schedules and testing times had multiplicative effects on the rate of lever pressing, as predicted.

3. Generalization: Selective Influence and Other Combination Rules

When processes are not independent, what does it mean to selectively influence one? This question was considered first by Townsend and Ashby (1983), and most recently by Dzhafarov. The work considerably extends the scope of selective influence, and quite general combination rules can be tested.

When factor α is at level i and factor β is at level j, let A_{ij} be the duration of process a and B_{ij} be the duration of process b. Let $A \cong$ mean A has the same distribution as $\cong$. Factors α and β selectively influence the durations of processes a and b, respectively, if there are independent random variables P_1 and P_2, and functions G and H such that

$$A_{ij} \cong G(P_1, P_2; i) \quad \text{and} \quad B_{ij} \cong H(P_1, P_2; j) \qquad (2)$$

and some additional technical conditions are met (Dzhafarov in press). As A_{ij} depends only on i, and B_{ij} depends only on j, denote them as A_i and B_j, respectively. Because A_i and B_j are functions of the same random variables, P_1 and P_2, they may be stochastically dependent. One form of dependence, relevant here, is perfect positive stochastic interdependence. Suppose there is a single random variable P, uniformly distributed between 0 and 1, such that

$$A_i \cong G(P; i) \quad \text{and} \quad B_j \cong H(P; j)$$

Then A_i and B_j are said to be perfectly positively stochastically interdependent, written $A_i \parallel B_j$. (A random variable's distribution can always be written as the distribution of its quantile function applied to a uniformly distributed random variable. Required here is that for A_i and B_j, it is the same uniform random variable.) Expressions such as $T_{11} \parallel T_{22}$ are defined analogously.

Now consider any binary operation ◆ which is associative, commutative, strictly monotonic, and continuous in both arguments, or is maximum or minimum. Let T_{ij} be the random variable observed when factor α is at level i and factor β is at level j. Then there exist random variables A_1, A_2, B_1, and B_2 such that

$$T_{11} \cong A_1 \blacklozenge B_1 (A_1 \parallel B_1)$$
$$T_{12} \cong A_1 \blacklozenge B_2 (A_1 \parallel B_2)$$
$$T_{21} \cong A_2 \blacklozenge B_1 (A_2 \parallel B_1)$$
$$T_{22} \cong A_2 \blacklozenge B_2 (A_2 \parallel B_2)$$

if and only if

$$T_{11} \blacklozenge T_{22} \cong T_{12} \blacklozenge T_{21} (T_{11} \parallel T_{22} \quad \text{and} \quad T_{12} \parallel T_{21})$$

For gist, consider Equation (1) with ◆ substituted for $+$. For details and uniqueness, see Dzhafarov and Schweickert (1995).

The thrust of theoretical work is toward statements of the form above, that a model with certain properties accounts for the data if and only if the data satisfy certain conditions. Usually, the model is not unique, that is, under the same conditions, other models with radically different properties may also account for the data (e.g., Townsend 1972). One can state only that the brain produces data indistinguishable from the predictions of a model with certain properties. One cannot validly conclude that brain and model operate the same way. Methods based on selective influence cannot overcome this limitation. What they can provide is the conclusion that the brain behaves as if made of separately modifiable components (Sternberg 1998). They also provide explicit relations between changes in the experiment, the model, and the data. Without these relations, an analysis of the entire system would be uninterpretable.

Administration in Organizations

Administration in organizations—sometimes referred to as administrative science—is a mid-twentieth century construct. Social sciences consider management issues and practices as a specific field of inquiry. It deals with action and action taking in social units which follows some particular purpose: public agencies, firms, and voluntary associations (see *Bureaucracy and Bureaucratization*). How far is it possible within such rational entities to mobilize resources and people so as to achieve some degree of compatibility and some level of efficiency between differentiated tasks and between heterogenous logics of action? The challenge is to offer a set of theories and informations that explain and even predict behaviors and outcomes. Two main approaches of management emerge: the organization as an arena for strategic behavior and the organization as a moral community.

1. *From Principles to Concepts*

Modern management and organization thinking is rooted in the industrial revolution of the 1700s. How to organize and control complex economic and technical ventures such as factories has led the professions of mechanical engineering, industrial engineering, and economics to formulate prescriptions. What is often called the classical theory was dominant well into the 1940s. Its basic assumptions are that organizations exist to accomplish economic goals, that they act in accordance with rational criteria of choice, and that there exists one best way to solve a problem. Some of its leading figures are well known, such as Taylor (1911) an American practicing manager or Fayol (1949), a French engineer. Such a classical school claimed that administration was a matter of science. Action guidelines can be derived from universally applicable principles, whatever the type of organization is. Models and procedures are provided such as centralization of equipment and labor in factories, specialization of tasks, unity of command, and financial incentives based upon individual productivity. While Fayol was handling the issues of how to manage a firm as a whole, Taylor was defining expertise about how to get the individual worker organized. Optimism prevailed: managers have to learn a set of principles, to get them translated into procedures by experts, and, with the additional help of control and discipline, employees' behaviors will conform.

A strong attack was launched after World War II challenging such oversimplistic mechanistic views of administration. The rebellion against the classical school was led by organizational theorists trained in sociology and in political science.

Simon (1946) emerges as a pioneer and perhaps as its best known figure. In his opinion, the principles as defined by Taylor, Fayol, and others are instead mere proverbs: they are neither true nor false. He criticizes explicitly and rather violently the relevance of the principles approach. Specialization of the tasks, span of control, unity of command led to impasses, according to Simon. They are conflicting and inconsistent with most situations administrations face. With equal logic they are applicable in diametrically opposed ways to the same sets of circumstances. Therefore, in order to become a really scientific theory, administration in organizations has to substitute concepts to principles and make them operational.

In a subsequent book, Simon (1947) lays the ground for administration as a specific field of inquiry. He sketches a conceptual framework, which meaning corresponds to facts or situations empirically observable. He questions, for instance, the relevance of the principle of rationality. In organizations, even if they are purposive, an individual does not have the intellectual capacity to maximize, and they are also vulnerable to the surrounding social and emotional context. What human beings do is to satisfice: they try to find trade-offs between preferences and processes, they do the best they can where they are. Human and organizational decisions are subject to bounded rationalities. Simon also shows that efficiency is not a goal shared the same way by everyone in the organization, including the managers, and which can be defined *ex ante*. It should be a research question, starting from the hypothesis that the individuals or the organizations themselves carry a specific definition of what is good or correct from an efficiency point of view. In more general terms, contexts vary, and they make a difference.

Simon follows Max Weber's perspectives: administration belongs to the domain of rational action. Firms or public agencies are organizations driven by purposes. But managers rely upon the mediation of an organized setting in order to implement goals, purposes, or values. Therefore, the organization simultaneously provides a resource and becomes a constraint, managers experience it as a solution as well as a problem. Simon underlines the necessity for social sciences to approach management as a field aimed at understanding the nature of empirical phenomena. Its primary goal is not to formulate solutions for action but to consider action as a problem under scrutiny.

Practicing managers could nevertheless rely upon relevant findings and apply such a body of knowledge—or part of it—to enlighten problem solving. Such an agenda is structured around the study of the actual functioning of organizations. In a more specific way, Simon defines decision-making processes—or action—as the center of the scientific discipline of management. Any decision or action can be studied as a conclusion derived by the organization or by an individual from a set of premises. Some premises are factually grounded: they link a cause to an effect. Therefore, they are subject to a test by experience. Other premises are of a different nature: they are value grounded, made out of norms or ethical references. In this case they are not checkable empirically. While both categories are not separable in action, analysts have to separate them and focus upon factual premises only.

Firms and public agencies should also be treated as open organizations. They do not and cannot exist as self-contained islands within society and the market. They are linked to specific environments. The relationships which are structured between the inside and the outside play a very important function. Where and how an organization is embedded, what is exchanged, are phenomena which have an impact on the inner functioning as well as on the environment. A major theoretical breakthrough was offered by a sociologist, Philip Selznick (1949). The concept of co-optation which he elaborates describes how an organization gains support for its programs within the local communities where its execution agencies operate. An empirical study is offered by Selznick about an American federal agency, Tennessey Valley Authority. Co-optation refers specifically to a social process by which an organization brings outside groups and their leaders into its policy-making process, enabling such elements to become allies, not a threat to its existence and its mission. Bringing the environment back in solves a major difficulty the classical approach would not consider, especially when dealing with public administrations. Two of his founders, Woodrow Wilson and Frank J. Goodrow, had been calling for a theory of management which should make a dichotomy between politics and administration, between the elaboration of the policy of the state and the execution of that will. Selznick suggests that such a postulate should become a research question. He also proposes that, beside organizational phenomena as such, science should consider institutionalization dynamics, which means how values and norms are diffused, appropriated, and what impacts they have on managerial action-taking.

2. *Managing Arenas for Strategic Behavior*

Simon's agenda was recognized only in the 1960s as a milestone. It paved the way for what could be called the behavioral revolution in the field of administration. In the early part of the twenty-first century, it is still one of the most influential schools in business education and public management.

During the 1950s progress was made basically around the Carnegie Institute of Technology and under the leadership of Simon himself. With March he reviewed the studies of bureaucracies developed by social scientists such as Robert K. Merton, Philip Selznick, and Alvin W. Gouldner. Various models of bureaucratic behavior were formalized and compared (March et al. 1958). In highly proceduralized organizations, whether private or public, individuals and groups do not remain passive: they reinterpret rules and procedures, they play with and around them, they use them for secondary purposes of their own such as increasing their autonomy inside the hierarchical line of authority or as bargaining their participation to the organization. At an organizational level, management by rules favors or induces dysfunctional processes. Managers relying upon formalization and procedure are trapped in vicious circles. In order to fight unintended consequences of such tools for action, they reinforce formal rules.

The Carnegie School also addressed and criticized the theory of the firms as defined by orthodox microeconomics. Organizational decision making is the focal point. Is utility maximization the main function that business firms do, in fact, achieve? Cyert and March (1963) studied how coalitions are structured and activated inside a company around action taking and choice processes. Negotiations occur through which coalitions impose their demands on the organizational objective. Simon's conception is demonstrated as being applicable to economic actors: satisficing is a much more powerful concept to explain their strategic decisions than maximizing economic profit. Such is specifically the case of pricing in an oligopolistic market. In other terms, some characteristics of organizational structure determine rational behavior.

The implications of such a perspective are essential. From a knowledge point of view, conflict is a basic attribute of any organization. Business firms and public agencies as well are not monolithic entities sharing one common purpose. They behave as pluralistic systems in which differentiated and even antagonistic interests float around, conflict, or cooperate. They look like political coalitions between subgroups (March 1962). From an action-taking or managerial perspective, organizations require their leaders to develop skills that are less analytical than behavioral. Administrations are close to political brokers, negotiating and bargaining inside their organizations being a crucial task to fulfill. A firm looks like an arena for strategic microbehaviors, a collection of subunits pursuing separate goals. The role of management is to structure inducements so that each individual subunit identifies its interests with

those of the firm and, thereby, contributes to its mission.

In the 1960s, the behavioral approach has widened internationally and given birth to a stream of organizational researches about decision-making, power, and efficiency.

Allison (1971) studies the same event—the USA presidential handling of the 1962 Cuban missile crisis—comparing three different paradigms about decision making. An organizational process model, which is clearly derived from the Carnegie School approach, completed with a so-called governmental political model, which deals with partisan politics and presidential tactics on the public-opinion scene, shows a superior ability than a rational actor or classical model to explain how John F. Kennedy addressed the challenge and which outcomes were elaborated, despite the manifest of theory game based techniques used by the executive. Lindblom (1959) too takes a hard look at the rational model of choice. He rejects the notion that most decisions are made by total information processes and suggests that synoptic approaches provide self-defeating strategies for action. Instead, he sees the whole policy-making processes as being dependent upon small instrumental decisions that tend to be made in a disjointed order or sequence in response to short-term political conditions. Such a muddling through view prescribes managers to make small changes at a time and at the margin, not focusing too much and explicitly about content, whenever it is possible and, if needed, making some minor concession (two steps forward and one step backward). March and Olsen (1976) develop a garbage-can model of choice. Choices are characterized by ambiguity about goals, intentions, technologies, causation, participation, and relevance. What is a problem for actor A looks more like a solution for actor B, formal opportunities for choice look after problems to handle, decisions are made without being considered by the participants as being made. Such anarchic contexts occur in specific organizational settings such as bureaucracies and very loosely formalized structures. Nobody is really in control of the process and decisions are experienced as random-based outcomes. The implications of such a model for top managers are that they should not use quantitative tools as instruments of government or intervene in tactical ways but keep their hands free for what they consider as fundamental issues and use as action tools two basic vehicles: the selection of their immediate subordinates and a redesign of the formal structures of their organization.

Power phenomena are viewed as key variables for understanding and managing. Crozier (1963) offers a perspective that helps inter-relating micro-processes—such as the behavior of single actors—and macroprocesses—such as the functioning of the whole organization. Individuals and groups are pursuing rational strategies: they try to fulfill goals that are structured by the specific and local context within which they act daily. Asymetric interdependance relationship link them together: some are more dependant than others. Those who control a source of uncertainty from which others depend control power bases and are able, in exchange of their good will, to set up the rules of the game. In other terms, organizational functioning and change derives from the social-regulation processes as induced by the actors who, at various levels of the pyramid, try to make their specific and heterogenous strategies or logics of action compatible. From a managerial point of view, such a comprehensive framework implies that management is about the art and skills to reallocate uncertainties and power inside the organization, therefore, to structure interests inducing the actors to cooperate or not. Bower (1970) applies such a perspective to stretegic investment planning in a giant corporation. Allocating capital resources is a process that requires management to identify the various organizational components such as routines, parochialism, attention to issues, and discretionary behaviors of action controlling major uncertainties.

A third major critical examination of the classical school made by organizational theorists deals with rationality and efficiency. Landau (1969) argues that redundancy within a firm or a public agency is not a liability—or a symptom of waste and inefficiency—but a fundamental mechanism of reliability. Duplication and overlap provide solutions for action-taking in general. The breakdown of one part does not penalize the whole system. The arrogance of a subsystem controlling a monopoly on a problem or a function is diminished. Duplication and overlap may create political conflicts; they also generate conditions for communication, exchange, and co-operation. They lower risks. Organizations are not self-evaluating entities. They tend to substitute their own knowledge to the information generated by their environment. Economic efficiency and optimality as defined by economists are normative enterprises. In reality, management is much more related to failure avoidance and to fault or error analysis in a world where total control of events remains an impossible task to fulfill.

3. Moral Community Building as an Alternative Approach

While the behavioral revolution successfully challenges basic postulates upon which the classic theories of organization (a set of principles) and economics (optimality) are grounded, it nevertheless assumes that management and administration handle a firm or a public agency through an economy of incentives. Incentives are the rewards and sanctions imposed by leaders, and they generate behaviours. Well-designed incentives—whether financial or organizational—align individual goals and collectively produce man-

agerially desired action. Designed poorly, incentives may produce subunit conflict and poor firm performance. Implicit in this view of the organization is the assumption that organizational actors, either persons or subunits, possess preferences and influence resources which include position or office, functional or professional expertise, side payments, and the like. The relative salience of influence resources may be viewed as the weights that should be attached to predictions of the effects of influence attempts.

Another view treats preferences as endogenous. While it still assumes that organizational actors hold resources that may drive decision-making, it differs from the first view, however, by relaxing the assumption of strong preferences for specific action outcomes. The role of administration is to take actions that are designed to help structure more or less plastic preferences. Mechanisms include leadership, especially charismatic leadership, ideology, socialization, recruitment, and environmental constituencies to which individuals have personal or professional loyalty. The organization is understood and managed as a moral community. Common to all these mechanisms is the attempt to foster identifications and loyalties, the normative order providing the backbone of the organization. Management is about forging and changing values, norms, and cognitive characteristics: it may also have to do with preaching and educating.

The role of management in structuring preferences is documented by a set of literature on missionary, professional, and community organizations. Institutionalization as studied by Selznick (1949) offers a vehicle to mobilize an organization for meaning and action. Knowledge, or interpretations in action, structures the community. The theoretical roots of such an approach relate to two different social sciences traditions. Shils (1975) identifies in each society the existence of a center or a central zone that is a phenomenon of the realm of values and beliefs as well as of action. It defines the nature of the sacred and it embodies and propounds an official religion, something that transcends and transfigures the concrete individual existence, the content of authority itself. The periphery in mass society is integrated through a process of civilization. Anthropologists such as Geertz (1973) demonstrate that culture as a collectively sustained symbolic structure is a means of 'saying something of something,' Through emotions common cognitive schemes or common meanings are learned: they provide an interpretative fonction, a local reading of a local experience, which is a story the participants tell themselves about themselves.

More recent contributions have laid down perspectives focused specifically around organizations and their administration. Various processes within firms could actually play the role of center: brainstorming sessions, informal encounters, networks linking persons across departments and units, socialization mechanisms of newcomers, etc. Strong centers can create rigidity phenomena in terms of cognitive blindness, the firm as a community being unable to catch signals emitted by its environment. Daft and Weick (1984) propose a model of organizations as interpretation systems that stresses their sociocognitive characteristics more than the economic ones. Interpretation is the process through which information is given meaning and actions are selected and fulfilled. Kogut and Zander (1996) treat firms as organizations that represent social knowledge of coordination and learning: identity lies at the heart of such social systems, which implies a moral order as well as rules for exclusion.

Administrative Law

Administrative law refers to the body of laws, procedures, and legal institutions affecting government agencies as they implement legislation and administer public programs. As such, the scope of administrative law sweeps broadly. In most countries, bureaucratic agencies make up the largest part of the governmental sector and generate most of the decisions having a direct impact on citizens' lives. Administrative law governs agency decisions to grant licenses, administer benefits, conduct investigations, enforce laws, impose sanctions, award government contracts, collect information, hire employees, and make still further rules and regulations.

Administrative law not only addresses a wide and varied array of government actions, it also draws its pedigree from a variety of legal sources. Administrative law, as a body of law, is part constitutional law, part statutory law, part internal policy, and, in some systems, part common law. The organization and structure of administrative agencies can be shaped by constitutions or statutes. The procedures used by these agencies can be dictated by constitutional law (such as to protect certain values such as due process), by generic procedural statutes (such as the US Administrative Procedure Act), or by statutes addressing specific substantive policy issues such as energy, taxation, or social welfare. As a result, administrative procedures can vary significantly across agencies, and even within the same agency across discrete policy issues.

Administrative law, in all its varied forms, speaks ultimately to how government authority can and ought to be exercised. By directing when and how governmental power can be employed, administrative law of necessity confronts central questions of political theory, particularly the challenge of reconciling decision-making by unelected administrators with democratic principles. The study of administrative law is characterized in part by prescriptive efforts to design rules that better promote democratic and other values, including fairness, effectiveness, and efficiency. At its core, administrative law scholarship seeks to understand how law can affect the behavior of governmental officials and organizations in such a way as to promote important social objectives. As such, administrative law is also characterized by positive efforts to explain the behavior of governmental organizations and understand how law influences this behavior. A specific emphasis in administrative law scholarship is placed on the empirical study of how courts influence administrative policy. Although administrative law scholarship has a rich tradition of doctrinal analysis, the insights, and increasingly the methods, of social science have become essential for achieving an improved understanding of how administrative law and judicial review can affect democratic governance.

1. *Administrative Law and Democracy*

Administrative agencies make individual decisions affecting citizens' lives and they set general policies affecting an entire economy, but they are usually headed by officials who are neither elected nor otherwise directly accountable to the public. A fundamental challenge in both positive and prescriptive scholarship has been to analyze administrative decision-making from the standpoint of democracy. This challenge is particularly pronounced in constitutional systems such as the United States' in which political party control can be divided between the legislature and the executive branch, each seeking to influence administrative outcomes. Much work in administrative law aims either to justify administrative procedures in democratic terms or to analyze empirically how those procedures impact on democratic values.

A common way of reconciling decision-making by unelected administrators with democracy has been to consider administrators as mere implementers of decisions made through a democratic legislative process. This is sometimes called the 'transmission belt' model of administrative law (Stewart 1975). Administrators, under this model, are viewed as the necessary instruments used to implement the will of the democratically controlled legislature. Legislation serves as the 'transmission belt' to the agency, both transferring democratic legitimacy to administrative actions and constraining those actions so that they advance legislative goals.

As a positive matter, the 'transmission belt' model underestimates the amount of discretion held by administrative officials. Laws require interpretation, and in the process of interpretation administrators acquire discretion (Hawkins 1992). Legislation often does not speak directly to the varied and at times unanticipated circumstances that confront administrators. Indeed, legislators may sometimes lack incentives for making laws clear or precise in the first place, as it can be to their electoral advantage to appear to have addressed vexing social problems, only in fact to have passed key tradeoffs along to unelected administrators. For some administrative tasks, particularly monitoring and enforcing laws, legislators give administrators explicit discretion over how to allocate their agencies' resources to pursue broad legislative goals.

Scholars disagree about how much discretion legislators ought to allow administrative agencies to

exercise. Administrative minimalists emphasize the electoral accountability of the legislature, and conclude that any legislative delegations to agencies should be narrowly constructed (Lowi 1979). The expansionist view emphasizes most administrators' indirect accountability to an elected executive and contends that legislatures themselves are not perfectly representative, especially when key decisions are delegated internally to committees and legislative staff (Mashaw 1985). While disagreement may persist over the amount of authority to be delegated to agencies, in practice administrative agencies will continue to possess considerable discretion, even under relatively restrictive delegations.

The study of administrative procedure takes it as given that agencies possess discretion. The aim is to identify procedures that encourage administrators to exercise their discretion in reasonable and responsive ways. A leading approach has been to design administrative procedures to promote interest group pluralism (Stewart 1975). Transparent procedures and opportunities for public input give organized interests an ability to represent themselves, and their constituencies, in the administrative process. Such procedures include those providing for open meetings, access to government information, hearings and opportunities for public comment, and the ability to petition the government. Open procedures are not only defended on the grounds of procedural fairness, but also because they force administrators to confront a wide array of interests before making decisions, thus broadening the political basis for administrative policy. These procedures may also protect against regulatory capture, a situation which occurs when an industry comes to control an agency in such a way as to yield private benefits to the industry (Stigler 1971).

A more recent analytic approach called 'positive political economy' seeks to explain administrative procedures as efforts by elected officials to control agency outcomes (McCubbins et al. 1987). Administrative law, according to this approach, addresses the principal–agent problem confronting elected officials when they create agencies or delegate power to administrators. The problem is that administrators face incentives to implement statutes in ways not intended by the coalition that enacted the legislation. It is difficult for legislators continually to monitor agencies and in any case the original legislators will not always remain in power. Analysts argue that elected officials create administrative procedures with the goal of entrenching the outcomes desired by the original coalition. Such procedures can be imposed by the legislative as well as executive branch, and they include formal procedures for legislative review and veto, general requirements for transparency and interest group access, and requirements that agencies conduct economic analysis before reaching decisions.

A recent area of empirical debate has emerged in the United States over which branch of government exerts most control over administrative agencies. The resulting evidence has so far been mixed, as might be expected, since most agencies operate in a complicated political environment in which they are subject to multiple institutional constraints. Indeed, the overall complexity of administrative politics and law presents a major challenge for social scientists seeking to identify the effects of specific kinds of procedures under varied conditions. The recent positive political economy approach advances a more nuanced analytical account of democratic accountability than the simple 'transmission belt' model of administrative law, but the ongoing challenge will be to identify with still greater precision which kinds of procedures, and combinations of procedures, advance the aims of democratic accountability as well as other important social values.

2. *Courts and Administrative Law*

As much as the connections between elected officials and administrators have been emphasized in administrative law, the relationship between courts and administrators has figured still more prominently in the field. Even when administrative procedures are created through legislation, the enforcement of such procedures often remains with judicial institutions. Courts have also imposed their own additional procedures on agencies based on constitutional and sometimes common law principles. As with democratic issues, scholarly attention to the role of the courts has both prescriptive and positive aspects.

The main prescriptive focus has been on the degree to which courts should defer to the decisions made by administrative agencies. Much doctrinal analysis in administrative law acknowledges that administrative agencies' capacity for making technical and policy judgments usually exceeds that possessed by courts. Even in legal systems with specialized administrative courts, agency staff often possess greater policy expertise than judges, not to mention that administrators are probably more democratically accountable than tenured judges. These considerations have long weighed in favor of judicial deference to administrative agencies. On the other hand, it is generally accepted that some credible oversight by the courts bolsters agencies' compliance with administrative law and may improve their overall performance. The prescriptive challenge therefore has been to identify the appropriate strategies for courts to take in overseeing agency decision-making.

This challenge typically has required choosing a goal for judicial intervention, a choice sometimes characterized as one between sound technical analysis or an open, pluralist decision-making process (Shapiro 1988). Courts can defer to an agency's policy judgment, simply ensuring that the agency followed transparent procedures. Or courts can take a careful look at the agency's decision to see that it was based on a

thorough analysis of all relevant issues. The latter approach is sometimes referred to as 'hard look' review, as it calls for judges to probe carefully into the agency's reasoning. Courts also face a choice about whether to defer to agencies' interpretations of their own governing legislation instead of imposing judicial interpretations on the agencies. Prescriptive scholarship in administrative law seeks to provide principled guidance to the judges who confront these choices.

Judicial decisions are influenced in part by legal principles. Empirical research has shown, for example, that after the US Supreme Court decided that agencies' statutory interpretations deserved judicial deference, lower courts made a significant shift in favor of deferring to agency interpretations (Schuck and Elliott 1990). Nevertheless, just as administrators themselves possess residual discretion, so too do judges possess discretion in deciding how deferential to be. Other empirical research suggests that in administrative law, as in other areas of law, political ideology also helps explain certain patterns of judicial decision-making (Revesz 1997).

In addition to empirical research on judicial decision-making, the field of administrative law has been concerned centrally with the impact of judicial review on agency decision-making. Normative arguments about judicial review typically depend on empirical assumptions about the effects courts have on the behavior of administrative agencies. Indeed, most legal scholarship in administrative law builds on the premise that judicial review, if employed properly, can improve governance (Sunstein 1990, Edley 1990). The effects often attributed to judicial review include making agencies more observant of legislative mandates, increasing the analytic quality of agency decision-making, and promoting agency responsiveness to a wide range of interests. Administrators who know that their actions may be subjected to review by the courts can be expected to exercise greater overall care, making better, fairer, and more responsive decisions than administrators who are insulated from direct oversight.

Notwithstanding the beneficial effects of courts on the administrative process, legal scholars also have emphasized increasingly courts' potentially debilitating effects on agencies. It has widely been accepted, for example, that administrators in the United States confront a high probability that their actions will be subject to litigation. Cross-national research suggests that courts figure more prominently in government administration in the USA than in other countries (Brickman et al. 1985, Kagan 1991). The threat of judicial review has been viewed as creating significant delays for agencies seeking to develop regulations (McGarity 1992). In some cases, agencies have been said to have retreated altogether from efforts to establish regulations. The US National Highway Traffic Safety Administration (NHTSA) is usually cited as the clearest case of this so-called 'ossification' effect, with one major study suggesting that NHTSA has shifted away from developing new auto safety standards in order to avoid judicial reversal (Mashaw and Harfst 1990). Other research, however, indicates that the threat of judicial interference in agency decision-making has generally been overstated. Litigation challenging administrative action in the United States occurs less frequently than is generally assumed (Harrington 1988, Coglianese 1997), and some research indicates that agencies can surmount seemingly adverse judicial decisions to achieve their policy objectives (Jordan 2000).

Concern over excessive adversarialism in the administrative process persists in many countries. Government decision makers worldwide are pursuing collaborative or consensus-based processes when creating and implementing administrative policies. In the USA, an innovation called negotiated rulemaking has been used by more than a dozen administrative agencies, specifically in an effort to prevent subsequent litigation. In a negotiated rulemaking, representatives from government, business, and nongovernmental organizations work toward agreement on proposed administrative policies (Harter 1982). In practice, however, these agreements have not reduced subsequent litigation, in part because litigation has ordinarily been less frequent than generally thought (Coglianese 1997). Moreover, even countries with more consensual, corporatist policy structures experience litigation over administrative issues, often because lawsuits can help outside groups penetrate close-knit policy networks (Sellers 1995). In pluralist systems such as the USA, litigation is typically viewed as a normal part of the policy process, and insiders to administrative processes tend to go to court at least as often as outsiders (Coglianese 1996).

Courts' impact on the process of governance has been and will remain a staple issue for administrative law. In order to understand how law can have a positive influence on governing institutions within society, it is vital to examine how judicial institutions affect the behavior of government organizations. Empirical research on the social meaning and behavioral impact of litigation in an administrative setting has the potential for improving prescriptive efforts to craft judicial principles or redesign administrative procedures in ways that contribute to more effective and legitimate governance.

3. *The Future of Administrative Law*

Administrative law lies at several intersections, crossing the boundaries of political theory and political science, of public law and public administration. As the body of law governing governments, the future of administrative law rests in expanding knowledge about how law and legal institutions can advance core

political and social values. Democratic principles will continue to dominate research in administrative law, as will interest in the role of courts in improving administrative governance. Yet administrative law can and should expand to meet new roles that government will face in the future. Ongoing efforts at deregulation and privatization may signal a renegotiation of the divisions between the public and private sectors in many countries, the results of which will undoubtedly have implications for administrative law. Administrative law may also inform future governance in an increasingly globalized world, providing both normative and empirical models to guide the creation of international administrative institutions that advance both public legitimacy and policy effectiveness. No matter where the specific challenges may lie in the future, social science research on administrative law will continue to support efforts to design governmental institutions and procedures in ways that increase social welfare, promote the fair treatment of individuals, and expand the potential for democratic decision making.

Adolescence, Psychiatry of

For psychiatrists, adolescence holds a particular fascination. A period of rapid and often dramatic growth and development, adolescence presents countless challenges to those faced with making the transition from childhood to adulthood. While the vast majority of adolescents make this transition without any need for help from mental health professionals, others are not so fortunate. The psychiatric disorders of this period present treatment providers with unique challenges, because as with adolescence itself, they represent a distinctive mixture of childhood and adult components. However, adolescent psychiatric patients are frequently capable of making tremendous progress, and treating adolescents is often as rewarding as it is challenging.

In this article, we will briefly review the major psychiatric disorders affecting adolescents. We have divided the article into six sections, each representing a separate area of psychopathology. In each section, we list the major disorders, focusing on definitions, etiology, and treatment. For the purposes of this article, we have decided to follow the diagnostic criteria of the *Diagnostic and Statistical Manual of Mental Disorders*, Fourth Edition (*DSM-IV*, American Psychiatric Association 1994). We based this decision on the fact that the *DSM-IV* is the most

widely used diagnostic system not only in the United States, but in the world as a whole (Maser et al. 1991).

1. *Anxiety Disorders*

Everyone experiences anxiety; this is especially true for adolescents. Yet whereas normal levels of anxiety can be adaptive, helping individuals avoid danger and promoting development, too much anxiety can become problematic. When anxiety hinders, rather than helps an individual function in the world, it is considered pathological. Disorders that involve pathological levels of anxiety are referred to as 'anxiety disorders,' and they are quite common among adolescents. The most prevalent adolescent anxiety disorders are: *separation anxiety disorder*; *generalized anxiety disorder*; *obsessive-compulsive disorder*; *social phobia*; and *panic disorder*.

1.1 *Separation Anxiety Disorder*

The essential feature of separation anxiety disorder (SAD) is excessive anxiety concerning separation from home or attachment figures. While this disorder is frequently associated with younger children, it is not uncommon among adolescents. There is some evidence to suggest that this disorder is more prevalent in lower socio-economic groups, and that it occurs most frequently in girls (Last et al. 1987).

The presentation of SAD varies with age. Younger children tend to express their anxiety through specific fears of harm coming to their attachment figures. The child might worry that a parent will be kidnapped, or attacked by a burglar. Adolescents, alternatively, frequently deny anxiety about separation; as a result diagnosis becomes more difficult. Among adolescents, separation anxiety is often expressed through school refusal and recurrent somatic complaints (Francis et al. 1987).

Behavioral interventions, psychodynamic psychotherapy, and pharmacotherapy have all been shown to be effective treatment interventions for SAD. Frequently, a multimodal approach (one that uses various interventions depending on the characteristics of the patient and the pathology involved) is indicated. Medication alone is not recommended (American Academy of Child and Adolescent Psychiatry 1997).

1.2 *Generalized Anxiety Disorder*

Previously referred to as overanxious disorder, generalized anxiety disorder (GAD) is characterized by excessive anxiety and worry. Adolescents who suffer from this disorder tend to worry about everything: their competence, their appearance, their health, even potential disasters such as tornados or nuclear war. This anxiety often causes significant impairment in social and school functioning. Other manifestations such as sleep disturbances and difficulty concentrating are common. Rates of GAD appear to be the same for boys and girls (Last et al. 1987).

The treatment of choice for GAD among adolescents is psychotherapy—including cognitive, psychodynamic, and family systems approaches. While some studies have shown symptom reduction following treatment with anti-anxiety medications (e.g., Kutcher et al. 1992), results have been equivocal with regard to the overall effectiveness of pharmacotherapy in treating GAD.

1.3 *Obsessive-compulsive Disorder*

Obsessive-compulsive disorder (OCD) is characterized by recurrent obsessions and/or compulsions of sufficient severity to significantly disrupt an individual's day-to-day functioning. Common obsessions include themes of contamination, of harming others whom one cares about, and of inappropriate sexual urges. Common compulsions (which often serve to ameliorate the anxiety brought about by obsessive thoughts) include the repeated washing of hands, counting tiles on a floor or ceiling, and checking to make sure that a door is locked. One need not have both obsessions and compulsions in order to receive a diagnosis of OCD. The disorder is more common among girls than boys.

OCD frequently goes undiagnosed among adolescents (Flament et al. 1988). This is particularly unfortunate given the fact that both cognitive-behavioral therapy and pharmacotherapy have been shown to be effective in treating the disorder (American Academy of Child and Adolescent Psychiatry 1999). While psychodynamic psychotherapy can be useful in helping an adolescent deal with the effects of the disorder on his or her life, it has not been shown to be effective in treating the disorder itself.

1.4 *Social Phobia*

Adolescents with social phobia are more than just shy. Their fear of interacting with new persons, or of being embarrassed in a social situation, provokes such intense anxiety that they often avoid such situations altogether. It is not uncommon, for instance, for persons with social phobia to avoid eating in public, using public restrooms, or even writing in public. The anxiety associated with social phobia is often experienced somatically: racing pulse; profuse sweating; and lightheadedness are all physical manifestations associated with the disorder.

As with specific phobias, the treatment of choice for social phobia is behavior therapy. There is also some evidence to suggest that medications such as *Prozac* (Fluoxetine) may be effective in reducing the symptoms of social phobia among adolescents (Birmaher et al. 1994).

1.5 Panic Disorder

The essential feature of panic disorder is the presence of panic attacks, which involve the sudden, unexpected onset of symptoms such as palpitations, sweating, trembling, shortness of breath, and fears of 'going crazy.' Panic disorder usually first appears during adolescence, with an average age of onset of between 15 and 19 years (Von Korff et al. 1985). Panic disorder may or may not be accompanied by agoraphobia, the fear of being in places or situations from which escape might be difficult. Panic disorder with agoraphobia can be especially debilitating, as adolescents with this disorder may become virtual prisoners, afraid to leave their homes even to go to school.

Panic disorder appears to occur more frequently in girls than in boys (Whitaker et al. 1990). Children who carry an earlier diagnosis of separation anxiety disorder are at increased risk of developing panic disorder (Biederman et al. 1993).

The treatment for panic disorder in adolescents is similar to that of panic disorder in adults: cognitive and behavioral therapy, and pharmacotherapy. Unfortunately, these treatments have not been well researched in adolescent populations, and clinicians are often forced to extrapolate from studies that have been conducted on adults.

2. Mood Disorders

As the name suggests, the essential feature of a mood disorder is a disturbance in mood. Mood disorders may involve depressed mood, elevated mood, or both. While normal fluctuations in mood are a regular occurrence for all of us, when an individual's ability to function is hindered by prolonged periods of depressed or elevated mood, he or she may be suffering from a mood disorder.

Many people hold the misperception that adolescence is inevitably a time of great emotional turmoil. Research has demonstrated that this is not the case (e.g., Offer and Schonert-Reichl 1992). In fact, when an adolescent experiences prolonged periods of 'moodiness,' he or she may in fact be suffering from a mood disorder. The most common mood disorders of adolescence are *major depressive disorder* and the *bipolar disorders*.

2.1 Major Depressive Disorder

The essential feature of major depressive disorder (MDD) in adolescents is a period lasting at least two weeks during which there is either depressed or irritable mood or a loss of interest or pleasure in nearly all activities. Changes in sleep and/or appetite, decreased energy, and feelings of worthlessness and guilt are also often present. Suicidal thoughts, plans, and attempts are not uncommon.

Table 1
US suicide rates[a] by race and sex for 15–19 year-olds, 1994–97

Race		1997	1996	1995	1994
White	M	15.97	16.27	18.17	18.43

a Per 100,000.

Rates of depressed mood and clinical depression rise significantly during adolescence. By middle to late adolescence, rates of MDD approach those seen in adult populations. Depression is much more likely to occur in girls than boys—one study found that among 14–16 year-olds, girls with depression outnumbered boys by a ratio of 5:1 (Kashani et al. 1987). Such figures may overestimate actual gender differences in adolescent depression, however, because depressed boys are more likely than girls to express their depression by demonstrating behavior problems.

Cognitive-behavioral therapy, psychodynamic psychotherapy, family therapy, group therapy, and pharmacotherapy are all used to treat adolescent depression. Unfortunately, outcome studies on the above treatments in adolescent populations are sparse, and caution is indicated in applying adult-based research findings to adolescent populations. Given the relatively high mortality rates associated with depression and suicide (Bell & Clark 1998), it is critical that clinicians identify adolescents with depression and make appropriate interventions in a timely manner.

With regard to adolescent suicide, it is troubling to note that rates of completed suicide within this age group in the United States tripled between 1950 and 2000 (Rosewater and Burr 1998). However, the most recent statistics available suggest that this trend may have reversed itself (see Table 1). Major risk factors for adolescent suicide include psychiatric illness—especially the presence of a mood disorder—and substance abuse. Efforts to prevent adolescent suicide include school-based programs and teacher training to identify at risk youth.

2.2 Bipolar Disorders

There are two major bipolar disorders: bipolar I disorder and bipolar II disorder. Both disorders involve the presence of mania. Mania is defined as a period of abnormally elevated, expansive, or irritable mood. When an individual experiences mania in its severest form, called a manic episode, he or she usually requires psychiatric hospitalization. In its less severe

form, referred to as a hypomanic episode, functioning is impaired, but not to such an extent that a hospitalization is necessitated. Bipolar I disorder requires the existence of a manic episode, and bipolar II disorder requires the existence of a hypomanic episode as well as a major depressive episode.

Bipolar disorders in adolescents are much less common than the other mood disorders. While there is some evidence to suggest that bipolar disorders occur more frequently in girls than in boys (e.g., Krasa and Tolbert 1994), other studies have failed to replicate these findings.

A multimodal approach, incorporating psychosocial and psychoeducational interventions as well pharmacological ones, is the treatment of choice for adolescent bipolar disorder. Persons with bipolar disorders frequently have high rates of noncompliance with treatment, perhaps because they miss the 'high' associated with periods of mania. As a result, relapse prevention (including family involvement with treatment and frequent follow-ups) is a crucial aspect of treating bipolar disorder in adolescents.

3. *Eating Disorders*

Many people 'watch their weight,' and adolescents (primarily adolescent girls) are no different. In fact, adolescents are particularly concerned about appearance and acceptance; as a result they are especially affected by societal pressures to be thin. When a healthy awareness of one's ideal weight gives way to excessive measures in order to lose weight and keep it off, one is at risk of acquiring an eating disorder. There are two primary eating disorders: *anorexia nervosa* and *bulimia nervosa*.

3.1 *Anorexia Nervosa*

The essential features of anorexia nervosa include a distorted body image, an intense fear of gaining weight, and a refusal to maintain a minimally normal body weight. Postmenarchal women with this disorder are often amenorrheic (they stop having regular menstrual periods). Up to 95 percent of patients with anorexia nervosa are females who tend to be both white and middle to upper-middle class (Herzog and Beresin 1997).

If treated soon after onset, anorexia nervosa in adolescents has a relatively good prognosis. However, if not treated it may become a chronic condition that carries with it serious and even life-threatening consequences. Treatment approaches for this disorder include behavioral modification techniques, family therapy, and pharmacotherapy. Insight-oriented psychotherapy can be useful, but not during acute phases. In severe cases, psychiatric and medical hospitalizations are often required.

3.2 *Bulimia Nervosa*

Persons suffering from bulimia nervosa alternate binge eating with purging (vomiting, use of laxatives). As with anorexia nervosa, bulimia nervosa primarily affects females (9 out of 10 sufferers are women). Treatment of bulimia nervosa among adolescents differs from that of anorexia nervosa primarily in that the former rarely requires hospitalization.

4. *Psychotic Disorders*

Psychotic disorders are among the most devastating psychiatric illnesses. They involve a disturbance in an individual's ability to perceive the world as others do. Persons suffering from psychotic disorders may experience auditory hallucinations ('hearing voices'), delusions, and disordered thinking, among other symptoms.

Psychotic disorders are rare among adolescents, but they can and do occur in this age group. The most common psychotic disorder seen in adolescent patients is *schizophrenia*.

4.1 *Schizophrenia*

Schizophrenia involves what are referred to as 'positive' and 'negative' symptoms. Positive symptoms include hallucinations, delusions, and disorganized thinking. Negative symptoms include diminished emotional expressiveness, decreased productivity of thought and speech, and difficulty initiating goal-directed behaviors. As a result of these symptoms, adolescents with schizophrenia have a great deal of difficulty functioning in the world. Their personal hygiene may deteriorate, their ability to perform in school may decrease, and their relationships with other people may suffer.

Initial symptoms of schizophrenia in adolescents may appear rapidly or slowly. There is some evidence to suggest that a slow onset is associated with a worse prognosis. The disorder occurs more frequently in boys than girls before the age of 14. As mentioned previously, adolescent schizophrenia is rare, with only 4 percent of adult schizophrenics having developed the disorder before the age of 15 (Tolbert 1996).

The recent introduction of new antipsychotic medications has greatly changed the way schizophrenia is treated. While by no means a cure-all, these drugs provide many schizophrenics with relief from their symptoms without sedating them to such an extent that they are unable to function. Furthermore, thanks largely to these medications, persons with schizophrenia require fewer hospitalizations than they once did, and are often able to lead productive lives. Nevertheless, schizophrenia is more often than not a chronic condition that requires intensive treatment in order to keep its symptoms under control. In addition

to medication, supportive individual and group psychotherapy are important components of treating schizophrenia.

5. Disruptive Behavior Disorders

When adolescents are disruptive, their behavior tends to attract the attention of their parents and teachers. As a result, disruptive behavior disorders (DBDs) are a common reason for referral to child and adolescent psychiatrists. The essential features of DBDs are aggression, poor self-regulation, and excessive opposition to authority. The most common DBDs in adolescents are: *attention-deficit hyperactivity disorder*; *conduct disorder*; and *oppositional defiant disorder*.

5.1 Attention-deficit Hyperactivity Disorder

Attention-deficit hyperactivity disorder (ADHD) involves a chronic pattern of distractibility and hyperactivity or impulsivity that causes significant impairment in functioning. The presentation of this disorder varies with age. For instance, whereas younger children with ADHD may display more overt signs of agitation, adolescents may experience an internal feeling of restlessness. Other signs of adolescent ADHD include an inability to complete independent academic work and a propensity toward risky behaviors (automobile and bicycle accidents are not uncommon among adolescents with ADHD).

ADHD is a highly prevalent disorder. Some have estimated that it may account for as much as 50 percent of the patients in child psychiatry clinic populations (Cantwell 1996). Prevalence of the disorder appears to peak during late childhood/early adolescence.

The treatment strategy of choice for adolescent ADHD is a multimodal approach that incorporates psychosocial interventions with pharmacotherapy. Parent management training, school-focused interventions, and individual therapy are all important elements of such an approach. Additionally, central nervous system stimulants have proven effective in treating the symptoms of ADHD, with response rates exceeding 70 percent (Cantwell 1996).

5.2 Conduct Disorder

The essential feature of conduct disorder (CD) is a persistent pattern of violating the rights of others and disregarding societal norms. Common behavior associated with CD include aggressive or violent conduct, theft, and vandalism.

CD is one of the most prevalent forms of psychopathology in adolescents, and it is the single most common reason for referrals of adolescents for psychiatric evaluations. As with ADHD, boys with CD outnumber girls with the disorder. This gender gap becomes less pronounced toward late adolescence.

Table 2
US homicide rates[a] by race and sex for 15–19 year-olds, 1994–97

Race		1997	1996	1995	1994
White	M	10.92	12.07	14.30	14.98
	F	2.87	2,92	3.91	3.43

a Per 100,000.

The most effective treatments for CD are family interventions and psychosocial interventions (such as problem-solving skills training). Preventative measures aimed at reducing levels of CD have shown promise, but more research is needed before their effectiveness can be fully assessed (Offord and Bennett 1994).

5.3 Oppositional Defiant Disorder

When adolescent defiance toward authority figures becomes excessive and out of control, it may in fact represent a syndrome called oppositional defiant disorder (ODD). This disorder involves persistently negativistic and hostile attitudes toward those in authority, as well as spiteful, vindictive, and generally defiant behavior. In order to qualify for a diagnosis of ODD, an adolescent's behavior must clearly be excessive in comparison with that which is typically observed in his or her peers.

Treatment for ODD is similar to that for CD, utilizing a multimodal approach that emphasizes both individual and family therapy as well as psychosocial interventions.

Diagnoses of CD and ODD are frequently associated with juvenile delinquency. As a result, a high percentage of adolescents with these disorders find themselves involved with the criminal justice system. Yet as the emphasis in the American criminal justice system shifts from rehabilitation to punishment, fewer and fewer inmates receive the mental health services that they need. This is particularly unfortunate, because a number of programs aimed at reducing juvenile delinquency have been demonstrated to be effective in doing so (Zigler et al. 1992).

As the number of incarcerated juveniles increases, so do the number of crimes committed by adolescents. The overall level of arrests for juveniles in 1996, for instance, was 60 percent higher than it was in 1987 (Snyder 1997). However, as with adolescent suicide, the number of adolescent homicides in the United States has declined since then (see Table 2).

6. Substance Use Disorders

In recent years, there has been an increased effort on the part of many governments to curb adolescent substance use and abuse. The results of such efforts have been mixed. Alcohol is currently the most widely used psychoactive substance among adolescents, with marijuana being a close second.

There are many treatment philosophies when it comes to adolescent substance abuse. Inpatient programs, outpatient programs, and residential treatment centers have all been shown to be effective methods of treating substance use disorders. Recently, a greater emphasis has been placed on preventative measures, including school-based programs aimed at educating students on the dangers of substance abuse. However, the effectiveness of such programs has yet to be adequately demonstrated.

7. Summary

In this article we reviewed six areas of adolescent psychopathology: anxiety disorders; mood disorders; eating disorders; psychotic disorders; disruptive behavior disorders; and substance use disorders. We looked at the major diagnoses in each category, focusing on definitions, etiology, and treatment. In the bibliography, we indicate those readings that are recommended to those wishing to learn more about the topics covered

Adolescence, Sociology of

Adolescence, as a stage in the life course, was not invented during the early decades of the twentieth century, as is sometimes suggested by cultural historians. It was, however, identified and institutionalized during the period when many Western societies were shifting from primarily agrarian to predominantly industrial economies. The extension of schooling and the emergence of a high paying labor market, accompanied by the disappearance of employment opportunities for youth, all contributed importantly to create a more distinct phase between childhood and adulthood—a period when parental control was relinquished and peer influence became more prominent. Prior to the twentieth century, youth remained an ambiguous and ill-defined period including children and teenagers or even young adults who remained semidependent well into adulthood.

1. The Discovery of Adolescence

The 'discovery' of adolescence does not imply that youths had not always experienced some of the features of adolescence—desiring greater autonomy, becoming more sensitive to peer influence, or questioning adult authority and limits. Moreover, puberty obviously has always occurred, with its potentially unsettling effects. From all accounts, teenagers and young adults before the twentieth century could be disruptive and, on occasion, threatening to the social order (Shorter et al. 1971, Kett 1977). However, the period of adolescence was not universally noted until after G. Stanley Hall popularized the term, helping to draw professional and public attention to this part of the lifespan. No doubt, too, the creation of developmental science in psychology, sociology, and anthropology helped to establish expectations, norms, and social understanding.

The idea that adolescence is especially problematic was presumed by Hall and his followers. Adolescence, Hall argued, has its source in the disjuncture of biology and culture. The asynchrony of physical development and social maturation introduces the cultural dilemma of managing youths who are physically but not socially adults. Relegated to a social category in which they are treated neither as children or adults, adolescents are inclined to turn away from the adult world, at least temporarily, and regard age peers as their natural allies. At the same time, in modern economies, parental oversight inevitably declines as the family relies increasingly on outside institutions, most notably the school and community. This process reinforces the power of peers, as youths are socially channeled into settings and institutions that generally do not afford the same level of social control provided inside the familial household.

Hall's hypotheses surely overstated what had occurred, but it brilliantly foreshadowed processes that came about in later decades. Moreover, the cultural construct of adolescence immediately took root in US society, where it became almost an ideology that helped to bring about the phenomenon of adolescence itself. In a society that already revered personal initiative and self-direction, it is easy to see why the US teenager emerged from the wings. This social category seemed almost culturally inevitable and developmentally imperative. Much of developmentally oriented social science merely reframed or institutionalized what was, to some extent, already familiar practice. Youths had always been granted some leeway to 'sow their wild oats' in rural communities. In both urban areas and rural communities, youths had long been apprenticed or boarded out. This was undoubtedly a time-honored way of managing difficult and economically unproductive children by sending them to the households of kin or neighbors for moral education as well as economic training (Morgan et al. 1993).

Adolescence as a life stage was more actively embraced in the USA and other Anglophone nations than in Continental Europe, where parental and community controls remain relatively high. Yet in Europe, too, the cultural construct of adolescence has taken hold to some extent. Differences in the salience of this age category across nations reveal the degree to

which adolescence has cultural, social, and political dimensions that are at least as important as the economic sources to which greater attention has been shown in social science research and discussions (Bachman et al. 1978).

Although 'discovered' in the first decade of the twentieth century, the study of adolescence did not take firm root until the middle part of the century, when legions of social scientists began to focus on the problematic features of this life stage in Western nations. Work in psychology by Karl Mannheim, Charlotte Buhler, Kurt Lewin, Roger Barker, and Gardner Murphy; in sociology by W. I. Thomas, Robert Lynd, Helen Lynd, and Willard Waller; and, in anthropology by Ruth Benedict and Margaret Mead, to mention but a few of the luminaries, helped to establish adolescence and early adulthood as a legitimate field of cross-disciplinary research in the second third of the century.

In the aftermath of World War II, however, a widespread estrangement occurred between European traditions of research (which were diminished for two or three decades after the war) and US social science. In the USA, fields of study became more specialized by discipline. This specialization is evident in the withdrawal of cultural anthropology from the examination of postindustrial societies, the narrowing of psychology to cognitive and often acontextual studies, and the limited attention given to the biological and psychological features of human development by sociologists. There were important exceptions such as the monumental program of research by Urie Bronfenbrenner and his students, the seminal writing of Erik Erikson that continued to focus on cross-cultural differences, and several classic field studies in sociology by Hollinghead and Redlick, Eaton and Weil, and Coleman in the middle decades of the twentieth century. But all of these writers bucked a trend toward disciplinary segregation that continued at least until the 1990s.

While specialization is likely to continue, efforts at international and disciplinary integration occurred in the latter decades of the twentieth century. The formation of cross-national collaborations and societies began to spring up in Europe and the USA. More and more, theory and research practice dictates against exclusive treatments by particular disciplines and demands a more holistic treatment that examines development in multiple contexts, using multiple methods including cross-national comparisons, ethnography, and historical research.

2. *The Demography of Adolescence*

In many respects, the history of adolescence reflects and responds to demographic changes that occurred during the twentieth century. Until the twentieth century, youths made a prolonged and often ill-coordinated transition from childhood to adulthood. Labor began early and independence was often delayed, depending on opportunities as much as skills. Accordingly, youths frequently resided with their parents or boarded with employers. Establishing one's own household often occurred after marriage, which itself was delayed by economic considerations and controlled to some extent by family interests.

In the twentieth century, the growth of industrial jobs liberated youths from kinship control and gradually created a labor market shaped by economic needs and demand for skills. Educational training became more necessary and parental influence became more indirect; it was achieved through parents' investment in schooling. The two world wars also lessened parental influence by exposing legions of young men to the authority of the state. In the USA, the benefits granted to veterans allowed large numbers of men to marry earlier than they otherwise might. This helped to spark the 'marriage rush' in the middle of the century that preceded the 'baby boom.' In a matter of two decades, the period between childhood and adulthood contracted dramatically. Youths married and formed families earlier than they ever had before. The time between schooling, leaving the parental household, and establishing one's own family shrank by several years in most Western countries from the 1940s to the 1960s. A widely read book in the USA declared that adolescence was vanishing (Friedenberg 1964). Social institutions, most notably the high school, co-opted youth, discouraging dissent and thwarting individual development. Youths were being 'oversocialized,' and prematurely inducted into adult society. The problem with adolescents in the 1950s was that there was not enough adolescence.

This idea quickly disappeared in the 1960s as the huge baby boom cohorts in all Western countries entered their teens. At the same time, the price of entering adulthood grew as the labor market began to require higher skills and jobs growth slowed. The growing need for credentials and the economic slowdown swelled the ranks of high schools and colleges, creating a heightened age-consciousness that was reflected in a growing youth culture. Commercialization and the expansion of media channels directed toward youth helped to shape a popular culture that divided youths from adults. Finally, the Vietnam War had a huge effect on both the culture and social identity of teenagers and young adults. Youth was prolonged and politicized in the late 1960s and early 1970s.

The rapid slowdown of Western economies in the 1970s and 1980s might have been expected to continue to the trend toward greater age-oriented political consciousness, but this did not occur. The end of the Vietnam War and the public reaction to the cultural era of the 1960s seemed to put an end to politically oriented youth culture. The aging baby boomers began to become more conservative as they entered the labor force and began to form families.

At the same time, youthful behavior was perceived to be increasingly problematic in the 1970s and 1980s. Concerns about idleness, nonmarital childbearing, crime, substance abuse, and mental health among adolescents and young adults increased during this period as social scientists, politicians, and the public discovered new arenas in which to make adolescence more problematic. It is not clear from available data whether actual behavioral trends reflect the growing public concern about problem behavior. From all available evidence, it appears that few linear trends in problem behavior can be detected from data sources. Certain manifestations of problems, such as delinquency or suicide, have increased and then fallen off. Moreover, these trends rarely are reproduced in all Western nations during the same time or in the same form. Therefore, it seems highly unlikely that there has been a steady increase in problem behaviors or a decrease in prosocial behavior in any country, much less throughout the West.

Public concern about youth, on the other hand, does appear to be steadily rising, at least judging from data in the USA. There is a growing perception that children and adolescents are being less well cared for and accordingly exhibiting more problems entering adulthood. Again, it is not at all evident that youths are any less committed to mainstream notions of success, or any less capable of or prepared for achieving adulthood than they were in earlier times. It is obvious, however, that the entrance to adulthood is coming later than ever before, if we mean by that the conjunction of leaving the parental household, entering the labor force, and establishing a family. In many countries, these status transitions are occurring later than they did a century ago and much later than at the middle of the twentieth century. Sociologically, adolescence has been extended well into the twenties, or it could be said that we are witnessing the reemergence of the period of semiautonomy that was common a century or more ago.

This has important economic, social, and psychological implications for the development of adolescents and young adults. Youths are more dependent on elders for economic support while simultaneous claims in support of the aging baby boom cohorts are being made. The extension of life, along with the unusually large size of the population at midlife and beyond, is straining both public and private resources and is likely to increase in the future. The possibility of generational conflict over resources is also bound to increase as societies face the difficulty of choosing to invest in increasing youth productivity or allocating resources to the care of the elderly.

Socially, the lengthening period of dependency has consequences for how much youths are willing or permitted to invest in the larger society. Youths not integrated, incorporated, or involved may lead to political and social alienation. The role of youth is focused more on consumption than production. Participation of young adults in society may shift to playing a symbolic role in the media rather than actually performing in arenas of social power. Thus, young people are visible (indeed overrepresented) in media portrayals and underrepresented in the labor force or in political bodies. This delay could have consequences on social commitments such as forming lasting bonds with a partner, having children, or engaging in civic activities such as voting or political activity.

Finally, the nature and quality of psychological maturation must change as individuals linger in the state of semiautonomy for longer periods. With youths either dependent on their families or society for social support, formation of selfhood becomes prolonged. One might expect adolescents and young adults to take on a more fluid and impermanent sense of identity. This has advantages for a job world in which flexibility and mobility are required, but it is likely to have some fallout for establishing relationships. Cohabitation permits and promotes flux in interpersonal commitments as individuals resist settling down until they are sure of who they are. But in withholding commitments, it becomes increasingly difficult to resolve the problem of identity. Thus, identity becomes a lifelong project rather than a stage of development that is more or less established by the entrance to adulthood.

If the end of adolescence has been delayed, its beginning has gradually moved up into the preteen years. The earlier onset of adolescence seems paradoxical, especially as most Western nations have given greater importance in the twentieth century to protecting children from the harsh realities of the workplace, sexual exploitation, and abuse from families. Viviana Zelizer describes this as the 'priceless child' phenomenon—the movement of children from precocious involvement in economic roles to a greater emphasis on emotional development and psychological investment by parents (Zelizer 1985).

Yet adolescence itself has become earlier, judging from the behavior of younger teens and preteens. The onset of sexual behavior occurs several years earlier on average than it did in the 1950s, when most teenagers waited until after or just before getting married to initiate coitus. There are several ways of explaining this downward trend: earlier ages of puberty owing to better nutrition and higher living standards; later age at marriage, making it more difficult for young people to delay; lower social control, as teens are less subject to parental monitoring; availability of contraception, making it possible to prevent some of the untoward consequences of sexual experimentation; and greater tolerance for premarital sex, as chastity is less prized.

Sex is just one indicator of an earlier adolescence. Dress, demeanor, and media consumption are other signs that preteens have been given over to expressions of adolescence. The tastes of preteens may be different from older teens, but they are surely even more

different from their parents. How has this come about even when parents are increasingly concerned about the corruption of their children's tastes and sensibilities?

Obviously, the commercialization of the media has played a part in cultivating younger audiences into market groups. The number of media outlets has grown, along with the marketing skills to identify and reinforce tastes and practices. The rise of computer literacy, no doubt, contributes to the growing sophistication of children in their preteens about features of the social world that were previously inaccessible to them. Another source of influence may be the schools and related agencies, such as the health care system and juvenile justice system, which have increasingly classified preteenagers into institutions for adolescents. In the USA, the growth of the middle school provides just such a case of grouping preteens with younger teenagers. This may well have fostered an earlier development of 'adolescence,' by which children sense that they should behave more autonomously. Finally, parents are ambivalent about these forces that have created an earlier adolescence for their children. While protective of their children's innocence, they are sensitive to the cultural cues that promote earlier development and generally are unprepared to resist the forces outside the family that foster early development. Indeed, many parents are encouraging of these forces because they do not want to see their children left behind. Earlier adolescence might be thought of as partly emanating from biology and partly from social systems governed by age-graded cultural and social norms that are malleable and adaptive to current conditions.

Not enough attention has been devoted to how such norms are influenced by public policies and private responses. The ways that adolescence interprets and responds to social and cultural signals is a frontier area for future researchers. How policies at the family, school, community, and societal level are instantiated in everyday practice is a promising topic for further research. Similarly, we need to examine how developmental processes themselves affect the reading of these social cues. For example, the ways in which younger and older adolescents interpret legal and social sanctions is a topic of great importance, especially in the USA, where legislators are putting into practice criminal statutes affecting increasingly younger children. Similarly, age of consent, labor laws regulating youth employment, political participation, and a number of other rules governing the timing of adultlike activities rest on developmental assumptions that have not been widely investigated.

Adolescent Behavior: Demographic

1. From Standard Biography to Choice Biography

During young adulthood, young men and women are confronted with various life transitions and have to make decisions about their future. How long will they continue in full-time education, when will they look for a job, or will they combine work with schooling? Will they seek a partner, or choose to remain single? What are their attitudes towards starting a family of their own? This period in life is generally regarded as a first step towards adulthood in that it incorporates a move from dependence towards independence, in both financial and emotional terms as well as in terms of a young adult's social life. As such, it is an important life-course phase because each transition changes and determines the young adult's position within society.

Each society is characterized by a different set of normative life-course models which vary according to the gender and social background of the individuals living within that society. Individual life courses tend to mirror these socially established patterns to a certain extent, despite the fact that these patterns often include a considerable margin for individual choice. Some of the status passages are considered as desirable, others are considered risky and undesirable (Levy 1997). At the beginning of the twentieth century, many young adults had a limited range of behavioral options. For example, most young men and women left the parental home to marry. A smaller proportion left the parental home to take up employment. The timing of home leaving varied much more widely than it does today (Liefbroer and de Jong Gierveld 1995) and was influenced by parental encouragement or discouragement and prevailing family obligations and employment opportunities. Some adult children remained in the parental home, either because they were needed as caregivers or because they were designated as heirs to the family's land and property. The type of household these young adults started and the potential level of their household income were inextricably linked with the options that their paternal background provided. A young man born into a family of servants stood a strong chance of becoming a servant himself. Compared with their peers who lived at the beginning of the twentieth century, young adults born in the second half of the twentieth century had a much broader range of options and considerable freedom to choose the pattern and timing of their life transitions.

Sociologists summarize these developments by the opposing concepts of 'standard biography' (leaving home, followed by marriage, followed by childbirth) and 'choice biography' (the sequencing of transitions based on personal choice: e.g., leaving home, living alone, returning home, leaving home a second time, unmarried cohabitation, and marriage). Personal choice has become more or less obligatory (Giddens 1994).

2. Leaving the Parental Home; Changing Patterns of Determinants

Leaving home, the first of the young adult's transitions, is to be considered as a migratory movement triggered by other parallel life course careers (Mulder 1993). The most important parallel careers are union formation (marriage or unmarried cohabitation), higher education, and a change of work. An examination of home-leaving trends and determinants must therefore take account of young adults' preferences and behavioral patterns as regards these parallel careers.

The second half of the twentieth century witnessed profound sociostructural and cultural changes that influenced the parallel careers and home-leaving behavior of young adults. These changes included an improvement in the standard of living, a rise in educational levels and female labor force participation, the increasing equality of men and women, a decline in traditional and religious authority—including a slackening of parental supervision over the behavior of young adults—and the diffusion of individualization (Buchmann 1989, Lesthaeghe and Surkyn 1988, Liefbroer 1999, Van de Kaa 1987). As a result of these developments, young men and women increasingly prefer to have a period in life characterized by independence and the postponement of decisions that entail strong commitments (Mulder and Manting 1994). Union formation in general and marriage in particular, as well as parenthood, are decisions that are frequently postponed.

3. Leaving the Parental Home; Facts and Figures

Table 1 provides data on home leaving in selected European countries and in the US. The data were taken from the Family and Fertility Survey conducted in many countries under the auspices of the UN Economic Commission for Europe. The surveys used the same questionnaire modules in order to obtain the best possible comparability. The data used in this contribution relate to two birth cohorts: one from the early 1950s and one from the early 1960s. Data on later birth cohorts are incomplete as far as home leaving is concerned.

3.1 Leaving the Parental Home for the Purpose of Union Formation

Table 1 provides information about the reasons for leaving the parental home. In Spain, Italy, Portugal,

Within brackets the percentages of young adults who had left home by the time of the FFS interview. b Median age in years. c No data available.

Belgium (Flanders), Poland, the Czech Republic, and Hungary, marriage was by far the most important reason why birth cohorts of the early 1950s left home. For cohorts born in the early 1960s, leaving home to marry was still the most dominant reason in Spain, Italy, Belgium (Flanders), Poland, and the Czech Republic, as well as, to a lesser extent, Portugal and Hungary. However, the percentage of home leavers born in the early 1960s in these countries who went on to marry decreased considerably compared with those born in the early 1950s. Marriage as a motive for leaving home decreased in *all* of the selected countries in northern, western, and southern Europe and in the US. The pattern for the Eastern European countries was more diverse. For example, the pattern in Hungary, the Czech Republic, and Slovenia, which were characterized by a decrease in marriage as a reason for leaving home, differed from that in Poland, Latvia, and Lithuania.

The decrease in marriage was coupled with an increase in unmarried cohabitation as a reason for leaving home in several countries, as can be seen by comparing columns in Table 1. This was very apparent in Finland and France, where more than 30 percent of the 1960–4 birth cohort combined leaving home with embarking on unmarried cohabitation. A comparison of the cohorts born in the early 1950s and early 1960s reveals that unmarried cohabitation cannot compensate in all countries for the declining importance of marriage. Union formation in general was a less important reason for leaving home for the birth cohorts of the early 1960s than those of the early 1950s in France, Belgium (Flanders), the Netherlands, Italy, Spain, and the US. In the northern European countries, however, the percentage of young adults leaving home for union formation was already low in the early 1950s, and continued to be low in the early 1960s. In some Central European countries leaving home for union formation increased. So, differences between regions mirror the ideas of the second demographic transition.

3.2 Leaving the Parental Home for Other Reasons

The percentage of young adults leaving the parental home to pursue postsecondary education in conjunction with living alone is increasing all over Europe. This in turn has led to a lowering of the home-leaving age.

Nowadays, leaving home to achieve personal freedom and independence—another current trend—is more apparent among young home leavers who do not wish to pursue postsecondary education. Most of them are (wholly or partly) financially independent due to their participation in the labor market. Young adults with a job leave home at a younger age than the unemployed (Cordón 1997).

Today, as in the past, some young adults leave the parental home at a fairly young age in order to extricate themselves from a difficult domestic situation, such as an unstable family structure (a stepfamily or one-parent family), or after the death of a parent (Goldscheider and Goldscheider 1998). Other 'negative' reasons for leaving home include friction with parents due to the parents' low income, or the unemployment of the child (Berrington and Murphy 1994).

Baanders (1998) emphasizes that the normative pressure exerted by the parents in terms of encouraging or discouraging young adults to leave the parental home is an important factor behind young adults' intentions, even among recent cohorts. Whether or not young adults are able to realize their preferences and intentions to leave will depend partly on their own resources (a job, income, or a partner able to provide these prerequisites), but also on the resources provided by the parents. In this context Goldscheider and DaVanzo (1989) distinguished between parents' location-specific resources (the number of siblings and the time the mother spends at home), and parents' transferable resources (income). De Jong Gierveld et al. (1991) expanded on this conceptual framework by distinguishing between the material and nonmaterial resources of the parents. The cross-tabulation of these two dimensions gives rise to four types of parental support that encourage young adults either to leave or to prolong their stay in the parental home.

3.3 Timing of Home Leaving

The reasons that trigger home leaving affect the timing of leaving home in various, and sometimes conflicting, ways. Mulder (1993) examined the trend towards postponement of home leaving for the purpose of union formation, concluding that there was an 'individualization effect' behind this trend accompanied by an additional (temporary) effect caused by unfavorable economic conditions that made it difficult to find affordable housing. The trend towards increasing participation in post-secondary education is proving to be a catalyst for young adults to leave home at relatively early ages. Leaving home to seek independence and live alone is becoming characteristic of young adults in more and more western and northern European countries, and this, too, is decreasing the age at home leaving.

The last two columns of Table 1 provide information about the timing of leaving home. In most of the northern and western European countries, the median age at leaving the parental home for cohorts born in the early 1950s and early 1960s is between 19 and 22 for young women, and between 20 and 24 for young men. Table 1 also indicates that in some European countries the end-result of both trends (postponing and bringing forward home leaving) is a stabilization of the median ages at home leaving for

the birth cohorts of the early 1950s and early 1960s (Mulder and Hooimeijer 1999).

A comparison of the cohorts born in the 1950s and 1960s shows that median ages at home leaving in Poland, Latvia, and Lithuania increased. More research is needed to gain insight into the mechanisms behind this trend.

In the southern European countries, median ages at leaving home were 22.5 years and over for young women, and ranged between 24.8 and 27.5 years for young men. In the southern European countries the overall trend was towards a rise in the age at home leaving, particularly among men. This trend is related to a persistence of traditional patterns, a fact which is borne out by the virtual absence of living alone and unmarried cohabitation among young adults. This southern European situation was analyzed in-depth in a special issue of the journal *Family Issues* (1997, pp. 18, 6), which stated that young adults in Italy and Spain prefer to lengthen the period of young adulthood through longer co-residence in the parental home. Some authors describe this period as a 'chronological stretching' of young adulthood (Rossi 1997).

4. *Successful Home Leaving and Returning?*

The growing acceptance of a reversal of former lifestyle decisions is one of the current life-course patterns. Returning home after leaving the parental home is one of these. Reasons to return include separation and divorce. The percentage of young adults who return to the parental home after leaving is high among those who left home at very young ages, and who left to start a non-family household (White and Lacy 1997). According to Zinnecker et al. (1996), about one in five young adults in the former West Germany—aged between 23 and 29—who currently live in the parental home can be characterized as returnees. Some authors attribute this to the disorderliness of the transitional period of young adulthood. Others contend that, by trying so hard to effect their own personal choices, young adults often end up making decisions that resemble decisions made by other young adults.

Adolescent Development, Theories of

Adolescence, the second decade of the human life cycle, is a transitional period that bridges childhood and adulthood. Because the nature of the transition is multifaceted, writers interested in adolescence have, over the years, addressed many different aspects of development during this period, including biological development, cognitive development, emotional development, and social development. The purpose of this article is to provide brief summaries of the major theoretical viewpoints and highlight the central contributions each has made to understanding development during the adolescent decade.

1. *Views of Adolescence in History*

Although scientific theorizing about adolescence did not appear until the beginning of the twentieth century, philosophers and educators have written about this period of development for centuries. Early writings on the period pointed to the youthful energy and vitality of the teenage years, and often depicted adolescents as both enthusiastic and impulsive. From the beginning, adolescence has been portrayed as a period of potential difficulty, either for the young person, who was presumed to have difficulty coping with the challenges inherent in the transition to adulthood, or for adults, who were presumed to have difficulty in controlling and reining in the adolescent's energy and impulses. This notion—that adolescence is a potentially difficult period for adolescents and for those around them—is a recurrent theme throughout most theoretical writings on the period. Accordingly, much of what has been written about adolescence has a strong problem orientation, with theorists either attempting to explain why adolescence is as difficult as it is or offering accounts about how the period might be made less stressful and more pacific. Although this problem orientation is less pervasive today than was the case earlier in the twentieth century, the focus on adolescence as a time of difficulty persists in contemporary writings on this stage of development.

The multifaceted nature of adolescence—the fact that it has biological, psychological, and social components—has made the period the focus of attention to theorists from many different disciplines, including biology, psychology, sociology, history, and anthropology. Not surprisingly, theorists writing from different vantage points bring a variety of emphases to their discussion of the adolescent transition. Biologists and psychologists have emphasized the changing physical, intellectual, emotional, and social capabilities of the individual and have asked whether and in what ways individual functioning during adolescence differs from functioning during childhood or adulthood. Sociologists, anthropologists, and historians, in contrast, have focused on the transition of individuals into adult status and have posed questions about the nature of these changes in roles, rights, and responsibilities.

2. *Biological and Psychological Theories of Adolescence*

2.1 *G. Stanley Hall's Theory of Recapitulation*

Theorists who have taken a biological view of adolescence stress the hormonal and physical changes of puberty as driving forces that define the nature of the period. The most important theorist in this tradition was G. Stanley Hall (1904), considered the founder of the scientific study of adolescence. Hall, who was very much influenced by the work of Charles Darwin, the author of the theory of evolution, believed that the development of the individual paralleled the development of the human species, a notion referred to as his *theory of recapitulation*. Infancy, in his view, was equivalent to the time during human evolution when we were primitive, like animals. Adolescence, in contrast, was seen as a time that paralleled the evolution of our species into civilization. For Hall, the development of the individual through these stages was determined primarily by biological and genetic forces within the person, and hardly influenced by the environment.

The most important legacy of Hall's view of adolescence is the notion that adolescence is inevitably a period of *storm and stress*. He believed that the hormonal changes of puberty cause upheaval, both for the individual and for those around the young person. Because this turbulence was biologically determined, in Hall's view, it was unavoidable. The best that society could do was to find ways of managing the young person whose 'raging hormones' would invariably lead to difficulties. This, he believed, was analogous to the taming of the human species that occurred as civilization evolved.

Although most scientists no longer believe that adolescence is an inherently stressful period, the contemporary study of adolescence continues to emphasize the role that biological factors—hormonal changes, somatic changes, or changes in reproductive maturity—play in shaping the adolescent experience. Indeed, the study of the impact of puberty on adolescent psychosocial development has been, and continues to be, a central question for the field, with some theorists emphasizing the direct and immediate impact of puberty on adolescent psychological functioning, and others focusing on the timing of the adolescent's maturation relative to that of his or her peers.

2.2 Psychoanalytic Theories

In psychoanalytic theory, as in Hall's theory of recapitulation, adolescence is seen as an inherent time of upheaval triggered by the inevitable changes of puberty. According to Freud, the hormonal changes of puberty upset the psychic balance that had been achieved during the prior psychosexual stage, *latency*. Because the hormonal changes of puberty are responsible for marked increases in sexual drive, the adolescent was thought to be temporarily thrown into a period of intrapsychic crisis, and old psychosexual conflicts, long buried in the unconscious, were revived. Freud and his followers believed that the main challenge of adolescence was to restore a psychic balance and resolve these conflicts. Working through these conflicts was necessary, Freud believed, in order for the individual to move into what he described as the final and most mature stage of psychosexual development—the *genital stage*. It was not until this stage of development that individuals were capable of mature sexual relationships with romantic partners.

Freud's daughter, Anna Freud (1958), extended much of her father's thinking to the study of development during the second decade of life. Her most important work, entitled *Adolescence*, continued the tradition begun by Hall in casting adolescence as a time of unavoidable conflict and both intrapsychic and familial turmoil. According to her view, the revivification of early psychosexual conflicts, caused by the hormonal changes of puberty, motivated the adolescent to sever emotional ties to his or her parents and turn to peers as objects of sexual desire and emotional affection. She described adolescence as a period of 'normative disturbance' and argued that the oppositionalism and defiance many parents encountered in their teenagers was not only normal, but desirable. Indeed, Anna Freud believed that adolescents needed to break away from their parents in order to develop into healthy and mature adults, a process known as detachment.

Over time, psychoanalytic theories of adolescence came to place less emphasis on the process of detachment or the motivating role of puberty, and began to emphasize the psychological capacities that developed as the adolescent negotiated a path toward independence and adult maturity. Psychoanalytic theorists of adolescence in the second half of the twentieth century turned their attention away from the analysis of drives and focused instead on the skills and capabilities individuals developed in order to resolve inner conflicts and establish and maintain mature relationships with others, especially others outside the family. The three most important writers in this neoanalytic tradition are Peter Blos (1979), whose theory of adolescent development emphasizes the growth of emotional autonomy from parents, a process called individuation; Harry Stack Sullivan (1953), whose view of adolescence revolves around the young person's growing need and capacity for intimate, sexual relationships with peers; and Erik Erikson (1968), who focused on the adolescent's quest for a sense of identity. By far the most important of the three theorists has been Erik Erikson.

Erikson's theory of the life cycle proposed eight stages in psychosocial development, each characterized by a specific 'crisis' that arose at that point in development because of the interplay between the internal forces of biology and the unique demands of society. According to him, adolescence revolves around the crisis of *identity vs. identity diffusion*. The challenge of adolescence is to resolve the identity crisis successfully and to emerge from the period with a coherent sense of who one is and where one is headed. In order to do this, the adolescent needs time to experiment with different roles and personalities. Erikson believed that adolescents needed a period of time during which they were free from excessive responsibility—a psychosocial moratorium, as he described it—in order to develop a strong sense of identity. This vision of adolescence as a period during which individuals 'find themselves' through exploration and experimentation has been a longstanding theme in portrayals of adolescence in literature, film, and television. Indeed, Erikson's notion of the identity crisis is one of the most enduring ideas in the social sciences.

2.3 Cognitive-developmental Theories

In contrast to psychoanalytic and neoanalytic theorists, who emphasized emotional and social development during adolescence, cognitive-developmental theorists characterized adolescence in terms of the growth of intellectual capabilities. The most influential theorist in this regard has been Jean Piaget (Inhelder and Piaget 1958), whose theory of cognitive development dominated the study of intellectual growth—not only during adolescence, but during infancy and childhood as well—for most of the latter half of the twentieth century.

Piaget believed that, as individuals mature from infancy through adolescence, they pass through four stages of cognitive development, and that each stage is characterized by a type of thinking that is qualitatively distinct from that which characterized intellectual functioning in other stages. In Piaget's theory, adolescence marks the transition from the stage of concrete operations, during which logical reasoning is limited to what individuals can experience concretely, to the stage of *formal operations*, during which logical reasoning can be applied to both concrete and abstract phenomena. According to this theory, adolescence is the period during which individuals become fully capable of thinking in abstract and hypothetical terms, an achievement which engenders and permits a variety of new intellectual and social pursuits. The development of formal operational thinking in adolescence

has been posited to undergird adolescents' ability to grasp such diverse phenomena as algebra, scientific hypothesis testing, existential philosophy, satire, and principles of human motivation.

One well-known application of Piaget's theory to adolescent development is found in the work of Lawrence Kohlberg (1969). Like Piaget, Kohlberg believed that reasoning during adolescence is qualitatively different from reasoning during childhood. More specifically, Kohlberg believed that adolescents were capable of viewing moral problems in terms of underlying moral principles, like fairness or equity, instead of limiting their moral thinking to concrete rules and regulations. Similar applications of Piaget's work can be found in theories of adolescent decision-making, political thinking, interpersonal relationships, religious beliefs, and identity development.

3. *Sociological, Historical, and Anthropological Theories*

The emphasis within most biological and psychological theories of adolescence is mainly on forces within the individual, or within the individual's unique environment, in shaping his or her development and behavior. In contrast, sociological, historical, and anthropological theories of adolescence attempt to understand how adolescents, as a group, come of age in society and how coming of age varies across historical epochs and cultures.

3.1 *Sociological Theories*

Sociological theories of adolescence have often focused on relations between the generations and have tended to emphasize problems that young people sometimes have in making the transition from adolescence into adulthood, especially in industrialized society. Two themes have dominated these discussions. One theme, concerning the marginality of young people, emphasizes the difference in power that exists between the adult and the adolescent generations. Two important thinkers in this vein are Kurt Lewin (1951) and Edgar Friedenberg (1959), both of whom stressed the fact that adolescents were treated as 'second class citizens.' Contemporary applications of this viewpoint stress the fact that many adolescents are prohibited from occupying meaningful roles in society and therefore experience frustration, restlessness, and difficulty in making the transition into adult roles.

The other theme in sociological theories of adolescence concerns *intergenerational conflict*, or as it is more commonly known, 'the generation gap.' Theorists such as Karl Mannheim (1952) and James Coleman (1961) have focused not so much on the power differential between adults and adolescent, but the fact that adolescents and adults grow up under different social circumstances and therefore develop different sets of attitudes, values, and beliefs. This phenomenon is exacerbated by the pervasive use of *age-grading*—the separation of individuals on the basis of chronological age—within our social institutions, particularly schools. As a consequence of this age-segregation, there is inevitable tension between the adolescent and the adult generations. Some writers, like Coleman, have gone so far as to argue that adolescents develop a different cultural viewpoint—a 'counterculture'—that may be hostile to the values or beliefs of adult society.

Although sociological theories of adolescence clearly place emphasis on the broader context in which adolescents come of age, rather than on the biological events that define adolescence, there is still a theme of inevitability that runs through their approach. Mannheim, for example, believed that because modern society changes so rapidly, there will always be problems between generations because each cohort comes into adulthood with different experiences and beliefs. Similarly, Lewin believed that marginality is an inherent feature of adolescence because adults always control more resources and have more power than young people.

3.2 *Historical and Anthropological Theories*

Historians and anthropologists who study adolescence share with sociologists an interest in the broader context in which young people come of age, but they take a much more relativistic stance. Historical perspectives, such as those offered by Glen Elder (1974) or Joseph Kett (1977), stress the fact that adolescence as a developmental period has varied considerably from one historical era to another. As a consequence, it is impossible to generalize about such issues as the degree to which adolescence is stressful, the developmental tasks of the period, or the nature of intergenerational relations. Historians would say that these issues all depend on the social, political, and economic forces present at a given time. These forces may result in very different adolescent experiences for individuals who are members of different *cohorts*, or groups of people who come of age at a similar point in historical time. Even something as central to psychological theories of adolescence as Erikson's notion of the adolescent 'identity crisis,' historians argue, is a social invention that arose because of industrialization and the prolongation of schooling. They suggest that before the industrial revolution, when most adolescents followed in their parents' occupation, crises over identity did not exist, or were a privilege of the extremely affluent.

One group of theorists has taken this viewpoint to its logical extreme. These theorists, called inventionists, argue that adolescence is entirely a social invention (Bakan 1972). This position is in stark contrast to that adopted by the biological and psychological theorists discussed earlier, who view adolescence as a

biologically determined reality. Inventionists believe that the way in which we divide the life cycle into stages—drawing a boundary between childhood and adolescence, for example—is nothing more than a reflection of the political, economic, and social circumstances in which we live. They point out that, although puberty has been a feature of development for as long as humans have lived, it was not until the rise of compulsory education that we began treating adolescents as a special and distinct group. They also note that where we draw the line between adolescence and adulthood vacillates with political and economic vicissitudes. This suggests that social conditions, not biological givens, define the nature of adolescent development.

A similar theme is echoed by anthropologists who have written about adolescence, the most important of whom were Ruth Benedict (1934) and Margaret Mead (1928). Anthropologists have examined how different cultures structure the transition to adulthood and the nature and meaning of different sorts of *rites of passage*, the ceremonies used to mark the transition. Based on their cross-cultural observations of the transition into adulthood, Benedict and Mead concluded that societies vary considerably in the ways in which they view and structure adolescence. As a consequence, these thinkers viewed adolescence as a culturally defined experience—stressful and difficult in societies that saw it this way, but calm and peaceful in societies that had an alternative vision. Benedict, in particular, drew a distinction between continuous and discontinuous societies. In *continuous societies* (typically, nonindustrialized societies with little social change), the transition from adolescence to adulthood is gradual and peaceful. In *discontinuous societies* (typically, industrialized societies characterized by rapid social change), the transition into adulthood is abrupt and difficult.

4. Contemporary Status of Theories of Adolescence

Over time, the prominence of the 'grand' theories of adolescence discussed in this article has waned somewhat, as scholars of adolescence have oriented themselves more toward understanding very specific aspects of adolescent development and have become less interested in general, broad-brush accounts of the period. Today's scholars of adolescence are less likely to align themselves consistently with single theoretical viewpoints and more likely to borrow from multiple theories that may derive from very different disciplines. As such, contemporary views of adolescence attempt to integrate central concepts drawn from a wide range of biological, psychological, sociological, historical, and anthropological perspectives. The emphasis in these integrative and eclectic approaches has been on understanding the way in which the social context in which young people mature interacts with the biological and psychological influences on individual development.

Adolescent Health and Health Behaviors

1. Definition of Adolescent Health Behavior

The topic of adolescent health behavior comprises two related areas. One concerns behaviors that may create threats to health during adolescence; the other concerns behaviors that place individuals at increased risk for chronic diseases in adulthood that have behavioral

components (cardiovascular disease or cancer). Research on adolescent health behavior determines factors related to increased risk for maladaptive behaviors such as cigarette smoking (*risk factors*), and variables that decrease risk for these behaviors (*protective factors*) and also may operate to reduce the impact of risk factors (*buffering effects*). This article considers factors related to adolescents' substance use, sexual behavior, violence, and suicide risk (see *Health Behaviors*).

2. Intellectual Context

The study of adolescent health behavior arose from epidemiological research during the 1950s and 1960s, which demonstrated that mortality from chronic disease in adulthood, such as heart attack or cancer, was related to factors such as substance use, dietary patterns, and life stress. Combining these findings with results from studies on longitudinal tracking of behavioral and physiological risk factors gave recognition to the concept that risk status began to develop earlier. This concept suggested a focus on studying health-related behaviors and dispositions at younger ages (e.g., cigarette smoking, hostility) so as to indicate early preventive approaches that would result in better health status over the long term (see *Adolescent Development, Theories of*).

The focus of this article is guided by data on causes of mortality during adolescence and young adulthood. United States data for 1997 show that for persons 15–24 years of age the most common causes of mortality are: accidents (prevalence of 35.4 per 100,000 population), homicide (15.8), and suicide (11.3). These prevalences are much greater than rates of mortality from congenital and infectious diseases. The most common causes of mortality for persons 25–44 years of age are: accidents (30.5 per 100,000), malignant neoplasms (25.8), heart disease (18.9), suicide (14.4), AIDS (13.4), and homicide (9.9). Though the relative rates for different causes could vary across countries, these statistics draw attention to the fact that three causes (accidents, violence, and suicide) are leading causes of mortality during both adolescence and adulthood. Thus, inquiring into factors related to these outcomes is of primary importance for the study of adolescent health.

The conditions that place adolescents at risk for adverse outcomes span several domains. Substance use has been linked to all the major causes of mortality during adolescence, including accidents, violence, and suicide (Goreczny and Hersen 1999). Chronic emotional distress (including depression and anger) is implicated in risk for substance use and violence (Marlatt and VandenBos 1997). Unprotected sexual intercourse, a factor in adolescent pregnancy, HIV infection, and sexually transmitted diseases, is related to many of the factors that predict adolescent substance use (S. B. Friedman 1998). The chapter focuses on research relevant to these conditions, noting also that various risk behaviors tend to occur together (e.g., substance use and unprotected sex).

3. Dominant Theories and Changes in Emphasis Over Time

3.1 Early Theoretical Models

Work on adolescent health was based initially in *cognitive and attitudinal* approaches to prediction of behavior (see *Health Behavior: Psychosocial Theories*). The Health Belief Model, developed by Rosenstock and Becker, assumed health behavior to be a function of the perceived benefits of the behavior, the costs (health, social, or economic) associated with the behavior, and the perceived barriers to engaging in the behavior. This model was used sometimes to generate research strategies for maladaptive behaviors, but this did not work out too well, as knowledge measures typically failed to correlate with behavior and prevention programs based on 'scare tactics' failed to deter smoking. Attitudinal approaches such as the Theory of Reasoned Action, developed by Fishbein and Azjen, posited that favorable attitudes would lead to intentions to perform a given behavior, and intentions would then be related to occurrence of the behavior. While intentions at one time point predicted behavior at subsequent time points, this model did not generate predictions about how attitudes develop in the first place, and prevention programs aimed at attitude modification had mixed results (Millstein et al. 1993).

The *social influence model* proposes that many behaviors are acquired through observing and modeling the behavior of influential others. This model was articulated by Richard Evans in primary prevention programs that used filmed or live models who demonstrated how to deal with situations where peers offered cigarettes and applied pressure to smoke. This approach showed preventive effects for adolescent smoking onset and made this model influential for a generation of smoking prevention programs (Ammerman and Hersen 1997). However, some studies showed reverse effects among students who were already smoking, suggesting that factors beside social pressure should be considered.

The *problem behavior model*, developed by Richard and Shirley Jessor, viewed adolescent substance use as a socially defined deviant behavior linked to rejection of conventional values as represented by family, school, and legal institutions. This model proposed that attitudes tolerant of deviance are related to several domains of variables, including personality, poor relationship with parents, low commitment to conventional routes to achievement (e.g., getting good grades), and affiliation with peers who were engaging in deviant behaviors (Jessor 1998). The problem

behavior model proposed that individuals who reject conventional values will demonstrate independence through adopting multiple deviant behaviors (e.g., heavy drinking, marijuana use, precocious sexuality). This model accounted for the observed intercorrelation of problem behaviors. Preventive implications were less clear, since it was not obvious whether to focus on self-esteem, deviant attitudes, family relationships, school performance, or deviant peer groups. This theory influenced several types of preventive interventions.

3.2 Changes in Focus Over Time

In the 1990s there have been several conceptual changes in approaches to understanding adolescent health behavior. The range of variables shown to predict substance use and other health-related behaviors has led to statistical models emphasizing how risk or protection arises through an interplay of contributions from individual, environmental, and social factors (Sussman and Johnson 1996). Thus, recent research on adolescent health has tested multiple domains of predictors, recognizing that health-risk behavior is not due to any single cause but rather arises from combinations of factors (Drotar 1999, Wills et al. 2001).

A specific change is in the conceptualization of social influence processes. Previously it was assumed that adolescent smoking, for example, was attributable to explicit pressure applied by smoking peers to unwilling (or ambivalent) targets. However, research has shown that some individuals have relatively favorable perceptions of smokers and perceive relatively greater frequency and/or acceptance of smoking among their peers and family members; it is these individuals who are most likely to adopt smoking. Similar processes have been demonstrated for teenage alcohol use and sexual behavior (Gibbons and Gerrard 1995). Hence there is more attention to how health behaviors may be motivated by social perceptions about persons who engage in those behaviors.

Earlier theories gave relatively little attention to emotional factors, but recent evidence shows that problem behavior occurs more often among adolescents experiencing higher levels of anxiety/depression, subjective stress, or anger (Marlatt and VandenBos 1997). Current theories have drawn out the linkages of emotional variables to patterns of peer affiliations and willingness to use substances if an opportunity presents itself. This question has drawn attention to why some individuals experience difficulty in controlling their emotions and behavior, and several theoretical models include self-control as a central concept, studying the consequences of poor control for health-risk behavior (Wills et al. 2001).

Finally, recent research has shown that characteristics measured between 3 and 8 years of age predict substance use in early adolescence or mental health problems in adulthood; these include temperamental characteristics, coping and self-control skills, and aggressive behavior. The observation that characteristics measurable in childhood predict health-related behavior at later ages has led to theories aimed at understanding how early temperament attributes are related to development of risk for complex problem behaviors (Wills et al. 2000a).

4. Emphases in Current Research

This section summarizes current knowledge about variables that are related to adolescent health behaviors. Listing a variable as a predictive factor does not indicate that it is the sole cause—or even necessarily a strong cause—of a behavior. A given variable may be, statistically, a weak predictor of a behavior but a combination of variables can be a strong predictor of the behavior. Also, buffering effects are common in health behavior, for example a person with high life stress might experience few adverse health outcomes because he/she also had a high level of social support. Thus there is no 'magic bullet' that can be used to tell who smokes and who doesn't. To predict health behavior with much confidence, one would have to assess multiple variables and to consider the balance between levels of risk factors and levels of protective factors.

This section considers predictor variables that are relevant for each of the health behaviors noted previously, because there are substantial intercorrelations among risk behaviors and a substantial degree of commonality in the predictors for the various outcomes. One would not expect, for example, that all adolescent smokers would have high rates of sexual intercourse; but separate lists of predictors for the various behaviors would have a high degree of overlap (DiClemente et al. 1996). The reader can understand the predictive context for a particular health behavior in more detail through reading some of the references at the end of this chapter.

4.1 Demographic Variables

Substance use among US adolescents varies by gender (males typically showing higher rates), ethnicity (higher rates among Caucasians, lower rates among African–Americans), family structure (higher rates in single-parent families), religiosity (lower rates among persons who attend a religious organization), and parental socioeconomic status (SES), with higher rates among adolescents from lower-SES families. However, effects of demographic variables may change over time, as has happened with cigarette smoking, with boys and girls reversing positions in US data

from the 1970s through the 1980s (Johnston et al. 1999). Socioeconomic effects also are complicated, with different patterns for various indices of smoking and alcohol use. It is found typically that effects for demographic variables are mediated through other risk and protective factors listed subsequently, though ethnicity tends to have direct effects, which indicates specific cultural influences. Demographic effects observed in US data could differ in other cultures, so in other countries, reference to local data is warranted.

4.2 Environmental Variables

Environmental variables are a type of influence that may operate independent of other characteristics. The limited data available suggest elevated risk for substance use in neighborhoods with lower income and higher crime rates, and where the neighborhood is perceived by residents as dangerous and/or neglected by the local government. Noting the existence of a relationship, however, fails to characterize the great variability in effects of environmental variables. For example, a large proportion of persons growing up in poverty areas may go through adolescence showing little or no substance use. This is believed to occur because processes in families and educational systems provide protective effects that offset the risk-promoting potential of the environment.

4.3 Dispositional Constructs

Temperament dimensions of attentional orientation, the tendency to focus attention on a task and avoid distraction, and positive emotionality, the tendency to smile or laugh frequently, are indicated as protective factors. Indicated as risk factors are activity level, the tendency to move around frequently and become restless when sitting still, and negative emotionality, the tendency to be easily irritated and become intensely upset. It appears that these variables act through affecting the development of generalized self-control ability (Wills et al. 2000a). Two other constructs have been related to substance use, drunken driving and sexual behavior in adolescence. Novelty seeking reflects a tendency to need new stimuli and situations frequently and to become bored easily (Wills et al. 1999a). Sensation seeking is a related construct in which high scorers prefer intense sensations (e.g., loud music) and are characterized as spontaneous and disinhibited (Zuckerman 1994).

4.4 Supportive Family Relationships

A positive relationship with parents is an important protective factor with respect to several health behaviors. High supportiveness is present when adolescents feel that they can talk freely with parents when they have a problem, and the parents will provide emotional support or practical assistance when it is needed. Family support and communication are consistently observed to have buffering effects, reducing the impact of risk factors such as poverty and negative life events. Family support acts through multiple pathways, associated among adolescents with better self-control, more value on achievement, and less acceptance of substance use (Wills et al. 1996).

4.5 Conflictual Relationships

A conflictual relationship with parents, involving disagreements and frequent arguments, is a significant risk factor for various adolescent problem behaviors. Family conflict and family support vary somewhat independently in the population, and various combinations of support and conflict can be observed. It should be noted that some argumentation between parents and children is normal, as teenagers establish autonomy from their parents and work toward their own identity; but a high level of conflict, in the absence of protective factors, is potentially problematic. Young persons who feel rejected by their parents look for other sources of acceptance and approval and tend to gravitate into groups of deviance-prone peers, which can lead to detected problem behavior and further family conflict, pushing the adolescent into increasing disengagement from the family and greater involvement in deviant peer groups. Note that there is no invariant relation between family conflict and serious child abuse (physical or sexual). It cannot be assumed that adolescent problem behavior necessarily indicates a history of child abuse, or conversely that severe child abuse is necessary to create risk for problem behavior. The noteworthy fact is that a high level of arguments and criticism by parents is a significant risk factor, and ameliorating family conflict is an important focus for counseling and prevention programs (Peters and McMahon 1996).

4.6 Good Self-control

A central protective factor is the construct of good self-control, also termed 'planfulness' or 'executive functions.' It is measured by several attributes involved in the planning, organizing, and monitoring of behavior. For example, soothability is the ability to calm oneself down when excited or upset; problem solving involves an active approach to coping with problems through getting information, considering alternatives, and making a decision about solving the problem. Good self-control contributes to emotional balance, helps to promote valuable competencies (e.g., academic competence), and ensures that problems get resolved rather than worsening and accumulating over time (Wills et al. 2000b). Individuals with good self-control also seem to be more discerning in their choice

of companions, so that they inhabit a social environment with more achievement-oriented peers and fewer deviant peers.

4.7 Poor Self-control

Poor self-control, also termed 'disinhibition' or 'behavioral undercontrol,' is based on a core of related characteristics. For example, impatience is the tendency to want everything as soon as possible; impulsiveness is the tendency to respond to situations quickly, without giving much thought to what is to be done. Irritability (e.g., 'There are a lot of things that annoy me') is sometimes included as part of this complex. It should be recognized that poor self-control is not simply the absence of good control; the two attributes tend to have different antecedents and different pathways of operation. Poor self-control is related to less involvement in school and seems to be a strong factor for bringing on negative life events. In later adolescence, poor control is related to perceiving substance use or sexual behavior as useful for coping with life stresses, an important factor in high-risk behavior (Wills et al. 1999a). Good self-control has been found to buffer the effects of poor control, so level of poor control by itself is not as predictive as the balance of good and poor control systems (see *Health: Self-regulation*).

4.8 Aggressiveness and hostility

Though anger-proneness is correlated strongly with indices of poor self-control, it is discussed separately because aggression or conduct disorder in children has been studied as a risk factor for problem behaviors. Physical aggression is highly stable over time from childhood onwards, leading to difficulties with parental socialization and peer social relationships, and aggressive tendency is a strong predictor of substance use and other problem behaviors. A predisposition to respond aggressively in interpersonal situations is conducive to injury through violent encounters and hence makes this an important factor in adolescents' morbidity as well as injury to others (Goreczny and Hersen 1999). It should be noted that overt physical aggression is only part of a predictive syndrome that also involves impulsiveness and negative affect, and diagnostic studies sometimes show the majority of children with conduct disorder also have depressive disorder. The combination of high levels of aggression and depression (referred to as comorbid disorder) is a particular risk factor for both substance abuse and suicide in adolescents. However, clinical-level disorder is not a necessary condition for risk, as simple measures of irritability or hostility predict substance use in adolescence and adulthood (Wills et al. 2001). Thus, the core characteristic for risk is probably a complex of attributes that reflect difficulty in regulating reactions to irritation or frustration.

4.9 Academic Involvement

Low involvement in school is a notable risk factor for adolescent substance use and other problem behaviors. This may be reflected in negative attitudes toward school, low grades, poor relationships with teachers, and a history of discipline in school (Wills et al. 2000a). The effect of academic involvement is independent of characteristics such as SES and family structure, though it is related to these to some extent. The reasons for its relationship to problem behavior are doubtless complex. Low involvement in school can be partly attributable to restlessness or distractibility, which make it difficult to adjust to the classroom setting, or to aggressive tendencies that make it difficult for the child to keep friends. Disinterest in getting good grades may derive from a social environment that devalues conventional routes to achievement or a conflictual family that does not socialize children to work toward long-term goals. It should be noted that many adolescents have one bad year in school but do better in subsequent years, without adverse effect; but a trajectory of deteriorating academic performance and increasing disinterest in school could be predictive of subsequent problems such as frequent substance use.

4.10 Negative life events

An accumulation of many negative life events during the previous year has been implicated in adolescent substance use and suicide. The events may be ones that occur to a family member (e.g., unemployment of a parent) or ones that directly involve the adolescent him/herself (e.g., loss of a friend). The pathways through which life events are related to substance use have been studied to some extent. Negative events are related to increased affiliation with deviant peers, apparently because experiences of failure and rejection predispose the adolescent to disengage from conventional institutions and spend more time with peers who are themselves frustrated and alienated. Another pathway is that negative events elevate perceived meaninglessness in life, thus setting the stage perhaps for drug use as a way to restore feelings of control. Life events also may prime the need for affect regulation mechanisms to help deal with the emotional consequences of stressors (Wills et al. 1999a).

4.11 General Attitudes, Norms, and Perceived Vulnerability

Persons who perceive the behavior as relatively accepted in some part of their social circle, and/or who

perceive they are less vulnerable to harmful consequences, are more likely to engage in problem behavior (Wills et al. 2000a). Attitudes do not have to be totally favorable in order to create risk status; for example, attitudes about cigarette smokers tend to be negative in the adolescent population, but those who have relatively less negative attitudes are more likely to smoke (Gibbons and Gerard 1995). The source of attitudes and norms is not understood in detail. It is likely that some variance is attributable to attitudes communicated by parents, that influential peers also communicate norms about substance use (which may differ considerably from those held by parents), and that media advertising also communicates images about substance use and sexual behavior. Attitudes may be shaped to some extent by dispositional characteristics; for example, high novelty-seekers tend to view substance use as a relatively desirable activity and perceive themselves as less vulnerable to harmful effects of tobacco and alcohol. Ongoing studies conducted among US teenagers have shown that rates of marijuana use vary inversely with the level of beliefs in the population about harmful effects of marijuana. The source of these beliefs has not been decisively linked to any specific source, but school-based preventive programs and government-sponsored counteradvertising are suggested as influential (see *Vulnerability and Perceived Susceptibility, Psychology of*).

4.12 Specific Attitudes and Efficacies

Specific attitudes and efficacies may be relevant for particular behaviors. In the area of sexual behavior and contraceptive use, for example, attitudes about sexuality and perceived efficacy for various types of contraceptive use are relevant (DiClemente et al. 1996). There are widely varying attitudes about condom use and differences across persons in the degree to which they feel comfortable in communicating with partners about condom use. Thus studies should always make an attempt to elicit and address specific beliefs and attitudes about a health behavior (Cooper et al. 1999). Perhaps the one general statement that can be made is about resistance efficacy, the belief that one can successfully deal with situations that involve temptation for a behavior (e.g., being offered a cigarette at a party). High resistance efficacy has been noted as a protective factor from relatively young ages. The source of this efficacy has not been extensively studied but some data relate high efficacy to a good parent-child relationship, to good self-control, and (inversely) to indices of anger and hostility (Wills et al. 2000a).

4.13 Emotional States

Negative emotional states including depression, anxiety, and subjective stress have been linked to adolescent substance use and other problem behavior. The source of the stress may be from recent negative events, from dispositional characteristics (e.g., neuroticism), or from living in a threatening environment. Some current evidence supports each of these perspectives. It is important to recognize that emotional states are linked to beliefs about oneself and the world. An individual reporting a high level of negative mood on a symptom checklist is also likely to endorse beliefs that they are an unattractive and unworthy person, that their current problems are uncontrollable, and that there is no clear purpose or meaning in their present life (Wills and Hirky 1996). Evidence has linked components from this complex (lack of control, pessimism, and perceived meaninglessness) to adolescent substance use and suicide risk, but the dynamic of the process is not well understood; it is conceivable that affect *per se* is less important than the control beliefs and world views that are embedded in the matrix of current emotions. Note that positive affect —which is not simply the absence of negative affect— is a protective factor for various problem behaviors and that positive affect has buffering effects, reducing the impact of negative affect on substance use (Wills et al. 1999a). Thus, in studying emotional states and risk status it is valuable to assess the balance of positive and negative affect for an individual.

4.14 Peer Relationships

Peer relationships are one of the most important factors in adolescent health behavior. Across a large number of studies it has been noted that adolescents who smoke, drink, fight, and/or engage in sexual behavior tend to have several other friends who do likewise (DiClemente et al. 1996, Marlatt and VandenBos 1997). Frequency and extent of use is the major consideration for risk status. For example, many teenagers will end up at times in situations where a friend is using some substance, but when many of a person's friends are smoking and drinking frequently, perhaps engaging in other illegal behaviors, and feeding a growing cycle of alienated beliefs, then concern would mount. Several aspects of the context of peer group membership should be considered. While engagement in peer group activity is normative for adolescents, it is when a person has high support from peers and low support from parents that substance use is particularly elevated. Also, there may be several different types of peer networks in a given school, including groups that are grade-oriented, athletes, persons identifying with painting or theater, and cliques focused around specific themes (e.g., skateboarding, 'heavy metal' rock music); hence the frequency of peer activity may be less important for risk than the types of peers and their associated behaviors. Appropriate responding to peer behavior has been a primary focus in prevention programs,

which have aimed to teach social skills for responding assertively in situations where an opportunity for a problem behavior occurs (Sussman and Johnson 1996).

4.15 Coping Motives

Persons may engage in a given behavior for different reasons, and the reasons have significant implications for adolescent health behavior. Problematic substance use and sexual behavior are prominent particularly among individuals for whom these behaviors are regarded as an important coping mechanism, perceived as useful for affect regulation and stress reduction (Wills et al. 1999a). This aspect distinguishes adolescents who use tobacco and alcohol at relatively low rates from those who use multiple substances at high rates and experience negative consequences because of inappropriate or dependent use. Coping motives for substance use are related to parental substance use, to poor self-control, and to a dispositional dimension (risk-taking tendency), hence are based in a complex biopsychosocial process involving self-regulation ability. Motivation concepts are also relevant for health-protective behavior such as condom use (Cooper et al. 1999).

5. Future Directions

This article has emphasized that meaningful risk is not predictable from knowledge about a single variable; rather it is the number of risk factors and their balance with protective factors that is most informative. The concept that health behavior is related to variables at several levels of analysis (environmental variables, personality variables, family variables, and social variables) has been emphasized, and the article has discussed how these variables interrelate to produce health promoting vs. problematic behavior.

Several future developments can be anticipated in this area. One is increasing use of theories that delineate how different domains of variables are related to problem behavior. For example, epigenetic models suggest how simple temperament characteristics are related over time to patterns of family interaction, coping, and social relationships, which are proximal factors for adolescent substance use and other behaviors (Wills et al. 2000b). Research of this type will be increasingly interdisciplinary, involving collaborations of investigators with expertise in developmental, social, and clinical psychology.

Another development is increasing integration of genetic research with psychosocial research. It has been known for some time that parameters relevant for cardiovascular disease (e.g., blood pressure and obesity) have a substantial heritable component; recent research also has shown substantial genetic contributions for liability to cigarette smoking and alcohol abuse/dependence. Although these health-related variables are shown related to genetic characteristics, there is little understanding of the physiological pathways involved (Wills et al. 2001). Current investigations are studying genes coding for receptors for neurotransmitters that have been linked to vulnerability to substance abuse and suicide, and identifying physiological and behavioral pathways for effects of genetic variation.

Finally, recent lifespan research has indicated that simple personality variables measured at early ages predict health-related outcomes over time (H. S. Friedman et al. 1995, Wills et al. 2001). Such research suggests investigations into whether early temperament characteristics are related directly to physiological pathways from the hypothalamic–pituitary axis, operating to dysregulate metabolic systems so as to create risk for cardiovascular disease and diabetes. Behavioral pathways are also possible in the observed longevity effects through liability for smoking or accident-proneness. Integrative research is suggested, using concepts from physiology and behavioral psychology to understand the mechanisms of psychosocial processes in premature mortality.

Adolescent Injuries and Violence

Injuries are probably the most underrecognized public health problem facing the nation today. More adolescents in the United States die from unintentional injuries and violence than from all diseases combined. In 1998, 13,105 US adolescents aged 10 to 19 years died from injuries—the equivalent of more than one death every hour of every day (CDC 2001b). Injuries can affect dramatically an adolescent's development, social and physical growth, family and peer relations, and activities of daily living. The societal costs are enormous, including medical costs, lost productivity, and often extended welfare and rehabilitation costs. Because injury takes such a toll on the health and well-being of young people, approximately 50 Healthy People 2010 national health objectives address the reduction of injuries and injury risks among adolescents (US DHHS 2000). Families, schools, professional groups, and communities have the potential to prevent injuries to adolescents, and help youth to establish lifelong safety skills.

1. Unintentional Injury and Violence

An injury consists of unintentional or intentional damage to the body that results from acute exposure to thermal, mechanical, electrical, or chemical energy, or from the absence of such essentials as heat or oxygen. Injuries can be classified based on the events and behaviors that precede them, as well as the intent of the persons involved. Violence is the intentional use of physical force or power, threatened or actual, against oneself, another person, or a group or community, that either results in or is likely to result in injury, death, psychological harm, maldevelopment, or deprivation. Types of violence include homicide, assault, sexual violence, rape, child maltreatment, dating or domestic violence, and suicide. Unintentional injuries are those not caused by deliberate means, such as injuries related to motor vehicle crashes, fires and burns, falls, drowning, poisoning, choking, suffocation, and animal bites. These are often referred to as 'accidents,' although scientific evidence indicates that these events can be prevented.

Almost 72 percent of the 18,049 deaths of adolescents aged 10 to 19 years are attributed to only four causes: motor vehicle traffic crashes (34 percent), all other unintentional injuries (13 percent), homicide (14 percent), and suicide (11 percent) (CDC 2001b). Unintentional injuries, primarily those attributed to motor vehicle crashes, are the leading cause of death in the United States throughout adolescence. However, the relative importance of homicide and suicide increases from early to late adolescence. Homicide is the fourth leading cause of all deaths to US adolescents aged 10 to 14 years, and the second leading cause of death among adolescents aged 15 to 19 years. Suicide is the third leading cause of death among adolescents aged 10 to 19 years. From early to late adolescence, the number of suicides increases fivefold and the number of homicides increases eightfold.

Nonfatal injuries are even more common during adolescence. For every injury death in the United

States, approximately 41 injury hospitalizations occur, and 1,100 cases are treated in hospital emergency departments (CDC 1993). More than 7.4 million US adolescents aged 15 to 24 years suffer injuries requiring hospital emergency department visits annually (210.1 per 1,000 persons). Injuries requiring medical attention or resulting in restricted activity affect more than 20 million children and adolescents, and cost $17 billion annually in medical costs.

2. Priority Injuries

2.1 Motor Vehicle-related Injuries

More young people die in the United States from motor vehicle-related injuries than from any other cause. The majority of adolescent traffic-related deaths occur as motor vehicle occupants—60 percent of traffic-related deaths among adolescents aged 10–14 years and 86 percent of traffic-related deaths among those aged 15–19 years. In addition, 750,000 adolescents in the United States are victims of nonfatal motor vehicle injuries each year (Li et al. 1995). The likelihood that children and adolescents will suffer fatal injuries in motor vehicle crashes increases if alcohol is used. Teenaged male driver death rates are about twice those of females, and crash risk for both males and females is particularly high during the first years teenagers are eligible to drive. Traffic-related injuries also include those sustained while walking, riding a bicycle, or riding a motorcycle.

Collisions with motor vehicles are the causes of almost all bicycle-related deaths, hospitalizations, and emergency room visits among adolescents. Bicycles are associated with 60 adolescent deaths, 6,300 hospitalizations, and approximately 210,000 emergency room visits annually among US adolescents (Li et al. 1995), 90 percent of which are attributed to collisions with motor vehicles. Severe head injuries are responsible for 64 percent to 86 percent of bicycle-related fatalities. Children aged 10 to 14 years have the highest rate among all age groups of bicycle-related fatalities. In 1998, 463 US adolescents died as pedestrians, and 145 as motorcyclists (CDC 2001b).

2.2 Homicide, Assaults, and Interpersonal Violence

Adolescents are more likely than the general population to become both victims and perpetrators of violence. Between 1981 and 1990, the homicide rate among adolescents aged 10–19 years in the United States increased by 61 percent, while the overall rate in the population decreased by 2 percent (CDC 2001b). From 1990 to 1998, the homicide rate decreased by 31 percent among adolescents, and 34 percent in the overall population. Most adolescent homicide victims in the United States are members of minority ethnic and racial groups. In 1998, the homicide rate among males aged 10 to 19 years was 3.0 per 100,000 among white, non-Hispanic males; 6.4 per 100,000 among Asian/Pacific Islander males; 11.1 per 100,000 among American Indian/Alaskan Native males; 18.4 per 100,000 among Hispanic males; and 38.8 per 100,000 among black, non-Hispanic males (CDC 2001b). In 1998, adolescents aged 10 to 17 years accounted for one out of every six arrests for violent crimes in the United States (US DHHS 2001).

Females aged 18 to 21 years in the United States have the highest rate of rape or sexual assault victimization (13.8 per 1,000), followed by those aged 15 to 17 years (12 per 1,000) (Perkins 1997). More than one-half of female rape victims are less than 18 years of age (Tjaden and Thoennes 1998). Being raped before age 18 doubles the risk of subsequent sexual assault; 18 percent of US women raped before age 18 were also rape victims after age 18, compared with 9 percent of women not raped before the age of 18 (Tjaden and Thoennes 1998). Sexual violence is often perpetrated by someone known to the victim.

2.3 Suicide and Suicide Attempts

In 1998, 2054 adolescents aged 10 to 19 years completed suicide in the United States (CDC 2001b). One of the first detectable indications of suicide contemplation is suicidal ideation and planning. In 1999, 19 percent of US high school students had suicidal thoughts and 15 percent had made plans to attempt suicide during the preceding year (CDC 2000). Three percent of US high school students reported making a suicide attempt that had required medical treatment during the preceding year.

Depressive disorders, alcohol and drug abuse, family discord, arguments with a boyfriend or girlfriend, school-related problems, hopelessness, and contact with the juvenile justice system are commonly cited risk factors for suicide. Exposure to the suicide of others also may be associated with increased risk of suicidal behavior.

3. Settings for Adolescent Injuries

3.1 School-related Injuries

The most frequently treated health problem in US schools is injury. Between 10 percent and 25 percent of child and adolescent injuries occur on school premises, and approximately 4 million children and adolescents in the United States are injured at school each year (Posner 2000). Although the recent wave of school shootings in the United States has captured public attention, homicides and suicides are rare events at school: only 1 percent of homicides and suicides among children and adolescents occur at school, in

transit to and from school, or at school-related events (Kachur et al. 1996).

School-associated nonfatal injuries are most likely to occur on playgrounds, particularly on climbing equipment, on athletic fields, and in gymnasia. The most frequent causes of hospitalization from school-associated injuries are falls (43 percent), sports activities (34 percent), and assaults (10 percent). Male students are injured 1.5 times more often than female students (Di Scala et al. 1997). Middle and high school students sustain school injuries somewhat more frequently than elementary school students: 41 percent of school injury victims are 15 to 19 years of age, 31 percent are 11 to 14 years of age, and 28 percent are 5 to 10 years of age (Miller and Spicer 1998).

3.2 Sports-related Injuries

In the United States, more than 8 million high school students participate in school- or community-sponsored sports annually. More than one million serious sports-related injuries occur annually to adolescents aged 10 to 17 years, accounting for one-third of all serious injuries in this age group and 55 percent of nonfatal injuries at school (Cohen and Potter 1999). For those aged 13 to 19 years, sports are the most frequent cause of nonfatal injuries requiring medical treatment among both males and females.

Males are twice as likely as females to experience a sports-related injury, probably because males are more likely than females to participate in organized and unorganized sports that carry the greatest risk of injury, such as American football, basketball, gym games, baseball, and wrestling (Di Scala et al. 1997). Among sports with many female participants, gymnastics, track and field, and basketball pose the greatest risk of nonfatal injury. Among sports with male and female teams (such as soccer or basketball), the injury rate per player is higher among females than males (Powell and Barber-Foss 2000).

3.3 Work-related Injuries

Half of all US adolescents aged 16–17 years, and 28 percent of those aged 15 years, are employed. On average, these adolescents work 20 hours per week for about half the year. In 1992, more than 64,000 adolescents aged 14–17 years required treatment in a hospital emergency department for injuries sustained at work. In the United States, approximately 70 adolescents under 18 years of age die while at work every year (Cohen and Potter 1999).

Adolescents are exposed to many hazards at work, including ladders and scaffolding, tractors, forklifts, restaurant fryers and slicers, motor vehicles, and night-time work. In particular, motor vehicles and machinery are associated with on-the-job injuries and deaths. Night work is associated with an increased risk of homicide, which is the leading cause of death while at work for female workers of all ages.

4. Risk Behaviors Associated with Injury

4.1 Alcohol Use

Each month, half of US high school students drink alcohol on at least one day and 32 percent engage in episodic heavy drinking—consuming five or more drinks on a single occasion (CDC 2000). Alcohol use is associated with 56 percent of motor-vehicle-related fatalities among people in the United States aged 21–24 years, 36 percent of fatalities among those aged 15–20 years, and 20 percent of fatalities among children less than 15 years of age. Alcohol use is a factor in more than 30 percent of all drowning deaths, 14–27 percent of all boating-related deaths, 34 percent of all pedestrian deaths, and 51 percent of adolescent traumatic brain injuries.

Alcohol use is also associated with many adolescent risk behaviors, including using other drugs and delinquency, carrying weapons and fighting, attempting suicide, perpetrating or being the victim of date rape, and driving while impaired. In the United States, in a given month, 13 percent of high school students drive a motor vehicle after drinking alcohol, and 33 percent ride in a motor vehicle with a driver who has been drinking alcohol (CDC 2000).

4.2 Access to Weapons

In 1998, firearms were the mechanism of injury in 82 percent of homicides and 60 percent of suicides among adolescents aged 10 to 24 years in the United States (CDC 2001b). People with access to firearms may be at increased risk of both homicide and suicide (Kellermann et al. 1993). In approximately 40 percent of homes with both children and firearms, firearms are stored locked and unloaded (Schuster et al. 2000). In 1999, 17 percent of high school students reported carrying a weapon, such as a gun, knife or club, and nearly 5 percent reported carrying a firearm during the previous month. During the same time period, 7 percent carried a weapon on school property (CDC 2000).

4.3 Inadequate Use of Seat Belts and Helmets

Proper use of lap and shoulder belts could prevent approximately 60 percent of deaths to motor vehicle occupants in a crash in the United States (CDC 2001a). Motorcycle helmets may be 35 percent effective in preventing fatal injuries to motorcyclists, and 67

percent effective in preventing brain injuries. Proper bicycle helmet use could prevent up to 56 percent of bicycle-related deaths, 65 percent to 88 percent of bicycle-related brain injuries, and 65 percent of serious injuries to the face.

Adolescents are among the least frequent users of seat belts or helmets. In the United States, 16 percent of high school students claim that they never or rarely use seat belts when riding in a car driven by someone else. Of the 71 percent of US high school students who rode a bicycle in 1999, 85 percent rarely or never wore a bicycle helmet (CDC 2000). Peer pressure and modeling by family members may keep adolescents from using seat belts and bicycle helmets.

5. *Injury Prevention Strategies*

Most injuries to adolescents are both predictable and preventable. Preventing adolescent injuries requires innovations in product design and changes in environment, technology, behavior, social norms, legislation, enforcement, and policies.

Strategies such as product modifications (e.g., integral firearm locking mechanisms), environmental changes (e.g., placing soft surfaces under playground equipment), and legislation (e.g., mandating bicycle helmet use) usually result in more protection to a population than strategies requiring individual behavior change. However, behavioral change is a necessary component of even the most effective legislative, technological, automatic, or passive strategies (Gielen and Girasek 2001): even when seat belts or bicycle helmets are required by law, they must be used correctly and consistently to prevent injuries effectively.

While legislative strategies, such as graduated driver licensing laws to control adolescent driving behavior, or school policies to reduce violence, hold promise, they must be supported by parents and the public, and must be enforced by local authorities to be effective (Schieber et al. 2000). Other approaches, such as zero tolerance alcohol policies, primary enforcement safety belt use laws, enhanced law enforcement, lowered permissible blood alcohol levels, minimum legal drinking age laws, and sobriety checkpoints, have been shown to be effective in reducing motor vehicle-related injuries and death (CDC 2001a). To prevent youth violence, parent and family-based strategies, regular home visits by nurses, social-cognitive and skills-based strategies, and peer mentoring of adolescents have been recommended as 'best practices' (Thornton 2000).

The broad application of these and other health promotion strategies can lead to reductions in adolescent injury. It is not allegiance to a particular type of intervention but flexibility in combining strategies that will produce the most effective mix (Sleet and Gielen 1998). For example, to yield the desired result, legislation requiring the use of bicycle helmets should be accompanied by an educational campaign for teens and parents, police enforcement, and discounted sales of helmets by local merchants. Education and social skills training in violence prevention must be accompanied by changes in social norms, and policies that make the use of violence for resolving conflict less socially acceptable.

6. *Conclusions*

Injuries are the largest source of premature morbidity and mortality among adolescents in the United States. The four major causes of adolescent deaths are motor vehicle crashes, homicide, other unintentional injuries, and suicide. Risk-taking behaviors are an intrinsic aspect of adolescent development but they can be minimized by emphasizing strong decision-making skills, and through changes in the environment that facilitate automatic protection and encourage individual behaviors which result in increased personal protection. Interventions to reduce adolescent injuries must be multifaceted and developmentally appropriate, targeting environmental, product, behavioral, and social causes. Injury policy development; education and skill building; laws and regulations; family-, school-, and home-based strategies; and enforcement are important elements of a comprehensive community-based adolescent injury prevention program. The public health field cannot address the adolescent injury and violence problem effectively in isolation. Youth and families, schools, community organizations and agencies, and businesses should collaborate to develop, implement, and evaluate interventions to reduce the major sources of injuries among adolescents.

L. Barrios and D. Sleet

Adolescent Vulnerability and Psychological Interventions

Adolescents face special sources of vulnerability as they expand their lives into domains beyond their guardians' control. The magnitude of those risks depend on the challenges that their environment presents and teens' own ability to manage them. Psychological interventions seek to improve teens' coping skills, and to identify circumstances in which society must provide more manageable environments.

1. Assessing Personal Vulnerability

Adults often say that teens do reckless things because they feel invulnerable. If that is the case, then teens' perceptions resemble those of adults, for whom the phenomenon of unrealistic optimism is widely documented. In countries where such research has been conducted, most adults are typically found to see themselves as less likely than their peers to suffer from events that seem at least somewhat under their control. Moreover, people tend to exaggerate such control. Thus, for example, most adults see themselves as safer than average drivers, contributing to their tendency to underestimate driving risks. Unrealistic optimism can lead people to take greater risks than they would knowingly incur. As a result, exaggerated feelings of invulnerability can create actual vulnerability. Such feelings might also provide the (unwarranted) confidence that people need to persevere in difficult situations, believing, against the odds, that they will prevail (e.g., Kahneman et al. 1982, Weinstein and Klein 1995).

The relatively few studies assessing the realism of teens' expectations have typically found that, if anything, teens are somewhat less prone to unrealistic optimism than are adults (e.g., Quadrel et al. 1993). These results are consistent with the general finding that, by their mid-teens, young people have most of the (still imperfect) cognitive capabilities of adults (Feldman and Elliott 1990). How well teens realize this potential depends on how well they can manage their own affect and others' social pressure. For example, if

teens are particularly impulsive, then they are less likely to make the best decisions that they could. Conversely, though, if they feel unable to make satisfactory choices, then they may respond more impulsively, or let decision making slide until it is too late for reasoned thought.

The vulnerabilities created by imperfections in teens' (or adults') judgments depend on the difficulty of the decisions that they face. Some choices are fairly forgiving; others are not (von Winterfeldt and Edwards 1986). In very general terms, decisions are more difficult when (a) the circumstances are novel, so that individuals have not had the opportunity to benefit from trial-and-error learning, either about how the world works or about how they will respond to experiences, (b) the choices are discrete (e.g., go or stay home, operate or not) rather than continuous (e.g., drive at 100 or 110 kph, spend *x* hours on homework), so that one is either right or wrong (rather than perhaps close to the optimum), (c) consequences are irreversible, so that individuals need to 'get it right the first time,' and (d) sources of authority are in doubt, so that reliable sources of guidance are lacking (and, with them, the moral compass of social norms or the hard-earned lessons of prior experience).

In these terms, teens face many difficult decisions. In a brief period, young people must establish behavior patterns regarding drugs, sex, intimacy, alcohol, smoking, driving, spirituality, and violence, among other things—all of which can affect their future vulnerability and resiliency. These situations are novel for them, require making discrete choices, and portend largely irreversible consequences (e.g., addiction, pregnancy, severe injury, stigmatization). Adult guidance, even when sought, may not be entirely trusted—especially in nontraditional societies, where part of the 'work of adolescence' is learning to question authority. By contrast, adults who have reached maturity intact often have established response patterns, with trial and error compensating for cognitive limits.

A further source of vulnerability arises when people know less about a domain than they realize. Such overconfidence would reduce the perceived need to seek help, for individuals who lack the knowledge needed for effective problem solving. It could make tasks seem more controllable than they really are, thereby creating a condition for unrealistic optimism. As a result, even if they are just as (un)wary as adults, regarding the magnitude of the risks that they face, teens may make more mistakes because they just do not know what they are doing and fail to realize which situations are beyond their control.

A complementary condition arises when teens do things that adults consider reckless because they, the teens, feel unduly vulnerable. If their world feels out of control, then teens may take fewer steps to manage the situations confronting them. They may also see much worse long-term prospects to the continuity of their lives. If, as a result, they overly discount the future, short-term gains will become disproportionately valuable: There is less reason to protect a future that one does not expect to enjoy. There is also less reason to invest in their personal human capital, by doing homework, acquiring trades, looking for life partners, and even reading novels for what they reveal about chart possible life courses.

Teens might also discount the future if they felt that they might survive physically, but not in a form that they valued. They might fear being so damaged, physiologically or psychologically, that they wanted to enjoy themselves now, while they could and while it would be most valued. In addition to threats to well being that adults would recognize, teens might view adults' lives *per se* as less valued states. Although adults might view such rejection as immature, it could still represent a conscious evaluation. It would be fed by the images of a youth-oriented media and by directly observing the burdens borne by adults (health, economics, etc.).

A final class of threat to the continuity of life is finding oneself physically and mentally intact in a world that seems not worth living in. Such existential despair need not prompt suicidal thoughts to shorten time perspectives. Teens (like adults) might tend to live more for the moment, if they foresaw catastrophic declines in civil society, economic opportunity, or the natural environment—if each were critically important to them. Such discounting could parallel that associated with willingness to risk forfeiting a future that entailed great loss of physical vigor. Studies of unrealistic optimism typically ask participants to evaluate personal risk, relative to peers. One could feel relatively invulnerable, while living in a world that offers little overall promise.

2. *Assessing Actual Vulnerability*

Either overestimating or underestimating personal vulnerability can therefore lead teens to place disproportionate value on short-term benefits, thereby increasing their long-term vulnerability. The costs may be direct (e.g., injury) or indirect (e.g., failure to realize their potential). Adults concerned with teens' welfare have an acute need to understand the magnitude of these risks and convey them to teens (focusing on those places where improved understanding will have the greatest impact) (Schulenberg et al. 1997).

A first step toward achieving these goals is to create a statistical base estimating and tracking risks to young people. Many countries have such surveys which are, indeed, required for signatories to the UN Convention on the Rights of the Child. Estimating vulnerability (for teens or adults) has both a subjective and an objective component. The former requires identifying events so important that they constitute a

threat to the continuity of a life—sufficiently great that people would want to change how they lead their lives, if they thought that the event had a significant chance of happening. This is a subjective act because different teens, and different adults, will define significance (and, hence, 'risk' and 'vulnerable') differently. The UN Convention offers a very broad definition. In contrast, some public health statistics just look at deaths, whereas surveys might focus on the special interests of their sponsors (e.g., pregnancy, early school leaving, drug use).

Collecting statistics is 'objective,' to the extent that it follows accepted procedures, within the constraints of the subjectively determined definition. Different definitions will, logically, lead to different actions (Fischhoff et al. 1981).

Mortal risks to teens in developed countries are statistically very small. In the USA, for example, the annual death rate for 15-year-olds is about 0.04 percent (or 1 in 2,500). Of course, among those teens who died, the probability of going into their final year was much higher for some (e.g., those with severe illnesses), somewhat higher for yet others (e.g., those living in violence-ridden neighborhoods), and much lower for many others (e.g., healthy teens, living in favored circumstances, but victims of freak accidents). If perceived accurately, that probability might pass the significance threshold for some teens, but not for others. Whether it does might depend on whether teens adopt an absolute or a relative perspective (asking whether they are particularly at risk of dying). It might also depend on the time period considered. An annual risk of 0.1 percent might be seen as 2.5 times that of the average teen, or as a 1 percent risk in 10 years or a 2.5 percent risk, either of which could be seen as 'dying young.'

Although probability of death is relatively easy to estimate, it is a statistic that diverts attention away from adolescents. It treats all deaths as equal, unlike 'lost life expectancy' which gives great weight to the years lost when young people die prematurely. It also gives no direct recognition to physical or psychological conditions that might be considered severe enough to affect life plans. Some of these could precipitate early mortality (e.g., anorexia, diabetes, severe depression, cancer), others not (chronic fatigue, herpes). Estimating and weighting these conditions is much more difficult than counting deaths. However, it is essential to creating a full picture of the vulnerabilities facing teens, and which they must assess, in order to manage their lives effectively—within the constraints that the world presents them (Dryfoos 1992).

3. *Reducing Vulnerability*

Adults can reduce adolescents' vulnerability either by changing teens or by changing the world in which they live. Doing either efficiently requires not only assessing the magnitude of the threats appropriately, but also evaluating the feasibility of change. There is little point in worrying about big problems that are entirely out of one's control, or to exhorting teens to make good choices in impossible environments, or expecting behavioral sophistication that teens cannot provide. Where interventions are possible, they should, logically, be directed at the risk factors where the greatest change can be made at the least cost. ('Cost' here could mean whatever resources are invested, including individuals' time, energy, or compassion—as well as money.). Estimates of the effectiveness of interventions aimed at specific risk factors can be found in articles dedicated to particular risks, throughout this section of the Encyclopedia (e.g., drug abuse, depression).

This competition for resources, among different interventions aimed at reducing a specific vulnerability, parallels the competition for resources among vulnerabilities for the attention of researchers and practitioners (the topic of the previous section). Estimating the opportunities for reducing vulnerability raises analogous subjective and objective measurement questions. Providing answers is increasingly part of prioritizing research and treatment. When that occurs, researchers face pressure to analyze their results in terms of effect size (and not just statistical significance); administrators face pressure to justify their programs in such terms.

These pressures can promote the search for risk factors that run across problems, creating multiple vulnerabilities, and opportunities for broadly effective interventions. One such theoretical approach looks at problem behaviors that are precursors of troubled development. As such, they would provide markers for difficult developmental conditions, as well as targets for early intervention. The complementary approach seeks common sources of adolescent resilience, protecting them against adversity (Jessor et al. 1991, Fischhoff et al. 1998).

One multipurpose form of intervention provides skills training. These programs are roughly structured around the elements of the decisions facing teens. They help participants to increase the set of options available to them (e.g., by teaching refusal skills for gracefully reducing social pressures). They provide otherwise missing information (e.g., the percentages of teens actually engaging in risk behaviors). They help teens to clarify their own goals, and how likely those are to be realized by different actions. Delivered in a group setting, they might change teens' environment, by shaping their peers' expectations (Millstein et al. 1993, Fischhoff et al. 1999). Although such programs might focus on a particular risk behavior (e.g., sex, smoking), they teach general skills that might be generalized to other settings (Baron and Brown 1992).

These, and other, programs can be distinguished by the extent to which they adopt a prescriptive or empowering attitude. That is, do they tell teens what

to do or provide teens with tools for deciding themselves? The appropriate stance is partly a matter of social philosophy (what should be the relationship between adults and teens?) and partly a matter of efficacy (which works best?). Whereas the designers of an intervention may be charged with reducing a particular problem (e.g., smoking), teens must view it in the context of the other problems that they perceive (e.g., relaxation, social acceptance, weight gain).

These issues may play out differently across cultures and across time. As a result, this article has not offered universal statements about the scope and sources of adolescent vulnerability, or the preferred interventions. Rather, it has given a framework within which they can be evaluated: What consequences are severe enough to disrupt the continuity of adolescents' lives? How well are they understood by teens and their guardians? What missing information would prove most useful? How well can even the best-informed teens manage their affairs? Answering these questions requires integrating results from diverse studies regarding adolescents and their environments.

Adolescent Work and Unemployment

In comparison to other postindustrial societies (Kerckhoff 1996), school-to-work transitions are relatively unstructured in North America. Most adolescents are employed in the retail and service sectors while attending high school. In European countries where apprenticeship is institutionalized (Germany, Austria, and Switzerland), adolescent employment is part of well-supervised vocational preparation programs (Hamilton 1990). In the developing countries, many adolescents leave school to take menial jobs in the informal economy.

While nonemployed students may be considered unemployed (if actively seeking employment), they are unlikely to acquire this social identity, since attendance in school normatively constitutes full engagement. High school dropouts are most vulnerable to unemployment, as the labor market favors applicants with higher degrees and strong technical skills. In addition to educational attainment, unemployment is affected by social and personal resources. Deficits in efficacy, work motivation and values, and poor mental health increase the risk. Unemployment, in turn, diminishes these psychological assets even more, and limits the acquisition of information-yielding contacts, engendering further disadvantage in the labor market (Mortimer 1994).

1. The Debate over Adolescent Work

There is lively controversy in the USA (Steinberg and Cauffman 1995) and Canada about whether working causes 'precocious maturity,' drawing youth away from school and developmentally beneficial 'adolescent' activities. The critics contend that employed teenagers are distracted from what should be the central focus of their lives—learning and achieving in school (Greenberger and Steinberg 1986, Steinberg et al. 1993). They argue that employed youth not only will have less time for homework and extracurricular activities, they will also come to think of themselves prematurely as adults and engage in behaviors that affirm this status. Many adolescent workers drink alcohol and smoke, legitimate behaviors for adults, but prohibited by law for minors. Such youth may chafe at what they perceive as dependent, childlike roles, such as that of the student, get in trouble in

school, and move quickly into full-time work. Finally, teenagers who work may be exposed to stressors and hazards which jeopardize their mental and physical health (NRC Panel 1998).

According to a more salutary perspective, working adolescents participate in an important adult social realm (Mortimer and Finch 1996). Although they are unlikely to be employed in the same jobs that they aspire to hold in adulthood, their jobs teach them valuable lessons about timeliness, responsibility, and what constitutes appropriate behavior in the workplace. Participating in the world of work can serve as an antidote to the isolation of young people in schools, from 'real world' adult settings. If employment fosters confidence about being able to succeed in a domain of great significance for the future adult 'possible self,' mental health and attainment could be enhanced.

Employment may encourage psychological engagement in the future prospect of working, interest in the rewards potentially available in adult work, and consideration of the occupations that would fit emerging interests and capacities. Work experiences can thus foster vocational exploration in a generation of youth described as 'ambitious but directionless' (Schneider and Stevenson 1999).

2. *The Empirical Evidence in North America*

Concerns about adolescent employment in the USA and Canada have generated much empirical research. Consistent with the critics' concerns, employment and hours of work are associated with problem behaviors, especially alcohol use (Mortimer et al. 1996), smoking, and other illicit drug use (Bachman and Schulenberg 1993), as well as minor delinquency. Of special interest is whether such problems herald long-term difficulties. In one longitudinal test, youth who worked intensively during high school were compared four years after high school with their counterparts who did little or no paid work. Because the other students had essentially 'caught up,' more frequent alcohol use among the more active workers was no longer manifest (Mortimer and Johnson 1998, McMorris and Uggen 2000).

Some studies find hours of work are linked to lower grade point averages (Marsh 1991); others find no significant association (Mortimer et al. 1996, Schoenhals et al. 1998). Youth who invest more time in work during high school manifest a small decrement in later educational attainment, while at the same time exhibiting more rapid acquisition of full-time work, more stable work careers, higher occupational achievement and earnings (NRC Panel 1998, Carr et al. 1996).

Since adolescents invest substantial time in work, typically about 20 hours per week, it may appear self-evident that academic work would suffer. But this line of reasoning is predicated on the supposition that work and school constitute a zero-sum game, with the amount of time devoted to work necessarily, and in equal measure, detracting from educational pursuits. However, Shanahan and Flaherty (2001) find that most working adolescents combine employment with many other involvements; relatively few focus on work to the neglect of school (or other activities). Other research shows that time spent watching television diminishes when adolescents work (Schoenhals et al. 1998). If adolescents make time to work by lessening their involvement in activities with little educational value, school performance could be maintained with little difficulty.

Instead of a mechanical zero-sum formula with respect to work and educational involvement, the adolescent should be viewed as an active agent, whose goals influence time allocation among diverse activities. In fact, children and adolescents with less interest in school and lower academic performance make more substantial subsequent investments in work and achieve higher quality work experiences than their more academically oriented peers.

Adolescents' self-concepts, values, and mental health, like those of adults, are responsive to work experiences, e.g., learning and advancement opportunities, supervisory relations, and work stressors (Mortimer and Finch 1996). Those enabled to develop skills on the job increase their evaluations of both intrinsic and extrinsic occupational rewards (Mortimer et al. 1996).

3. *Adolescent Work in the Context of Apprenticeship*

In countries that structure the school-to-work transition by apprenticeship, young (age 10–12 in Germany) children are channeled toward an academic track (the Gymnasium), preparatory to higher education (close to a third of the cohort) and professional and managerial occupations, or toward school programs eventuating in a three- to four-year apprenticeship placement (beginning at age 16 and 17) and vocational certification. (While Gymnasium students may hold odd jobs like their North American counterparts, their experience of work is quite unlike those who enter the vocational training system.)

The apprentice spends much of each week working in a firm, and one or two days in schoolwork linked to vocational training (Hamilton 1990). The amount of time spent at work, and the kinds of activities entailed, are set by the structure of the apprenticeship experience, not carved out by each adolescent (and employer) individually, as in North America.

Structured school-to-work experiences offer a context for the exercise of youth agency which is quite different from the unstructured North American setting. The young person's task is to acquire the best

apprenticeship placement, given that future life chances are at stake. Active exploration of the available possibilities has high priority. The fact that the vocational education and training system encompasses a broad range of occupations (in 1996, 498 in all, 370 of which required apprenticeships, and 128 required only school-based vocational education) instills motivation on the part of those who do not enter higher education to do well in school so as to optimize future prospects.

Because school and work experiences are integrated by design, and because the apprenticeship is part of a widely accepted early life course trajectory, there is no concern about young people 'growing up too soon' or getting into trouble as a result of working. On the contrary, the apprenticeship is a legitimate mode of entry to a desirable adult work role (Mortimer and Kruger 2000). Instead of a 'precocious adulthood,' apprenticeship fosters a biographical construction that motivates work effort and serves as a point of reference in evaluating career-related experiences (Heinz 1999). Concerns focus on the availability of sufficient placements for all who seek them, and the adequacy of the system in times of rapid change (Mortimer and Kruger 2000). While apprenticeship provides a bridge to adult work, the system of vocational credentials can restrict individual flexibility (and economic expansion) in a rapidly changing technological environment.

In Germany, only a small minority of adolescents (3–6 percent) participate neither in apprenticeship nor in higher educational preparation. These young people will be subject to high rates of unemployment, as they lack required qualifications in a highly regulated labor market.

4. *Adolescent Work in the Developing World*

In the developing countries, education is key to both fertility control and economic development. Gainful employment and schooling are in direct competition; adolescents (and children) who work typically cannot attend school, and are relegated to adult work in the informal economy, as street traders, day laborers, domestic workers, etc. (Mickelson 2000, Raffaelli and Larson 1999). Adolescents have little or no choice; family poverty propels them into the labor market where they are likely to encounter exploitative and health-threatening work conditions.

Children in the developing world who are not able to find gainful work are unemployed, like their adult counterparts. Indeed, the distinction between adolescent and adult, commonplace in the developed world, lacks clear meaning in a situation in which children must leave school to support their families economically. In these settings, more advantaged youth (especially boys) attend schools that are often more oriented to work opportunities abroad than to the local labor market. Adolescent work in developing societies provides neither an institutional bridge to desirable adult work, nor a source of occupational direction and anticipatory socialization while school and work are combined. While serving immediate economic needs (of the adolescent, the family, and the society), it restricts the acquisition of human capital through schooling that is sorely needed for economic development.

5. *Conclusion*

Adolescent work behavior, including employment and unemployment, must be understood within the broader context of the transition to adulthood. The debate over adolescent employment poses a fundamental question: can youth be incorporated into the adult world of work so as to enjoy the benefits which this exposure can entail without jeopardizing their educational and occupational prospects and placing them at risk? Future research should consider the societal conditions that make the more salutary outcomes more probable.

Adolescents: Leisure-time Activities

Adolescents spend many hours per week on various leisure activities—4 to 5 hours in East Asia, 5.5 to 7.5 hours in Europe, and 6.5 to 8 hours in North America. This data on leisure time for adolescents attending school is inversely related to time spent on school work; that is, adolescents in Asian countries do school work for the same length of time as those from North America engage in leisure (Larson and Verma 1999). Overall, leisure time in North America and Europe amounts to about 40 percent of waking hours, more than school and work combined.

By definition, leisure activities are chosen by the young in contrast to obligatory activities and are typically non-instrumental. Although some activities may be wasted time from a developmental standpoint, the majority of free time happens in contexts that are conducive to psychological development.

This paper focuses on time use in adolescence. In a historical perspective, such research is part of the interest shown in daily activities by sociologists, marketing researchers, and governments, since the early nineteen hundreds. The first descriptions of such behaviors regarding adolescence were provided by Barker and Wright (1951) who researched into behavior settings, thus foreshadowing the role of opportunities and individual choices in leisure activities.

1. *Time Spent on Leisure Activities*

Empirical research has distinguished two broad categories: media use (inactive leisure), including watching TV, reading, and listening to music; and active leisure, including working on hobbies, socializing with friends, and playing sports and games. (Where not otherwise stated, data are from a seminal paper on time budget studies by Larson and Verma (1999)).

Concerning media use, the most common activity is watching TV (about 2 hours daily) followed by reading (15 minutes in the US, 40 minutes in Europe and East Asia) and listening to music (about half an hour). TV watching serves as a form of relaxation and default activity when other options are not available, but does not seem to displace other, more socially valued activities. In the 1990s, however, TV watching has been challenged by computer games and new interactive media.

Active leisure concerns physically or mentally active undertakings, such as working on hobbies or socializing with peers. During adolescence, time spent conversing with friends (particularly via the telephone) increases rapidly, and chatting, particularly about the behavior of peers, becomes an important leisure activity (Silbereisen and Noack 1988). Such social interactions seem to be essentially spontaneous and mainly self-regulated.

In terms of more structured and adult-supervised leisure, such as participation in organizations and athletics, large differences exist between North America, Europe, and East Asia. Sports amount to at least one hour in the USA, compared to about half an hour per day or less in the other countries, with a declining trend across adolescence. The data for playing music and other structured activities (typically in groups) show the opposite national differences. Seen in a developmental framework, the degree of adult super-

vision inherent in the activities and contexts diminishes with age, opening up a vista for activities more or less self-chosen by the young and their peers (Hendry 1983).

2. *Company During Leisure Activities*

The main categories of companionship are family and peers. However, about 25 percent of waking hours is spent alone in their bedroom, which is typically a private space decorated with trophies signifying their emerging sense of self. Favorite leisure activities are listening to music, reading magazines, watching videos, and daydreaming.

The time spent with family declines from childhood through adolescence, parallel to the growing duties in school. Whereas in the US adolescents spend about 15 percent of waking hours with their family, in East Asia it is almost 40 percent. Such differences point to the role of cultural values: cohesion within the family rather than individualistic goal pursuit is central to collectivist orientations, and leisure within the vicinity of the family may be a reflection of the broader value systems.

Being together with peers is often associated with adolescent leisure. Indeed the figures for the US and Europe show that adolescents spend up to 30 percent of non-school waking hours going out to parties, attending discotheques, and other away-from-home activities (compared to less than half that for East Asia).

Time spent dating is in the order of one hour per day among adolescents in Europe and North America (Alsaker and Flammer 1999), whereas data on East Asian samples are close to one hour per week, again reflecting higher family control and lower appreciation of western-style self-regulated behaviors. On average, the company of other-sex peers in the US and Europe represents about twice the time adolescents spend with family. As peers select themselves on the basis of shared focal attributes (school achievement, substance use, etc.) and also have a mutual socialization influence, this large amount of time is particularly interesting for developmental consequences.

According to Raymore et al. (1999) leisure activities can be clustered into four groups that show only slight differences between genders. The 'positive-active' group is especially engaged in socially valued activities, like volunteering for community projects. Adolescents in the 'risky' group are more likely to do things for kicks (including substance use) and hang out with friends. The 'diffused' group spends little time in any activity, and thus has no clear preferences. The 'home-based' group applies predominantly to females and involves activities at home with family (including TV watching), whereas males engaged in frequent sports-related activities are over-represented in the 'jock' group. Across the transition to early adulthood, most of these clusters show remarkable stability (about 40 percent of the individuals remain in the same cluster).

However, leisure activities can also change dramatically. Social change such as the breakdown of the socialist countries in Europe is a case in point. The entire system of state-run youth organizations, which were major promoters of structured leisure activities, broke apart. As replacements came in slowly and were often commercial in nature, many lost their social networks and meeting places. Such events partly explain the upsurge of violent peer groups in former East Germany.

3. *Consequences for Psychosocial Development*

In a theoretical framework, leisure activities (particularly the active type involving peers) are an example of active genotype-environment correlation, where individuals seek out opportunities that match their personal propensities. Utilizing a twin design, Hur et al. (1996) analyzed the relative influence of genetic and environmental conditions on leisure time interests (which may differ from actual behavior). Whereas sports, music, and arts showed a strong genetic influence, TV viewing, dating, and various kinds of social activities were characterized by strong shared environmental influences. The latter points to the role of contextual opportunities. Moreover, the effect of shared environment was larger in adolescence than in young adulthood, indicating the new freedoms gained.

With regard to media use in particular, public concern is typically related to the exposure of adolescents to certain contents considered detrimental (sexuality plays a high role in TV programs and pop lyrics). However, as the decline in TV watching with age seems to indicate, such contents may not affect adolescents' behavior. Violent TV programs and videos are also often discussed because of their violence and their possible role in the development of aggression. Although the causal nexus is difficult to assess, studies in various nations show that exposure to media violence is prospectively related to aggression (Wartella 1995).

Media are also major forums for information and participation in popular culture that serve important roles in identity formation. Listening to music helps to forge important elements of one's identity; demonstrating shared preferences with others through behavioral style and outfit accessories helps location within an emerging social network.

A number of other functions of adolescent media use can be distinguished. Often it simply helps to make fun activities even more fun (e.g., driving around in a car with blasting rock music) or fulfills youths' propensity for high sensation (e.g., listening to heavy metal music). Media use may also serve as a general purpose coping strategy for calming down or over-

coming anger. Finally, media are used to connect to networks of peers sharing similar idols and values (Arnett 1995).

Some of the genres of music consumed by adolescents (e.g., rap, soul, heavy metal, and pop) represent the core of their taste culture as well as the more general youth culture. In psychological terms, two focal themes stand out—the expression of defiance toward authority and of love found or lost. Usually, the young select themselves into real or imaginary interactive groups, thereby achieving not only mood management (making bad things less bad, and good things even better), but also status and distinction as a cultural elite (in their own understanding) among peers (Zillman and Gan 1997). This is accomplished and reinforced by a set of other identity-providing attributes, such as particular attire, hairstyle, accessories, and mannerisms. Although often disruptive for psychosocial adaptation in the short term (e.g., acceptance of violence after exposure to rock music videos laden with defiance to authority), long-term negative effects are rare. This is probably due to the transitional nature of participation in such groups and their role in identity development.

The most relevant aspect of active leisure developmentally is the fact that such activities require initiative, planning, and organization of place, time, and content. The individuals themselves have to exercise control over their actions and regulate their emotions, and all this is accomplished in the company they choose. Adolescence in general is the time when individuals take the initiative concerning their own psychosocial growth, and consequently one should assume that leisure is purposively chosen to pursue development among other issues. Indeed, research in various countries has shown that adolescents entertain clear, age-graded conceptions of what they want to achieve, that they look for leisure locales suitable to pursue such goals, and that they are successful in this regard. Silbereisen et al. (1992) and Engels and Knibbe (2000) showed that adolescents who perceive a discrepancy between their current and hoped-for future state of romantic affairs seem to select leisure settings, such as discotheques, because they offer opportunities for contacts with the other gender. Moreover, once the mismatch between current and future state is resolved, their preferences change again, this time for more private encounters.

Certainly leisure activities do not affect all the developmental tasks of the second decade of life in the same ways. However, experiences in leisure have a carry-over effect to other arenas, such as occupational preparation and socialization. Research on entrepreneurs has shown that they took responsibility for others in out-of-school contexts from an early age (Schmitt-Rodermund and Silbereisen 1999). Thus, more structured active leisure, such as sports, may be more relevant for the future world of work, since they are organized by goals and standards of performance, include competition, and demonstrate that planned effort is effective.

The development of individual and collective agency seems particularly to profit from engaging in structural leisure activities. Heath (1999) reported changes in adolescents' conversations about their activities once they had entered youth organizations. Remarkably, they referred more often to issues such as monitoring, goal achievement, or adjusting their behavior. Positive effects on self-esteem and school achievement were also reported as an outcome of participation in civic activities (Youniss et al. 1997). However, some leisure activities may have negative long-term implications. Some team sports, for instance may foster accentuated gender roles and lead to excessive alcohol use (Eccles and Barber 1999).

4. *Future Directions*

In closing, time-budget studies have shed light on how, and to what effect, adolescents spend their leisure. Nonetheless, future research needs to address further the particular psychological qualities of the activities-in-context. Without such information, research on the selection of leisure experiences and the investigation of consequences for psychosocial development lack an understanding of the mediating links. New leisure activities (such as interactive media) and the role of societal change in general, represent another focus of much needed research.

Adoption and Foster Care: United States

1. Introduction

In the year 2000, more than $20 billion in federal, state, and local tax dollars was spent on public child welfare services in the USA. This does not include the hundreds of millions in private dollars (e.g., united ways, religious charitable agencies and organizations, foundations and privately arranged adoptions both in the US and abroad) that was spent on such services. Clearly, child welfare is a big business in the USA. This article focuses on two fundamental and important child welfare programs, adoptions, and foster care.

2. Trends in Foster Care

As indicated in Fig. 1, the rate of children entering the foster care system has been increasing steadily over the past decades (Schwartz and Fishman 1999). The most recent statistics indicate that at the end of the Adoption and Foster Care Analysis Reporting System's (AFCARS) six-month reporting period,

Figure 1
Foster children adopted by type of placement, 1998 (Total: 36,000). Source: US Department Health and Human Services, Adoption and Foster Care Analysis and Reporting System [www.acf.dhhs.gov]

there were 547,000 children in foster care in March 1999. It is generally agreed that this number is unacceptable and efforts are being made to reduce rising foster care caseloads. Initially, policies such as the Adoption Assistance and Child Welfare Act of 1980 encouraged family preservation with the expectation that children would not need to enter the foster care system or would return quickly to their families if those families were given supports (e.g., family services, counseling, parenting education). The law, however, was vague about how long services should be provided or when to make the determination that a child could not be returned to her/his family. As a result, a growing number of children either languished in foster care or entered the system as older children—making it more difficult for those children to get adopted. New policies that seek to arrest the rate of foster care caseloads recently have been implemented that mandate more timely permanent placements (preferably adoptions) for children in foster care and encourage both formal and informal kinship foster placements.

3. Current Responses

3.1 Adoption and Safe Families Act

As the foster care system grew to unmanageable proportions, the government looked for ways to ameliorate the situation. The Adoption and Safe Families Act, signed into law in November 1997, established a new benchmark for child welfare policy. Among other things, the new law authorized incentive payments to the States for increasing the number of foster children adopted in any given year. The law also required States to document their adoption efforts, lifted geographic barriers to cross-jurisdictional adoptions, and changed the timeline for permanency hearings from 18 to 12 months. Although the law continued and even expanded family preservation efforts under the auspices of the Safe and Stable

Families Program, it also mandated that States initiate termination of parental rights and approve an adoptive family for any child in the foster care system longer than 15 months. States are still required to make reasonable efforts to preserve and reunify families, but the new law makes exceptions to this requirement in cases where parents have been found guilty of chronic abuse, sexual abuse, murder of another child, felony assault resulting in bodily injury to a child, or termination of rights to a sibling (Child Welfare League of America 2000, Christian 1999).

By the end of 1998, 38 States enacted ASFA-related legislation. Since continued funding is contingent on such legislation, all States are expected to eventually comply. Although there are no specific plans to evaluate the impact of the Adoption and Safe Families Act, some level of review may be possible through the new Federal Monitoring Program, implemented in January 2000 and regulated by the Department of Health and Human Services (Testimony before House Ways and Means Committee 2000). This monitoring process is designed to assess the effectiveness and efficiency of the child welfare system overall by focusing on concrete outcomes.

3.2 President's Initiative on Permanency Planning

The Department of Health and Human Services, the Administration for Children and Families, the Administration on Children, Youth and Families, and the Children's Bureau recently collaborated on the development of an adoption and foster care initiative designed to promote State governance of permanency planning for children. The initiatives developed guidelines designed to assist States in their efforts to reform and revitalize their child welfare systems. Permanency, as used in the guidelines, means that 'a child has a safe, stable, custodial environment in which to grow up, and a life-long relationship with a nurturing caregiver' (Duquette et al. 1999). The initiative recommends that support services be put in place as soon as possible after a child enters State care and that these services constitute a reasonable effort to rehabilitate families for purposes of permanent reunification. The initiative waives the 'reasonable effort' requirement, first mandated by the Federal Adoption Assistance and Child Welfare Act of 1980, in cases where the parent is convicted of committing murder or specific crimes against children, where parental rights have previously been terminated, where children have been abandoned or severely abused, or when the parent voluntarily refuses services.

The guidelines regarding reasonable efforts reinforce the centrality of permanency in the new child welfare paradigm by insisting that such efforts include concurrent planning leading toward timely final placement. The initiative explicitly identifies adoption as the preferred method of permanent placement for those children who cannot be raised by their biological parents. The guidelines also support court-approved post-adoption contact agreements between adoptive and birth parents, but emphasize that such agreements do not endanger the irrevocability of the adoption contract itself. If adoption, for whatever reason, is not possible, the remaining options are identified as permanent guardianship, standby guardianship, and planned long-term living arrangements with a permanent foster family. Permanent guardianship is used primarily for children of 12 years or older and placement with a relative is preferred, particularly if the child has been in care of the relative for at least one year. Standby guardianship is used in cases where the birth parent is chronically or terminally ill. Long-term permanent foster care is the least-preferred method of placement; the guidelines support its use only in cases of children with serious disability and then only with older, established foster families.

3.3 Privatization

Although State contracting for delivery and/or management of child welfare services is not a new phenomenon, the original idea of partnership with non-profit organizations has been expanded to include contracting with for-profit companies. The child welfare system traditionally limited its use of private services, but a new trend toward Statewide privatization using a managed care approach was initiated in 1996 when Kansas began the process of privatizing its foster care system (Petr and Johnson 1999). The Kansas approach features a capitated, fixed-price pay system that promotes competition and operationalizes performance standards to enhance accountability (Eggers 1997). Attracted by the cost-saving potential of private enterprise and the possibility of improved performance, other States soon implemented their own privatization efforts. The Department of Social Services in Michigan partnered with the non-profit sector to reduce the length of time children wait for adoption to be finalized and North Dakota attributes its status as the State with the highest adoption rate in the country to its use of private contractors (Poole 2000). The State initiatives have been evaluated, but opinion remains divided as to actual outcomes. For every report detailing successful use of privatization methods and public-private partnerships, there is another report indicating failure. Part of the problem lies in the difficulty of establishing standard outcome measures, but work by the Child Welfare League and other child-focused agencies may eventually solve the problem and lay the foundation for rigorous outcome-based evaluations.

3.4 Kinship Care

Although research is inconclusive on whether children placed with relatives fair any better in terms of

Figure 2
Children in foster care by type of placement, March 1999 (Total: 547,000). Source: US Department Health and Human Services, Adoption and Foster Care Analysis and Reporting System [www.acf.dhhs.gov]

Figure 3
Rate per 1,000 of children in foster care, 1985–94 and 1999. Source: Schwarz and Fishman 1999

behavioral and emotional outcomes than children placed with non-relatives (Iglehart 1994, Berrick et al. 1994), the number of relatives fostering children is steadily increasing (Berrick 1998). As indicated in Fig. 2, 27 percent of the children in foster care in March 1999 were living with relatives. While kinship families often provide stable placements, they tend to stop short of pursuing legal guardianship or adoption of their foster children. Many kinship caregivers are reluctant to consider adoption because they consider themselves 'family' already (Berrick et al. 1994). In fact, adoption rates for children placed with relatives are lower than adoption rates for children placed with non-relatives (Berrick 1998). This is apparent in Fig. 3, which indicates that in 1998, only 15 percent of the adoptions of foster children were kinship adoptions. Policy initiatives that support permanent adoptions by kinship caregivers both culturally and economically are needed to ensure that children have the option of being raised among capable and concerned family members.

4. *Conclusion*

As this article indicates, public child welfare services in the USA are in the midst of change. Increased emphasis is being placed on insuring safety and permanency for abused and neglected children. To this end, there is a gradual movement toward kinship care and privatizing child welfare services, introducing such private sector concepts as incentives, performance indicators, and the use of technology into the system.

Adorno, Theodor W (1903–69)

In a letter from the 1940s in which Thomas Mann asked Theodor W. Adorno to characterize his origins, Adorno wrote: 'I was born in Frankfurt in 1903. My father was a German Jew, and my mother, herself a singer, is the daughter of a French officer of a Corsican, but originally of Genoese descent and a German

singer. I grew up in an atmosphere completely steeped in theoretical (also political) and artistic, but above all musical interests'. Like many other members of the generation of Jewish intelligentsia born at the turn of the twentieth century, his mental disposition also formed in resistance to the assimilated Christian-convert parental home. The philosophically coded motifs of Jewish mysticism and theology strewn throughout his work originate from this.

Theodor Wiesengrund Adorno the individual eludes every classification into academic field or discipline. He was no ordinary run-of-the-mill citizen of the scholar republic, but as Habermas notes, 'an artist amongst civil servants.' Adorno was a composer, music theorist, literary theorist and critic, philosopher, social psychologist, and last but by no means least, a sociologist. In the early years of his academic life, it could not have been foreseen that he would become a world-famous sociologist. In 1925 he moved to Vienna to study theory of composition with Alban Berg. But instead of becoming a composer by profession, he returned to Frankfurt in 1927, in order to write his 'habilitation'-thesis. In these years his relationship with the discipline of sociology was not free from resentment. Indeed, his evaluation of the subject in a review of Karl Mannheim's works in the early 1930s seemed almost formed out of contempt. At that time he placed 'sociology' on a par with a sociology-specific lesson in ideology, that is to say, a formalistic consideration of cultural content which is not concerned with the mental substance of the analyzed person.

Adorno's vivid rhetoric about the sociologist as a 'cat burglar' is also notorious. The sociologist—so the image goes—feels his way exclusively around the surface of social architecture, whereas only the philosopher is capable of decoding its ground plan and inner structure. If one further adds Adorno's later position in the positivism debate to this biographically early perception of sociology, one might form the impression that he tackled the subject with nothing but disdain. But such stereotyping would be unfair to Adorno.

In 1933 after Hitler's rise to power, he went to England. But different from his colleagues who definitely left Germany and immigrated to the USA, Adorno kept returning to Germany various times until it got too dangerous. He joined the Institute for Social Research in New York in 1938.

For sociologists, his name is associated with three great empirical studies, each one of which was, in its own right, pioneering in its respective field of research. In the late 1930s, he worked on the 'Radio Research Project' led by Paul Lazarsfeld which was to establish the modern field of media research. In the 1940s he moved together with Max Horkheimer to California, USA. They started to write the book *Dialectics of Enlightenment*, which only appeared after the end of the war. At the same time he worked within a team of sociologists on the famous study *Authoritarian Personality*, a classic of prejudice research even today. In 1949 Theodor W. Adorno and Max Horkheimer returned to Frankfurt, in order to reopen the *Institut für Sozialforschung*.

In the 1950s, he inspired the study entitled *Group Experiment*, one of the first studies into the political consciousness of West Germans. While there were still conflicts between Lazarsfeld and Adorno over the latter's criticism of a purely quantitative orientation of research, Adorno set out in both of the aforementioned seminal socio-psychological studies his own qualitative methods of analysis which showed a close proximity to phenomenological approaches. However, Adorno's contribution to sociology did not merely amount to these empirical and methodological works.

In a work written after his return from exile, Adorno revealed an astounding knowledge of the sociology he seemingly scorned, the history of its dogma from Comte to Marx, and its contemporary German and American proponents. The latter he knew from his period of emigration, in the most part personally through his active involvement in the committee of the German Sociological Association.

He proudly accepted his nomination to the chairmanship in 1963; and in 1968, at the Sociologists' Day held in Frankfurt, and against the backdrop of the student protests, he gave the closely followed key note lecture 'Late Capitalism or Industrial Society.'

Adorno's contributions to a critical theory of society certainly had an extensive cultural-scientific effect reaching far beyond the sole discipline of sociology. The *Dialectic of Enlightenment*, written together with the philosopher Max Horkheimer that first appeared in a small number of copies in Amsterdam in 1947, enjoyed a paradigmatic status, but its effect was only really felt in the 1970s.

In the *Dialectic of Enlightenment*, Horkheimer and Adorno construe the beginning of history as a *Fall of Man*—as mankind's breaking out of its context in nature. For them, the evolution of mankind's treatment of nature is—contrary to almost the entire bourgeois and socialist thought tradition—not the road to guaranteed progress but the well-beaten track to a regression of world history. In the *Dialectic of Enlightenment*, they attempt to expose this track by means of a paradoxical figure of thought. The development of the history of mankind is, in the current meaning of the phrase, 'originating in nature'—that is, invisible and heteronomous—for as long as mankind cuts itself off from the consciousness of it own naturalness. Horkheimer and Adorno conceive the course of the history of mankind with the psychoanalytical motif of the return of the repressed. It is in the catastrophic evolution of history where irreconcilable nature seeks vengeance. The central connecting theme of this development is professed through perverted reason which, cut off from its own basis in

nature, can only get hold of itself and its object in instrumentally limited identifications. The critique of this identification principle is the system-philosophical center of Adorno's theory of society.

It is in this way that he criticizes a form of cognition which brings to the phenomena being perceived a medium which is external and conceptual to them, and which within this medium only pretends to 'identify' them. He criticizes a societal type of work which denies individuals the development of a relationship to the self exactly because it compels them to 'dispose of' their labor in the medium of exchange value. He criticizes the identity compulsion of political institutions that gain their false stability precisely by means of their intolerance of subjective differences. He criticizes a form of socialization and upbringing, which demands of individuals a biographical consistency, which is external to their naturalness.

It should be remembered when fixing Adorno's socio-theoretical reflections in philosophical terms, so as not to form the wrong impression, that they conform to a theory in the sense of a network of empirical hypotheses which can be reconstructed by discursive means.

The historicist motif of identifying the invisible power of integration of the avenging domination of nature in the economic, socio-psychological, and cultural forms of society therefore forms the basis of Adorno's fully developed theory of society. He is helped in this plan by the image—construed in terms of an ideal type—of liberal market capitalism acting as a foil. Against this backdrop, the form of social integration that became obviously totalitarian in National Socialist society came to the fore. In critical theory in general, as in Adorno's work in particular, this image of society consists of three socio-theoretical components: (a) a political economy theory of totalitarian state capitalism; (b) a socio-psychological theory of authoritarian character; (c) the theory of mass culture.

(a) Under the term 'state capitalism,' the economist Friedrich Pollock subsumes the structural characteristic of a new politico-economic order as formed in Germany in the 1930s. In 'state capitalism,' the liberal separation of the political and economic spheres is done away with. The heads of the major companies become subordinate government agencies. Through state terror, worker organizations are robbed of their rights to the representation of their interests and forcibly incorporated into the planned system. The ruling power in state capitalism is a political apparatus that emerges from the fusion of state bureaucracy and the heads of major companies. In this apparatus, plutocratic exploitation interests and political ruling interests become intermingled to form a closed cyclical system.

The concept of 'state capitalism'—from the point of view of a Marxist crisis theory—was to help explain the paradoxically emerging phenomenon of 'organized capitalism.' It was meant to show how capitalism could, through the installation of 'planned economic' elements delay its own end.

At that time (1943) Adorno even went so far as to see in the post-liberal economic structure denoted by the term 'state capitalism' a symbol for the primacy of politics over the economy—of course, under the conditions of, and at the price of, totalitarianism. This acceptance conformed to the historicist image of a prehistory of domination which was coming to an end and which would only be slowed down by the interlude of liberal capitalism.

(b) On the basis of Erich Fromm's empirical analyses and Max Horkheimer's theoretical considerations, Adorno presupposed—for Western societies in general and for German society in particular—the decline of a bourgeois social character which had, for a short historical period of time, made the formation of autonomous individuals possible. From this point of view, classic bourgeois society had allowed at least some of its male members the cultivation of an ego identity which was only prepared to accept such limitations of freedom which themselves appeared necessary in the light of rational inquiry. On the other hand—so the theory goes in short—the conditions for the formation of the individual in the late bourgeois age now only produce forms of dumb obedience to social and political claims to power.

Adorno, in his *Studies on Fascist Propaganda Material* and in his critique of psychoanalytical revisionists, once again reformulated the changed post-liberal conditions for socialization in the terms of psychoanalytical socialization theory. He showed that, as the extra-familial forms of social authority land directly—i.e., no longer mediated via the socialization achievement of the father—on the child, the socially necessary achievement of the establishment of conformity is accordingly no longer performed by the 'mediating power of the ego.' The dominating directness of social obligation now takes the place of the conscious reflexive ego-function. The domination of society over the individual—or rather within the individual—does not, for Adorno, limit itself to the weakening of the ego-function, described as the unleashing of the super-ego. The socially produced weakening of the former set dynamism in motion in the psychological apparatus of the individual which the very deprivation of power of the ego strengthens further. The ego which is overpowered by the super-ego tries to save itself by virtue of an archaic impulse of self-preservation through a libidinous self-possession which is characteristic of the pre-Oedipal phase.

This narcissistic regression manifests itself in irrational desires for fusion with the social power that is now no longer parental, but direct and anonymous. The conscious achievement of conformity of the ego is thus threatened from two unconscious poles simultaneously—from the unmediated super-ego and the identification with the aggressor. In this way, Adorno

attempted, in the terms of Freud's theory of personality, to explain how the National Socialist regime was successful in that the imposition of an unlimited reality principle could still be experienced by the subjugated subjects with such zest.

(c) Adorno also describes the peculiarity of late capitalist culture—like other critical theorists—through the stylized juxtaposition of high bourgeois and late bourgeois eras. In the former, art still offered the opportunity for productive leisure in which the bourgeois could, through the enjoyment of art, rise above the business of everyday life. The classic bourgeois works of art portrayed the utopia of human contact, which bourgeois everyday life certainly belied. Art was consequently ideological because it distracted from the realization of a truly human society; at the same time it was the form in which bourgeois society presented the utopian images of better opportunities under the appearance of beauty.

In late bourgeois culture, especially manifest in National Socialist cultural politics and in American mass culture (which Adorno was experiencing at first hand at that time), the precarious unity of utopian and ideological moments, which bourgeois culture still kept a firm hold of, was in decline. 'National' art and the consumer products of mass culture serve—albeit with different strategies—the sole purpose of ideological integration. This integrative directness of late capitalist culture is the end result of an ousting, over two centuries, of pre-capitalist remnants from artistic production. As the capitalist logic of exploitation also takes hold of culture, it reveals itself as that which it has been since the prehistoric origins of the instrumental mind—throughout all pre-modern historico-cultural epochs—that is, a medium for a dominating safeguard of conformity.

After the interlude of autonomous bourgeois art in the liberal capitalist epoch, the utopian function granted to aesthetic culture could only be kept intact in art forms which systematically elude the maelstrom of mass communication by virtue of their esoteric conception.

These are no longer utopian in the sense of a positive representation of unseized opportunities, but rather as a negative censure, as a 'wound,' which is meant to call to mind the irreconcilable condition of the social world.

These were—according to differences specific to the fields of political economy, social psychology, and culture—the main thematic strands of a theory which starts from a natural history of domination which came to an end in the Nazi system. At the Fascist end of history, the integrity of nature, violated in prehistory, takes its revenge in totalitarian social integration, that is, one in which all control of rational subjects is lost. An exchange rationality which becomes totalitarian and hermetic, a socializing structure which embeds the claim of authority of a power which has become anonymous in the ego-structure of the subjects themselves, and an industrially fabricated mass culture which serves the sole purpose of manipulative rectification, all combine together to form the terrifying image of a perfectly and systemically integrated society. This terror, set out in the theory, also had a determining influence on Adorno's socio-theoretical reflections when their immediate contemporary historical cause had lapsed due to the military defeat of National Socialism.

The inner architecture of Adorno's theory of society is, in spite of its anti-systematic claim, of a suggestive conciseness. Its consistent dominating functionalism is even in the twenty-first century capable of causing sparks to fly, the flashes from which are lighting up the problematic aspects of modern societies. It is nevertheless difficult to ascribe to the theory a direct, comprehensive, and contemporary diagnostic relevance. This comes as a result of the basic assumption—set out in the *Dialectic of Enlightenment* and popularized in Herbert Marcuse's *One Dimensional People*—that modern societies which have been shaped by scientific and technical developments have fallen into entropic systems, that is, into systems which are incapable of overcoming their own status quo.

In the light of contemporary developments, this assumption of hermetic unity, of total integration, no longer proves adequate. Present-day societies can better be described in a perspective of disintegration. This not only means the dramatic end of the post-war period with the collapse of Communist imperium. It also alludes to the foreseeability of further ecological disasters, diverse political lines of conflict and social fractures that globalized capitalism leaves in its wake, and the decline of nation state and bureaucratic organizational structures. Also worth mentioning are changes in the world of work with the expansion of the service sector, the flexible forms of industrial rationalization, and above all the unforeseeable consequences of biotechnology on the life world, as well as cultural changes such as the emergence of post-materialist, i.e., hedonistic and participation-oriented value-orientations and the erosion of traditional norms, role models, and modes of living. All of these developments point to a 'society of disintegration,' i.e., societies which—in system-theoretical terms—are not in a position to control their own environment.

Whoever did not have the luck to have experienced Adorno in person will perhaps find it paradoxical that a critic of society like Adorno lived and worked in post-war West German society and, to a large extent, was able, through public statements and radio lectures, and through the education of his students, to influence them politically. Even though this is, however, completely out of the question according to his theory of a hermetically fixed status quo.

If one looks at his *Introduction to Sociology*, the last lectures Adorno delivered, this contradiction loses much of its sharpness. One may accuse these lectures of having a lack of philosophical depth. But they make

up for this lack with a sociological depth which acts as a complement to the sociological pallor of Adorno's philosophical theory of society which actually hardly gets beyond a hermetic functionalism.

It is in fact a dialectic version of the integration of a society via exchange that paved the way to a productive development of critical theory. In the lecture *Introduction to Sociology*, the positions are already clearly marked out where a short time later Juergen Habermas, Claus Offe, and others would break up the orthodox version of the theory of an exchange society. Dialectic here means a socio-theoretical view of integration, according to which society does not merely reproduce itself as a system, that is, behind the backs of individuals, but also reproduces itself through them. Critical social research has to establish itself at the sources of friction of that which Habermas later called 'system' and 'life world.' Adorno already sets out a post-Marxist view in Marxian terms in his second lecture. Unlike in Marx's time, when the key starting-point had in fact been the forces of production, the starting-point here is, under the conditions of contemporary late capitalism, the primacy resides in the relations of production, i.e. their political mediation. It is in fact necessary to assume the concept of exchange analytically in the analysis of society, but at the same time to bear in mind that a pure implementation of the exchange principle destroys a society. In consequence, this means that an analysis of the political means by which the exchange society defers or delays its own destruction has to be an inherent part of the theory. The historical evolution of the exchange principle does not—as one might have thought with Adorno the philosopher—simply lead to a perfectly integrated society, but rather to a varied overlapping of integration and disintegration phenomena. This overlapping of integration and disintegration is actually the real sociological substance of what Adorno meant with the concept of *Dialectic of Enlightenment*:

> And if you want to reduce to a formula to learn what is meant by the *Dialectic of Enlightenment* in real social terms, this is the time. I would like to go a step further and at least broaden the problem horizon by asking whether intersecting tendencies towards disintegration oppose each other more and more, in the sense that the different social processes which have welded together arise extensively from divergent or self-contradictory interest groups and not from the increasing integration of society, rather than maintaining that moment of neutrality, of relative indifference to each other, which they once had in the earlier phases of society. (Adorno 1972, p. 79)

The considerations that Adorno sets out in the fourth lecture on the status of political reform in late capitalism to some extent go against the grain of hermetic functionalism. Were the reader to take the hermetic image of society from the philosophical writings seriously, the person who had been enlightened by the *Dialectic of Enlightenment* would be confronted with the hair-raising alternative of whether to pursue a career in closed society or to lose his mind outside its walls. Social criticism would have no place in society itself if there were no third way between the extremes of perfect integration and total disintegration. Within the term 'criticism' itself, this third way is presupposed. Adorno links the conditions for the possibility of a 'critical' influence on society with a dialectic contemplation of the status of political reforms in democracy:

> It would be a bad and idealistic abstractness if, for the sake of the structure of the whole, one were to trivialize or even negatively accentuate the possibility for improvements within the framework of the existing conditions. There would in fact be a concept of totality in this which disregards the interests of the individuals living here and now, and this calls for a kind of abstract trust in world history which I, in any case, am absolutely unable to summon up in this form. I would say that the more the present social structure has the character of a monstrously rolled-up second nature, and that as long as this is the case, the most wretched intrusions into the existing reality will also have a much greater, indeed symbolic, meaning than befits them. Therefore, I would think in the present social reality one should be much more sparing with the reproach of so-called reformism than in the past century. Where one stands in respect to reform is, to a certain degree, also a function for evaluating the structural relations within the whole, and since this change in the whole no longer seems possible in the same directness as it did around the middle of the past century, these questions pass over into a completely different perspective. That is what I wanted to tell you at this point. (Adorno 1972, p. 53)

Theodor W. Adorno died in Sils-Maria, Switzerland, on August 6, 1969.

Adult Cognitive Development: Post-Piagetian Perspectives

There has been an abundant history of experimental work on how cognitive processes such as memory and attention decline with age. However, a different picture may emerge if a life-span developmental approach is taken. From a traditional developmental perspective, the question to ask is whether there are adaptive qualitative changes in cognition that take place beyond adolescence. In initial attempts to address this question, the 1970s brought a proliferation of studies examining Piaget's theory of cognitive development in adulthood. However, much like the experimental cognitive aging work, cross-sectional studies indicated that many adults do not attain formal operations, Piaget's final stage of cognitive development (Kuhn 1992). Formal operational thinking is characterized by hypothetico-deductive reasoning about abstract concepts in a systematic fashion, that is, scientific thinking. It is governed by a generalized logical structure that provides solutions to hypothetical problems. In response to these findings, Piaget (1972) concluded that formal operations is probably not universal, but tends to appear only in those areas in which individuals are highly trained or specialized.

The major problem with simply examining adult cognitive development in terms of age differences in formal operational functioning in adulthood is that it may underestimate the cognitive functioning of adults. In other words, comparing age groups on formal operations uses adolescent or young adult thinking as the standard of competence. Is this a valid assumption to make when examining adaptive cognition in adulthood? Or, do more mature ways of thinking emerge during adulthood?

In response to this concern, Riegel (1976) proposed one of the first alternative models of cognitive development beyond formal operations. He argued that formal operations is limited in its applicability, in that the hypothetico-deductive mode of reasoning does not adequately represent the qualitatively different types of thinking that adults use. Other researchers also pointed out that Piaget's stage of formal operations is primarily limited to explaining how individuals arrive at one correct solution. In other words, the manner in which adults discover or generate new problems and how they consider several possible solutions are not explained. Finally, the fact that adults often restrict their thinking in response to pragmatic constraints is contradictory to the unconstrained generation of ideas characteristic of formal operations. The limitations of formal operations in explaining adult thinking set the stage for a wave of research documenting a continued cognitive growth beyond formal operations called postformal thought (Commons et al. 1989, Sinnott 1996).

1. Definition of Postformal Thought

Postformal thought is characterized by a recognition that (a) truth varies from situation to situation, (b) solutions must be realistic to be sensible, (c) ambiguity and contradiction are the rule rather than the exception, and (d) emotion and subjective factors play a critical role in thinking. These characteristics result in two types of thinking: relativistic and dialectical thinking. Relativistic thinking involves the ability to realize that there are many sides to any issue, and that the right answer depends upon the circumstances. Dialectical thinking involves the ability to consider the merits of differing viewpoints and synthesize them into a workable solution. Both of these modes of thinking accept the fact that knowledge and decisions are necessarily subjective. Thus, postformal thinkers adopt a contextual approach to problem solving in that solutions must be embedded in a pragmatic context (i.e., applying knowledge and decisions to changing circumstances of one's life).

For example, in a seminal study on cognitive growth beyond adolescence, Perry (1970) traced the developmental trajectory of relativistic and dialectical

thinking across the undergraduate years. He found that cognitive development moves from reliance on the expertise of authorities in determining what is true or false to increased levels of cognitive flexibility. The first step in this process is a shift toward relativistic thinking. This type of thinking produces a healthy dose of skepticism and lack of certainty regarding potential solutions to problems. However, Perry demonstrated that adults, in order to progress beyond skepticism, develop commitments to particular points of view. Thus, later stages allow adults to engage in dialectical thinking. They recognize that they are their own source of authority, that they must make a commitment to a position, and that others may hold different positions to which they are equally committed.

2. *Research on Postformal Thought*

Perry's research on the development of relativistic thinking opened the door to further studies documenting systematic changes in thinking beyond formal operations. King and Kitchener (1994) extended Perry's investigation of the relativistic nature of adult thinking by mapping out the development of reflective judgment. On the basis of longitudinal studies of young adults, they identified a systematic progression of thinking. The first three stages in the model represent prereflective thought. In these stages, individuals do not acknowledge that knowledge is uncertain, and maintain that there must be a clear and absolutely correct answer. In stages 4 and 5, individuals recognize that there are problems that contain an element of uncertainty. However, they are not adept at using evidence to draw a reasonable conclusion. The final stages 6 and 7 represent true reflective judgment. Individuals realize that knowledge is constructed and thus must be evaluated within the context in which it was generated. Progression through stages involves both skill acquisition, a gradual process of learning new abilities, and an optimal level of development, the highest level of cognitive capacity that a person can reach. However, because the environment does not provide the support necessary for high-level performance on a daily basis, individuals do not operate at their optimal level most of the time (King and Kitchener 1994).

Sinnott (1996) examined relativistic thinking in the area of interpersonal understanding. Sinnott investigated the degree to which individuals are guided by the fact that points of view in interpersonal relations are necessarily subjective and can be contradictory. She found that when solving problems designed to assess both formal and relativistic thinking in real-life situations, young adults tended to solve all types of problems by a formal mode of thinking, i.e., looking for one correct answer. In contrast, older adults were more likely to use relativistic thinking.

On a measure assessing paradigmatic beliefs about the social world, adults of all ages endorsed statements reflecting dialectical thinking more than statements reflecting relativistic thinking and absolutist thinking (i.e., endorsing one correct point of view) (Kramer and Kahlbaugh 1994). Furthermore, adults' scores on paradigmatic beliefs were unrelated to verbal intelligence and various personality variables such as tolerance of ambiguity. From these findings, it appears that dialectical thinking is rated higher than relativistic thinking in mature thought.

Finally, the interpersonal flavor of postformal thinking is reflected in Labouvie-Vief's theory of adult cognitive development (1992, 1997). Labouvie-Vief contends that adults, as they grow older, develop the ability to integrate emotion with logic in their thinking. From this perspective, a major goal of adult thinking is to handle everyday living effectively. Instead of generating all possible solutions to problems, adults make choices on pragmatic, emotional, and social grounds. This demands making compromises and tolerating ambiguity and contradiction. Researchers speculate that in the area of social reasoning, middle-aged and older adults have some expertise due to their respective accumulation of experience (Blanchard-Fields 1997, Labouvie-Vief 1997). For example, findings indicate that younger age groups reason at a lower developmental level (e.g., less relativistic thinking), especially when confronted with problems that are emotionally salient to them (Blanchard-Fields 1986, Blanchard-Fields and Norris 1994).

Finally, research on the pragmatics of intelligence in the form of wisdom (Baltes et al. 1998, Staudinger and Baltes 1996) also demonstrates adult reasoning that is related to postformal development. According to the Berlin Wisdom Paradigm, wisdom involves the coordination of cognition, motivation, and emotion in a combination of exceptional insight and mature character (Staudinger and Baltes 1996). Specifically, wisdom embodies five criteria closely related to the characteristics of postformal thought. These include factual knowledge, procedural knowledge, contextualism, value relativism, and the acceptance of uncertainty. Studies assessing wisdom ask participants to think aloud about difficult life problems, which are evaluated on the five wisdom-related criteria. Findings indicate that there are no negative age trends in wisdom-related performance. Second, older adults with wisdom-facilitative experiences (e.g., older clinical psychologists and wisdom nominees) disproportionately represent individuals with a large share of the higher-level responses.

Overall, there is some evidence that adults tend to reason more in a postformal manner than younger adults and adolescents, although the age differences are not strong. Indeed, postformal thinking is qualitatively different from formal operational thinking, which relies primarily on a formal logical mode of analysis. It provides a counterperspective to the view

that with increasing age comes inevitable decline. More specifically, postformal reasoning affords adults the ability to embrace the complexities of social reality and emotional involvement in problem solving. The importance of socioemotional aspects of adult reasoning is reflected in recent research trends in social cognition and aging and solving practical problems. However, although there is an emerging consensus that adulthood yields qualitatively different styles of thinking, such as relativistic or dialectic, there is no consensus on whether postformal thinking reflects a true adult developmental cognitive stage.

3. *Postformal Thought as a Stage of Development*

As indicated above, there is much debate in life-span cognitive development on the question of whether adult cognitive development progresses in stage-like fashion toward higher levels of reasoning (Baltes et al. 1998, Basseches 1984, Labouvie-Vief 1992). Although there is evidence that some adults conceptualize reality by postformal styles of reasoning, especially in socioemotional domains, there is a substantial amount of evidence that a large proportion of adults do not display all of the characteristics of postformal development (Labouvie-Vief 1997). Thus, a number of researchers have taken a functionalist approach to explain the lack of a strong positive developmental trajectory in postformal thinking during adulthood. In this case, development is characterized as adaptations to the local environment (Baltes and Graf 1996, Labouvie-Vief 1992). From this perspective, changes in experiences and demands in life determine whether different styles of adult thinking emerge across the latter half of the life span. Thus, the hallmark of adult development is interindividual variability rather than uniformity of cognitive functioning.

A second approach to explaining the variability in the maturity of adult thinking is that in adulthood knowledge becomes more specialized on the basis of experience, a development which in turn reflects a lesser role of age-related neurological development and social demands for increased specialization of knowledge and expertise (Hoyer and Rybash 1994). Thus, knowledge becomes encapsulated in that it is increasingly complex and resistant to change. Because it is experientially based, cognitive development in adulthood is directed toward mastering competency in specific domains rather than being uniform across domains, as in childhood stages of cognitive development (Hoyer and Rybash 1994).

4. *Future Directions*

In conclusion, research on cognitive development beyond adolescence highlights the positive aspects of cognitive changes (i.e., adaptive cognitive reasoning in a social context) in the aging adult from a contextual perspective. The goal of development is successful adaptation to the individual's context of living. However, it is important to acknowledge that many older adults may not achieve higher levels of postformal thinking. Future research needs to address this issue. For example, is it the case that the loss of fluid abilities well documented in the literature on psychometric intelligence and aging may influence postformal thinking styles? Or, is it the case that postformal assessment strategies do not adequately tap into the domains specific to complex reasoning in older adulthood? Future researchers may need to pay more attention to methods explicitly focused on the nature of reasoning styles in areas more relevant in advanced age.

Finally, including an individual differences approach to the study of cognitive development in adulthood promises to advance the field in important ways. The individual differences approach makes it explicit that age is only probabilistically associated with levels of cognitive functioning, and that this association can in fact be influenced and even moderated by a host of relevant variables (e.g., beliefs, attitudes, dispositional styles, and ego level). Thus, an individual differences model could make it possible to evaluate the conditions under which adults of varying ages and of different personological and developmental characteristics are likely to engage in qualitatively different strategies of cognitive functioning.

F. Blanchard-Fields

Adult Development, Psychology of

Many of the classic developmental theories hold to the view that development takes place in childhood but not during adulthood. For example, psychoanalytic (e.g., Freud) and organismic (e.g., Piaget) approaches to development include end states (genital stage or formal operations, respectively) which occur in early adolescence. A number of subsequent theories have challenged these child-centric views of development (e.g., Buhler and Masarik 1968, Erikson 1963, Jung 1971), and many recent theories acknowledge the possibility of development and change throughout the adult years (Baltes et al. 1997). The realization that many aspects of psychological functioning show both growth and declines in the adult years has led to the study of the nature of the changes as well as their antecendents and consequences. Key theories and findings in the adult development field will be summarized below.

1. *The Adult Years*

Some researchers suggest the use of chronological age as a marker for the timing of adulthood, whereas others suggest the transition to adulthood is better characterized by events or rites of passage such as graduation from school, starting a job, or having a family (Neugarten and Hagestead 1976). Adulthood is usually divided into several periods: young or early adulthood (approximately aged 20–39), middle adulthood (40–59), and old age (60+). Old age is typically divided into the periods of young old (60–75) and old old (75 and up).

Subjective definitions of age are also important. When adults are asked how old they feel, their responses often do not correspond to their actual chronological age. Those in adolescence often feel slightly older then their age, young adults usually report feeling close to their age, whereas in midlife and old age adults feel on average 10–15 years younger than their age (Montepare and Lachman 1989). The older one is, generally, the larger the discrepancy between age and subjective age. Feeling younger than one's age is typically associated with better health and well-being.

The social clock is another important organizing framework for adulthood. Based on cultural and societal norms, there is a sense of when certain events or milestones should be achieved. Thus individuals can gauge whether or not they are on-time or off-time relative to these norms (Neugarten and Hagestead 1976). There are consequences associated with being early or late with regard to certain events (graduation, marriage, having a child, getting a job). However, the research indicates that many individuals set their own timetables which do not correspond to societal norms. For example, those with more education will be likely to get married, start a family and begin a job at later ages than the general population. It is one's own constructed timetable that appears to be most important for well-being, and the social clock may be less critical.

2. *Life-span Approach to Adult Development and Aging*

According to a life-span developmental approach (Baltes et al. 1997) there are a number of guiding principles for the study of adult development and aging. First is the assumption that development is a lifelong process, and is just as likely to occur in adulthood as at other points in the life span. De-

velopment is also assumed to take many forms, in that there are multiple paths to the same outcome and there are many outcomes that are desirable or adaptive. Changes during adulthood may be gradual or abrupt. Functioning and behaviors in most domains are modifiable through interventions or changes in environmental conditions. The nature of development is best understood by considering persons within their contexts. In addition to examining psychological functioning, it is also useful to consider the social, biological, anthropological (cross-cultural), economic, political, and historical (cohort) manifestations and intersections. Also, according to a life-span view, all developmental changes in adulthood are the result of both nature and nurture, although at different points in the life span and for different areas of functioning the influence of either heredity or environment may be more salient. Developmental changes may be influenced by normative age-graded factors (e.g., puberty or retirement), normative history graded factors (Great Depression, polio epidemic), or nonnormative events (illness, loss of spouse). Development at all points in the life span is best understood as a cumulative process of gains and losses.

3. *Theories of Adult Development*

Freud's ([1916–17] 1963) theory describes psychological development in a series of psychosexual stages completed by adolescence. Personality was determined based on the resolution of these stages in interaction with the social environment, especially the mother. Carl Jung ([1933] 1971) disagreed with Freud on a number of points, including the primary role of sexuality in development as well as the potential for change during adulthood. Jung ([1933] 1971) held that personality can develop throughout life, and called this the individuation process. According to Jung, the individual strives to become whole by integrating the unconscious undeveloped parts of the psyche with the more conscious ones.

Erikson (1963) also modified Freud's psychosexual theory and formulated a psychosocial approach to development across the life span. This epigenetic theory involves a series of eight stages from infancy through old age. At each stage there is a central crisis to resolve. The adult stages include intimacy vs. isolation, generativity vs. stagnation, and ego integrity vs. despair. The theory suggests that individuals negotiate the crises of each stage in a fixed sequence and the way earlier crises are resolved influences the outcomes of later stages. Thus, according to Erikson, before it is possible to successfully negotiate the issues surrounding intimacy in adulthood, it is critical to resolve one's identity vs. role confusion during adolescence. The stage of generativity does not imply only a focus on one's own offspring, but rather a broader interest in the succeeding generation, in the world at large, at work, among family and friends, as well as in terms of passing on one's legacy such as through works of art or literature.

Vaillant and Milofsky (1980) tested and expanded Erikson's theory. Through this research comparing well-educated college men and inner city men, they found evidence that Erikson's stages were equally applicable to both socioeconomic groups. Moreover, they found evidence that the stages were negotiated in the same sequence in both social realms. However, the natures of the issues addressed at each stage were different in content. Moreover, Vaillant and Milofsky (1980) further differentiated the adult stages by adding two substages. Between the intimacy and generativity stages they added a substage called career consolidation. In this stage they found that adults were focused on establishing their work identity and working towards accomplishing career goals. Resolution of this stage then led to the generativity stage in which workers often became mentors to the younger generation. The generativity stage often lasts for 20 years or more and Vaillant and Milofsky (1980) found evidence for a substage called 'keepers of the meaning.' In this stage, adults were concerned with transmitting their values and ideas to the next generation.

Ego integrity vs. despair is the final stage of life proposed by Erikson (1963). In this period the adult is faced with accepting that death is inevitable. To navigate this stage successfully involves coming to terms with one's life and accepting it and moving on to make the most of the remaining time. Those who go the route of despair, however, are often filled with regrets about what did not happen and often fear death because they do not have a sense of accomplishment or sense that they have lived a good life. This period is often characterized by an intensive life review (Butler 1963). This involves a therapeutic and useful process of sorting through one's life and reminiscing about the past in order to make sense of it. It is through this process that one is able to accept one's life and this allows people to focus on the present and the future so as to age successfully. Although there is evidence that people reminisce at many different points in life, it is more common in later life and should be considered a natural part of the aging process.

4. *Personality Theories*

Some aspects of personality remain relatively stable throughout life, whereas others appear to change. From a trait perspective there is longitudinal and cross-sectional evidence for long-term stability of the Big Five personality dimensions: extraversion, neuroticism, agreeableness, conscientiousness, and openness to experience (Costa and McCrae 1994). Over time, people maintain their rank orders on these key personality traits relative to others. However, there is some evidence for changes in overall level, with older

adults on average becoming less extraverted, less neurotic, and less open to experience, but more agreeable. When other dimensions of personality such as components of well-being are considered, there is evidence for greater changes in personality (Ryff 1995). Purpose in life and personal growth were found to decrease with age, whereas environmental mastery and positive relations were found to increase with age.

There is also evidence for changes in sex role characteristics in adulthood. The evidence suggests that with aging, the genders become less differentiated in terms of masculine and feminine traits. In a classic study, Neugarten and Guttman (1968) found that men adopted more communal characteristics as they aged and women adopted more agentic ones. This integration of masculine and feminine characteristics with age is consistent with what Jung called the process of individuation. Jung's theory suggested that with aging the process of individuation involves an integration of the conscious and unconscious parts of the ego. For men the feminine side is usually repressed, as is the masculine side for women. With aging, the process of bringing the undifferentiated aspects of the self into awareness is considered adaptive.

In addition to the objective data on personality over time, subjective analyses have yielded information about the processes of perceived change in personality and well-being. Adults typically expect to change in the future and see changes relative to the past (Ryff 1991). By reflecting back on the past and projecting into the future, there is evidence that adults have experienced change and expect to undergo further changes. The present functioning is in part understood in relation to what has come before and what is anticipated in the future.

5. *The Self*

The self in adulthood comprises many components such as self-esteem, self-confidence, self-concept, multiple selves, self-efficacy, and the sense of control. Some aspects of the self change, whereas other aspects remain stable in adulthood. The number of imagined or possible selves appears to decrease in later life; however, the number of undesired or dreaded selves increases. Moreover, the number of health-related selves increases in later life (Cross and Markus 1991). The sense of self is differentiated across domains. Whereas overall mastery remains relatively stable, there are some domains in which perceived control declines (Lachman 1991). Perceived control over children, physical functioning, and memory decline in adulthood, whereas perceived control over marriage relationship and work increase in adulthood (Lachman and Weaver 1998). Self-efficacy influences the choice of tasks as well as persistence and level of anxiety and stress. Those who have a greater sense of control are more likely to exert effort and choose effective strategies. There appears to be a physiological link as well. Lack of control is associated with greater stress and poorer immune system functioning. Although there appear to be fewer critical life events in late adulthood, the events that do occur typically are associated with greater stress than those experienced in young adulthood. Two strategies for handling stress are problem-focused and emotion-focused coping (Aldwin 1994). Older adults are more likely than younger ones to use emotion-focused approaches to coping. Also when in the face of difficult circumstances or challenges, it is adaptive to use primary approaches (changing the environment to meet personal goals) and secondary approaches (changing the self to accommodate to the environmental demands) to control. Although primary control strategies are used consistently throughout adulthood, the use of secondary control strategies increases with aging (Heckhausen and Schulz 1995).

6. *Cognitive Functioning*

There is evidence that some aspects of cognitive functioning decline in adulthood, whereas others increase (Baltes et al. 1997). Again, a multidimensional perspective is most useful given the different trajectories of change. For the pragmatics of intelligence, also known as crystallized intelligence, there is continued growth in adulthood. These aspects of intelligence are related to accumulated experience and knowledge and are associated with education and acculturation. Thus, the longer one lives in general the more knowledge one acquires. Presumably with aging one also can attain greater wisdom, or the ability to solve complex problems. In contrast, for the mechanics of development there is decrement starting in early adulthood. This includes mechanisms such as speed of processing, memory, and fluid intelligence. These functions rely on more biologically based processing and thus show decrements that are tied to changes in the central nervous system and brain-related changes.

7. *Social Relationships*

In adulthood, the nature of social relationships changes in both quality and quantity. The number of close friends and confidants increases in young adulthood and remains relatively stable during midlife (Antonucci and Akiyama 1997). In later life, one may begin to lose family and friends due to retirement from one's job, moving to a new residence, or death. Carstensen (1995) has found that in later life adults prefer to have a smaller number of close relationships, and they become increasingly selective in their choice of those with whom they interact. Social support is an important resource throughout adulthood, and especially in later life. It may involve material assistance

or help with tasks and chores, as well as emotional support. Social support may be provided by formal (e.g., institutions or community organizations) or informal (e.g., family or friends) sources. Those who report greater social support tend to be healthier and live longer (Antonucci and Akiyama 1997).

8. Successful Aging

People have long sought after the fountain of youth, looking for ways to live longer and to improve the quality of life. Not only are people now living longer than in the earlier part of the twentieth century, the quality of life is also improving. What factors contribute to a successful later life? Research has shown that there are many factors that involve lifestyle choices that are associated with successful aging (Baltes and Baltes 1990, Rowe and Kahn 1998). Some of the psychosocial factors and behavioral factors are exercise, healthy diet, sense of efficacy and control, mental stimulation, and social support. Those who have friends and family they can rely on report less depression and greater well-being. There is also evidence that having access to support from others is associated with better health and greater longevity. It is not yet known what the mechanisms are that link social support with health. It is likely to be a combination of factors such as reducing stress and boosting immune functioning (Rowe and Kahn 1998). It is clear that there are many factors and behaviors under one's control that affect the nature and course of adult development and aging.

9. Future Directions

We have learned a great deal about the nature of adult development and aging over the past few decades. We know that there are wide individual differences in later life and that the extent and direction of change varies across people. Researchers are conducting studies to investigate the processes that link psychosocial functioning with biomedical factors. It will be useful to understand how beliefs and attitudes such as the sense of control or personality factors contribute to health and longevity. Some of the promising biomarkers are cortisol (stress hormone) and fibrinogen (blood clotting substance). It is likely that psychosocial factors have an effect on the immune system as well as on health behaviors such as exercise and healthy diet. Ultimately, researchers are interested in developing treatments and interventions not only to cure and remediate problems in adulthood and old age, but also to prevent them by taking precautions and action during earlier age periods.

Adult Education and Training: Cognitive Aspects

Various cognitive functions do change with age. Decreases in memory performance, problem solving, speed and precision of perception, and concentration can be described as common age-related losses. In fact, experiencing decreases in cognitive functioning often leads people to changes in self-categorization and self-concept, i.e., the feeling of being or becoming old. However, age-related decline in basic cognitive processes does not correspond to cognitive performance in everyday context. The more experiences and knowledge are necessary to cope with everyday tasks, the less age differences in performance can be found. Moreover, decreases in basic cognitive functions show a high amount of interindividual variability; cognitive functioning in old age is highly influenced by lifelong educational processes and competencies developed in earlier phases of the life span can be used to compensate for developmental losses. As life situation in old age can be interpreted at least in part as the result of lifelong developmental processes, it is of interest whether competencies that could not be developed in earlier phases of the life span can be learned in later years as well, so that higher levels of performance, e.g., effective coping with tasks and challenges of the current life situation, become possible. The assumption that deficits in performance can be compensated for by the use of effective learning strategies is central for most adult education and training programs. However, the question whether training programs should try to educate general strategies or specific techniques that do depend very much on contextual factors has not yet been answered.

This contribution proceeds from research on older people's use of learning strategies and performance in memory tasks. In a second step the question whether adult education programs should engage in the improvement of basic cognitive processes or specific everyday activities is addressed. In the third part it is argued for a theoretical approach that challenges the traditional dichotomy of two components of human intelligence, i.e., fluid and crystallized intelligence. From this perspective the concept of practical intelligence is essential for an adequate understanding of intellectual functioning and cognitive performance in old age. In this section results from empirical studies on performance in younger and older workers and principal demands for training in the context of occupational activities are also discussed. The final part is concerned with the relationship between education and healthy aging. From a life span developmental perspective it is argued that education improves health via perceptions of control and self-effectiveness which in turn increase effective agency and healthy lifestyles.

1. *Learning Strategies of Older People*

Those who could not acquire effective learning strategies in earlier phases of development show more difficulties in organizing and restructuring new information, rarely use mnemonics and mediators, and often fail to establish associative bounds between specific contents. When people fail to organize and restructure new information effectively, they are not able to recall whole semantic clusters but have to remember single words or units instead. For this reason they need more repetition and show poorer memory performance altogether. However, memory performance can be improved through good instructions guiding the process of encoding and the training of learning strategies even in very old age. In empirical studies semantic references (i.e., expounding structural similarities between specific units) and mnemonics (e.g., imagination of pictures that summarize learning contents) proved to optimize memory performance in older people.

Difficulties in recalling stored information are also often due to a lack of effective learning strategies. Poor accessibility of learned material is seen to be caused by omission to include additional information during the encoding process which could facilitate recall. Additionally, failing to organize and restructure learning material makes recall more difficult.

Many older people had no opportunity to gain effective and differentiated strategies for encoding and decoding learning materials. Consequently, empirical studies show that older people (a) do not differ significantly from younger people in recognition tasks, (b) do not reach the performance of younger people in free recall tasks, (c) can reach higher levels of free recall performance when important features of the learned material are given as an aid. Moreover, the data suggest that the failure of older people to organize and restructure new information effectively is not due

to deficits in relevant abilities and skills, in fact they simply do not organize and restructure new information spontaneously, since they are unfamiliar with the context of a test situation.

Cognitive training primarily aims to foster acquisition and use of encoding and decoding strategies. The use of such strategies should help to compensate for deficits in training and practice among older people. Results from longitudinal intervention studies prove the effectiveness of cognitive training programs (e.g., Oswald and Rödel 1995).

Whether and to what extent the learning strategies used by older people are to be described as deficient is discussed as controversial (see Berg et al. 1994). A strategy can be defined as one of alternative methods to solve a specific cognitive task, a procedure that is optional and intentional simultaneously. Age differences in the use of strategies have been studied as possible causes for poorer performance of older people in various cognitive tasks, including memory, spatial imagination, problem solving, and solving of everyday problems. The hypothesis of deficient strategies of older people has important implications for learning from a life span developmental perspective since it is exactly the aim of numerous training programs that older people should use more efficient strategies (Willis 1987, 1990). However, from a closer look at relevant research it is obvious that the deficiency hypothesis must be rejected. Instead, empirical data support the assumption that differences between younger and older people reflect the specific adaptive functions in different ages, depending on the cognitive and pragmatic tasks in given developmental contexts. Consequently, recent research has concentrated on interindividual differences in the use of different strategies. These differences can be explained for by variables similar to those that can explain for differences in psychometric intelligence, i.e., education, experience, stimulating contexts, continuous use, etc.

2. *Training of Basic Processes vs. Training of Everyday Activities*

The distinction between two components of human intelligence, i.e., fluid intelligence as an age-related ability to solve new and unfamiliar problems and crystallized intelligence as an ability to solve familiar problems that can be preserved or even improved in old age (Horn 1982), does not mean that these components are independent of each other. Since every complex cognitive activity contains elements from fluid and crystallized intelligence and intellectual performance as a product can result from different proportions of the two components, expertise, i.e., a high level of crystallized intelligence, offers opportunities to compensate for losses in fluid intelligence.

The possibility to compensate for losses in basic cognitive processes has been proven in numerous empirical studies, especially in the field of occupational activities, but also in other meaningful everyday activities. It has been shown that performance in complex cognitive tasks does not decrease as fast as could be supposed from decreases in basic cognitive processes (Willis 1987). Strategies that allow for compensation in basic cognitive processes are, e.g., an intentional slowing of action, additional checks of solutions, restriction to a small number of activities and aims. However, as could be shown in the testing-the-limits paradigm, compensation in favor of the optimization of specific aspects generally leads to a prolongation of the time required for the task (Baltes and Baltes 1990, Kliegl et al. 1989).

The proven possibility to compensate for losses in intellectual abilities leads to the question whether everyday competence in old age can be improved by training of useful strategies and basic processes. In this context the person-centered intervention approach of Willis (1987) is instructive. According to this author complex everyday activities can be optimized by a training of basic processes. In the first step the significance of specific processes for clusters of important daily activities (e.g., reading operating instructions or an instruction leaflet) has to be determined. In a second step those processes that have an impact on performance in numerous activities can be trained. A training of basic processes would be very attractive for intervention research since participation in training programs could heighten performance in numerous contexts and activities. However, basic cognitive processes are at the very beginning of everyday performance; the relationship between the two is only poor and a satisfying prognosis of performance from basic processes is not possible. As a consequence, recent development in intervention research indicates a preference for another paradigm: the training of specific everyday activities. Since the context-independent training mnemonics failed to have the expected impact on everyday memory performance, it was proposed to offer specific courses aimed to improve memory of names or prevent people from mislaying glasses or keys instead of courses aimed to improve general memory performance. Following this approach it is necessary to create contexts of person-centered intervention that correspond very much to problematic situations in everyday living.

Consequently, from the perspective of this approach a detailed examination of individual life situations is demanded. This demand illustrates the principal dilemma of person-centered intervention programs: the expenditure of training so many people in so many specific situations is out of all proportion to the possible intervention effects. Intervention programs are often used to search for potentials for action and development, especially in the age-related component of intelligence. Numerous empirical studies have differentiated our understanding of human intelligence by demonstrating reserves of capacity for intellectual

performance. Cognitive functions can be improved through adequate training programs, especially when individual, social, and occupational aspects of the life situation are taken into account. Moreover, cognitive training can also be helpful for reaching noncognitive aims, another indication of the significance of cognition for successful management of life in our culture.

However, effects of cognitive training remain specific for concrete problems and situations. Moreover, according to Denney (1994), most training studies (naturally) focus on age-related abilities and skills where similar gains can be reached through exercise alone. Additionally, training has the greatest impact on skills that are not needed in everyday life. Therefore, Denney (1994) raises the question why people should participate in conventional training programs and whether it would not be better to create new programs that concentrate on well-developed abilities and skills, where little effects could have a great impact on possibilities to maintain an independent and self-responsible life.

3. *Practical Intelligence and Training in the Context of Occupational Activities*

The traditional research on human intelligence refers to abilities and skills that are acquired through education in adolescence and early adulthood, whereas abilities and skills required in later years, e.g., for successful occupational development, are neglected in operational definitions of this construct (see Labouvie-Vief 1985). Only since the mid-1980s did psychological research on the development of human intelligence begin to conceptualize and discover the acquisition of area-specific skills and practical intelligence (see Kruse and Rudinger 1997). The latter can be defined as the ability to solve practical everyday problems and to cope effectively with everyday tasks, i.e., as a dimension of human intelligence that may be correlated with the fluid and the crystallized component, but constitutes an own dimension that cannot be reduced to specific aspects of these two other components. Practical intelligence subsumes area-specific skills as well as more general abilities essential for effective coping with problems and tasks, e.g., overall perspective on a working field, competence in preparation and realization of decisions, development and further improvement of effective strategies.

Until recently, the development of practical intelligence has seldom been studied empirically, but the few studies are essential for understanding performance in occupational activities. In a study by Klemp and McClelland (1986), practical abilities for leadership were analyzed. For participation in this study, 150 successful senior managers were nominated; these subjects should give a detailed description of highly developed abilities and strategies for effective leadership behavior. Additionally, employees of the managers were also asked about abilities and strategies for effective leadership. According to Klemp and McClelland (1986), among the abilities and strategies that seemed to be characteristic of effective leadership in senior managers, the following eight deserve special mention: (a) planning of behavior and causal thinking, (b) synthetic and conceptual thinking, (c) active search for relevant information, (d) exerting control, (e) motivating employees, (f) ability to cooperate and teamwork, (g) serving as a model for others, (h) self-confidence and motivation. The study of Klemp and McClelland is not only illustrative of the impact of developed strategies on working performance, but also points to the demand for a continuous 'training on the job' as a precondition of higher job performance. Various studies on working expertise in older workers do show that continuous occupational activity may be associated with the development of specific skills and knowledge which can be used to compensate for age-related losses, especially in the fluid component of intelligence (e.g., Krampe 1994). In fact, meta-analyses suggest that there are no significant differences in the performance of younger and older workers (see Warr 1995). Moreover, empirical data do show that there is more variance in performance within than between age groups, i.e., age-related losses are a poor predictor of job performance (Salthouse 1984). However, age-related decline in biological and physiological processes may have an impact on performance in specific professions, e.g., occupational activities that are associated with severe and unbalanced strain of the motor system or with outside work under bad climatic conditions. Ilmarinnen et al. (1991) showed that a certain change in job profiles for older workers, e.g., reduction of physical strain (from 4,000 to 3,000 kg per shift in women packers) while handing over new experience-based duties (instruction of younger workers), can have a positive impact on health status and job performance in older workers. Results from empirical studies show that the assumption that older workers profit from a general change in job profiles from muscle work to brain work must be rejected. For example, losses in sensory functions can lead to chronic bad posture, which in turn can contribute to degenerative diseases of the motor system. Evaluation of various intervention programs showed that general conceptions and programs are less successful in maintaining functional status than specific programs for individual working conditions.

The principal demands for training in the context of occupational activities can be summarized as follows. (a) It has been shown that expertise in the field of work is to be regarded as a potential age-related gain which can be used to compensate for age-related losses; job performance of older people is not necessarily lower than job performance in younger people. Therefore, older people should have the opportunity to participate in occupational training programs to a greater

extent. (b) Bad working conditions do have a greater impact on job performance of older workers than on the job performance of younger workers. However, age-related losses in performance can be compensated for through changes in job profiles, which take into account specific job-related skills and experiences of older people. Skills and experiences of older workers can be used effectively for increasing job performance in younger workers.

4. *The Impact of Education on Healthy Aging*

Mirowsky and Ross (1998) tested three variants of the human-capital and learned-effectiveness hypothesis, i.e., the assumption that education improves health through fostering effective agency. Using data from a 1995 national telephone probability sample, these authors could show that (a) education enables people to integrate health-promoting behaviors into a coherent lifestyle, (b) education is associated with a sense of control, i.e., that outcomes in one's own life are not incidental but contingent upon intentional behavior, which in turn encourages a healthy lifestyle, (c) educated parents motivate a healthy lifestyle in their children. From the results of this research the lifelong effects of education in earlier phases of development on the possibility to maintain a personal satisfying perspective on life become apparent; older people do benefit from both education in adulthood and education in earlier phases of the life span. Consequently, from the perspective of life span development the positive effects of educational programs for younger people extend beyond jobs and earnings, i.e., they can contribute to the prevention of health problems in old age by enabling people to gain the ability to exert control over their own development. Moreover, even in old age it is not too late to foster perceptions of self-effectiveness and control; adult education can contribute to healthy aging by motivating health-producing behaviors and lifestyles.

Adult Mortality in the Less Developed World

Demographers study death as a process that reduces the size of populations and alters their characteristics. This process is mortality. The term adult mortality is sometimes used to refer to the mortality of everyone except children and sometimes to refer to the mortality of young and middle-aged adults but not the old. Either way, deaths of adults represent a growing proportion of all deaths in the less developed world. In response, health policy and research interest in adult

mortality has grown since the late 1980s. Despite this, statistics on adult mortality remain unreliable for much of the world. This article outlines what is known about adult mortality in less developed countries and places adult mortality in the context of debates about international health policy.

1. Introduction

Measures of mortality are required to calculate life expectancy. Demographers use data on current and past mortality by age to forecast mortality trends and produce population projections (see *Population Forecasts*). Epidemiologists use statistics on cause-specific mortality to investigate the etiology of diseases that kill adults. Social scientists investigate socioeconomic inequalities in adult mortality and behavior that influences adults' risk of dying. Thus, data on adult mortality are important inputs into health policy making and program evaluation, into actuarial work in the public and private sectors, and into economic and social planning more generally.

A life table provides a full description of mortality at all ages (see *Life Table*). Various measures based on the life table have been proposed as summary indices of adult mortality, including life expectancy at 15 years or some other age chosen to represent the onset of adulthood. However, to calculate life expectancy accurately one needs reliable data on old age mortality. No such data exist for most less developed countries. For this reason, and to distinguish the death of working age adults from mortality in old age, adult mortality is often measured using indices such as life table survivorship or partial life expectancy that summarize mortality between two ages representing the onset of adulthood and old age respectively. In particular, the World Bank and World Health Organization have adopted the life table probability of dying between exact ages 15 and 60 (denoted ${}_{45}q_{15}$) as their preferred measure of adult mortality (World Bank 1993, WHO 1999).

2. Data on Adult Mortality

The basic descriptive statistics on adult mortality in the less developed world are deficient. In most poor countries, few deaths are attended by physicians and no effective system exists to ensure that deaths are certified before a funeral can take place. Thus, civil registration of adult deaths is only complete in some small island states and about a dozen larger less developed countries. Even when deaths are registered, the information obtained on the cause of death is often inadequate. Moreover, inadequate and underfunded administrative systems frequently introduce further errors and delays into the production of statistical tables based on death certificates.

A few countries, such as India, have established sample systems for the registration of vital events. In addition, data on adult mortality can be collected using retrospective questions in surveys and censuses. Questions are used about deaths of household members in the year before the inquiry and about the survival of specific relatives, in particular parents and siblings (Timæus 1991). While some national statistical organizations regularly collect such data, others have never done so. Moreover, failure to report deaths or dead relatives and misreporting of ages at death or dates of death are sometimes major problems.

Data on adult mortality in the less developed world are usually analyzed using indirect methods (see *Demographic Techniques: Indirect Estimation*). The word 'indirect' originally denoted methods that estimate life table survivorship from unconventional data on the survival of relatives. In the measurement of adult mortality, however, it also describes methods that use models of demographic processes to evaluate and adjust conventional data on deaths by age.

Statistics on the mortality of old people in less developed countries are even more deficient than those on younger adults. Direct reports of deaths in old age are distorted by exaggeration of ages at death, and estimates made from data on the survival of relatives reflect the mortality of young and middle-aged adults. Moreover, so many deaths in old age are ascribed to senility and ill-defined causes that data on causes of death in elderly populations are frequently impossible to interpret.

In the absence of reliable data on adults, both international agencies such as the United Nations and national governments often publish life tables and summary indices of life expectancy that are based solely on data on children. Mortality in adulthood is imputed on the basis of infant or under-five mortality. However, adult mortality is only loosely associated with mortality in childhood and such estimates may be badly biased. Life tables produced in this way can overestimate or underestimate life expectancy at birth or at age 15 by several years. Such estimates can be very misleading and are not presented in this article.

3. Levels and Trends in Adult Mortality

In the lowest mortality countries in the developed world, only about 10 percent of men and 6 percent of women who survive to age 15 die before their 60th birthday (see *Life Expectancy and Adult Mortality in Industrialized Countries*). In 1909 in Chile, by contrast, about 63 percent of men and 58 percent of women who lived to age 15 died before age 60 (Feachem et al.1992, Chap. 2). Moreover, in India in the early twentieth century these statistics were about 77 and 71 percent, respectively (Mari Bhat 1989). In parts of francophone West Africa, adult mortality remained this high as late as the 1950s (Timæus 1993). By the 1970s though, such

Table 1
Probability of dying between ages 15 and 60 ($_{45}q_{15}$) per 1000, selected countries, 1998

Country	Women	Men
Uganda (1995)	556	547

elevated mortality no longer existed except in populations afflicted by war and famine. Even in the highest mortality countries, at least half of those who lived to age 15 could expect to survive to age 60.

By the late 1990s, the level of adult mortality in a less developed country depended largely on whether it had developed a generalized epidemic of HIV. Most of the severely affected countries are in Eastern and Southern Africa (see *Mortality and the HIV/AIDS Epidemic*). For example, in Uganda, the probability of dying between ages 15 and 60 rose from about 25 percent in the early 1980s to about 55 percent in 1995, while in South Africa the rise was from around 24 percent in 1990 to about 35 percent in 1997 (see Table 1). More up-to-date statistics will only gradually become available but, by the end of the twentieth century, the probability of dying between 15 and 60 probably exceeded 50 percent across most of Eastern and Southern Africa.

Elsewhere in the less developed world, adult mortality has continued to fall. By the late 1990s, the probability of dying between ages 15 and 60 had dropped below 30 percent in all countries without generalized AIDS epidemics for which data exist. (Mortality is almost certainly higher than this in some countries that lack data, especially those with a history of war or civil war such as Afghanistan or Sierra Leone.) In some less developed countries, the probability of dying between ages 15 and 60 is now less than 10 percent for women and around 15 percent for men. These probabilities are well within the range found in the industrialized world. Indeed, adult men's mortality is much higher than this in most of Eastern Europe.

At the national level, adult mortality is associated only loosely with standards of living. It tends to be high in the least developed countries even if they have not been affected by AIDS. Yet, adult mortality is also rather high in some middle-income countries and has fallen to a fairly low level in parts of West Africa, for example, Senegal (see Table 1).

Except for a noticeable 'injuries hump' in early adulthood in the mortality schedule for men, death rates rise rapidly with age in most populations. Mortality decline disproportionately benefits young adults. Thus, in high mortality populations, the probabilities of dying between ages 15 and 45 and ages 45 and 60 are about equal but, in low mortality populations, people are about three times more likely to die in the older age range. Populations with severe HIV epidemics have very unusual age patterns of mortality. Most AIDS deaths occur at quite young ages and the risk of dying may decrease substantially in middle age before rising again in old age.

Middle-aged and elderly men always experience higher mortality than women. However, because of high rates of childbearing and associated risks, young women have higher mortality than men in parts of South Asia and Africa. Many middle-income countries, particularly in Latin America, are characterized by a large gender gap in mortality: adult men's mortality remains rather high but women's mortality is now quite low.

4. *Causes of Adult Death*

It is almost impossible to obtain useful information on causes of death in retrospect. Thus, accurate data on causes of death can be collected only in countries with an effective death registration system. Very few developing countries exist in which one can study over several decades the contribution to the mortality transition made by different causes of death. One such country is Chile.

Adult mortality was still fairly high in Chile in the 1950s (see Table 2). Nevertheless, communicable disease mortality at ages 15–60 was only slightly higher than mortality from cardiovascular disease. The non-communicable diseases, and cardiovascular disease in particular, account for a substantial proportion of adult deaths in all populations.

Between 1955 and 1986, the probability of dying between ages 15 and 60 in Chile more than halved, dropping more for women than men. Mortality from the communicable diseases fell most rapidly. By the

Table 2
Probability of dying between ages 15 and 60 ($_{45}q_{15}$) per 1000 by cause, Chile, 1955 and 1986

	Women		Men	
Cause of Death	1955	1986	1955	1986
Communicable & Maternal	74	9	85	16
Diarrhea	2	1	1	0
Tuberculosis	31	2	48	5
Sexually transmitted	1	0	2	0
Respiratory infections	24	3	31	8
Maternal	15	1	–	–
Noncommunicable	171	83	205	118
Neoplasms	46	36	38	32
Endocrine	3	3	2	3
Cardiovascular	50	19	68	31
Respiratory	2	2	3	2
Digestive	27	11	37	31
Ill-defined	26	5	29	8
Injuries	11	11	78	59
Unintentional	10	4	69	18
Suicide	1	1	5	5
Homicide	0	0	4	3
Undetermined	0	6	0	32
Total	256	103	369	193

Source: Calculated from Feachem et al. (1992, Chap. 2)

mid-1980s, they accounted for only 8 percent of adult mortality. Nevertheless, the noncommunicable diseases also made a substantial contribution to the decline in mortality. This is normal. The only diseases from which it is common for mortality to rise during the transition to low mortality are lung cancer, breast cancer, and perhaps diabetes.

In Chile, as in most countries, tuberculosis accounts for more of the decline in adult mortality than any other single disease (Timæus et al. 1996, Chap. 10). Falling mortality from respiratory infections and cardiovascular disease also had a substantial impact. In addition, a reduction in deaths associated with pregnancy and childbirth made a substantial contribution to the decline in women's mortality. Such deaths accounted for about 6 percent of women's mortality in adulthood in 1955 but less than 1 percent in 1986.

Low mortality countries like Chile in the less developed world usually have higher infectious and digestive system disease mortality than industrialized countries. However, mortality from cardiovascular disease is substantially lower (Timæus et al.1996, Chaps. 7–9, 14). In contrast, the main reason why adult mortality remains rather high in some middle-income countries is that noncommunicable disease mortality, and in particular cardiovascular mortality, has fallen by less than in Chile.

Injuries are an important cause of death in adulthood, especially for young men. The level of mortality from injuries varies markedly between countries, largely reflecting the incidence of fatal road traffic accidents, homicide, suicide, and war deaths. Injuries partly account for the relatively high mortality of men in much of Latin America (Timæus et al. 1996, Chaps. 17, 18). For example, men's mortality from injuries remains high in Chile despite the substantial contribution that the external causes made to the overall reduction in adult mortality during the three decades prior to 1986 (see Table 2).

Except in the highest mortality countries, the major noncommunicable diseases, along with influenza and pneumonia, are probably the most important causes of death in old age. For example, the most important causes of death in old age in Latin America are much the same as in North America (PAHO 1982).

In high mortality countries, most child deaths are from infections. As the risk of dying from infections has shrunk, infant and child mortality have fallen more rapidly than adult mortality (see *Infant and Child Mortality in the Less Developed World*). More children now survive to adulthood and adult mortality is emerging as a residual problem of growing *relative* importance. This process is often described as the 'epidemiological transition' (see *Mortality, Epidemiological, and Health Transitions*). Communicable disease and child health are being replaced by noncommunicable disease and adult health as the most important health issues confronting society.

The impact on the age structure of deaths of declining communicable disease mortality is being compounded by changes in the age structure of the

population. The last third of the twentieth century saw the onset of fertility decline in most of the less developed world. As a result, their populations are beginning to age (see *Population Aging: Economic and Social Consequences*). About 56 percent of the developing world's population was aged 15–59 in 1985 and about 6 percent aged 60 years or more. These proportions are projected to rise to 62 percent and 9 percent respectively by 2015.

5. *Socioeconomic Inequalities in Adult Mortality*

Data on socioeconomic inequalities in adult mortality in the less developed world are even scarcer than data on mortality trends and causes of death. The little information that is available suggests that differentials in adult mortality are large. In Peru, for example, survey data on the fathers of respondents aged 25 to 29 showed that 72 percent of educated fathers were alive, compared with only 55 percent of uneducated fathers, representing a difference of 17 percent (World Bank 1993). Lesotho is a small rural, ethnically homogenous Southern African country. Even in this context, an *absolute* difference of about 14 percent in the probability of dying between ages 15 and 60 existed in the 1970s between individuals with uneducated families and those with well-educated families (Timæus 1993).

The few data that exist on socioeconomic differentials in adult mortality by cause reveal patterns that are broadly consistent with what one might infer from trends in mortality. Data from China's Disease Surveillance Points show that women living in wealthier areas of the country have much lower mortality than women living in poor areas (Feachem et al. 1992, Chap. 2). Noncommunicable disease mortality is higher in the poorer localities but the differential is much smaller than that in mortality from the communicable diseases and injuries. This suggests that inequalities in adult mortality may shrink as overall mortality falls. Equally, interventions directed at communicable disease may be more equitable than those directed at noncommunicable disease because they benefit the poor disproportionately.

6. *Determinants of Adult Health*

The fundamental determinant underlying much adult ill-health in developing countries is poverty. For instance, poor quality and overcrowded housing and malnutrition are important risk factors for the airborne infectious diseases, including tuberculosis, that are common among adults. Similarly, use of cheap polluting fuels can cause chronic respiratory disease; inadequate storage and processing of subsistence crops and other foodstuffs can raise the incidence of cancers and other diseases of the digestive system; and living in a city in a less developed country often exposes the poor to an insecure and stressful environment and to the risk of violence.

In some developing countries as many as one third of deaths in adulthood may be linked to infections and other conditions acquired in childhood (Mosley and Gray 1993). For example, low birth weight is a risk factor for chronic respiratory disease in later life. In much of Africa and Asia, most people are infected with hepatitis B as children and 5–15 percent of them become chronic carriers. At least one quarter of adult carriers of hepatitis B die of cirrhosis or primary liver cancer.

The most worrying recent development affecting the health of adults in the less developed world is the epidemic of HIV/AIDS in Eastern and Southern Africa (see *Mortality and the HIV/AIDS Epidemic*). The less severe or more localized epidemics of HIV/AIDS found in other regions may yet spread and affect millions more people. This could produce a massive rise in adult mortality worldwide.

Development exposes adults to new risks to their health. Many of the known behavioral risk factors for premature death in adulthood are becoming more prevalent in the less developed world. In particular, the prevalence of tobacco smoking has grown rapidly. Among men, it is now more common than in the developed world. A massive epidemic of smoking-related deaths will inevitably follow during the next few decades. In countries where occupational health legislation is nonexistent or unenforced, both industrial work and the growing mechanization of agriculture are associated with a high incidence of fatal injuries and poisonings. Moreover, as the number of motor vehicles grows, mortality from road traffic accidents tends to rise.

7. *Adult Health Policy*

Until the late 1980s, few researchers and experts working on public health in the less developed world were interested in adult health and mortality. This reflects the history of international health policy. The 1970s saw a drive to redirect resources from hospital-based medicine into primary health care. The concept of primary health care was originally an integrative one, which encompassed the health of adults as well as children (WHO 1978). As a program for action, however, primary health care has concentrated on a limited number of interventions intended to reduce mortality from common communicable diseases. The United Nations Children's Fund energetically promoted the idea of a 'child survival revolution' and many agencies and governments came to implicitly or explicitly concentrate their efforts in the health sector on the reduction of child mortality (Reich 1995).

In part, the recent growth in concern about adult health and mortality is a response to the growth in the

relative importance of adult ill-health and to the epidemic of AIDS in Africa. It has also been realized that, although adult ill-health still absorbs much of the health care budget in many less developed countries, tertiary hospitals no more benefit poor adults in rural areas than they do their children. The World Bank became a major donor in the health sector by the late 1980s allowing it to promote interest in such issues. Adult health fits well with the World Bank's overall mission to promote economic development.

Despite the growing heterogeneity of the developing world, research at the World Bank (Feachem et al. 1992, Chap. 6, Jamison et al. 1993) has identified several measures that are priorities for the improvement of adult health almost everywhere. The first such measure is a negative one: withdraw public expenditure from ineffective health programs and those that benefit only a few adults. Such programs include the nonpalliative treatment of most cancers, medical management of hypertension, and antiviral therapy for adults with AIDS. Cost-effective measures to reduce adult mortality that should be available more widely include effective referral systems for obstetric emergencies, the treatment of sexually transmitted infections, tuberculosis, and leprosy, and screening for cervical cancer. Various preventive measures delivered to children, in particular hepatitis-B immunization, are priorities for the improvement of adult health. Several crucial interventions, such as fiscal measures to reduce smoking, fall outside the area of responsibility of ministries of health.

Perhaps even more than for children, effective action to reduce adult mortality is likely to meet with political opposition. For example, measures intended to reduce the prevalence of smoking will be fought by the tobacco industry and perhaps the ministry of finance; screening for cervical cancer may conflict with cultural norms about the seclusion of women; and in some countries attempts to reduce expenditure on inappropriate tertiary care have been blocked by the medical profession. Most government policy in the developed world is determined without considering its impact on mortality. Establishing the reduction of adult mortality as a major goal of governments in the less developed world is likely to be a slow process.

Adult Psychological Development: Attachment

In the last decade, Bowlby's attachment theory (1973) has become an important framework for understanding psychological development in adulthood. Theory and research has mainly focused on a person's style of relating to significant others ('attachment style') as well as on his/her beliefs about the self and the world ('internal-working models'). Initially, empirical efforts have been spent in examining the manifestations of attachment style in interpersonal behavior as well as in the quality of close relationships. With the progress of theory and research, more efforts have been invested in delineating the manifestations of attachment style in the process of affect regulation. In this article are presented the basic concepts of attachment theory and the psychological implications of attachment style are reviewed.

1. Attachment Style and Internal Working Models in Adulthood

According to Bowlby (1973), an attachment system evolved in humans to help maintain proximity to significant others (e.g., parents, lovers, friends) under

conditions of danger. Proximity maintenance can help the individual to manage distress with the help of other persons and to attain a sense of 'felt security' in the world. However, although all individuals need to maintain proximity to significant others in stressful situations, there are individual differences in the activation of attachment behaviors and in the extent to which people seek others' proximity and support. These individual differences reflect the pattern learned throughout the history of interactions with significant others. Whereas persons who have a history of positive interactions may develop a positive orientation towards proximity maintenance, persons who have interacted with cold and rejecting others may have serious doubts about the effectiveness of proximity maintenance as a way of obtaining comfort and security.

Attachment theory and research have conceptualized the above individual differences in terms of attachment styles—stable patterns of cognition and behaviors in close relationships. In adulthood, Hazan and Shaver (1987) proposed three prototypical attachment styles (secure, avoidant, anxious-ambivalent) that corresponded to the typical attachment typology in infancy. Brennan et al. (1998) concluded that this typology could be organized around two dimensions: avoidance and anxiety. Persons scoring low in these two dimensions correspond to the secure style and are characterized by a positive history of social interactions, comfort with proximity seeking, and confidence in others' availability in times of need. Persons scoring high in the avoidance dimension correspond to the avoidant style and are characterized by insecurity in others' goodwill and preference for social and emotional distance from others. Persons scoring high in the anxiety dimension correspond to the anxious-ambivalent style and are defined by insecurity in others' responses and an anxious and ambivalent approach to loved persons. Some recent studies have distinguished a subgroup of insecure persons who score high in both anxiety and avoidance dimensions (fearful persons) and tend to indiscriminately combine features of the avoidant and anxious-ambivalent styles.

Several self-report measures have been constructed tapping a person's attachment style (see Brennan et al. 1998 for a review). Some of these measures adopt a typological approach and ask persons to endorse the attachment style that best fits their feelings in close relationships. Other measures adopt a dimensional approach and ask persons to rate themselves along the various dimensions of attachment organization (e.g., avoidance, anxiety). Empirical efforts have also been invested in developing interview procedures, but most studies still employ self-report scales. It is important to note that all these measures assess global attachment style in adulthood rather than attachment orientation in a particular relationship or memories of childhood experiences. However, despite the tremendous development of measurement tools, more empirical work should be done in the construction of assessment techniques (e.g., observational) that could overcome the problems inherent in self-report measures.

In explaining the formation of attachment style in adulthood, attachment research has adopted Bowlby's (1973) concept of 'internal working models.' According to Bowlby, every interaction with significant others is mentally represented in terms of others' availability and responsiveness to one's attachment needs, the worthiness of the self, and the efficacy of proximity maintenance as a distress management device. In this way, people develop cognitive representations of the self and others that are generalized to new relationships and seem to be the source of continuity between past experiences and the attitude and expectations that we bring with us to current interactions. Bowlby labeled these representations as internal working models and viewed them as the building blocks of a person's attachment style. Collins and Read (1994) proposed that working models in adulthood include four components: (a) memories of attachment-related experiences, (b) beliefs and expectations about significant others and the self, (c) attachment-related goals, and (d) strategies related to the regulation of attachment needs.

According to Collins and Read (1994), persons differing in attachment style may differ in the quality of autobiographical memories of concrete episodes with significant others. Although Bowlby (1973) emphasized that these memories may be accurate reflections of a person's interactions, they may be reconstructed throughout the life span and may reflect the current organization of attachment experiences. Indeed, secure persons, compared to insecure persons, have been found to recall their parents as more available and responsive and to represent relationship histories in more positive and affectionate terms (see Shaver et al. 1996 for a review).

Attachment-style difference may also exist in a person's beliefs and expectations about significant others and the self (see Shaver et al. 1996 for a review). People who feel secure in their relationships may be prone to perceive others as loving and responsive and to feel valued by them. In contrast, people who feel insecure in their relationships may be prone to perceive others as cold and rejecting and may feel worthless in their eyes. In support of this view, secure persons, compared to insecure persons, are more likely to hold positive beliefs and expectations about their romantic partner and to explain partner's behaviors in positive and relationship-enhancing terms. Moreover, secure persons have been found to report higher self-esteem than anxious-avoidant and fearful persons. Interestingly, avoidant persons also hold positive self-views. However, whereas secure persons hold a positive self-view that is balanced by acknowledgment of negative aspects of the self, avoidant persons are reluctant to recognize these negative self-aspects.

The third component of internal working models concerns the goals people pursue in social interactions. Secure persons' positive experiences with responsive partners may teach them that attachment behaviors are rewarding and that they can continue to organize interpersonal behaviors around the basic goal of the attachment system—proximity maintenance. As a result, secure persons tend to construe their interaction goals around the search for intimacy and closeness. Insecure persons' experiences with nonresponsive others teach them that attachment experiences are painful and that other interaction goals should be developed as defenses against the insecurity caused by these experiences. In response to this insecurity, anxious-ambivalent persons hyperactivate the attachment system, construct their interaction goals around security seeking, and seek to minimize distance from others via clinging and anxious responses. In contrast, avoidant persons deactivate the attachment system and organize their interaction goals around the search for personal control and self-reliance.

The fourth component of internal working models concerns the strategies people use for achieving interaction goals and managing distress. Secure persons' interactions with supportive partners teach them that the attachment system is an effective device for attaining comfort and relief. As a result, these persons may learn to manage distress through the basic guidelines of the attachment system: acknowledgement of distress, engagement in constructive actions, and turning to others for support (Collins and Read 1994). In contrast, insecure persons learn that attachment behaviors are ineffective regulatory devices and that other defensive strategies should be developed (Bowlby 1988). Whereas anxious-ambivalent persons scoring tend to hyperactivate distress-related cues and aggrandize the experience of distress, avoidant persons tend to deactivate these cues and inhibit the acknowledgment and display of distress.

Overall, attachment research has delineated the cognitive substrate of adult attachment style. However, more research is needed examining the contribution of childhood experiences, family environment, parents' personality factors, and the person's own temperament to the development of internal working models. Accordingly, more research should be conducted on the specific ways the various components of these working models are manifested in interpersonal behavior and affect regulation.

2. *Attachment Style and Interpersonal Behavior*

According to Bowlby (1973), internal working models styles may shape the ways people interact with others and construe their close relationships. In support of this view, a growing body of research has documented attachment-style differences in the quality of close relationships and interpersonal behavior (see Shaver and Hazan 1993 for a review). However, it is important to note that most of the studies only present cross-sectional associations between self-reports of attachment style and interpersonal phenomena. Therefore, they cannot draw firm conclusions about causality (whether attachment style is an antecedent of interpersonal behaviors) as well as about the psychological mechanisms that explain these associations.

A review of research of attachment research allows us to delineate the pattern of interpersonal behaviors that characterize each attachment style. Overall, secure persons are highly committed to love relationships and tend to maintain them over long periods of time. Intimacy, supportiveness, trust, reciprocity, stability, and satisfaction characterize their romantic relationships. They tend to resolve interpersonal conflicts by discussing them with the partner and reaching integrative, relationship-enhancing solutions. They have a positive orientation toward intimate interactions and tend to disclose personal feelings to loved persons as a means of improving the quality of the relationship.

The pattern of interpersonal behaviors of avoidant persons seems to be characterized by attempts to maximize distance from partners, fear of intimacy, and difficulty depending on others. Specifically, these persons have been found to report low levels of intimacy, passion, and commitment in romantic relationships. They tend to have unstable, short-term relationships, and to grieve less than secure persons following a break-up. They feel bored during social interactions, do not like to disclose personal feelings to other persons, and do not like other persons who share intimate knowledge about themselves. They are pessimistic about romantic relationships and tend to withdraw from the partner in times of stress. Interestingly, they tend to use work and cognitive activities as an excuse for avoiding close relationships.

Obsession about partner's availability, emotional instability, worries about being abandoned, lack of satisfaction, strong physical attraction, jealousy, and a passionate desire for union characterized anxious-ambivalent persons' love relationships. They tend to construct highly conflictive relationships and to suffer from a high rate of break-up. They indiscriminately disclose their personal feelings without taking into consideration the partner's identity and responses; display argumentative and overcontrolling responses towards romantic partners; rely on strategies that aggrandize rather than reduce interpersonal conflicts; and elicit negative responses from partners. Overall, anxious-ambivalent persons' pattern of interpersonal behaviors reflects a demand of compulsive attachment from others, which may create relational tension, may result in the breaking-up of the relationship, and may exacerbate their basic insecurity and fear of rejection.

Importantly, the above patterns of interpersonal behaviors are also manifested in the nature and quality

of marital and same-sex friendship relationships. For example, husbands' and wives' attachment security seems to be related to less frequent use of destructive responses in marital conflict and to more positive marital interactions. Moreover, the marital relationship of secure spouses is characterized by more intimacy, cohesiveness, supportiveness, and flexibility than the marital relationship of insecure spouses. Secure persons also tend to have more intimate and rewarding same-sex friendships than insecure persons. Accordingly, they tend to be more committed to these relationships, to experience less conflictive friendships, and to engage in more selfless and playful interactions with same-sex friends than insecure persons.

3. *Attachment Style and Affect Regulation*

Attachment theory is highly relevant to the process of affect regulation and coping with stress. In Bowlby's (1988) terms, the attainment of a sense of felt security is an inner resource, which helps people to buffer distress. It seems to consist of expectations that stressful events are manageable, a strong sense of self-efficacy, and confidence in others' goodwill, which together evolve in an optimistic and constructive attitude toward life. As a result, secure persons tend to show better adjustment, less negative affect, and more moderate emotional reactions to stressful events than insecure persons (see Mikulincer and Florian 1998 for a review).

Attachment security is also involved in the adoption of adaptive ways of affect regulation. Studies have consistently found that secure persons attempt to manage distress by enacting effective coping responses (instrumental strategies, support seeking), coordinating attachment with other behavioral systems (exploration, affiliation), and acknowledging distress without being overwhelmed by it. There is also evidence that a sense of felt security allows people to revise erroneous beliefs and to explore strong and weak self-aspects. In this way, secure persons could develop more flexible and adjusted views of the world and the self and more reality-tuned coping plans (see Mikulincer and Florian 1998 for a review).

Along the above reasoning, insecure attachment seems to be a risk factor, which hinders well-being and leads people to adopt maladaptive ways of coping. Research has consistently shown that insecure persons tend to appraise stressful events in threatening and catastrophic terms and to have serious doubts about their abilities to deal with these events. With regard to ways of coping, avoidant persons tend to distance themselves from emotion-laden material and to show low cognitive accessibility of negative emotions. Moreover, they tend to suppress bad thoughts, to repress painful memories, and to escape from any confrontation with distress-eliciting sources of information. In contrast, anxious-ambivalent persons tend to experience an overwhelming arousal of negative emotions and an undifferentiated spreading of this arousal to irrelevant emotional themes. Moreover, they tend to mentally ruminate over negative thoughts and to approach distress in an hypervigilant way (see Mikulincer and Florian 1998 for a review).

The above strategies of affect regulation have also been found to underlie perceptions of the self and others. In dealing with stress, avoidant persons tended to inflate their positive self-view and to perceive other persons as different from themselves. Their attempt to suppress personal deficiencies favors self-inflation, whereas their attempt to maximize distance from others results in underevaluation of self–other similarity. In contrast, anxious-ambivalent persons tend to deal with stress by devaluating their self-view and perceiving other persons as similar to themselves. Their attempts to hyperactivate personal weaknesses and to elicit others' love favor self-devaluation, whereas their attempts to create an illusion of connectedness result in heightened self–other similarity. As a result, these persons tend to devaluate others. Interestingly, secure people hold more moderate and realistic views of the self and others. Their sense of felt security allows them to regulate affect without distorting mental representations.

4. *Concluding Remarks*

Attachment research clearly indicated that Bowlby's theory is a relevant framework for understanding psychological development in adulthood. Attachment style seems to be a core feature of adult personality that shapes our perception of the world and the self and guide how we interact with others, how we construe our close relationships, and how we regulate and manage distress. However, one should note that research has made only a first step in delineating attachment-style differences in interpersonal behavior and affect regulation. More research is needed tapping the involvement of attachment style in other areas of adult life as well as in the various facets of psychological development in adulthood stages. Accordingly, further research should examine the stability of attachment style, the formation, maintenance, and dissolution of particular attachments, and the protective function of attachment behaviors.

Adulthood: Dependency and Autonomy

Dependency strictly means the ongoing need for external support (e.g., from family members, professionals, state institutions, intensive care units, or assistive devices) in order to fulfill individual or societal expectations regarding what is a 'normal' life. A less strict interpretation of dependency also encompasses human needs for affiliation, attachment, and bonding to significant others, such as to one's partner, children, grandchildren, or close friends (Baltes and Silverberg 1994). Autonomy can be defined as 'a state in which the person is, or feels, capable of pursuing life goals by the use of his or her own resources' (Parmelee and Lawton 1990, p. 465). Autonomy thus means independent and effective functioning in a variety of life domains ranging from basic activities of daily living to complex decision processes.

Historically, developmental researchers have primarily examined the dynamics between dependency and autonomy from childhood to adolescence. In old age, dependency and loss of autonomy were long viewed as direct consequences of aging worthy of systematic description (e.g., in epidemiological studies), but basically inevitable and irrevocable. It was only in the 1970s that new research findings—based on a more optimistic image of old age and stimulated by a *social learning perspective*—demonstrated the plasticity of dependency and autonomy in old age. While research in the 1980s and 1990s significantly furthered this insight, middle adulthood, and also the transitions in dependency and autonomy that are experienced as the adult individual matures, have attracted little scientific interest.

1. On the Complexities of Dependency and Autonomy in Adult Life

From a life-span perspective, childhood and adolescence are periods when striving toward autonomy and reducing dependency are among the most important *developmental tasks* (Havighurst 1972). By young adulthood, or at the very latest by middle adulthood, one is normally expected to have accomplished this successfully. Conversely, old age may be characterized, at least to some extent, as a life period that poses the risk of becoming dependent or losing one's autonomy. However, the general assumption that autonomy gradually replaces dependency and then dependency gradually replaces autonomy over the life course is clearly simplistic.

Cultural relativity becomes particularly obvious in the autonomy–dependency dynamics across the life span. For example, while the developmental goal of maintaining autonomy in a wide variety of life domains over the life span is one of the highest values in most Western cultures, one of the most 'normal' elements of many developing countries' cultures is reliance on children in the later phases of life. Second, although autonomy and dependency play their roles as individual attributes, both should be regarded predominantly as contextual constructs depending strongly on situational options and constraints. For example, the dependent self-care behavior of an 85-year-old man or woman may not reflect physical or mental frailty at all, but may primarily result from the overprotective behavior of family members and professionals (Baltes 1996). Third, autonomy and dependency should both be regarded as multidimensional, that is, gain in autonomy in one life domain does not automatically lead to reduced dependency in other life domains and vice versa. For example, being able to meet the everyday challenges of life in an independent manner does not necessarily prevent a younger individual from relying strongly on parents or significant others when making crucial life decisions (such as selecting a partner). Fourth, and finally, autonomy and dependency have strong value connotations which shape action. In Western cultures, independent behaviors are generally regarded as posi-

tive and highly adaptive, worth supporting by all means, whereas dependency has negative value connotations and should be avoided at all costs. Such global value attributions can be questioned in terms of life complexity and richness. For example, emotional dependency upon another person lies at the heart of mature intimate relationships. Conversely, striving for autonomy may become detrimental when confronted with severe chronic illness, which necessitates help, support, and the delegation of control to the external environment. These differentiations have to be kept in mind as we examine autonomy and dependency in middle and old age more closely.

2. *Dependency and Autonomy—A Challenge in Midlife?*

Answers to this question must start with the developmental challenges associated with the life phase that occurs between roughly 45 and 65 years of age. According to life-span theorist Erik Erikson (1963), one central challenge of human midlife is *generativity*, that is, support of and solidarity with the following generations not only in terms of concrete child-rearing activities, but also in the broader sense of transfer of one's own life expertise and experiences to others. Coping with the 'empty nest,' establishing bonds to grown-up children, and becoming a grandparent are other typical challenges to be met in this life phase. With respect to women, the experience of menopause is the most typically age-graded event in this life period, while one of the most challenging nonnormative events of modern middle-aged women (very much less so for men) is taking over the care-giving role for one's father or mother.

What kinds of implications do these midlife challenges have with respect to autonomy and dependency? As Baltes and Silverberg (1994) have persuasively argued, the term *interdependence* best encompasses agency and autonomy *and* attachment and bonding needs in the middle years. Interdependence typically is at work in generativity, where the older generation is dependent on the younger generation in order to feel needed (particularly after children have left home). At the same time, interdependence can strengthen feelings of agency, competence, and autonomy by providing a forum for the transfer of advice, expertise, and 'world knowledge.' The new role of being a grandfather or grandmother further adds to interdependence, particularly in women. As has been argued (Hagestad 1985), women more easily express interdependence and attachment and thus contribute more to the maintenance of family and kinship. Furthermore, interdependence finds expression in social relations in midlife by helping others and receiving help, that is, by mutuality and reciprocity, thus contributing to the establishment of a *social convoy* which guarantees social support throughout life (Kahn and Antonucci 1980). However, providing care for a chronically ill parent may also negatively impact on well-balanced interdependence: the moral obligation to care for a family member, and also the loss of autonomy one endures in order to provide such care, can lead to severe psychological distress in midlife (Pearlin et al. 1996).

3. *On the Many Faces of Dependency and Autonomy in Old Age*

With respect to later life, Margret M. Baltes (1996) has introduced distinctions among structured, physical, and behavioral dependency. *Structured dependency* implies that human worth is determined primarily by participation in the labor force. According to this understanding, society is in a sense producing dependency among certain subgroups (such as the aged) in order to provide opportunity structures for other subgroups (such as younger persons). *Physical dependency* is closely linked to the age-related emergence of chronic physical and mental impairments such as severe mobility loss or Alzheimer's disease. *Behavioral dependency* primarily reflects the effect of the interaction between the older person and his/her social environment, thus emphasizing most strongly of all three forms of dependency the role of social and behavioral processes in order to explain dependency in the later years. Owing to the understanding of dependency in social and behavioral terms, a whole empirical research program has been conducted by Margret Baltes and associates (for an overview, see Baltes 1996). The major and very robust finding was that social interactions between older adults and social partners are prone to a *dependence–support script*, that is, dependent behavior among elders is reinforced by their social partners (typically by direct helping behavior), whereas autonomous behaviors are typically ignored.

Furthermore, structured, physical, and behavioral dependency interact with each other, that is, macrosocial, biological, and psychological processes must be considered in conjunction. Three theoretical approaches have been discussed to address this dynamic interplay and its outcomes. First, dependency in old age may be due in part to *learned helplessness*, that is, an existing noncontingency between action goals and consequences (Seligman 1975). Macrosocial (see again the term structured dependency) and noncontrollable biological impairments may contribute to dependency in this vein. Second, dependency may also be interpreted as a strong instrument for *passive control*. In this regard, the dependence–support script found in the Baltes research also reflects the power of dependent behaviors of elders to provoke positive responses (typically help) from their social environment and thus

maintain environmental control as long as possible. The adaptational value of this strategy is particularly suggested by the *life-span theory of control* (Heckhausen and Schulz 1995). Third, an even more complex interpretation of the dynamics between dependency and autonomy in old age comes into the play when adaptation and the striving for a successful course of aging are viewed in terms of *selective optimization with compensation* (Baltes and Baltes 1998). In this respect, dependent behaviors in certain life areas (such as basic care needs) may be seen as a powerful compensation tool in the late phase of the human life span in order to prepare the field for further optimization and development in selected other life domains with high personal priority.

4. Conclusions and New Research Directions

The dynamic interplay between dependency and autonomy occurs in different variations across the adult human life span. While the creation and regulation of interdependence is among the major tasks of middle adulthood, the particularities of old age call for the consideration of different pathways to explain the etiology and maintenance of dependency in old age. The insight of the behavioral model of dependency, pointing to the different roles that dependency can take as an adaptive tool in old age, also means a challenge for intervention. Owing to the potential role of dependent behaviors for successful aging, intervention efforts should always be framed within a change philosophy that leaves the elderly person in control of whether external autonomy-enhancing efforts should be exerted or not. Autonomy in old age, in this sense, may also mean the autonomy to decide for dependence in some life domains, even if this might mean the risk of losing available competencies in the long run by *disuse*.

New research directions should follow at least three avenues. First, research should examine forms of interdependency in midlife, with a view to understanding how they affect dependency in old age. Second, the interaction between social and physical environmental influences and personality traits, and also their effect on fostering dependency or maintaining autonomy, deserves more consideration. Third, more knowledge is needed on the day-to-day balancing and rebalancing of dependency and autonomy and their emotional and behavioral outcomes. For this kind of empirical research, the model of selective optimization with compensation (e.g., Baltes and Baltes 1998) and the life-span theory of control (Heckhausen and Schulz 1995) are probably the best theoretical alternatives to date.

Adulthood: Developmental Tasks and Critical Life Events

1. Systems of Influences on Individual Development

'Developmental tasks' and 'critical life events' represent concepts that are crucial to the framework of life-span developmental psychology, which views development as underlying, at least, three systems of influences, namely age-graded, non-normative, and history-graded (Baltes 1979). Age-grading refers to the extent to which the life span is structured and organized in time by age. Developmental psycholo-

gists have given attention to the age-relatedness of major transitions, as is represented by the concept of developmental tasks. Sociologists consider the life course as shaped by various social systems that channel people into positions and obligations according to age criteria.

In contrast, the system of non-normative influences on development is related to the concept of critical life events. These events are defined as clearly nonage-related, to occur with lower probability (as is true for many history-graded events), and to happen only to few people. Accordingly, these events are highly unpredictable, happening more or less 'by chance,' and occurring beyond the individual's control. Not surprisingly, they have been equated with 'the stress of life' threatening an individual's physical and psychological well-being, hence, were primarily the focus of clinical psychologists or epidemiologists.

Finally, history-graded events are defined as confronting large portions of the population at a given point in time, irrespective of peoples' ages or life-circumstances. Of particular interest is their differential impact depending on *when* within the life span they occur, although such a truly developmental perspective has rarely been adopted (for an exception see Elder 1998). Only recently the radical socio-historical changes associated with Germany's reunification have gained similar interest in terms of how they affect developmental trajectories in different age or birth cohorts (see Heckhausen 1999).

2. Developmental Tasks

Havighurst (1952) was one of the first to describe age-normative transitions by introducing the concept of developmental tasks, a particular class of challenges to individual development that arise at or about a certain period of time in the life span. Developmental tasks are seen to be jointly produced by the processes of biological maturation, the demands, constraints, and opportunities provided by the social environment, as well as the desires, aspirations, and strivings that characterize each individual's personality. These tasks as being age-normative has a twofold, although often not satisfactorily differentiated meaning. First, the concept refers to the statistical norm indicating that within a given age span a particular transition is (statistically) normal. Second, it also has a prescriptive connotation, indicating that at a given age individuals are expected to and have to manage certain transitions.

Evidently, due to its focus on (statistical) age-normativity, the traditional concept of developmental tasks cannot account for the overwhelmingly high variability that characterizes developmental processes particularly in adulthood. The life course is age-graded, but members of a birth cohort do not always move through it in concert according to the social roles they occupy. Some people do not experience certain transitions (e.g., parenthood), and those who do experience these transitions vary in the timing of events. In fact, the loose coupling between transitions and their age-related timing is highly reflective of individuals as producers of their own development, as is nowadays highlighted within action-orientated models of development (Brandtstädter 1998). Nevertheless, the concept has inspired the idea of age-gradedness of the life span, and developmental tasks have gained renewed interest as they are represented in individuals' normative (i.e., prescriptive) conceptions about (their own) development. These developmental conceptions set the stage for developmental prospects and goals to be attained within particular age spans ('on time') in a twofold way.

They guide social perception as age-related stereotypes (Filipp and Mayer 1999), and they inform the individual about the 'optimal' timing of investments in their development. In this latter sense, they represent nothing else than a mental image of one's own development that guides decisions and actions. Obviously, the self-regulatory power of the developing individual can be integrated into that theoretical perspective by conceiving of developmental tasks as organizers of developmental regulation (Heckhausen 1999).

Developmental tasks, moreover, share some common meaning with other traditional concepts. As is well known, Erikson (1959) proposed eight successive stages made up by a sequence of age-normative challenges. In addition, he focused on the disequilibrium associated with the normative shift of one developmental stage into another. At each of these stages, individuals are forced to manage the conflict between contradicting forces, for example, between generativity vs. stagnation (or self-absorption) in middle adulthood and between ego integrity vs. despair in old age. Similarly to the successful mastery of developmental tasks, resolution of these crises is seen to be a prerequisite of further growth; if this cannot be accomplished, various forms of psychological dysfunction may result.

Some theorists have incorporated elements of Erikson's approach into their conceptions of adult development, e.g., in addressing generativity as the developmental task of middle adulthood (e.g., Bradley 1997). At that time, individuals are seen to become 'senior members' of their worlds and to be responsible also for the development of the next generation of young adults. Yet, studies have provided mixed results on timing issues (McAdams and de St Aubin 1992, Peterson and Klohnen 1995). In addition, generativity has been conceived in terms of agency and communion, the latter representing the more mature form which is manifested through openness and union with others and in which life interest is invested in the next generation. Agentic generativity, in contrast, exists if a creation transferred to them is simply a monument to

the self, i.e., is associated with self-protection and self-absorption. Snarey (1993) has postulated that generativity is composed of three semihierarchical substages, namely biological, parental, and societal. According to his findings, having been an actively involved father at the age of 30 was linked to the expression of broad generative concerns at midlife. Marital satisfaction proved to be the strongest predictor of fathers' parental and societal generativity, underscoring that successful mastery of the preceding developmental task (intimacy vs. isolation) does in fact contribute to successful mastery of later developmental tasks.

3. *Critical Life Events*

Within the tradition of life-event research, the issue of what constitutes critical life events and of how their impact should be measured has been discussed extensively (see Filipp 1992). Various suggestions have been made, ranging from the disruptiveness or amount of change in people's lives apart from its meaning or direction up to multidimensional conceptions of what makes life experiences particularly critical ones. In general, critical refers to the fact that these types of events may be equated with turning points in the individual life span that result in one of three developmental outcomes: psychological growth, return to the precrisis level of functioning (as is stressed in homeostatic models), or psychological and/or physical dysfunctioning. Such a notion is widely acknowledged by crisis models of development, according to which transitions imply both danger and opportunity for growth. The same holds true for critical life events, as is inherent in the etymological origin of the word 'crisis' itself.

One of the most substantial contributions of a developmental perspective on 'the stress of life' was that the meaning of critical life events varies also according to their normative timetable. For instance, work place instability has different meanings across various ages, i.e., being more common before the age of 30, but being experienced rarely after the age of 50 and, thus, being more stressful in later years. Thus, life events may be considered 'critical' because they violate normative conceptions of an expected life span, e.g., death of spouse during middle rather than late adulthood. As deviations from the expected life course, off-time events can set in motion a series of off-time sequences. Due to their lack of normativity and affective quality, they evoke extremely strong reactions, provide the individual with a sense of undesirable uniqueness, and foster them to dramatically alter their conceptions of a 'good life.' In addition, critical life events are seen to interfere with the successful mastery of developmental tasks and the attainment of goals, people have set for themselves. Consequently, they bring about the necessity to disengage from commitments and to replace them with new options and goals—coping tasks that are particularly painful to accomplish (Filipp 1998). Furthermore, people normally are not 'taught' how to deal effectively with loss and crisis. Neither are they taught respective lessons at school, nor do they usually learn from models how to cope with critical life events. And even when such models were available, people rather prefer to look at the sunnier sides of life. According to the widely held belief in one's invulnerability and unrealistic optimism (Taylor and Brown 1994), people usually do not consider critical events as one of the possible realities they have to confront in their lives.

In that respect, one could borrow a term from cognitive psychology to conceive of critical life experiences as 'weakly scripted situations,' for which ways of acting (let aside behavioral routines) are not readily at hand. Some life events that accompany middle and old age are, at least partially, embedded into culturally shaped ways of responding (e.g., public rituals), often facilitating the coping process. Other events, like the initial diagnosis of cancer, represent existential plights and are seen to cause behavioral disorganization and fruitless attempts to find meaning in one's fate. In addition, almost all types of these events imply a threat to fundamental beliefs about the self (e.g., as being powerful or lovable) and the necessity to alter the self-system. Consistent with predictions of identity interruption theory (Burke 1996), one can assume that many ways of coping (like ruminative thinking, search for meaning) are ultimately related to and in the service of reconstructing the self-system. From that point of view, critical life events hardly allow for the notion of an individual that proactively regulates their development. Rather, they often put individuals in a purely reactive role for a long time, before they regain a secure basis for setting personal goals again.

4. *Conclusions*

In sum, both concepts, developmental tasks as represented in normative conceptions of development, as well as critical life events, have enriched our insight into the dynamics of life-span development. They focused our attention on road maps for human lives and regular life paths, on the one hand, and on the developmental plasticity during critical turning points within the life span, on the other. Nevertheless, a differential perspective needs to be adopted in order to account for the tremendous variability in developmental trajectories. For example, much of this work has been conducted with respect to male development in middle adulthood. Nevertheless, evidence of different developmental pathways for men and women in a variety of life domains is growing now, at least with regard to later adulthood (Smith and Baltes 1998), and this evidence definitely needs extension to the middle

years. In addition, individual strategies to cope with life challenges and demands need to be taken into consideration.

Adulthood: Emotional Development

1. Introduction and Historical Overview

Research on emotion in adult development and aging this century has been quite limited until recently and for a long time was without significant theoretical guidance. This lack of attention to emotion in human development stemmed chiefly from two phenomena: (a) the inherent complexity of emotion—which hindered definitional clarity; and (b) a long-standing Western bias against emotion, with emotion seen as an impediment to reason and rationality, rather than a psychological function in its own right.

During the 1960s and early 1970s a number of important theoretical contributions were made by Silvan Tomkins, Carroll Izard, Paul Ekman, and Robert Plutchick, building on the earlier work by Charles Darwin and William James. The latter, 'discrete emotions' theorists postulated a limited number of basic emotions—sadness, anger, fear, shame, joy, interest, contempt, disgust, and surprise—each having distinctive neurophysiological, physiognomic, motivational, and phenomenological properties. For example, there are unique motivational properties associated with each emotion: fear motivates flight, anger aggression, shame withdrawal, and so forth. It should also be mentioned that emotions are also conceptualized as having dimensional features within the discrete emotions framework; that is, emotions can vary in frequency, intensity, hedonic tone, and arousal level. These discrete emotions theories played an important role in bringing conceptual clarity to the study of emotion; they also served to challenge and undermine the view that emotions were merely disruptive and maladaptive forces in human life.

Important empirical work was conducted during the late 1970s. During this time, Ekman and Izard took issue with earlier theories which had proposed that emotions were undifferentiated. Using cross-cultural data, they were among the first to document the universality of human emotions, as well as the differential facial patterning of the fundamental emotions. Later, Robert Levenson and colleagues were able to demonstrate the differential physiologically patterning.

Although these studies led the way, a real groundswell in empirical research on the emotions did not occur until the late 1970s and early 1980s. The first inroads were made in the field of child development, and social and personality psychology. Within short order there was a rapidly expanding cadre of child, clinical, and social-personality psychologists doing very innovative research on emotion, but by and large the developmental studies were limited to the period of infancy, which was guided by a coherent body of theory. In contrast, there was little theoretical guidance for researchers interested in the adult years. For example, of the four theorists noted above, only Izard

took a developmental stance; however, almost all of his own empirical research was devoted to the study of emotional development during infancy and early childhood.

A few scattered studies on adult development that appeared during the 1970s and 1980s seemed to suggest that the course of development over the adult years was one of decline, including contradictory trends indicating affective blunting on the one hand and increased negativity on the other. However, this research was not theory driven and was based largely on institutional samples of older people. Research on emotion in adult development and aging using non-institutionalized persons only began to gain critical mass during the 1990s—largely owing to theoretical contributions that placed emotional development within a lifespan framework, including the differential emotions theory of Izard (newly expanded to actively engage issues of adult development and aging), Laura Carstensen's socio–emotional selectivity theory, and Gisela Labouvie-Vief and Powell Lawtons' regulatory models. Izard proposed that while there are changes in expressive behavior over the course of development, there is a core feeling state associated with each discrete emotion that remains constant across the lifespan. Carstensen's theory links emotions to social process, and proposes that individuals select and maintain social interactions to regulate affect and maintain self identity. In addition, Lawton's model suggests that adults engage in behavior that seeks to maintain an optimum level of arousal and that older adults become more proficient at affect regulation. Finally, Labouvie-Vief's cognitive-affective model suggests that emotion regulation is related to an individuals' cognitive-developmental level. Recent empirical research, by and large, supports these propositions. In the following, we consider this literature within the more general question of whether emotions and related socio-emotional processes undergo change over the lifecourse.

At the outset it is important to note that there are two fundamental aspects of emotions, one involving their motivational value, the other, social process. That is, emotions provide motivational cues to the self, directing the self to engage in flight, attack, approach, and so forth; because they also indicate preparedness to respond in certain ways, they provide social signals to others, inviting potential social partners to approach, to retreat, to avoid, to protect the self, and so on. Most of the basic emotions, which are part of a prewired set of behavioral propensities, depend simply on maturation for their development, and most emerge in the behavioral repertoire by the second year of life. However, they undergo modification during childhood in accordance with 'display rules,' a set of proscriptions concerning who can show what emotions, under what circumstances, to whom, and in what form. These display rules vary by culture, historical epoch, and familial patterns. Children learn to modulate and regulate their expressive behavior so as to achieve a fit with their culture and family, modifying the intensity and directness with which emotions are expressed. One may well ask whether there is anything about emotional processes that undergo change over the adult years after basic patterns have become established. Since emotions involve underlying neurophysiological patterns as well as behavioral patterns and feeling states, investigators have been interested in determining whether there are physiological changes in emotions with age, changes in expressivity, and changes in subjectivity over the adult years; they have also examined whether people's ability to regulate their emotions changes in adulthood and old age.

2. *Changes Over the Lifecourse*

2.1 *Are There Changes in Physiological Patterns?*

Given that the emotion system is grounded in basic neurophysiological processes, and given that there are widespread structural and physiological changes in the various organ systems of the human body over the adult years, including a decline in vision and hearing as early as the twenties, a slowing of metabolism with age, and neurological cell fallout in later life, we may well expect to see changes in the emotion system over the adult years. Unfortunately, there has been relatively little research in this area, with the exception of the work of Levenson and colleagues (Levenson 1992, Levenson et al. 1991). In this body of work, the autonomic nervous system responsivity of participants was monitored while they recollected and relived salient emotional events or while they assumed patterned facial expressions. Under these conditions, Levenson was able to demonstrate that there are emotion-specific patterns that distinguish between the emotions of anger, fear, sadness, and disgust. In studies of older people, he found that the latter exhibited the same emotion-specific patterns as younger people; the magnitude of the response was lower in older subjects. However, the older subjects reported the same degree of subjective emotional arousal.

2.2 *Are There Changes in the Expression of Emotion?*

The bulk of research on the nonverbal communication of emotion during this century and even during Darwin's time has been conducted on facial expressions. Research has shown that there is increasing conventionalization of facial expressions across the childhood years, which in large measure involves

adopting cultural and familial display rules and includes a general dampening of expressive behavior; there is far less research on adulthood. Although patterns of muscular activity remain basically the same, for example, oblique brows that signal sadness in children, signal sadness in younger and older adults as well, Carol Malatesta-Magai and colleagues have found several distinguishing differences in older vs. younger adult faces (see the review in Magai and Passman 1998). In one study, younger and older participants were videotaped during an emotion-induction procedure in which they relived and recounted emotionally charged episodes involving four basic emotions. Older individuals (50 years old or above) were found to be more emotionally expressive than younger subjects in terms of the frequency of expressive behavior across a range of emotions; they expressed a higher rate of anger expressions in the anger-induction condition, a higher rate of sadness during the sadness induction, greater fear under the fear-induction condition, and greater interest during the interest condition.

In another study, older adults were found to be more expressive in another sense. Malatesta-Magai and Izard videotaped and coded the facial expressions of young, middle-aged and older women while they recounted emotional experiences. Using an objective facial affect coding system, they found that while the facial expressions of the older vs. younger women were more telegraphic in that they tended to involve fewer regions of the face, they were also more complex in that they showed more instances of blended expressions where signals of one emotion were mixed with those of another. This greater complexity of older faces appears to pose a problem for those who would interpret their expressions. Young, middle-aged, and untrained 'judges' attempted to 'decode' the videotaped expressions of the women in the above study. With the objectively coded material serving as the index of accuracy, Malatesta-Magai and colleagues found that judges had the greatest difficulty with and were most inaccurate when decoding older faces; however, the accuracy with which judges decoded expressions varied with age congruence between judges and emotion expressors, suggesting a decoding advantage accruing through social contact with like-aged peers (Magai and Passman 1998).

Another aspect of facial behavior that appears to change with age has to do with what Ekman has called 'slow sign vehicle' changes—changes accruing from the wrinkle and sag of facial musculature with age. Malatesta-Magai has also noted a personality-based effect involving the 'crystallization' of emotion on the face as people get older; that is, emotion-based aspects of personality seem to become imprinted on the face and become observable as static facial characteristics in middle and old age. In one study, untrained decoders rating the facial expressions of older individuals expressing a range of emotions made a preponderance of errors; the errors were found to be associated with the emotion traits of the older expressors.

2.3 Are There Changes in the Subjectivity of Emotion?

Research suggests that older individuals are more likely to orient to the emotional content of their worlds than younger individuals, in the sense that emotion becomes a more salient experience for them, though experienced emotions may not be necessarily any more or less intense. Carstensen and colleagues tested older and younger participants for recall of narrative material they had read; they found that older individuals recalled more of the emotional vs. neutral material. In terms of changes in the intensity of emotion, the work of Levenson and colleagues indicates that younger and older persons do not differ from each other in the subjective intensity of emotions induced in the laboratory. Outside of the laboratory, there are conflicting results. Some studies find that there are no differences in frequency and intensity of reported positive and negative emotion across the adult years, whereas other studies indicate increasing positive affect in older individuals, at least up until late life. In late life (over 85 years of age), there appears to be a modest decline in positive affect, though there is not a corresponding increase in negative affect (Staudinger et al. 1999). The above pattern of results refute the earlier belief that aging is accompanied by an increase in negative affect (Carstensen et al. 1998, Levenson et al. 1991, Magai and Passman 1998).

Going beyond the issue of frequency and intensity, Labouvie-Vief and colleagues (Labouvie-Vief 1998) have examined the complexity of emotional experience. To this end they coded narrative transcripts of individuals recounting emotional experiences. They found that younger individuals rarely referred to inner subjective feelings, tended to describe their experiences in terms of norms and conventions, and controlled their emotions through such metacognitive strategies as forgetting or distracting the self. In contrast, older individuals were least bound by social convention, were more likely to refer to inner subjective states, and were more capable of discussing complex feelings and enduring states of conflict and ambivalence. Work by Lawton and colleagues (Lawton 1989) and Malatesta-Magai and colleagues (Magai and Passman 1998) has also supported the finding that older individuals are more verbally expressive of their subjective feelings. Other researchers have found that older individuals are more willing to engage in painful self-disclosure with an unfamiliar social partner than are younger individuals.

The above work suggests that people become more comfortable with their emotional selves as they age, that they are more likely to acknowledge their emo-

tional states, and that they are more capable of sustaining and reporting more complex inner affective lives. This body of work, however, does not directly address the issue of continuity of feeling states in the sense of Izard's constancy theory. While core feelings states associated with the discrete emotions may or may not remain essentially unchanged, it appears there is at least greater cognitive elaboration of inner subjectivity with age.

2.4 Are There Changes in the Ability to Regulate Emotion over the Adult Years?

It has long been noted that there is a narrowing of social networks in later life. Carstensen has proposed that this narrowing is an adaptive strategy people use to regulate emotion, a strategy that is crucial for the maintenance of well-being in later life, and which is linked to the need to conserve energy. A series of studies from her laboratory has supported this view (Carstensen et al. 1998). Older people indicate that they restrict their social contacts to those with whom they are most intimate; despite this narrowing of social networks, emotional communication is preserved, if not enhanced.

Research by Lawton and colleagues (1989) points to both an increasing ability to regulate emotion with age and the use of an optimizing emotion regulation strategy. That is, he has proposed that individuals actively create environments that permit them to achieve an optimal mix of emotionally stimulating vs. insulating features. In fact, studies have substantiated greater self-regulatory capacities in older individuals, with older people being higher in emotional control and emotional maturity through moderation. Older individuals were more likely to indicate they deliberately chose activities that would allow them to achieve just the right level of emotional stimulation.

In summary, the various strands of research that have been published since 1985 have materially advanced our understanding of emotion processes during the adult years. They take issue with earlier findings from research with institutionalized subjects and challenge stereotyped views of aging. Instead of revealing a bleak picture of diminished affective capacity and an inexorable drift towards negative affect, this latest generation of research suggests that individuals become more emotionally attuned and more emotionally complex with maturity. There are two caveats to this more comforting picture. The first is that emotional processes during advanced old age and during the chronic debilitating diseases may look quite different, as some recent studies by Lawton, Magai, and research of the Berlin Aging Study (Baltes and Mayer 1999) indicate. The second is that all of the foregoing research has been cross-sectional in nature and is thus potentially confounded by cohort effects; longitudinal research is crucial for advancing the state of knowledge in this area.

Adulthood: Prosocial Behavior and Empathy

Prosocial behavior represents a broad category of acts that are 'defined by society as generally beneficial to other people and to the ongoing political system' (Piliavin et al. 1981, p. 4). This category includes a range of behaviors that are intended to benefit others, such as helping, sharing, comforting, donating, or volunteering, and mutually beneficial behaviors, such as cooperation. Research on prosocial behavior has addressed not only the antecedents and consequences of these actions, but also the different motivations that may underlie these behaviors. Batson (1998), for

example, defines altruism as a motivational state with the ultimate goal of increasing another person's welfare, in contrast to egoistically motivated action, which has the ultimate goal of improving one's own welfare.

1. Research Trends

Research in this area has developed in several stages. The work of the early and mid-1960s typically focused on norms, such as social responsibility and reciprocity, that seemed to govern prosocial behavior. By the end of that decade and into the early 1970s, investigators, stimulated by public outrage at bystander apathy, investigated factors that reduced the likelihood of intervening in crisis and emergency situations. As researchers also explored the reasons why people *do* engage in prosocial activities, they began to consider more fully the role of empathy and developmental influences. In the 1980s, interest in prosocial actions declined somewhat and the questions moved primarily from *when* people help to *why* people help. Researchers frequently attempted to understand fundamental motivational processes, considering how different affective consequences of empathy could produce either egoistic or altruistic motivation. Research in the 1990s provided a clearer link between prosocial motivations and general personal, social, and intergroup orientations.

2. When Do People Help?

Research has identified a range of social and situational factors that influence helping and other prosocial actions (Schroeder et al. 1995). In terms of social factors, people are more likely to engage in prosocial activities for others with whom they are more closely related, with whom they are more similar, and with whom they share group membership; they are less likely to respond prosocially when others are seen as more responsible for their plight or otherwise undeserving of assistance. With respect to situational factors, people are more likely to help in situations that are more serious and clear. They are less likely to help when they believe that others are present and will take action, which relieves a bystander from having to assume personal responsibility for intervention.

Both affective (e.g., arousal and emotion) and cognitive (e.g., norms and perceived costs and rewards) processes are hypothesized to underlie prosocial behavior (see Dovidio and Penner in press). Cognitively, Latané and Darley's (1970) decision model of emergency intervention proposes that whether or not a person helps depends upon the outcomes of a series of prior decisions. This model has also been applied to nonemergency situations. Alternatively, a cost–reward analysis of prosocial action assumes an economic view of human behavior. In a potential helping situation, a person analyzes the circumstances, weighs the probable costs and rewards of alternative courses of action, and then arrives at a decision that will result in the best personal outcome. Current research is consistent with the central tenet of the cost–reward approach. The role of arousal in helping and other prosocial actions relates to the process of empathy.

3. Empathy

Empathy is 'an emotional response that stems from another's emotional state or condition, is congruent with the other's emotional state or condition, and involves at least a minimal degree of differentiation between the self and the other' (Eisenberg and Fabes 1990, p. 132). Empathy can be shaped by three different types of role taking (Davis 1994): (a) perceptual, relating to the capacity to imagine the visual perspective of another; (b) cognitive, involving beliefs about the thoughts, motives, and intentions of another person; and (c) affective, concerning inferences about another's emotional state. Perspective taking not only influences the degree of empathy that people experience but also, in combination with other cognitive processes, shapes the nature of the emotion that is experienced. Empathy can produce self-focused emotions, such as sadness or distress, or other-oriented emotions, such as sympathy or empathic concern.

There is substantial empirical evidence that people are fundamentally empathic and emotionally responsive to the needs of others. People are aroused physiologically and subjectively by the distress of others. This reaction appears even among very young children and occurs across cultures. In addition, people show greater empathy toward others who are closer and more similar to them. In fact, empathy is such a strong and universal phenomenon that some researchers have proposed that empathic arousal has evolutionary origins and a biological basis.

Although people appear to be generally inherently empathic, there are also systematic individual differences in dispositional empathy. Studies of identical twins, for example, have supported the heritability of empathy (see Schroeder et al. 1995). In addition, there is a general, positive association between dispositional empathy (and perceptual, cognitive, and affective perspective taking) and a broad range of prosocial actions (Davis 1994, Graziano and Eisenberg 1997).

3.1 Empathy and Emotion

Although most researchers agree that empathic arousal is important, there is much less agreement about the nature of this emotion and how it actually motivates prosocial behavior. Empathy can produce different emotions depending on the context. In severe emergency situations, bystanders may become upset

and distressed; in less critical, less intense problem situations, observers may feel sad, tense, or concerned and sympathetic (Batson 1998, Dovidio and Penner in press). How empathic arousal is interpreted, in turn, elicits either egoistic or altruistic motivation.

3.2 Empathy and Egoism

Models of egoistic motivation posit that helping is directed by the primary goal of improving one's own welfare; the anticipated benefit to others is secondary. From this perspective, empathy elicits self-oriented emotions (e.g., sadness or distress) that are experienced as unpleasant and motivate actions, such as helping, that are perceived to relieve them. Two of these approaches are the negative-state relief model and the arousal: cost–reward model.

According to the *negative-state relief model* (Cialdini et al. 1987), feelings of guilt or sadness motivate people to engage in behaviors that will improve their mood. Because through socialization and experience helping becomes self-rewarding in adults, helping represents one such behavior. Three fundamental implications of the negative-state relief model have received support (see Schroeder et al. 1995). First, a variety of negative states, including guilt from having personally harmed a person and sadness from simply observing another person's unfortunate situation, can motivate helping. Second, other events besides helping (e.g., receiving praise) may just as effectively make people feel better, and exposure to these events can thus relieve the motivation to help caused by negative states. Third, negative moods motivate helping only if people believe that their moods can be improved by helping. Negative feelings will *not* promote helping if people are led to believe that these feelings cannot be relieved or if, as with younger children, the self-rewarding properties have not yet developed.

Affective empathy can produce other emotional reactions, such as distress and upset, particularly among bystanders in emergencies. According to the Piliavin et al. (1981) *arousal: cost–reward model*, empathic arousal is generated by witnessing the distress of another person. When the bystander's empathic arousal is attributed to the other person's distress, it is emotionally experienced by the observer as unpleasant. The observer is therefore motivated to reduce it. The person then weighs various costs and rewards for helping or not helping, and chooses a course of action that relieves the unpleasant arousal while minimizing net costs and maximizing rewards. One normally efficient way of reducing this arousal is by helping to relieve the other's distress. Thus, from this perspective, arousal motivates a bystander to take action, and the cost–reward analysis shapes the direction that this action will take.

Supportive of the arousal: cost–reward model, empathic arousal attributed to the other person's situation motivates helping. Facial, gestural, and vocal indications of empathically induced arousal, as well as self-reports of empathically induced anxiety, are all positively related to helping (see Schroeder et al. 1995). Consistent with the hypothesized importance of attributing this arousal to the other's situation, people are more likely to help when arousal from extraneous sources such as exercise, erotic films, and aggressive films is attributed to the immediate need of another person. People are less likely to help when arousal generated by witnessing another person's distress is associated with a different cause (e.g., misattributed to a pill). In addition, work by Eisenberg and her associates (see Eisenberg and Fabes 1998) suggests that extreme empathic overarousal or the inability to regulate empathic arousal, which may interfere with the attribution process, can also reduce helpfulness.

3.3 Empathy and Altruism

In contrast to egoistic models of helping, Batson and his colleagues (see Batson 1998) present an *empathy–altruism hypothesis*. Although they acknowledge that egoistically motivated helping occurs, Batson and his colleagues argue that true altruism also exists. The primary mechanism in the empathy-altruism hypothesis is the emotional reaction to another person's problem. Empathy that is experienced emotionally as compassion and concern (i.e., as 'empathic concern') produces altruistic motivation. Because altruistic motivation has the primary goal of improving the other person's welfare, an altruistically motivated person will help if (a) helping is possible, (b) helping is perceived to be ultimately beneficial to the person in need, and (c) helping personally will provide greater benefit to the person in need than would assistance from another person also able to offer it.

In numerous experiments, conducted over a 20-year period, Batson and his colleagues have produced impressive empirical support for the empathy–altruism hypothesis (Batson 1998). Participants who experience relatively high levels of empathic concern (and who presumably are altruistically motivated) show high levels of helpfulness even when it is easy to avoid the other person's distress, when they can readily justify not helping, when helping is not apparently instrumental to improving the benefactor's own mood, and when mood-improving events occur prior to the helping opportunity. However, several researchers have proposed alternative explanations that challenge Batson's contention that helping can be altruistically motivated. These explanations have focused on (a) how feelings of empathic concern may be associated with special costs for not helping or rewards for helping, (b) how feelings of sadness that are aroused along with empathic concern actually are the primary determinants of helping, and (c) how manipulations used to induce empathic concern for another person

also create a greater sense of self-other overlap, or 'oneness,' so that helping may also have direct and primary benefits for the helper (see Cialdini et al. 1997). However, despite the critiques and controversies about aspects of the empathy–altruism hypothesis, the preponderance of evidence from more than 20 years of experimentation on this question strongly suggests that truly altruistic motivation may exist and that all prosocial behavior is not necessarily egoistically motivated.

4. *Sustained Helping*

In general, empathy has been viewed as much more influential for short-term, spontaneous forms of helping than for long-term, sustained volunteering, which has been hypothesized to be motivated by a range of personal (e.g., gaining knowledge, being among friends) and humanitarian goals (Clary et al. 1998). Nevertheless, developing a self-image of being empathic and helpful can produce longer-term commitments to helping others. For instance, the female gender role is often associated with the trait of 'communion,' being caring, emotionally expressive, supportive, and nurturant (Eagly and Crowley 1986). As a consequence, women may interpret empathic arousal in different ways than men and engage in different types of helping. In particular, although both men and women experience similar levels of physiological arousal when they observe distress in others, women may be more likely to interpret this arousal as a positive empathic response to the other person's needs. In accord with these findings, women are more likely than men to provide their friends with personal favors, emotional support, and informal counseling about personal or psychological problems. In contrast, consistent with their traditional gender role of being 'heroic' and effective, men are more likely than women to intervene in emergencies involving personal threat and to engage in instrumental forms of prosocial activities (Eagly and Crowley 1986). More generally, regular and public commitments to helping (such as donating blood or volunteering for charities), which may have initially been stimulated by feelings of empathy, can lead to the development of a role-identity consistent with those behaviors (Piliavin and Charng 1990, Penner and Finkelstein 1998).

5. *Conclusion*

The social context, the nature of the situation, the characteristics of the person in need, and the personality of the potential helper not only affect assessments of costs and rewards and the decisions about whether to engage in prosocial acts, but also shape empathic responses. How empathy is experienced emotionally is fundamental; empathy can produce either egoistic or altruistic motivation. Thus empathy may represent a basic mechanism for translating genetic prosocial predispositions, which may have evolutionary benefits, into action.

Adverbial Clauses

Adverbial clauses are known from traditional grammar, and basically all contemporary models of grammar, as one of three major classes of subordinate

clauses (the other two being relative and complement clauses). Their grammatical function is that of an adverbial, i.e., they provide information on the (temporal, locative, causal, conditional, etc.) circumstances depicted in the main clause. Correspondingly, the adverbial clauses in example (1) below are called temporal, locative, causal, and conditional clauses, respectively:

(1) They will meet …
  (a) before the sun rises.
  (b) where they first made love to each other.
  (c) because they need to find a solution.
  (d) if we let them.

Given the large spectrum of possible circumstances, adverbial clauses represent the most diverse semantically and (from the point of view of their interpretation) most challenging class of subordinate clauses. Given their subject–predicate structure, adverbial clauses are formally the most complex type of adverbials compared with adverbs (e.g., *soon*, *here*, *quickly*) and adverb phrases (e.g., *on Sunday*, *in the garden*, *very quickly*). Combined with a sentence frame like 'They will meet …' in (1), the latter two types of adverbial still yield a simple(x) sentence, whereas adverbial clauses yield a complex sentence. Beyond the complex sentence of which they form a part, adverbial clauses have a crucial function in the creation of a coherent discourse and are thus a prominent feature, especially of written texts. It seems that adverbial clauses can be found in all languages of the world (Thompson and Longacre 1985), even though in many languages they may look different from the prototypical adverbial clauses (with a finite verb and introduced by a subordinating conjuction such as *if* or *because*) we know from the major Indo-European languages. In the light of recent crosslinguistic research, adverbial clauses will be discussed in this article with regard to their structure (Sect. 1), the range and levels of their meanings (Sect. 2), structural properties influencing their interpretation (Sect. 3), and their functions in written and spoken discourse (Sect. 4).

1. *The Structure of Adverbial Clauses*

1.1 *Adverbial Clauses as Dependent Clauses*

Adverbial clauses are subordinate clauses in the sense that they depend for their occurrence on another, the main, clause. However, not all languages mark the distinction formally between dependent and independent clauses in the same way (e.g., German uses verb-final word order in dependent clauses and verb-second word order in independent clauses; other languages have a dependent mood: in Italian the subjunctive is used exclusively in dependent clauses). Nor do all languages make a formal distinction between these two types of clause in the first place (e.g., isolating languages Such as Chinese). In the languages of Europe nonfiniteness, i.e., the use of infinitives, participles, or related forms as predicates, is a clear indication of dependency and subordination. The same applies to the presence of certain types of lexemes serving as clause-linkers (typically) introducing, at least in languages where the verb precedes the object, a finite or nonfinite clause: relativizers such as *who*, *whose*, *whom*, *which*, *that*; complementizers such as *that*, *whether*, *if*; or adverbial conjunctions (alternatively known as adverbial subordinators) such as *where*, *when*, *after*, *before*, *because*, *if*, *although*.

Yet the presence of one of these clause-linkers by itself is no guarantee that the relevant subordinate clause can be classified as either a relative, a complement, or an adverbial clause. Just take subordinators such as *that* or *if* in examples (2) and (3), respectively, where their use as adverbial subordinators in the (a) sentences contrasts with their use as complementizers (*that* in (2b), *if* in (3b)), and the use of *that* as relativizer in (2c):

(2) (a) He talked so fast that most people couldn't follow.
  (b) He said that most people couldn't follow.
  (c) The talk that most people couldn't follow was given by a colleague of mine.

(3) (a) I'm more than glad if she's at home.
  (b) I wonder if she's at home.

What these examples show is that even in individual languages there may exist no inherent structural differences between the three major types of subordinate clause. Rather, it is the function they serve in the sentence of which they form a part that determines their classification: are they an integral part of the sentence typically serving as the argument of a verb (complement clause) or qualifying a noun (relative clause), or do they belong to the (optional) periphery of the sentence, modifying an entire state of affairs (adverbial clause)? Even then a clearcut classification may be impossible or depend on one's point of view, as the examples in (4) show:

(4) (a) She'll leave when John comes.
  (b) I forgot the bag where we met last time.

The subordinate clauses in example (4) are sometimes called *adverbial relative clauses* (with *when* and *where* analyzed as relative adverbs rather than adverbial subordinators) since they 'can be paraphrased with a relative clause with a generic and semantically relatively empty head noun' (Thompson and Longacre 1985, p. 179), such as *at the time* or *the moment* in (4a) or *at the place* in (4b). As a matter of fact, it is not difficult to find languages where in particular adverbial clauses of Time, Place, and Manner resemble and share properties with relative clauses and where, independently or in addition, the relevant adverbial subordinators 'are identical with or at least incorporate a largely desemanticized noun "place," "time," or "way, manner"' (Kortmann 1997, p. 65; on the evolution of adverbial subordinators see Kortmann 1997, 1998).

1.2 Nonfinite Adverbial Clauses

Due to their large inventories of adverbial subordinators and the pervasiveness of adverbial subordinators in adverbial clauses (obligatory in finite, optional in the much less frequent nonfinite adverbial clauses), the (mostly Indo-European) languages of Western and Central Europe, in particular, are called *conjunctional languages*. By contrast, most of the genetically rather diverse, largely non-Indo-European languages of the Eastern periphery of Europe (from Siberia down to the Caucasus) have relatively few adverbial subordinators, using rather so-called converbs, i.e., nonfinite verb forms whose main function is to mark adverbial subordination, and are thus called *converb languages* (see König 1995, Nedjalkov 1998). The division between conjunctional and converb languages and, more generally, between languages preferring either finite or nonfinite subordination strategies, correlates strongly with the basic word order found in the great majority of these two language types, namely SVO (conjunctional languages) and SOV (converb languages). Even conjunctional languages, though, make use of nonfinite (examples 5a, b) or even verbless (example 5c) adverbial clauses, albeit to differing degrees. English, for instance, stands out in this respect among the Germanic languages (see Kortmann 1991).

(5) (a) My head bursting with stories and schemes, I stumbled in next door.
(b) Inflating her lungs, Fiona screamed.
(c) Alone in his room, she switched on the light.

Interesting for the present purposes are two of their properties: even though they may have their own overt subject (so-called *absolute constructions* or *absolutes*, as in example (5a)), typically they have a subject that needs to be inferred from the main clause and is identical in reference to the subject of the main clause (known, for example, as *free adjuncts* in English, as in examples (5b, c)). More importantly, these clauses typically do not specify (for instance, by an adverbial subordinator) in which way (temporally, causally, conditionally, etc.) they modify the state of affairs expressed in the main clause, thus presenting the interpreting individual with a much more challenging problem than do most prototypical, i.e., finite, adverbial clauses (more on this in Sect. 3).

2. Semantic Types of Adverbial Clause

2.1 Circumstantial Relations

Traditionally, adverbial clauses are classified and grouped on the basis of the semantic relations that can hold between states of affairs (or propositions) depicted in different parts of a complex sentence or different chunks of discourse. The exact number and labeling of these semantic relations, variously called *adverbial*, *circumstantial*, *interclausal*, or *coherence relations*, is irrelevant. It can safely be assumed, however (and has been shown for the European languages in Kortmann 1997, that all languages use adverbial clauses and have adverbial subordinators for the expression of at least a subset of the relations in example (6) below, and perhaps for additional relations (e.g., French *faute que* expresses Negative Cause 'because no(t),' German *ohne dass* can signal both Negative Result 'as a result/consequence of which no(t)' and Negative Concession 'although no(t)'). The grouping of semantic relations suggested in example (6) corresponds largely with standard practice in many descriptive grammars when distinguishing between three major groups of adverbial clauses, each of which expresses relations which are closely related to each other: temporal clauses, modal clauses, and a third group expressing 'logical' relations, variously called causal or conditional clauses (shown here as CCC). For further discussion compare Kortmann (1997, pp. 79–89):

(6) (a) TIME — Simultaneity Overlap 'when,' Simultaneity Duration 'while,' Simultaneity Co-Extensiveness 'as long as,' Anteriority 'after,' Immediate Anteriority 'as soon as,' Terminus *a quo* 'since,' Posteriority 'before,' Terminus *ad quem* 'until,' Contingency 'whenever'
(b) MODAL — Manner 'as, how,' Similarity 'as, like,' Comment/Accord 'as,' Comparison 'as if,' Instrument/Means 'by,' Proportion 'the … the'
(c) CCC — Cause/Reason 'because,' Condition 'if,' Negative Condition 'unless,' Concessive Condition 'even if,' Concession 'although,' Contract 'whereas,' Result 'so that,' Purpose 'in order that,' Negative Purpose 'lest,' Degree/Extent 'insofar as,' Exception/Restriction 'except/only that'
(d) OTHER — Place 'where,' Substitution 'instead of,' Preference 'rather than,' Concomitance, Negative Concomitance 'without,' Addition 'in addition to'

One would assume that not all of these circumstantial relations are equally central to human reasoning. And indeed there is evidence suggesting a core of roughly a dozen cognitively most central circumstantial relations, including, above all, Simultaneity (Overlap, Duration) ('when,' 'while'), Place ('where'), Similarity ('as'), Cause, Condition, and Concession. It is for the latter three relations, for example, that all the conjunctional languages of Europe possess at least one adverbial subordinator;

similarly, it is these three relations for which the largest number of adverbial subordinators can be found in the European languages, i.e., for which the greatest need for explicit marking seems to be felt. Moreover, the adverbial subordinators marking the core relations tend to be more reduced morphologically (i.e., most lexicalized), much more frequently used, and older than those marking any of the peripheral relations (see Kortmann 1997, pp. 128–52).

Simultaneity and Cause also figure prominently in a large-scale semantic analysis of nonfinite adverbial

hardly distinguishable circumstantial relations which an equally high number of free adjuncts and absolutes can be taken to express, namely Addition/Concomitance ('and at the same time'), as in example (7), and Exemplification/Specification ('e.g., i.e., in that, more exactly,' etc.), as in example (8).

(7) (a) There he sat, wearing a white golfing cap.
(b) Sam threw himself to the ground, dragging Frodo with him.

(8) (a) Shares in Midland were worst hit, falling at one time 42p.
(b) He paid the closest attention to everything Lenny said, nodding, congratulating, making all the right expressions for him.

This shows that not all circumstantial relations are equally important in different structural types of adverbial clauses. Likewise, their relative importance as coherence relations depends on the type of discourse. For instance, Cause, Condition, and Concession play a much more important role in academic writing than they do in narrative fiction, where temporal relations as well as, for nonfinite adverbial clauses, Addition/Concomitance and Exemplification/Specification account for a much higher number of adverbial clauses (see Kortmann 1991 for statistics and a discussion of relevant literature).

2.2 *Content, Epistemic, and Speech-act Adverbial Clauses*

Adverbial clauses can be used and interpreted in different semantic domains or, alternatively, on different levels of discourse. A widely acknowledged distinction is the one suggested by Sweetser (1990), who distinguishes between three such domains: a content domain (9a), an epistemic domain (9b), and speech-act domain (9c).

(9) (a) John came back because he loved her.
(b) John loved her, because he came back.
(c) What are you doing tonight, because there's a good movie on.

In the content domain (9a), the adverbial (here causal) clause establishes a link between two objectively given, independently assertable facts; in the epistemic domain (9b) the link holds between a fact and some belief or assumption (i.e., 'John loved her' is no more than the speaker's conclusion given the fact that 'he came back'); in the speech-act domain (9c) the adverbial clause provides a motivation or justification for performing the speech act in the main clause (here asking a question). This three-level approach has been refined, modified, and complemented by other domains and notions in most recent studies (e.g., in various contributions to Couper-Kuhlen and Kortmann 2000). For example, a fourth, textual, domain is postulated, where the adverbial clause does not modify the state of affairs in the main clause, but a whole preceding text unit. For a concessive clause this is illustrated in example (10):

(10) My favourite poster is, I think, a French one for Nesquik, which shows a sophisticated-looking small boy leaning nonchalantly against something and saying that thanks to Nesquik he went back to milk. He really looks like a nice child. *Though*, there are some Adchildren that one would feel quite ashamed to have around the house …
(Greenbaum 1969 in Crevels 2000)

An important independent justification for the distinction between these domains is that there exist correlations between them and (a) the meaning and use of adverbial subordinators, and (b) the form and position of adverbial clauses. For instance, *since* has a temporal meaning only in the content domain; in the other domains it is always causal, as in 'Since you're German, how do you prepare Strudel?' Comma intonation and the causal clause following the main clause is essential for the epistemic causal in (9b); just by itself, i.e., without additional lexical or prosodic modification, a sentence like 'Because he came back John loved her' is extremely awkward, if not unacceptable. For crosslinguistic evidence of systematic correlations between the structure of adverbial clauses and the semantic domains in which they can be used, compare Hengeveld (1998) and Crevels (2000).

3. *The Interpretation of Adverbial Clauses*

There is something more than simply world knowledge or contextually grounded knowledge that is crucial for the interpretation of adverbial clauses. Formal (i.e., morphological, syntactic, and prosodic) features, too, enter into and may crucially influence the process of interpretation.

Problems of interpretation not only arise for the inherently vague nonfinite adverbial clauses (see Sect. 1.2); they also arise for finite adverbial clauses with polysemous adverbial subordinators: after all, polysemy can be observed for almost one third of the adverbial subordinators in the European languages, especially for those with a high text frequency (Kortmann 1997). Apart from that, as was shown in Sect. 2.2, formal characteristics may determine on

which discourse level(s) an adverbial subordinator may be interpreted to operate in a given adverbial clause. Here are some of the most important relevant features that may influence the interpretation (for further discussion see Kortmann 1991 and König 1995), always provided that the given language allows for a choice (i.e., has no constraints such as, for example, the obligatory use of the subjunctive mood in subordinate clauses, or subordinate clauses generally preceding their main clause):

(a) choice of tense and/or mood in the adverbial clause and, accordingly, in the main clause, as in the three semantic types of conditional (factual/real, hypothetical, counterfactual) in many languages: present tense (indicative mood) in factual/real conditional clauses (11a), past tense (or in other languages subjunctive mood) in hypothetical conditional clauses (11b), past perfect (or a conditional perfect) in counterfactual clauses (11c):

(11) (a) If she comes home, I will be very happy.
(b) If she came home, I would be very happy.
(c) If she had come home, I would have been very happy.

Many adverbial subordinators can express either Result ('so that') or Purpose ('in order to/that'). Which reading they receive in many (e.g., Romance) languages depends on the mood in the adverbial clause: indicative mood leads to a Result reading, subjunctive mood to a Purpose reading. Tense constraints hold for the two different meanings (temporal and causal) of English *since*: only when used with some past tense can *since* receive a temporal reading (but see also example (14) below).

(b) non-subordinate (in example (12) verb-second) word order is typical in spoken German for *weil*-causals and *obwohl*-concessives in the speech-act and textual domain, but can be found increasingly in the other domains, too:

(12) *Ich hab das mal in meinem ersten Buch aufgeschrieben. Weil dann glauben's die Leute ja.* ('I've written that down in my first book. Because people believe it then.')

(c) intonation, for example, the presence or absence of an intonation break (also relevant in examples (9) and (12) above): only when reading the complex sentence in example (13) as a single intonation group does the adverbial clause receive a concessive conditional reading ('even if'):

(13) /I wouldn't marry you if you were the last man on earth./
(Haiman 1986 in Kortmann 1997, p. 92)

(d) the choice of dependent vs. independent verb forms was shown to be relevant in point (a) already (indicative vs. subjunctive mood); example (14) illustrates the impact of the choice between finite and nonfinite form in the adverbial clause on the interpretation of an adverbial subordinator, here *since*. When introducing a free adjunct, *since* can only receive a temporal reading; a causal one is impossible:

(14) Since working with the new company, Frank hasn't called on us even once.

(e) constituent order, more exactly the relative order of adverbial and main clauses: in English, for example, the great majority of present-participial free adjuncts receiving a purely sequential interpretation relative to the main clause, i.e., either Anteriority ('after') or, much more rarely, Posteriority ('and then'), exhibit an iconic constituent order (see Kortmann 1991, pp. 142–57). The order of events is signaled crucially, or even solely, signaled by the relative order of adverbial and main clauses, as illustrated by the minimal pair in example (15):

(15) (a) She uncurled her legs, reaching for her shoes.
(b) Reaching for her shoes, she uncurled her legs.

The importance of iconic word order has been acknowledged for the interpretation of converbs in other languages as well (see König 1995, p. 75).

4. *Functions of Adverbial Clauses in Discourse*

Typically adverbial clauses provide background information—it is in the main clause that foreground information is given, and the plot or storyline is advanced. But they serve additional functions, including face-to-face interaction, as has been shown in a number of studies on the tasks that adverbial clauses fulfil in the organization of larger stretches of written and spoken discourse (see, for example, Thompson 1985, Ford 1993, and various contributions to Couper-Kuhlen and Kortmann 2000).

A first set of functions is concerned with the creation of a coherent discourse. Depending on whether they precede or follow their main clause, adverbial clauses create more global (or textual) coherence, or more local coherence, respectively. There is a tendency that preposed (or initial) adverbial clauses use, elaborate, and put in perspective against what follows information given in the (not necessarily immediately) preceding discourse. They serve a kind of guidepost or scene-setting function for the reader or listener by (a) filling in what has gone before, and (b) preparing the background for what is going to follow in the complex sentence, and often even a whole chunk of discourse. By contrast, postposed (or final) adverbial clauses typically have a much more local function; i.e., their scope is restricted to their immediately preceding main clause. They neither reach back into earlier parts of the discourse, nor foreshadow or prepare for what is going to follow. For instance, the subject of a postposed adverbial clause typically is identical with the main clause subject, whereas the subject of a preposed adverbial clause is often identical with that of (one of) the preceding sentence(s).

In addition to these discourse-organizing functions, adverbial clauses have been found to serve interactional functions in face-to-face conversation (Ford 1993). Thus initial adverbial clauses are often found at the beginning of relatively large speech units exactly when the speaker has maximum control of the floor. Final adverbial clauses also seem to serve a special conversational purpose, more exactly those final clauses which are separated from the main clause by an intonation break. They tend to be used preferably at those points in informal conversation where the interactants negotiate agreement. More specific interactional tasks can be identified for individual semantic types of adverbial clause.

Advertising Agencies

An advertising agency is an independent service company, composed of business, marketing, and creative people, who develop, prepare, and place advertising in advertising media for their clients, the advertisers, who are in search of customers for their goods and services. Agencies thus mediate between three different but interlocking social groups: industry, media, and consumers. The history of advertising is largely the history of the advertising agencies that have served the needs of these three groups (see *Advertising: General*). They link industry and media by creating new forms for messages about products and services; industry and consumers by developing comprehensive communications campaigns and providing information thereon; and media and consumers by conducting audience research to enable market segmentation.

1. Origins and Early Developments

Advertising agencies are the most significant organizations in the development of advertising and marketing worldwide. They came into existence in the United States in the mid-nineteenth century and, later, elsewhere because of the mutual ignorance of the needs of newspaper publishers and would-be advertisers and because of the opportunity for profit provided by both parties' desire for economic assistance. Initially, advertising agents facilitated the purchase and sale of space. In so doing they promoted the general use of advertising, helped advertisers find cheaper and more effective ways of marketing goods, and served to inform the public of the existence of those goods. They acted as a crucial bridge between the activities of selling products and of mass communication at a time when both were undeveloped and expanding rapidly (see *Journalism*; *Mass Media, Political Economy of*).

The first advertising agents were colonial postmasters in America who accepted advertisements for inclusion in newspapers. In 1843, Volney B. Palmer set up the first independent agency, soliciting orders for advertising, forwarding the copy, and collecting payment on behalf of newspapers that had difficulty in getting out-of-town advertising. This *newspaper agency* was the first of four stages through which the business of the advertising agent proceeded to pass. In the second *space-jobbing* stage, the agent became an independent middleman who sold space to advertisers and then bought space from newspapers to fill his orders, driving a hard bargain with both. In 1865, George P. Rowell initiated the third *space-wholesaling* phase when, anticipating the needs of advertisers, he bought wholesale from publishers large blocks of space that he then resold in smaller lots at retail rates. Finally, in 1867, some agents contracted annually with

168 to 177

commercial culture. For instance, the 1950s story of 'subliminal advertising,' in which unsuspecting US movie patrons were persuaded to buy cola and popcorn by flickering messages undetected in the film, is retold today as if it really happened. In actual fact, the whole event was a scam. James Vicary, the man who claimed to have accomplished this feat, was an unemployed market researcher when he reported his story to the press in 1957. While reporters and, soon, Congressmen investigated the validity of his claim, Vicary collected retainers from some of the nation's largest advertisers. But his claim quickly began to fall apart. First, the theater owner said no test had been done on his premises, as Vicary had claimed. Then, Vicary failed to produce the effect for a Congressional committee. Suddenly, less than 6 months after his name first appeared in the papers, Vicary disappeared. His closets and his checking account were left empty. He was never heard from again. Though many researchers have attempted to replicate his study, the purported effect has never been repeated. Even if Vicary was a charlatan, though, the true story does show that advertisers in the USA were willing to pay huge sums to learn how to advertise subliminally. So, however false this cultural myth may be, the suspicion of corporations that lies behind its continued viability is not without foundation.

5. *Conclusion*

Advertising seems to touch every aspect of life in the postindustrial world. As both form and institution, advertising is blamed for an array of social ills ranging from the mundane to the millennial. The poor standing advertising has in the global community at the opening of the twenty-first century is not based on the real existence of any secret formula, economic equation, or covert conspiracy. It is certainly not based on any demonstrable effect on prices, social conditions, or even sales. Rather, our attitudes toward advertising are probably a response to the rapid changes in everyday life brought about by industrial commerce, and are intensified by the knowledge that, at least some of the time, advertisers will make extreme attempts to have their way with the public. Nevertheless, the human mind, being far more subtle and sturdy than many theories would suggest, has shown remarkable resistance to all such attempts—the explosion of consumer culture notwithstanding. Our discomfort with advertising is also profoundly situated in ethnocentric prejudices against commerce, material comfort, sensual pleasure, and images. Rigorous thinking on the subject of advertising is rare—at least partly because we are blinded by these very fears and prejudices. Looking forward in a globalizing marketplace, however, should impress upon us the need to break out of such constraints.

Advertising, Control of

Advertising is a form of communication between a firm and its customers, that uses independent media to communicate positive messages about a good. Firms supply it to generate sales and to counter their competitors' advertisements, but there is also a demand for advertising because consumers lack information, and much of it comes from advertisements that help lower inevitable 'search costs,' that is, consumers' expenditure of time and money to select what goods to buy.

1. Advertising Failures

Like other institutions, advertising is prone to natural shortcomings (e.g., information is always incomplete) and artificial ones (e.g., agreements and rules not to advertise). Legal treatises and self-regulatory codes reveal that scores of advertising practices represent actual or potential failures that negatively impact the market system's dependence on adequate information and effective competition, and that impair the functioning of other institutions. Hence, control focuses on monopolistic power, consumer deception, unfairness, and social irresponsibility, although laws and codes vary in defining these concepts.

1.1 Monopolistic Power

Producers can erect 'barriers of entry' to superior and cheaper products by creating and advertising meaningless distinctions among brands. Furthermore, producers may collude to ban advertising, as in the case of legal services. Such rarely challenged restraints reduce competition and consumer welfare even when otherwise justified.

1.2 Consumer Deception

The representation of a product's features may mislead consumers acting reasonably. An advertisement cannot be as lengthy as an instruction manual or even a label, but should it include all significant information? This depends on how one defines 'information.' Do people want and need only 'objective' facts such as origin, ingredients, price, performance, and contraindications? Or should information refer to the attractiveness of a good in the context of a consumer's own buying criteria such as socioeconomic background, personality, lifestyle, aspirations, experience, and other factors—whether rational, emotional, or simply habitual? Thus, should government-sponsored lottery advertisements reveal that the odds of winning are abysmally low, such lotteries pay back the smallest share of any legal game, and the government's share is not fully or mainly used to support education or the arts, as was promised? Or should one accept the appeal of 'All you need is a dollar and a dream' because it reflects the needs of lower-income people? Both perspectives on information assume truthful communications although some puffery is tolerated (e.g., 'the King of beers'), and that advertisers should be able to substantiate their claims (e.g., 'the fastest copier').

1.3 Unfairness

'Unfair' means 'not sincere, frank, honest, loyal and right'—all subjective criteria. Unfairness is associated with particular practices such as denigrating through comparative advertising a competitive product or firm even if the latter is in fact inferior, and playing on the fears of people even when such fears are real (about sickness, death, social attractiveness, self-confidence, etc.) and could be alleviated through the advertised products and services (e.g., insurance and cosmetics). Although the legal definition of unfairness varies across countries, it usually involves: (a) malice (e.g., nobody mentions a competitor to say good things about it), or (b) calling attention to a product's benefits (e.g., comfort or relief) while minimizing or omitting mention of its costs (e.g., monetary harm or distress), or (c) the exploitation of the weaker by the stronger (e.g., large retailers out-advertising smaller ones).

1.4 Social Irresponsibility

Advertising should not undermine other institutions such as the state, the family, and the value system. Thus, advertising to children is thought to weaken parental authority and to develop consumeristic attitudes at an age where more important values should be impressed on the young. Larger and evolving questions about societal welfare and personal happiness are also involved. As a 'mirror of society,' does advertising reflect and magnify developments in ideologies and lifestyles through new symbols and habits detrimental to these goals? Is it even part of a plot to create a 'culture of consumption' essential for the capitalistic machine?

1.5 Extent of Advertising Failures

There are no counts of misleading, unfair, or irresponsible advertisements in the USA, but the self-regulatory UK Advertising Standards Authority has estimated that some 2 percent of British advertisements appear to violate some provision of its extensive Code of Advertising Practice. This is a low rate of malfeasance, compared to other institutions (e.g., the family and the educational system) and considering that much advertising misbehavior results from ignorance and carelessness rather than ill intent. Still, 2 percent of millions of advertisements add up to tens or hundreds of thousands of failures worldwide, suggesting a significant need for regulatory mechanisms to be used by competitors, consumers, governments, and concerned citizens.

2. Forms of Advertising Control

2.1 Mechanisms

Most people and organizations behave themselves because they want the esteem of other members of society, they fear losing markets, they are threatened by the law, and/or they want to lessen uncertainty

about their rivals' behavior. The community reacts to advertising's shortcomings by ignoring, discounting, and/or opposing it (e.g., defacing posters or criticizing tobacco advertisements). Individual and organizational self-discipline, in the forms of personal ethics and company codes of conduct (including media acceptance codes for advertisements), provides another vehicle for community-based control. Market responses include consumers shunning the goods of unreliable advertisers, and competitors countering advertisements with their own. State sanctions involve direct prohibition, restriction, obligation, public provision, and taxation, which reduce the reach and positive impact of advertisements, but the state can also facilitate legal action by customers and competitors. Under industry self-regulation, peers rather than outsiders establish and enforce self-imposed and voluntarily accepted rules of behavior, although such private governance may be mandated, regulated, and monitored. Since most advertisements require the use of media (the press, broadcasters, postal services, telephone companies, Internet service providers, etc.), their participation in self-regulation helps put an effective stop to objectionable advertisements.

2.2 Respective Strengths and Weaknesses

Effective control ultimately requires:

(a) developing standards;

(b) making them widely known and accepted;

(c) advising advertisers and agencies before advertisements are released;

(d) pre- and post-monitoring of compliance with the standards;

(e) handling complaints from consumers, competitors, and other parties; and

(f) penalizing bad behavior in violation of the standards, including the publicizing of wrongdoing and wrongdoers.

'Somebody' has to design, perform and fund these sizeable tasks.

Community control offers shared norms (e.g., against vulgarity) and broadly based pressure (e.g., boycotts) but lacks authoritative means to mobilize social resources beyond what can be obtained voluntarily on account of regard for others. Market competition generates more and better information but is weak on broader social responsibility issues. Government regulation benefits from universal coverage, compulsion, and legal enforceability although it may also impose high costs, stifle innovation, and be of limited effectiveness in dealing with complex and evolving issues such as bad taste and the reach of foreign media. Industry self-regulation can provide customer and competitor gains beyond the minimum standards of the law, and it benefits from the positive commitment of practitioners. However, industry support may be insufficient, unstable, and perceived as compromising the integrity of the system. Table 1 summarizes the respective strengths and weaknesses of the latter two systems—government regulation and industry self-regulation—which dominate advertising control.

2.3 Factors Affecting Use

The existence of some 200 nation-states with varying traditions, values, legal systems (common law versus civil or religious laws), economic resources, and advertising experiences precludes firm global conclusions. Still, the demand for controls reflects, first, that competitors want to protect their property rights in brands and reputations (e.g., against comparative advertisements) and to ensure fair competitive rules (e.g., against advertising allowances favoring large distributors); and, second, that customers and their associations are concerned about consumer deception, unfairness, and social irresponsibility.

On the supply side, governments are increasingly tackling such issues through regulation and (sometimes) the support of stronger market competition and self-regulation. Industry has offered self-regulation as a way of pre-empting or mitigating legislation and of improving the overall credibility of advertising. The proliferation of national and subnational 'states' as well as of supranational bodies (e.g., the European Union and the World Health Organization) has multiplied mandatory rules and advisory guidelines which have facilitated complaints, the stopping of advertisements through cease-and-desist injunctions, private suits, and even class actions by empowered competitors, consumers, and citizens.

Regulation and self-regulation are often complementary. Thus, all voluntary codes state that 'advertising must be legal,' although few self-regulatory bodies (e.g., the French Bureau de Vérification de la Publicité) pursue statutory infractions. Sometimes they specialize, as with the German ZAW industry organization that focuses on taste and decency because Germany's law against unfair competition applies to most other situations. Governments burdened by growing tasks and budget deficits increasingly invoke the principles of 'proportionality' and 'subsidiarity,' whereby higher control levels should not deal with what better informed and motivated lower levels can achieve more effectively. Even consumerist groups agree with these principles, provided they can meaningfully participate in self-regulation.

These developments reflect better knowledge about how advertising works (and how well) and about the effectiveness of controls. Thus, research has confirmed that market shares keep shifting when competitive advertising is allowed; the latter helps reduce consumer search costs; restrictions often result in higher prices and lower quality of services; and the cost of preventing and correcting harm to consumers, competitors, and citizens can be excessive. The US Supreme Court now requires that when public policy

Table 1
Strengths and weaknesses of advertising regulation and self-regulation

Advertising—control tasks	Government regulation	Industry self-regulation
Developing standards	+[a] Greater sensitivity to politicized concerns	−Greater lag in responding to such concerns
	−[b] Difficulty in elaborating standards for taste, opinion, and public decency	−More informed ability to develop and amend standards in these areas
	−Inertia in amending standards	+Faster response
Making standards widely known and accepted	+Everybody is supposed to know the law	−Difficulty in making the public aware of the industry's standards and complaint mechanisms
	−Compulsory nature of the law generates industry hostility and evasion	+Greater ability to make industry members respect both the letter and spirit of voluntarily accepted codes and guidelines
Advising advertisers about grey areas before they advertise	−Usually not provided by government	+Increasingly promoted and provided by industry—sometimes for a fee and even on a mandatory basis in the case of broadcast media and some products (toys, cosmetics, non-prescription drugs, etc.)
Monitoring compliance	±Routinely done or at the prompting of others but often with limited resources	±Increasingly done by the industry although restricted by financial resources
Handling complaints	+Impartial treatment is anticipated	−Treatment more likely to be perceived as partial
	+Potential to handle many complaints	−Limited capacity to handle many complaints in some countries
	−Slow and expensive	+Faster and less expensive
	−Cannot put the burden of proof on advertisers in criminal cases	+Usually puts the burden of proof on the challenged advertiser
Penalizing bad behavior, including the publicity of wrongdoings and wrongdoers	+Can force compliance	−Problems with non-compliers but the media usually refuse to carry ruled-out advertisements
	−Generates hostility, foot-dragging, appeals, etc.	+More likely to obtain adherence to decisions
	−Limited publicity of judgments unless picked up by the media, competitors, and activist groups	+Extensive publicity of wrongdoings and, to a lesser extent, of wrongdoers

a Strengths are indicated by '+'. b Weaknesses are indicated by '−'

justifies government controls, the latter be shown to be effective and not disproportionate to the goal to be achieved. Litigation (as in tobacco's case) is making available data about advertisers' strategies, budgets, and performance so that investigations, complaints, and suits are better informed.

Both regulation and self-regulation are being fostered by supranational governments (e.g., the European Union's directives on misleading and comparative advertising), international organizations (e.g., the World Health Organization's development of a global treaty to control tobacco sales and advertising), and industry groups (e.g., the International Chamber of Commerce's International Code of Advertising Practice, and its constant promotion of self-regulation).

2.4 *Impacts*

Self-regulatory bodies handle up to 10,000 complaints a year (with some duplications about the same advertisement) when they are actively solicited, as by the UK Advertising Standards Authority. However, the number of adjudicated cases can be relatively low

(about 100 a year by the very active US National Advertising Division of the Council of Better Business Bureaus) when these bodies choose to focus on exemplary cases that send strong signals or break new grounds. Government agencies are also very selective in their interventions (e.g., about 100 cases a year by the US Federal Trade Commission) for the same reasons and because of budgetary constraints. However, courts are increasingly handling advertising cases.

Contract law potentially protects customers everywhere against misrepresentation in advertisements. Private suing to stop advertisements or for damages has become common although usually done more by competitors than by consumers, as is also true of complaints to self-regulatory bodies. Consumers and their associations are slowly being empowered to bring class actions against companies whose products cause injury (e.g., cigarette advertisers). Under statutory law, certain practices are forbidden, circumscribed, or mandated (e.g., health warnings) and criminally punishable, but regulatory bodies can also issue civil law-based cease-and-desist injunctions as well as require corrective advertisements. Self-regulatory codes are being expanded to include more products (e.g., toys) and services (e.g., advertising by charities), as well as practices (e.g., Internet advertising).

How effective have regulation and self-regulation been in promoting truth, accuracy, fairness, social responsibility, and competition? No precise evidence exists, and their impacts vary depending on a country's level of development as well as on its priorities. There will always be crooks, so that control mechanisms can only aim at improving the overall quality of advertising at a reasonable cost through exhortation, coercion, punishment, denial of access to the media, and other mechanisms. Besides, new problems keep emerging on account of technological innovations (e.g., the Internet and satellite broadcasting, which ignore national borders), new entrepreneurial initiatives (e.g., sports sponsorship and political advertising), and citizen activism (e.g., growing concerns about children and advertising, and privacy invasion).

One can reasonably conclude that such problematic practices as unsubstantiated claims about weight reduction and other 'cures' have been significantly curbed in developed countries through regulation and self-regulation. Besides, the principle that advertisers have a 'prior reasonable basis' before making a claim has been broadly adopted and enforced in many states. More advertisements about particular goods (e.g. toys) and in certain media (particularly, broadcasting) must be approved in advance; certain claims (e.g., 'free, low-fat, and environmentally sound') are now restricted by law, while mandated information (e.g., annualized interest rates in financial advertisements) is proliferating.

However, such controls have also curbed competition and denied valuable information to consumers, as with bans on pharmaceutical, liquor, and legal-services advertising. Besides, protecting a lengthening list of 'vulnerable groups' (the young, the sick, the recently bereaved, the poorly educated, etc.) shrinks the pool of those whom advertising may target without legal or self-regulatory limitation.

3. *Ongoing Developments*

3.1 *Technology*

Means of reaching consumers keep multiplying: satellite broadcasting, international editions of newspapers, magazines and catalogs, the Internet, etc. However, technology also allows consumers to avoid advertisements (e.g., with zapping devices) and to access them only voluntarily and selectively; and it facilitates the fast sharing of information among consumers, associations, and governments as well as the filing of complaints. The Internet increasingly links advertisers, suppliers, customers, and citizens via computers, television sets, other receivers, and processors. Potentially, there will be many more millions of advertisements that can be quickly reformatted, as well as many more advertisers, including individuals. The lines between editorial content and advertising message, which have traditionally been separated, will become blurred because there will be many 'banner' advertisements and sponsors linked to programs and information. Advertising agencies that help screen advertisements may be less involved, replaced in part by less-informed and socialized Internet service providers.

3.2 *Laws and Codes*

Regarding the right to give and receive information, constitutions usually guarantee freedom of the press because democracies need independent media to challenge governments in 'the marketplace of ideas.' However, do these 'ideas' encompass non-misleading advertising messages, thereby providing for 'freedom of commercial speech?' Since the 1970s, the US Supreme Court has come to acknowledge such a right, supported also by the Council of Europe's Declaration on Freedom of Expression and Information, and by Article 10 of the European Convention on Human Rights. However, this new freedom is limited because it conflicts with growing rights to health, privacy, and sex equality—for example, pharmaceutical advertising remains restricted because it may lead to greater health expenditures.

Regulation and self-regulation may proliferate at subnational, national, and supranational levels, thereby making their harmonization less likely. Such heterogeneity will complicate the creation and delivery of advertisements although large advertisers can more

readily comply with varying rules. It also creates favorable loopholes to advertise where restrictions are lower, and to sue where litigation is most likely to succeed. Besides, more controls encourage the use of imagery ('Things Go Better with Coke') in lieu of challengeable claims.

When advertisements emanate from another sovereignty, both regulation and self-regulation face the problem of 'conflict of laws': what body, domestic or foreign, decides the case; what procedures (e.g., about required evidence) to follow; what law or code is applicable; how to recognize and enforce decisions? Governments have favored the laws of the advertisement's country of origin, and so does the self-regulatory European Advertising Standards Alliance, as well as international codes for pharmaceuticals and direct marketing. However, the European Union has recently granted consumers rights to sue locally.

Regarding the Internet, regulatory control will focus on: (a) criminalizing the sending of certain advertising contents (e.g., pornography and pharmaceuticals); (b) having advertisers and service providers notify advertisement-receivers of private-data collection practices (particularly from children) and of their right to check these data's accuracy, and be assured that such information is secure; and (c) obligating access providers (including telecommunication companies) to at least respond to complaints, since it is impossible for the latter to screen out millions of messages. Thus, the Internet will test and refine the control of advertising in coming years.

Advertising: Effects

1. Introduction

The phenomenal growth of advertising in the twentieth century helped usher in and sustain a defining consumer culture. That is advertising's surest effect. Consumers come into contact with literally hundreds of ads every day. This ubiquity has its effects. People use phrases and other utterances from ads in daily discourse (Friedman 1991, Ritson and Elliot 1999), revealing more than mere mimicry, but also the ad-inspired consumer ethos of contemporary consumer culture. Advertising is now part of the interstitial tissue of daily life on this planet. Yet, the effects of advertising are often anything but clear or easily detected. In fact, the effects of advertising run the gamut from obvious to perplexing and contradictory. On the one hand, most people, most of the time, don't care much about ads. They don't pay attention to them. But every now and then, they do. And even when they don't, the effects may still accrue.

2. Context

Advertisements have been studied in one way or another for about 100 years, yet we simply don't know much about their effects. There are at least three good reasons for this lack of knowledge. First, scholars have viewed advertising as unworthy of attention. This is the same high culture (and anticommercial) bias which led libraries to cut ads out of magazines before binding them for decades. Many libraries gave space to pornography but not advertisements. It was politically difficult to propose studying something that was regarded as thoroughly unworthy of study. This bias has had a profound effect on this scant scholarly enterprise. Relatively little research has been done, and much of it is more polemic than systematic. Second, the object of study itself presents an inherent difficulty. Advertisements are by their nature textual, generally ephemeral, and encountered as a common social object, situated within layer upon layer of social discourse. They are here and then they are gone. They are commercial rhetoric, actively interpreted by various audiences in various ways. While the general meaning of an advertisement is informed and bounded by cultural forces so as to produce more likely than less likely interpretations, there is no single, objective advertisement to study (Fish 1980, Scott 1994). What an advertisement is depends on who is interpreting it and why. This seemingly simple point has thoroughly eluded most advertising researchers. Further, ads exist in their particular social–temporal microclimate and then they become something else. Even the once-legendary 'Man from Glad' is not now what he once was. Typically stripped of context, we have little idea of what advertisements meant in their own milieu.

The third reason for the paucity of work in this field is inadequate method. It is extremely difficult to demonstrate the effects of advertising, and the job is made even more difficult within the confines of a single method, a single literature, a single paradigm. Survey data suffer from the scores of variables that lie between exposure and behavior. Experiments suffer from low ecological validity; they too often have little or nothing to do with how real people experience and interpret real ads in real contexts. Ethnographic work on advertising has been rare, but suffers from its lack of generalizability, the effects of intrusion, and the privileging of informants and text. Textual analysis, and even reader response, suffers from the authority of the one constructing the interpretation. Work by economists with aggregate data suffers from a long and troubling list of assumptions, particularly those positing rational thought. Advertising is a sociotextual phenomenon, which does not travel well outside its natural environs. In their natural space advertisements are a typically trivial background to daily life. Methods sensitive to this reality have yet to be employed to any significant degree.

But advertising certainly must have effects. How could something so widespread, so much a part of contemporary existence, and something which businesses worldwide continue to invest in massively, have no effect? Beyond the reasonable and predictable retort that 'real' effects are not necessarily detectable and demonstrable effects, there must be something to which we can point and say: 'we (probably) know this.' The more robust advertising effects findings are reviewed below.

3. *Economic Effects*

Economists have studied the effects of advertising spending on various outcome variables such as GDP, aggregate and category demand, brand switching, economic concentration, and barriers to entry. Borden (1947) was one of the first to attempt a systematic economic analysis. While acknowledging that advertising might increase 'selling costs,' (p. 881) his study points to the vital need for advertising in growing 'dynamic economies' (p. 881). He sees little downside to advertising. Running counter to this view are both Packard (1960), and Galbraith (1958), who see advertising as the engine of waste and the loss of consumer agency. These are not, however, empirical examinations, but more economic–philosophical theories. They represent the political left's view sans data.

Schmalensee (1972) conducted the next major empirical analysis of the economic effects of advertising. His work showed 'that total national advertising does not affect total consumer spending for goods' (p. 85). He argues in a very real and practical sense that sales cause advertising, much more than the other way around. He goes on to say that a major implication of this is that 'advertising cannot be all-powerful if it cannot influence the decision to save.' He finds national advertising to be particularly inconsequential in driving aggregate demand. In terms of competition, he says: 'the effects of national advertising spending by the various consumer goods industries cancel each other out in the aggregate' (p. 86).

The next major exhaustive empirical examination of advertising's economic effects is that of Albion and Farris (1981). Their work revealed a much more complex and nuanced set of findings than previously reported, but were generally supportive of Borden (1947) and Schmalensee (1972). In other words, most of the criticisms of advertising were not borne out by the data. They do, however, find advertising expenditures and industry concentration to be correlated, but argue that other factors, as well as reverse causality, may be at work. Most significantly, they note the overwhelming importance of context in these effects. Schudson (1984) also makes the case for context and the limited power of national consumer goods advertising. He argues that advertising follows affluence, targeting consumers who already consume large quantities of the goods or services concerned. He gives good examples of both advertising without sales, and sales without advertising. Luik and Waterson provide one of the more recent (1996) reviews of this literature and find that advertising affects aggregate demand early in a product's life, but as time goes by, has more of an impact on brand share, and less of an impact on aggregate demand. That is, for most mature product categories, advertising seems to impact on brand share, but not total category demand.

4. *Sociocultural Effects*

The cultural effects of advertising have largely been the purview of those in the humanities, as well as those in areas of communications, sociology and anthropology. More recently, a few in marketing have contributed as well. A wide range of orientations and methods has been brought to bear on the search for advertising's effect upon societies and culture. This in fact constitutes the single largest (and most widely accessible) literature on advertising effects.

These works claim that advertising has produced several effects at the sociocultural level. For one, advertising is said to have caused a more materialistic culture (Ewen 1988, Fox and Lears 1983, Pollay 1986, Richins 1991). This argument rests on the traditional modernist critique: the real has been replaced with artifice, community with mass society, and a human orientation with one in which material things are more central to human existence. By extension, it is claimed that advertising has placed more emphasis on brand names as symbols than on the actual sum and substance of goods and services. This privileges simu-

lacra over the 'real.' Likewise, advertising is said to have worked as a hegemonic force to the detriment of women, minorities, and other marginalized peoples (Faludi 1991, Seiter 1995). These are the major effects claims at the sociocultural level. Although there are many other derivations, they are largely subsumed by those categories outlined above.

The evidence for these claims is, however, rarely as strong as the accompanying rhetoric. Still, there are a few evidence-based conclusions. First, advertising has certainly made consumer culture possible. This may be the biggest advertising effect of all. To understand this, one has to appreciate advertising's role in advancing the practice of branding. Advertising made possible national brands, without which consumer culture would have died on the vine. Advertising projected brands and brand consciousness into national consciousness and into greater social centrality (Muniz and O'Guinn 2001). Advertising made a brand-oriented society possible—perhaps inevitable. In 1850, few things were branded; by the end of the twentieth century, water and dirt were branded. The whole purpose of a brand is, in economic terms, to create greater inelasticity. A primary predictor of inelasticity is the consumer's belief that there are few acceptable substitutes. For example, when advertising made Ivory more than just soap, demand for Ivory became less elastic than demand for mere 'soap.' The same thing happened with beer, and soft drinks, and thousands of other products. So, clearly advertising lead to a proliferation of brands, which contributed to a more brand-oriented society. The brand is now a defining construct in contemporary consumer culture. This is an effect of advertising. While societies have always been involved with material culture, the massive extent to which branded culture emerged is quite clear, and not just a matter of degree. This is an advertising effect. Whether or not this has caused individuals to value things more than before is unknown, although it does seem clear that it probably produced more value for the explicitly (and highly marked) commercial object. Whether it caused individuals to value things more in relation to humans than previous generations did is a much harder case to make.

What then of advertising and hegemony? Advertising did and does provide support to modal social structures. Advertising, by its nature, is generally (but not always) a supporter of the status quo. Most researchers do not find advertising to be a great friend to progressive social movements, although it certainly has been from time to time. Unfortunately, many of the arguments regarding the hegemonic dynamics of advertising are hyperbolic and ahistorical (Scott 2002). Further, the relationship between progressive movement, resistance, consumer agency, and advertising is far more complex than typically held (Muniz and O'Guinn 2001). Consumer resistance is now played out by the rejection of one brand (perhaps an ecologically friendly, green brand) over another brand. Belief in a 'star chamber' of corporate elite, or advertisers who control consumer's minds, is being thoroughly discredited (Scott 2002) by social history research.

Advertising's effects in the areas of race and gender are far from simple, but have generally been negative. There is every reason to believe that narrow, pejorative, and stereotyped social portrayals have had detrimental effects when it comes to people of color. The same is no doubt true in the case of women, gays and lesbians. The evidence for this is more inferential than direct, but is consonant with empirical studies in other domains. We know that these groups were absent, stereotyped or under-represented in typical advertising. Exactly what the effects are on self-perception and other types of perception is less well understood. We can assume it to be anything but positive, however.

In fact, social constructions of reality in general have been shown to be influenced by mass media and advertising portrayals of social reality (O'Guinn and Shrum 1997). Recently, O'Guinn (2002) has shown that those exposed to a great deal of advertising on television believe there to be higher than actual rates of 'ad-problems' such as gingivitis, athlete's foot, bad breath, etc. There is good reason to believe that advertising has a significant impact in terms of simply making certain things more heavily represented in consumer's constructions of social reality.

5. *Individual Effects*

A considerable amount of advertising 'effects' research focuses on the individual. Most has been published in two academic fields: mass communication and marketing, typically from a psychological perspective.

In the 1940s researchers became interested in the effects of mass communication in general. Given the post-World War II consumption boom, advertising was of obvious relevance. The working model of mass communication was at that time a very simple direct effects model: message strikes audience member like a bullet. Experience with propaganda efforts in the war, the ascendancy of psychology in both the academic and larger social world, and outright naiveté led to this very simple notion of hypodermic needle-like effects (O'Guinn and Faber 1990). There was a great deal of belief in the power of communications at a critical point in the social history of advertising. Exuberant communications researchers were going to wipe out bigotry, inform the electorate, and make things better in all aspects of life, including the realm of modern consumption. This belief was a popular and self-serving one for several groups, including the advertising industry itself.

It is not coincidental that the postwar period is literally drenched in Freudian and neo-Freudian notions. With the mind-control hysteria of the cold

war, the prominence of psychology as a science and references to the subconscious mind led to a new exuberance in advertising research in both industry and academia. While the social scientists and public Freudians such as Ernest Dichter had major philosophical differences with one another, they both led to a psychological effects tradition in advertising research. To this day, discussion of advertising effects is influenced by the pervasive (and misguided) beliefs of the period.

There were, however, some exceptions. In communication, Katz (1957) proposed the 'two-step flow' model in which certain social actors and their communication networks were seen as more important than others in the spread of information and influence. This was the first time that any kind of social consciousness was included in the 'effects model' at all. This model held that other social actors mattered as much as the communication message itself, if not more. Since advertising was mass-mediated communication it was assumed to act in the same way. It was at about this time that another new field, marketing, discovered the communication literature. From the late 1950s through the mid-1970s, several marketing researchers went looking for the elusive generalized opinion leader, a person to whom advertising could be effectively targeted. This person would then pass commercial information through interpersonal channels to great effect. But alas, the search was fruitless: the generalized opinion leader could not be found, and most marketing research again eschewed the social for the more psychological 'message in a bottle' approach, at least for a while.

Another critical effects notion came along in the 1960s: the 'hierarchy of effects.' The basic idea was that effects of communication (in particular advertising) occurred along a hierarchy: from exposure to behavior (Colley 1961). Each step along the way depended upon the step before. This helped to explain why advertising was generally inefficient, why it took so much to move consumers all the way to behavior from awareness. While a vast improvement compared with an undifferentiated bullet theory, it was still bound up in the idea of a linear and fairly inflexible progression of effects. But it inspired a great deal of advertising effects research. Generally speaking, research confirmed that not all ads lead to behavior. This was progress.

A significant trend in advertising effects research began in the mid 1970s. Known as the 'information processing' tradition, its orientation has been to study ads as the bearers of 'information,' which is then 'processed' by audience members. It was assumed that people actually did something with information gained from ads. This too was progress. These researchers held (at least implicitly) that underlying psychological processes would have to be understood in order to ultimately understand advertising's effects, and make them generalizable and predictable. Most of the earliest work in this tradition was heavily influenced by then-contemporary attitude theory (Fishbein and Azjen 1975), but later became increasingly more cognitive in orientation. Of all the things advertising does, its ability to get consumers to remember the brand, its name, and something good about it, has the longest research tradition. Interestingly, recall of advertising seems important in some instances, but completely useless in others. Keller (1993) demonstrates that advertisements are much better retrieved, and retrieved in a manner most desirable to the advertiser, when there is a carefully planned congruence between the advertisement itself and the point of purchase. The point of purchase should be rich with memory retrieval cues that are entirely consistent with elements found in the ad itself. This work is very important in that it explicitly links point of encoding and point of retrieval. This helps to explain why recall of the actual ad seems important sometimes, and at other times, relatively worthless.

One model has dominated research in the psychological realm. It is the elaboration likelihood model (ELM) of Petty and Cacioppo (1986). This model says that there are two routes to persuasion: one peripheral and one direct. The direct route is marked by attention, consideration, engagement; in other words, 'elaboration.' The consumer engages arguments, or attempts at persuasion in a variety of ways, but generally takes them head-on, agrees with some, counter-argues others, etc. The peripheral route is just the opposite; there is little cognitive effort or engagement, and little motivation to process. In addition to these two routes, various cues were also assessed as either peripheral or direct. For example, source credibility, presenter attractiveness, or executional elements such as music, color, etc., are thought to be peripheral. Research emanating from the ELM has been encouraging, and generally supportive of the theory. Peripheral cues are at their best in situations where the consumer is less involved, has less at risk, and attention is low; central processing is most effective when the opposite is true. It is generally thought that long-term advertising effects are greatest when the direct route is engaged. In the long run, getting people to pay attention to ads seems to predict their greatest effect. While it is not exactly clear where emotions fit in the ELM, work by Edell and Burke (1993) demonstrates that emotions (particularly warm and upbeat ones) do influence the overall evaluation of the brand, and are recalled just as well as other types of information.

Another contribution from the effects literature is in the distinction between search attributes and experience attributes (Nelson 1974, Wright and Lynch 1995). Search attributes are objective pieces of consumer information: how many miles to the gallon, does the car come in red, how much horsepower does it have, etc. Experience attributes are those things that one can only really know via direct experience: does the engine sound good, did the seats feel comfortable, does the

stereo sound good, etc? Wright and Lynch (1995) show that search attributes are actually better learned through exposure to advertising, while experience attributes are better learned through direct contact and use of the product or service. This effect is stronger under low involvement conditions than under high involvement. This finding is important because it has long been assumed that advertising was a fairly weak force compared to direct experience, in almost all cases. This is an important qualification of advertising effects. Similar findings by Edell and Burke (1986) show that consumer's pre-existing attitudes toward the brand have a great deal to do with the attitude-to-the-ad/ attitude-to-the-brand connection, particularly as they mediate through motivation to process the ad.

Another interesting research area is the 'third person effect' (Davison 1983). This work demonstrates that individuals attribute much greater power to advertising when asked about some other (third) person than himself or herself. In other words, they believe advertising to affect others much more than themselves. The effect is particularly strong when those doing the judging are higher in socioeconomic status (Atwood 1994). So, relatively more affluent and educated people think that others, particularly poorer and less educated people, are more affected by advertising than they are. This effect has considerable implications for effects research in general, and public policy in particular. This work is typically carried out through surveys.

6. *Special Audiences*

Two audiences receive special attention in terms of advertising effects: young children (those under 12 years of age) and the elderly. The clearest findings are those reported by Roedder-John and Cole (1986). They find that significant processing difficulties exist in both children and the elderly. These are identified as 'memory-strategy' usage deficits, or strategies for the effective encoding and retrieval of stored information. These strategies are important in knowing how to effectively gain information from advertisements, and to defend oneself against some forms of deception (intentional or not). In addition, young children suffer from knowledge base deficits. They simply do not yet possess the requisite knowledge base to know how to interpret some advertisers' messages. The implication is that the effects of advertising on these populations may be significantly different than for others.

7. *Going Forward*

The arguments surrounding the relative worth of this literature are fairly typical philosophy of science ones. Experimentalists argue that the only way one is ever going to be able to understand the effects of advertising is to understand them within the tightly controlled confines of the laboratory, where all other noise is ostensibly screened out, and process is detected and discerned. More naturalistic researchers counter that advertising cannot be divorced from its social context and construction, and thus the pursuit of such effects is a comfortable conceit. Not too surprisingly, both sides make valid points. There are certain processes which would simply be hard, by their definition, to study outside a laboratory, at least where the detection of psychological process is concerned. On the other hand, things closer to actual behavior are more entangled, by their nature, in discourse, and social circumstance. Ethnographic work holds some promise. Actually watching people watch ads (at least on television) makes some degree of sense (Ritson and Elliot 1999). Yet this work is limited to what people do with advertising content in their daily lives, or the social uses of advertising. We do not typically see ethnographic research at the point of exposure, or have any idea what is going on inside the audience member's head. Furthermore, there are all the familiar criticisms of ethnography: lack of control and ungeneralizable findings. Historical and textual methods also offer promise but it is certain that no single method is going to reveal enough about advertising effects on its own. The phenomenon is simply too large, too layered, and too multifaceted.

One of the problems beyond method is that advertising is simply not very important to most people, most of the time. As Klapper argues in his 1960 limited effects model: mass communication is only effective under two conditions: (a) where the communication is completely consonant and resonates with some social theme, or (b) in a total *tabula rasa* situation. In other words, it does two things very well: delivering information and increasing knowledge. Beyond that it is an extremely weak force at the micro-individual level. The original VW Bug ads of the late 1950s and 1960s are good examples of the former. The VW advertising rode a developing wave of pop consumer counterculture. The ads provided information consonant with this social movement. In other instances, literally nothing is known about specific goods or services, and advertising provides that information. A good example is the introduction of the compact disc player. In that instance advertising supplied consumers with essential information about something that was completely unknown to them. Advertising wrote useful information on a blank slate. But this is rare. Most of the time it is the noise in the background while we are preparing dinner, or the things between the segments of our television shows. Its effects are, by advertising's nature, difficult to pin down.

Advertising: General

Advertising is central to the study of media and the commercial applications of the social sciences. Not only does advertising revenue provide the major source of income for print and broadcast media owners, but it gives those media their characteristic look and sound, and orients their content towards the kind of audiences which advertisers want to reach. Ad-

vertising can be defined as a kind of cultural industry which connects the producers of consumer goods and services with potential markets through the diffusion of paid messages in the media. What is loosely referred to as advertising in everyday language is really just the most visible form of marketing, in which particular images become associated with branded goods and services. It is the imaginary dimension of what may be called the manufacturing–marketing–media complex of modern societies, the whole institutional structure of production and consumption.

1. *Advertising as a Cultural Industry*

Not all media depend upon the sale of their space and time for advertising—films, for example, don't carry advertising as such—and not all advertising depends upon the media for its diffusion. Some companies spend more on 'below the line' or nonadvertising forms of promotion, such as direct mail. However, in most countries of both the developed and the developing world, the largest advertisers of consumer goods and services, many of them global corporations, have determined the direction and character of print and broadcast media development because of their demand for the means ('media') which allow them to reach potential consumers. This is true regardless of whether the media are owned by private interests or the state, as is seen in the case of the rapid commercialization of television in Europe in the 1980s and 1990s.

Advertising is cultural in that it deals in images which give public expression to selected social ideals and aspirations, but it is also an industry because of its crucial intermediary role in the manufacturing–marketing–media complex. It was in this sense that Raymond Williams called it 'the official art of modern capitalist society' (1980, p. 184).

The intermediary role is carried out by advertising agencies (see *Advertising Agencies*). These 'agents' produce and place advertising for their 'clients,' the consumer goods or service companies who are the actual advertisers. However, while the clients pay the agencies for their services, agencies also derive income directly or indirectly from the media in the form of a sales commission paid in consideration of the media space and time, such as newspaper pages or television 'spots,' which the agencies purchase on behalf of their clients.

This is the crux of the manufacturing–marketing–media complex referred to above. Indeed, this form of dealing in media space and time was the origin of advertising agencies as a form of business in the latter nineteenth century, and continues as a fundamental aspect of the industry today. The judicious purchase of media space and time is part of the range of functions routinely performed for clients by 'full-service' agencies, while there have emerged specialized agencies which deal in such media purchasing alone.

Looking at the complex of relations between advertisers, agencies, and media from the point of view of the media as an institution, it becomes evident that in most countries, the dominant print and broadcast media are 'commercial,' as distinct from government-funded or nonprofit media. This means that the measurement of readerships and audiences becomes an issue for advertisers, as they want to be sure that their advertisements are reaching the kind and range of the prospective consumers they seek (see *Audience Measurement*). For their part, the media must seek to attract those prospective consumers as readers or viewers, and this becomes the basis for the kind of content they provide.

While this relation is easiest to observe in the case of broadcast television and its constant striving to offer programs which can attract the largest audiences, mostly for the benefit of national advertisers of packaged consumer goods, to many advertisers, the kind of audience can be more important than the size. The agency's expertise in the choice of medium for the client is a key element in their mediation of the process of fitting people to products. Thus, while the broad appeal of television content might reflect 'the demographics of the supermarket' (Barnouw 1979, p. 73), other media such as prestige newspapers and special interest magazines are supported more by advertisers who are interested in reaching only affluent consumers or niche markets respectively.

All of these industrial connections are of most interest to political economists of the media, while social science and cultural studies more generally have been more concerned with the cultural output of agencies, in the form of the marketing campaigns which they devise for their clients, and the actual advertisements which they produce. Here once again, full-service agencies provide various other marketing activities, including market research, a major form in which social science methods are applied for commercial purposes (see *Market Research*). However, it is the 'creative' side of the agencies' work, including that of specialist creative 'hot shops,' which gives advertising its cultural significance.

2. *The Development of Advertising*

Advertising has its origins not just in the sale of space and time, but in its role of providing distinct identities to branded goods and services. It arises in the US and UK around the late nineteenth century when packaged household products began to replace generic goods bought in bulk: Pears rather than soap, to name one of the world's very oldest brands. By giving brands a particular character and often a logo or slogan to make them recognizable, advertising contributed to the national, and later the international, expansion of brands such as Lipton's, Gillette, Kodak, and Ford. By the 1920s, advertising was forging an alliance with what were then the still fairly new social and

behavioral sciences, drawing on sociological techniques for market research, and devising psychological appeals for advertisements themselves.

Also around this time, some of the longest-established US agencies began to expand overseas. For example, J. Walter Thompson upgraded its sales office in London, while McCann-Erickson was opening up branches in Latin America. In both cases, this expansion was initiated at the request of large clients whose brands they handled in the US, and that wanted similar advertising services provided for them on a 'common account' basis in the foreign markets they were opening up. US brands such as Coca-Cola thus became known worldwide.

However, the most important period for the internationalization of the advertising industry was the period after World War II. Apart from this being the era in which many US companies transformed themselves into multinational corporations, it was also the time when television was a new medium being adopted by one country after another around the world. Because the US agencies had their common account agreements with their clients from their home market as well as some experience with television, they were able to quickly dominate the advertising industries of those countries they entered.

Indeed, by the 1970s, this movement had provoked some resistance, and US advertising agencies became one of the targets of the rhetoric against 'cultural imperialism' in that decade. Subsequent expansion then had to proceed more through joint ventures in conjunction with national agencies. However, a more elaborate pattern emerged in the 1980s, particularly with the growth of certain British agencies, notably Saatchi & Saatchi. No longer was the worldwide advertising industry defined by a fairly simple conflict between US-based multinationals vs. the various national interests, but there were more complex tendencies emerging.

First, what the British agencies did was to keep their new US acquisitions intact and incorporate them into 'megagroup' structures, a strategy already undertaken by McCann-Erickson following its merger with SSC&B:Lintas. This was a way of dealing with 'client conflicts': for example, British Airways could be handled by Saatchi & Saatchi, while other airline accounts could be assigned to different agencies in the same group without fear of marketing secrets being leaked from one to the other. Apart from this kind of integrated concentration in the English-speaking world, there has been a trend to the interpenetration of national markets and of world-regional markets, including joint ventures by French and Japanese agencies in particular (Mattelart 1991). These trends have become more marked with the globalization of the 1990s (see *International Advertising*).

Globalization has had controversial effects upon the content of advertising. While some agencies have advocated the standardization of advertising campaigns throughout the world ('one sight, one sound, one sell'), others have argued for what the Sony Corporation calls the 'glocalization' of both products and their marketing: that is, adapting them in accordance with the cultural differences evident between the various national markets. In practice, services such as credit cards or airlines appear to benefit from global advertising, but goods such as packaged foods do not (Sinclair 1987, Mueller 1996).

3. *The Critique of Advertising*

As the advertising industry has been consolidating itself at its most intensive level of globalization ever, it is ironic that the social critique which accompanied it during its previous decades of expansion has been fading into obscurity. However, for most of the latter part of the twentieth century at least, advertising has been subject to considerable critique from various quarters of society, and on economic as well as cultural grounds, so it is worth reviewing the terms of the debate and the sources of criticism.

It has been the critics of advertising who have made the most elaborate claims about its economic importance. Marxist and liberal critics alike have argued that advertising creates and controls demand, thus attributing to it a key function in the perpetuation of consumer capitalism. Certainly, modern marketing gives producers a wide range of sophisticated strategies and techniques, but advertising is only one element among them. Furthermore, the fact that the vast majority of new products still fail when they are introduced to the market suggests that there is no one in control of demand.

Another economic criticism of advertising is that it adds to the price of goods and services, because advertising costs are real costs which are passed on to the consumer. The rebuttal is, that because 'advertising is the shortest distance between producer and consumer,' to quote J. Walter Thompson, it rationalizes the distribution process, generating only small costs which are spread easily over the large volumes of production which advertising helps to make possible.

The defenders of advertising argue that it is necessary to maintain competition, and that if producers don't advertise to maintain their market share, they will be driven out by their competitors, creating oligopolies, or markets dominated by very few producers. However, it follows that advertising is also a barrier against the article of new players, who must be able to achieve high levels of advertising from the beginning. This favours the 'market power' of the existing producers, so advertising would appear to favour oligopolistic markets.

In practice, it is evident that some of the industries which advertise the most heavily, such as packaged foods, or household and personal cleaning products, do indeed have tendencies to oligopolistic concen-

tration. Furthermore, it is worth noting that such oligopolies tend to maintain themselves not by the mass advertising of just one product line, but by product differentiation: for example, different shampoos for different types of hair. Advertising is implicated here because of its crucial role in branding, 'positioning,' and otherwise creating apparent differences between products for different types of consumer.

The connection between the ideological and the cultural dimensions of advertising is achieved most fully in the Marxist critique, where advertising is seen to perform ideological 'functions' which reproduce the capitalist system as a whole. In the US, Stuart Ewen has argued that department store owners and other ideologues of capitalism in the 1920s embarked on a 'project of ideological consumerization' (1976, p. 207) to draw working people into compliance with capitalism. More recent theory would see this as part of the 'pact' between capital and labor which stabilized the growth of capitalism in the first part of the century, the age of 'Fordism.'

In the UK, Marxist critics such as Raymond Williams (1980) were also influenced by a British tradition of social critique which denounced advertising on moral grounds, not so much because of its materialist values, but more because of its persuasive appeals and irrational associations. Something of this is also found in the critique of the Frankfurt School theorist Herbert Marcuse, who sees capitalism as sustained by 'false needs': 'The prevailing needs to relax, to have fun, to behave and consume in accordance with the advertisements' (1968, p. 22).

The Marxists have not been isolated in the critique of advertising, however. Liberal critics of capitalism in the US in the 1950s, a formative period in the history of the manufacturing–marketing–media complex, were read throughout the English-speaking world, thanks to the innovation of paperback publishing. Particularly in the context of the Cold War and popular fears about ideological 'brainwashing,' exposés of 'motivational analysis,' and the 'manipulation' of symbolic meanings in advertising, notably Vance Packard's *The Hidden Persuaders*, first published in 1957, found a ready audience. The following year, J. K. Galbraith's *The Affluent Society* came out criticizing the US economy for the way it produced the very needs which its goods were intended to satisfy (1974).

The twentieth century's last phase in the social criticism of advertising came from the women's movement, beginning in the 1970s. Advertising was a major cultural field which women cited as evidence of the social processes through which sex-roles were represented and reproduced through 'stereotyping.' In particular advertising was seen to perpetuate women in subordinate domestic roles, at the kitchen sink in detergent advertisements, for example, or alternatively, as sexual objects presenting themselves for the pleasure of the male gaze. Women's criticism of the 'sexism' of their representations in advertising was sustained into the 1980s, often with accompanying activism, even as advertising began more to represent the 'new' independent woman (van Zoonen 1994). In the 1990s, feminist critique has been absorbed into a broader academic approach to consumer culture.

In addition to the specific economic effects attributed to advertising, as outlined earlier, each of these phases of social criticism focuses on one of advertising's alleged cultural effects—that advertising has an ideological role in papering over social inequalities, that it creates false and irrational needs, and that it subordinates and degrades women. As well, there are other social concerns, with a similar perception of its power, which legitimize a public interest in the regulation of advertising—that it takes advantage of children, for example, or that it encourages young people to take up smoking (see *Advertising, Control of*).

Accordingly, advertising attracts some form of regulation in all countries, but with great variation, particularly in the ratio of self-regulation by the industry itself, as compared with government-prescribed regulation. Apart from the considerable cultural variations about what is acceptable in advertising images, advertising regulation typically restricts the type of product which may be advertised, such as alcohol and tobacco; the media which may be used, and at what times; the extent of product claims and invidious 'comparative' advertising; and in some cases, the use of foreign-produced advertisements.

No doubt the capacity of advertising to exert social influence is greatly overestimated, and its structure and processes much misunderstood, as Schudson has so thoroughly argued (1984), but even in an age of 'deregulation,' most governments are reluctant to surrender much of their control over advertising.

4. *Advertising in Social Theory*

The social criticisms of advertising referred to in the previous section, arising from liberalism, Marxism, and feminism, are grounded not just in those various social and intellectual movements as such, but in the considerable academic theorization and research which they have generated in the social sciences.

While it would be less true of the US than the UK, Canada, and Australia, Marxism provided the dominant paradigm in cultural studies and much social science, particularly sociology, from the mid-1970s until at least the end of the 1980s. This was a 'Western' Marxism in which there were two main trends: one towards 'political economy,' which emphasized the ownership, control and functioning of the economic structure of capitalism; and the other towards the cultural analysis of role of ideology in maintaining the

system as a whole. In both trends, but particularly the latter and more influential way of thinking, advertising was seen to have a crucial role to play in stabilizing a society which would otherwise be torn apart by its own contradictions. Following the French Marxist structuralist philosopher Louis Althusser, Marxist social theory in the 1980s thus shifted its analytical focus away the economic structure as the basis for capitalist society, and towards ideological reproduction—the representational and signifying practices of capitalist culture, including advertising.

This tendency in cultural Marxism found common cause with semiological structuralism (see *Semiotics*), derived from Ferdinand de Saussure, but mobilized most famously with regard to advertising by Roland Barthes (1977). In this approach, advertisements themselves became the main object of analysis, such that the emphasis was upon how the various meaningful elements, or the 'signifiers' in an advertisement, related to each other so as to produce the meaning of the advertisement as a whole (see *Advertising and Advertisements*). This is a qualitative, interpretive approach which contrasts with the quantitative method of 'content analysis.' The latter, with its roots in US behaviorism, nevertheless has been applied in complementary and productive ways in conjunction with semiological analysis, such as in Leiss et al.'s study of changing images of well-being in US advertising (1986).

Along with Marxist and semiological structuralism there has been a contribution from anthropological structuralism, stemming from Claude Lévi-Strauss. These strands are all brought together, along with feminism and the psychoanalytic development theory of Lacan, in Judith Williamson's *Decoding Advertisements*, one of the most definitive books on the analysis of advertisements (1978). She provides a coherent fusion of these theories, and applies them in the qualitative analysis of scores of magazine display advertisements, to evince such processes as 'interpellation' and the invocation of ideological 'referent systems' in the interpretation of advertisements. Apart from Williamson's application of Lévi-Strauss's theory of 'totemism' to explain how certain kinds of people become associated with particular products in advertising, such as the 'Pepsi generation,' anthropological structuralism provides a way of understanding how goods become endowed with cultural significance through their position in a total system of meaning (Douglas and Isherwood 1979, Appadurai 1986). Advertising visibly contributes to this process of giving meaning to goods, but by no means exclusively. For example, of several different international brands of sportswear advertised in similar ways, it will be the peer group that decides which of them is to be the preferred brand in any given locality.

The same relational quality of the cultural meaning of goods is also found in the poststructuralist contribution of Jean Baudrillard (1981). In his view, capitalist social structure is the source of needs as well as of the meaning of goods, and like certain of the liberal and Marxist critics of advertising cited above, Baudrillard sees the rise of consumer capitalism as a device by which the system has avoided the need to redistribute its wealth. Thus, class differences are concealed beneath an apparent democracy of consumption, a connection which is lost in the bewildering and endless display of signification.

With the advent of poststructuralism and postmodernism, the diversification of feminism, and the eclipse of Marxism, there has been much less critical attention paid to advertising as such during the 1990s. Rather, although traditional press and magazine display advertisements, television commercials, and billboards continue to provide the examples of postmodern visual culture which are cited, contemporary theory and research sees advertising in a broader and now much more theorized context. This is even wider than the manufacturing–marketing–media complex described above. Thus, for Wernick (1991), advertising is just a part of 'the promotional condition of contemporary culture,' which goes beyond the marketing of commercial goods and services to include the mode of public communication now embraced by all major social institutions, from political parties to universities, and also found in the presentation of one's own self.

In ways like this, current theory and research is moving beyond the study of advertising as such, and more towards consumer culture in general (see *Consumer Culture*). Not only has this shift encouraged attention to the role of hitherto-neglected institutions such as the department store and the supermarket, but also to transformations in work, domestic life, and cultural identities, insofar as these have become expressed and commodified in terms of consumer goods (Lury 1996). This agenda in turn gives rise to studies of how specific groups have been constructed, represented, and appealed to by marketing strategies, and of how they have responded (Nava et al. 1997).

Such a line of investigation is a welcome corrective to the preponderance of attention given to the content of advertisements themselves, without regard to their audiences, which has characterized nearly all theorization and research about advertising to date. Furthermore, it provides some insight into the 'reflexiveness' with which audiences are now seen to regard media and consumption in the era of globalization (Lash and Urry 1994). This entails a postmodern esthetic in which consumers express themselves as individual subjects by means of how they mobilize their knowledge of the codes of meaning which goods carry, codes which are partly bestowed by the images in advertising, marketing, and the media, but which become the rules of the game on the street. Clearly, this cultural relation of mediated images and their expressive use can not be understood by analysis of the images alone.

Finally, as far as studies of the manufacturing–marketing–media complex are concerned, the challenges are to keep pace with globalization, to comprehend its complexities, and to monitor the new relationships which are taking place between marketing and media with the growth of new technologies. As the much-vaunted end of the age of 'mass' media slowly becomes reality, for example, as free-to-air 'broadcast' television loses audiences to subscriber or 'narrowcast' services, advertisers are becoming more discriminating and strategic in their use of these media, and more aware of the interactive 'pointcast' access to potential consumers available over the Internet (Myers 1999). The capacity to deliver audiences to advertisers will continue to determine the development of media into the new twenty-first century as it did in the old.

Advertising, Psychology of

1. Short Historical Overview

Ever since mankind has advertised for a specific goal, he has considered how the advertisement should be designed to optimalize reaching the target. As early as 1898 Lewis had formulated his well-known rule, 'AIDA' (Attention, Interest, Desire, Action). This is still used today, although it is not scientifically substantiated.

Scientific research in applied psychology had already began considering the effects of advertising by the beginning of the twentieth century (Scott 1908, Münsterberg 1912). The impact of a certain stimulus on the observer was examined. Classical advertising psychology adopted the Economic Advertising Impact Model: it assumed that advertising effects on the (purchasing) behavior of the target group could only be predicted through the characteristics of advertising—the 'Stimulus–Response Model' (SR Model). Processes within the individual were not considered.

It was not until research showed that the SR Model did not provide the required information that researchers changed the direction of their investigations. This movement was towards the cognitive, motivational, and emotional processes within the individual. A new dimension was introduced into psychology—the SR model evolved into the 'Stimulus–Organism–Response Model' (SOR Model). This continues to be used today, at times in a modified form, to explain and examine relevant processes.

2. Advertising as a Part of the (Socio-) Marketing Mix

Advertising can be perceived as a supplier-initiated, purposeful method free of obligation. It is used to influence the target individuals through specific communication methods to such an extent that they accept an offer. It is a so-called distribution-political measure, in addition to the pricing, the distribution channels, and the offer itself. The offer can be a product (for example, a car or shampoo), a service (for example, a medical service or a taxi ride), or an idea (for example, religious ideas or political programs). These distribution measures are called a marketing mix when the products have a real market price (for example, cars) and a socio-marketing mix when there is no market price (for example, a political program).

3. Definitions Used in Advertising Psychology

Different fields approach advertising from different viewpoints, for example, history, law, communication, and economics. Advertising psychology takes a special look at the experience and the behavior of the recipients of advertising. This field is very specialized and therefore it is important for advertising psychologists to cooperate and work in an interdisciplinary fashion with members from other areas when analyzing and creating advertising.

A characteristic of the psychological viewpoint is that one of its main aspects, 'the experience,' is in the phenomenal world. Other characteristics of psychology are subjective perceptions and ideas. With regard to advertising this means that the psychological view of advertising cannot be seen independently from the offer, the price, and the distribution method. An economist can differentiate easily between the price and the advertising method, but advertising psychology studies have shown that the same advertising before and after a price increase can be perceived totally differently. Moreover, the same price can be experienced differently depending on the advertising used.

On the one hand, the psychology of advertising is an applied research science. It approaches questions out of applied areas and looks for methods used in basic research to answer these questions. The psychology of advertising is, however, also put into practice. It attempts, on the basis of the current state of research, to provide helpful answers to questions that occur in practice. This approach describes the professional life of an advertising psychologist not working in research (von Rosenstiel and Neumann 2001).

4. A Psychological Model of the Effect of Advertising

Various models in advertising psychology make the assumption that advertising is interpreted by the receiver as a stimulus coming from outside creating an

Figure 1
Psychological model of the effect of advertising (adapted from Neumann 2000, S. 18)

inner reaction. The person perceives this stimulus, is activated, and processes it cognitively, emotionally, and motivationally, which then results in a more or less extensive intention to act (for example, to ask for a brochure or to make the purchase). Whether or not this intention turns into action or not, depends on the competencies to act, the social norms involved, and the situational barriers. Figure 1 shows these relationships. Of course, this model, as all models, is a simplification and serves only to provide an understanding of the elements involved.

Figure 1 shows that advertisement, when seen as the influencing effect, is always interacting with other distribution-political measures, as well as with other factors which cannot be influenced, such as weather, economic swings, or political crises.

If advertising is to be successful and positively influence the behavior of the recipient, the psychological success criteria must be determined (as an in-between step) and indicators for their measurement must be operationalized.

The following aspects are important to analyze:

(a) Is the advertising noticed at all?

(b) Does it evoke enough general psycho-physical activation?

(c) Does it lead to optimal impressions?

(d) Is the incoming information adequately cognitively processed?

(e) Which of the following information is learned:

(i) Knowledge about the offer?

(ii) The feeling associated with the offer?

(iii) The all-encompassing motive associated with the offer?

(The learning processes (i), (ii), and (iii) can be described as image or attitude creation. Through this process the offer is positioned in the area of experience of the target person.)

(iv) Does the advertising cause a specific (motive) activation, which can then evolve into the motivation for a specific behavior?

Out of this motivation, in combination with the appropriate action competence (personal resources, such as buying power), the correct social norms as well as the beneficial or restricting conditions of the surrounding situation results the:

(v) Behavior (for example, ordering brochures, making an appointment for a test drive, or an actual purchase, which can be seen then as an indicator of economic success).

5. *Creating Advertising and the Methods for Measuring the Effects*

While the economic success of advertising can be registered by independent observers and is therefore objective in the sense of intersubjective agreement, it is only the individual perceiving the advertising introspectively. Therefore, one needs methods and procedures which make it possible to make these processes and phenomena accessible from the outside. Methods can be used which give answers to the questions about whether advertising is noticed, what feelings it evokes, or how efficient an existing image has been changed (Jones 1998). Selected methods for measuring psychological and economical advertising success can be seen in Fig. 2.

From experiences measuring future psychological advertising success (advertising success prognosis) or the actual advertising success (advertising success control), some basic principles have been determined regarding the development and use of advertising (Percy and Woodside 1983, Kroeber-Riel 1991). Examples of these are visually transported advertising such as newspapers, billboards, TV, and film.

Advertisements should be concise and clearly structured in terms of content and should correspond with the motives, attitudes, and expectations of the target group. This should make them noticeable. The written message or the picture should have topics which evoke emotions in order to create activation, but without taking the attention away from the actual product.

Regarding the overall format of the advertisement, attention must be paid to the choice of colors, shapes, and structure. Furthermore, it should not evoke negative emotions as a first impression and the written information and the picture should be easy to understand.

Since advertising often has the goal of improving the image, which can be defined as the attitudes regarding the offer, it is important to consider the following:

(a) Increase the specific knowledge about the offer by providing concise and clear information.

(b) Elicit positive emotions with pictures and words which can be applied to the offer and give it added value compared with other competitive products.

(c) Improve motivation by using written statements about potential effects of the purchase or models who show that they are successful with the offer.

In a real decision making process, these motives can turn into buying motivation if advertising is used, and this can be measured with appropriate scales which indicate the willingness to buy. Advertising is geared to access the intention to purchase and when the advertisement has hints about where, how, and under which conditions the product can be bought, the service acquired, or the idea be taken over, this can succeed. Some examples illustrating the relevance and importance of the above considerations are listed below. These show how relevant such tests before advertisement release can greatly improve the effectiveness of the advertisements on the target group.

The first example (from the authors) is of reading glasses to be used as a logo for a book club. There were two color variations for the frame, orange and red. An experiment using a tachistoscope where subjects were exposed to the glasses for 1/1,000 of a second which

Figure 2
Methods for assessing psychological and economical advertising success (adapted from Neumann 2000, S. 268)

meant only seeing the color, not the shape, resulted in the following emotional associations:

(a) orange—mainly positive associations such as sun, warmth, and holidays, but also a few negative associations such as chemicals and danger;

(b) red—mainly negative associations such as blood, accident, hospital, and death.

On the basis of this study, the decision was made in favor of the orange glasses as the logo. Another example (Spiegel 1970, S. 61) is advertisement with a country picture with vineyards and an old train, representing the origin of a brandy. In the initial phases of perceiving the picture, associations with an industrial landscape arose. Such initial thoughts did not follow the direction of the desired advertising message. However, a systematic variation of the white steam from the train engine resulted in removing the section of steam blocking a part of the vineyards. With this alteration, the initial negative perception was removed.

In addition, one study (Neumann 2000, S. 97) illustrates that positively experienced advertisements are remembered significantly more than those experienced as less positive. In the first step, subjects were shown four advertisements for cigarettes and four for drinks and asked to rate their relative liking of each on a scale. After 30 minutes, using unaided recall, the subjects were asked to note which of the advertisements they remembered. Figure 3 shows the results, where the correlation between the two steps was very high, 0.79.

Figure 3
Evaluation and unaided recall for eight advertisements

Figure 4
Name recognition rating and distribution over time (Zielske 1959)

In a classical study, Zielske (1959) tested spreading as opposed to massive printing of advertisements. A specific advertisement was shown to two parallel target groups 13 times: one group each week (massive), the other group spread over a year (spreading). The success can be read from the Fig. 4 which shows the percentage of the target group which were able to remember the advertisement.

If the target is a high level of name recognition rating massive advertisement is advisable. However the effect disappears rapidly. Typical examples for this are advertising campaigns before elections or summer/winter sales. Normally, the aim is a long-term effect where the second alternative is more appropriate, or, when the budget allows, a combination of both the massive and spreading approaches.

Finally, in a study (Neumann 2000, S. 217), four film spots were used which advertised 'alternative' targets: against torture, the killing of fur-bearing animals, nuclear power, and destruction of the ozone layer. Figure 5 shows sections of the results that were collected by using a specific characteristics profile of the optimal alternative advertising spot profile. Figure 6 shows the achieved factor analysis position of each spot based on this profile.

If the advertising method has been optimized according to psychological criteria and has been tested with the appropriate methods, then the measurement of the economic advertising success is to be seen as nearly equivalent to a test of the hypotheses for psychological advertising success. However, one has to take into account that other factors influence the economic advertising success and they must also be taken into consideration. Therefore it is hardly possible, despite optimal advertisement, to have economic success if the product is hard to find, the price is higher than what is seen as fair, or if the ownership or use of the product contradicts social norms or is perhaps even forbidden.

Figure 5
Characteristics profile of spots for alternative advertising (optimal conception—continuous line); spots against torture (from Amnesty International), and against the destruction of the ozone layer (from Greenpeace)

6. *Consequences and Value Problems*

Advertising is often criticized because it is created in such a way that as many people as possible notice it and because it is such an integral part of a market economy. Advertising is visible and audible for both children and adults, it influences our experience and our behavior, and it has a socializing effect. Therefore it does not come as a great surprise, but makes many upset, that for example, children know more car makes than they do tree or animal names or that the motivation to do something that costs money (for example, a cruise) is higher than to do something that is practically free of cost (for example, a hike in the nearby mountains).

There is also a great deal of criticism regarding the fact that consumer advertising shifts social norms. Advertising shows people, for example, who are astoundingly young, healthy, active, happy, and wealthy, so that an individual could perhaps see him/herself as underprivileged and then develop unrealistic expectations, consume too much, and go into great debt which could place them and their families' economic existence in danger. Especially the view of women in advertisement has been criticized

Figure 6
Factor analysis position of spots for alternative targets

greatly. By displaying extremely thin women in advertising, young girls and women could be in danger of eating disorders such as bulimia nervosa. In addition, some feel that women presented in advertising are degraded to object-status (only as objects of desire for men) and that this damages their sense of self-worth.

Critical discussions also took place regarding the assumption that advertising influences subconsciously with such weak stimulation that it is not even noticed consciously by the target individuals, but can still lead to specific consumer behavior. In the meantime, one knows through extensive research that this type of subliminal advertising has only a marginal if any behavioral effect. On the other hand, the accusation that advertising manipulates can be taken more seriously if manipulation is understood as an influencing technique which influences the target person. This would be the case if the advertising was carried out:

(a) Solely to the supplier's own advantage,

(b) Without considering the interest of the target person, and

(c) By using questionable methods which give the appearance that the target person is acting at their own free will.

Manipulative methods are typically recognized by using pictoral representations of socially unacceptable motives, whereby socially acceptable motives are displayed in writing. On the other hand, the demands made by consumer protection groups stating that advertising should only be informative are unrealistic, because they assume that humans are rational decision makers. Empirical research shows us, however, that not only rational decisions affect and influence buying behavior (Engel et al. 1992, Kroeber-Riel and Weinberg 1999).

Intense socially critical discussions have been carried out regarding the costs of advertising. In many organized industrial states with market economies the costs for advertising are higher than the costs for education. Critics say that this is a waste for society, because advertisement doesn't change the size of the cake that is to be divided up, but just changes the portions divided up by the competitors. This can be disproved, however, impulses for growth are generated by advertising.

Advocacy and Equity Planning

Until recently, most American city planners dealt solely with the physical city. They designed streets, parks, and boulevards, made plans for the way land was to be used in the community, and prepared regulations to control the use of land. Advocacy or equity planners are those professional planners who not only deal with the physical aspects of the community but who, in their day-to-day practice, also deliberately try to move resources, political power, and political participation toward the lower-income, disadvantaged populations of their cities. They are called 'advocacy' or 'equity planners' because they seek greater equity among different groups as a result of their work. Where the work of most city planners is rarely consciously redistributive, advocacy or equity planners often conceive the potential contribution of planning in broad economic and social terms and try to provide for a downward redistribution of resources and political participation in order to create a more just and democratic society.

Many observers place the birth of advocacy and equity planning in the decade of the 1960s when crowds were in the streets of American cities protesting the wholesale demolitions and displacements caused by urban renewal and the interstate highway program. These traumatic events and the anti-war and civil rights movements, which occurred at about the same time, challenged the belief in top-down planning by benign, value-free experts and created a demand for more social planning based on grassroots involvement. The events of the 1960s provided great support for advocacy and equity planning, but actually, an alternative planning practice oriented toward equity considerations had its roots in the turn of the twentieth century.

To begin this exploration into recent history, one must go back to the period between approximately 1880 and 1915, known as the Progressive Era, a time when the respectable urban bourgeois discovered the slum city festering beneath their urban world. At the time, America was rapidly changing from an agricultural to an industrial society. American farmers, forced off their homesteads, joined European immigrants flooding into industrial cities. The largest cities, as centers of manufacturing, exchange, and distribution, had grown most explosively without proper planning or the means to regulate growth. They became choked with slums built to house immigrant workers (Riis 1971). The slums, in cities like New York and Chicago, became such breeding grounds of disease, crime, and human misery that efforts at reform were introduced by civic and political leaders. It was this revulsion against the slum and the fear of revolutionary social unrest that brought housing reform and the social aspects of urbanism into modern urban planning. Progressive leaders believed that such dismal conditions could not wait on beneficent forces, but could be corrected by diligent and scientific health and housing policies.

The settlement house movement was one of their first efforts at neighborhood improvement. In the poor, immigrant neighborhoods of dozens of major cities, settlement houses like Hull House in Chicago, Henry Street Settlement in New York, and South End House in Boston, were established. These were mostly staffed by middle- or upper-class social workers who taught the English language and domestic arts to immigrants, lobbied city government for more neighborhood parks and other public facilities, and pressed for effective tenement housing reform. In the process, the settlement house workers hoped to improve housing and neighborhood conditions, and 'Americanize' the new immigrants. They were not urban planners but, then, advocacy for parks, better housing, and other improvements in the slums helped provide the reform underpinning for the nascent city planning profession.

Three typical progressive era reformers were Mary Kingsbury Simkhovitch, Benjamin C. Marsh, and Alice Constance Austin. Simkhovitch pursued a wide range of social justice issues, including women's suffrage, economic reform, and progressive politics. After establishing Greenwich House in New York City, she worked to improve housing density and building-code laws. During the 1930s, Simkhovitch performed her most important work when she helped draft the Wagner–Steagall Housing Act of 1937, providing federal participation in low-income housing for the first time in America.

Benjamin C. Marsh was the Secretary of the Committee on Congestion of Population, a prestigious committee formed in 1907 by 37 civic and philanthropic organizations to study, publicize, and promote programs to relieve the problems of excessive massing of people in New York City. Marsh was widely traveled and was strongly impressed by European city planning, especially by the ideas of the Englishman, Ebenezer Howard (Howard 1965). Howard, who loathed the industrial city with its filth and overcrowding, proposed a scheme of land development based on population dispersion into a regional pattern of small, self-contained cities. These garden cities would enjoy all the advantages of the core city including nearby jobs in industry, higher wages, and social opportunities, while also enjoying the benefits of the countryside with low rents, fresh air, agricultural gardens, and cooperative arrangements to maintain the land. A central feature of Howard's scheme included the common ownership of land so that the unearned increments in land values could be recaptured for the benefit of the entire community. Howard's sweeping planning ideas were enthusiastically adopted by Marsh, for whom city planning was a holy war against predatory forces, especially real-estate speculators. Marsh's energetic career as a skilled organizer and publicist of planning issues made the city planning movement better known nationally and more socially responsive. His small paperback book, *An Introduction to City Planning* (1909), set the stage for the First National Conference on City Planning and the Problems of Congestion convened in Washington, DC in 1909, which marks the formal birth of American city planning.

Alice Constance Austin also used Ebenezer Howard's new town ideas as examples of good city planning when she assumed the role of city planner and architect in 1915 for the partially built socialist city of Llano de1 Rio in California (Hayden 1976). Austin also learned from Patrick Geddes, a Scottish biologist, who drew up dozens of town plans in India and elsewhere, based on a cooperative model of city evolution. Austin's debt to Howard's garden city is reflected in her organization of the city of Llano del Rio, with its 'crystal palace'-like central buildings and its boulevards and street system. Her approach to building design was, however, distinctly feminist. Here, Austin proposed private gardens, but also communal kitchens and laundries to liberate women from drudgery.

Early American planners, most of whom were architects and engineers, believed that the way to bring the city under control was to reduce congestion, make physical development more attractive, and control the flow of traffic. They thought planning and zoning examples from Europe, especially from Germany and the UK, provided good direction. But, although early American planners used European models to define good planning, in one key respect the American approach diverged sharply from the European experience. In France, Germany, and the UK, the answer to the provision of low-income housing was government support; in the USA such support was decisively rejected. Lawrence Veiller, author of the New York City tenement-house legislation of 1901 who later founded the National Housing Association, maintained that only local government should concern itself with housing, but only to enforce local building regulations (Scott 1995). Otherwise, private benevolence could do the job. In Veiller's view, it was proper for local government to clear slums, but not to rehouse the displaced families.

A small group of visionaries rejected the physical determinism of most early planners. The Regional Planning Association of America (RPAA), formed in 1923, included such planning luminaries as Catherine Bauer, Stuart Chase, Benton MacKaye, Lewis Mumford, Clarence Stein, and Henry Wright. They believed in planning entire regions to achieve social objectives. Following the ideas of Howard and Geddes, RPAA members expounded their vision of small, self-sufficient communities scattered through regions in ecological balance with rich natural resources. In the distribution of electric power by regional grids and the speed of the automobile and truck, they saw new tools for rehabilitating declining urban neighborhoods and liberating large cities from congestion and waste.

The thinking and writing of RPAA's members was influential beyond their small numbers. Their ideas on regional planning and environmental conservation led in the 1930s to the creation of the Tennessee Valley Authority (TVA), the Civilian Conservation Corps, the 14-state Appalachian Trail and the regional studies of the National Resources Planning Board. RPAA member Benton MacKaye, who conceived the Appalachian Trail, was clearly one of the founders of the modern environmental movement.

RPAA's main practical experiment, however, was only a mixed success (Birch 1980). It was the garden city-inspired development of Radburn, in Fairlawn, NJ constructed in 1928 using Ebenezer Howard's ideas, but adjusted to American customs and laws. The elements of Radburn include the 'superblock,' the cul-de-sac and narrow loop lanes for residential traffic, the clustering of housing around large areas of parkland in common ownership, and the separation of vehicular and pedestrian traffic. Radburn also provided day care for working mothers and similar social services, as well as a community organization to administer commonly held land. Although Radburn has had an important influence on American planning thought and design, it failed to realize its sponsor's hopes of becoming a completely self-sustained community. It has now been swallowed up as part of northern New Jersey's amorphous sprawl.

By the time America emerged from World War I, the Progressive Era had lost much of its momentum. City planning, slum clearance and housing reform, which had been part of the upsurge of reform, now

suffered from a weakening of the liberal impulse. RPAA member Frederick L. Ackerman attacked the profession for no longer being concerned about 'the causes which give rise to the existing maladjustment' in cities. America had maladjusted communities, he said, because planners declined to interfere with 'the right of the individual to use the community as a machine for procuring individual profits and benefits, without regard to what happens to the community' (Ackerman 1919).

Urban planning and especially social or equity planning lagged during the 1920s with 'the business of America was business,' but the Great Depression and the New Deal administration of Franklin D. Roosevelt (FDR) brought both back. Roosevelt believed that the power of government should be used to restore misused land, harness wasted water, and revitalize despondent human beings. In his first term, FDR enacted legislation authorizing the widest application of planning yet proposed, including the TVA and the Resettlement Administration. By Executive Order, FDR also established the National Planning Board, later the National Resources Planning Board.

The National Resources Planning Board was America's first effort at national planning. The Board advised the Department of the Interior on regional planning, land and water conservation, and on issues of social insurance and poverty. As Secretary of the Interior, Harold L. Ickes, told city planners and members of the American Civic Association in 1933, 'long after the necessity for stimulating industry … . shall be a thing of the past, national planning will go on as a permanent Government institution.' However, the Board was resented by many old-line federal agencies like the Army Corps of Engineers who chafed under the Board's attempts to coordinate their projects, and by conservative Congressmen who feared that the agency was promoting foreign, socialist schemes. As a result, and to wide and dolorous lamentation among planners, Congress abolished the National Resources Planning Board in August, 1943.

The Resettlement Administration, established in 1935 under the leadership of Rexford G. Tugwell, suffered a similar fate. Tugwell, who once proposed that the (US) Constitution be changed to include planning as a fourth power of government, immediately embarked on an effort to improve living conditions for working people in metropolitan areas. He seized on the idea of the English suburban garden village, but adapted the concept to the American situation. The towns built by the Resettlement Administration were called Greenbelt Towns. Originally, Tugwell's staff identified eight metropolitan areas where new towns were to be built, but funding limitations narrowed the choices to three areas: Greendale, Wisconsin near Milwaukee; Greenhills, Ohio near Cincinnati; and Greenbelt, Maryland near Washington, DC. The three towns, all examples of high-quality planning, featured small homes in a well-planned garden setting and housed about 2,100 families in all. The distinctive feature of all three of the towns was the surrounding greenbelt protecting the towns from outside encroachment. The residents, largely industrial workers, were provided an opportunity to live in a low-cost, but far superior environment than they were used to. As a demonstration, the Greenbelt Towns made clear that superior alternatives existed to haphazard speculative sprawl. Unfortunately, before the Resettlement Administration could expand the three towns and build two others that were on the drafting table, Congress abolished the agency in June, 1938. It was left to post World War II British planners to build a substantial new towns program, while the USA had to content itself with the three Greenbelt towns and a few commercial initiatives including Reston, Virginia, and Columbia, Maryland.

Roosevelt's New Deal also produced the first major intervention in the field of low-rent housing. Pushed vigorously by RPAA member Catherine Bauer and others, the administration passed into law the Housing Act of 1937 which provided low-rent housing for the deserving working poor. For the first time, the federal government would provide support for the capital costs of public housing construction; tenant rents were to take care of subsequent operating and maintenance costs. Later, in 1949 and 1954, Congress returned to the public housing issue and emerged with a commitment to more low-income housing. But Congress also made a larger commitment to urban renewal, which ultimately demolished more low-income housing close to the city core than was built. The scale of demolition and forced relocation was large; a study by the National Association of Home Builders estimated that the total housing demolition by all public programs between 1950 and 1968 amounted to 2.38 million units. These units were disproportionately the homes of poor and near-poor black families.

Ultimately, a revolt broke out against these excesses. Within an astonishingly short time, this revolt caused an almost complete inversion of almost every basic value in American planning practice. Influential critics Jane Jacobs (1961) and Herbert Gans (1962) spoke for the preservation of older urban neighborhoods, as they pointed out that planners implementing the urban renewal program were thoughtlessly destroying valuable housing and irreplaceable social networks while providing opportunities for profitable real estate investments. The opposition to urban renewal coincided with the civil rights movement, and racial riots tore through the cities revealing just how little the planning process had done for the poor. Opposition to the war in Vietnam, and with it the Pentagon style of planning by top-down, bureaucratic experts, was at its peak. There was now a deep distrust of professional expertise and there was a demand for advocacy and equity planning based on grass-roots involvement.

Paul Davidoff, a lawyer, planner, and educator, made the most substantial contribution to the concept of advocacy planning (Davidoff 1965). He argued that advocacy could reinvigorate planning in three ways: by broadening public debate and participation, by sharpening the skills of planners who would have to defend their choices, and by shifting the focus of planning from the purely physical, to social and economic priorities. The essence of advocacy planning is the encouragement of alternative plans by all groups holding special values about the future of their communities. Advocacy planning would supplement the one, official city plan with alternative plans by Liberals, Conservatives, Democrats, and Republicans and other groups, but the emphasis would be on professional planning services for the poor, the black, and the underprivileged. Using legal analogies, the merits of these alternative plans were to be debated and the best plan would emerge from the debate. Davidoff's ideas were taken up by planning practitioners and educators with a strong cumulative effect.

During the 1960s advocacy planning organizations serving minorities, poor, and working-class whites were formed in many American cities (Heskin 1980). Exemplars were: Architects Renewal Committee of Harlem in New York City (1964); Urban Planning Aids in Boston (1967); and the Community Design Center in San Francisco (1967). The effectiveness of these grassroots organizations was limited given their inadequate resources and often defensive strategies, but they signaled a new diversity. A national organization called Planners for Equal Opportunity was established in the 1960s and in 1975, under the leadership of advocate planner Chester Hartman, continued as Planner's Network. By 1999, Planner's Network represented over 800 planners and academics concerned with social and economic justice. By the 1970s the American Planning Association, whose journal carried virtually no discussion of racial issues prior to 1970, had modified its Code of Ethics to reflect concern for vulnerable populations: 'A planner shall seek to expand choice and opportunity for all persons, recognizing a special responsibility to plan for the needs of disadvantaged groups and persons …'

Davidoff's writings on choice theory were important intellectual contributions to planning theory and they make him the pre-eminent symbol of progressive planning. They make perhaps the most persuasive argument on how a planner might reconcile professionalism with political engagement.

But Davidoff's substantial contributions to planning theory and practice were matched by his efforts at institutional innovation. He realized that from 1950 onward, the overwhelming preponderance of growth in population, jobs, and economic investment was not in America's cities but was in the suburbs. Because of racial discrimination and exclusionary land use controls, blacks were being shut away from the benefits of suburban growth. In response, Davidoff founded Suburban Action, a nonprofit institute for research, litigation, and advocate planning services within metropolitan regions (Davidoff et al. 1970). Suburban Action used its resources to legally challenge restrictive zoning and land use controls in the suburbs and enlarge suburban opportunities for the black and poor.

Davidoff's special concerns for the disadvantaged were also adopted in some official city planning agencies within local government. One of these was in Cleveland, Ohio, where planning director Norman Krumholz and a core staff of progressive planners developed a system of values and strategies in the 1970s which came to be called 'equity planning.' The central theme adopted by the Cleveland planners was contained in this statement: 'In the context of limited resources, first and priority attention should be given to the task of promoting wider choices for those Cleveland residents who have few if any choices' (Krumholz et al. 1975, Krumholz 1982). This goal made clear that Cleveland's poor and near-poor were to receive priority planning attention.

The Cleveland planners justified the choice of their goal with three arguments. First, they argued that a long-standing, historic moral commitment existed to seek more equity in the social, economic, and political relations among people. Second, building on the ideas of philosopher John Rawls (1971), they used reason as a means of justifying a more equitable society—the kind of society that free, equal, and rational people would establish to protect their own self-interests. Finally, they justified their goal by reality: making explicit the imbalances in income, education, health, and other social and economic variables that existed in Cleveland between city and suburb, and white and black citizens (Cleveland City Planning Commission 1975). Over the ten-year length of the equity planning experiment, and under three different mayors, the efforts of Cleveland's planners resulted in 'fair-share' low-income housing distribution plans for Cuyahoga County, progressive changes in Ohio's property law, improvements in public service delivery, enhancement of transit services for the transit-dependent population, the rescue of lakefront parklands, and many other improvements.

Another outstanding example of progressive politics and equity planning within city government was found in Chicago during the 1980s. Robert Mier, a planning professor who founded the Center for Urban Economic Development at the University of Illinois in Chicago, helped build a political coalition that in 1982 elected Harold Washington, Chicago's first black mayor. When elected, Washington took Mier and some of his associates into City Hall where they explicitly included 'redistributive and social justice goals within the governments's policy, planning and implementation frameworks' (Giloth and Moe 1999).

Mier and his fellow planners wrote the 'Chicago Economic Development Plan, 1984,' a model of equity planning. The plan proposed to use the full weight of the city's tax incentives, public financing, and infrastructure improvements to generate jobs for Chicago residents with emphasis on the unemployed. Specific hiring targets were set for minority and female employment; 60 percent of the city's purchasing was directed to Chicago businesses; 25 percent of that was to go to minority and women-owned firms.

The plan also sought to encourage a model of balanced, 'linked' growth between downtown Chicago and the city's neighborhoods. It offered public support to private developers interested in building projects in 'strong' market areas of the city, only if they would agree to contribute to a low-income housing trust fund or otherwise assist neighborhood-based community development corporations to build projects in 'weaker' areas.

Other American urban planners have adopted advocacy/equity approaches because they believe that planning along these lines holds the promise of better lives for the most troubled residents of their cities. In the 1980s and 1990s equity planning cases were documented in such cities as Denver, Jersey City, San Diego, Berkeley, and Santa Monica (Krumholz and Clave 1994). These cases make clear that there are often political and institutional barriers to equity planning practice, especially in a nation so strongly driven by market forces as the USA, and equity planners who question the status quo may face political reprisals. But obstacles to equity planning practice seem to lie primarily in the areas of the planner's personal confidence, motivation, and will.

A number of lessons seem clear. First, all forms of urban planning, especially advocacy/equity planning, prosper during periods of crisis which bring forward the reform elements of the American state. It was during the Progressive Era that housing reform and urban planning were initiated. Later, when the Great Depression brought forth FDR's New Deal, planning was introduced for the first time into the federal government, sweeping regional projects like TVA got their start and the federal government involved itself in the provision of low-income housing. During the 1960s, the ferment around civil rights, anti-war protests, and the demolitions of urban renewal and the interstate highway program, brought advocacy planners like Paul Davidoff, who combined commitment to social justice and democracy, to the fore.

Although the advocacy/equity planners often struggled against the more powerful currents of a strongly market-oriented society, they succeeded to an extent, and their work has been acknowledged and institutionalized. At the end of the twentieth century, American city planning was much more sensitive and collaborative than it had been earlier. Racial discrimination in housing and in mortgage lending has been prohibited by federal law, and citizens were encouraged to participate in the planning of programs that impacted their lives. Neighborhood-based development corporations have been successfully redeveloping parts of certain older neighborhoods, and some cities have been linking the benefits of downtown growth to their poor neighborhoods.

What remains troublesome, however, is the persistence of deep poverty in a growing number of urban neighborhoods; the continuance of patterns of racial segregation; the widening gap between rich and poor; the dismantling by conservative national administrations of the social safety net; the chronic competition among American cities that harms the vast majority of their citizens; and the growing spatial separation across metropolitan regions by race and class.

Given these challenges, a new generation of advocacy/equity planners is needed to help ease and resolve the most crucial of these social and physical issues, for what is at stake is nothing less than the future of urban life in America.

Advocacy in Anthropology

1. Definition, Scope, and Aims

Advocacy is a variety of applied anthropology advancing the interests of a community, often as a practical plea on its behalf to one or more external agencies (Paine 1985, Wright 1988). The community is usually indigenes, peasants, an ethnic minority, or refugees—those who are among the most oppressed, exploited, and abused. Advocacy is often connected to human rights, a framework internationally accepted in principle if not always followed in practice (Messer 1993). Advocacy encompasses a broad agenda for social and political activism—promoting cultural survival and identity, empowerment, self-determination, human rights, economy, and the quality of life of communities. Advocates reject the supposed neutrality of science and adopt a stance on some problem or issue to improve the situation of a community, ideally in close collaboration with it. Thus, as advocate the anthropologist is no longer just observer, recorder, and interpreter (basic research), nor consultant to an external agency (applied), but facilitator, interventionist, lobbyist, or activist for a community (advocacy).

2. Pivotal Position

Advocacy usually operates from an idealist rather than realist position, although these terms are problematic. Realists accept cultural assimilation and even ethnocide (forced cultural change or extinction) as a natural and inevitable correlate of 'civilization,' 'progress,' and 'development,' a position sometimes linked with social Darwinism. Idealists reject this, viewing ethnocide as a political decision, usually by a government violating human rights. Realists dismiss idealists as romantic, and/or trying to preserve indigenes as private laboratories, zoos, or museums. However, idealists do not argue that culture is static and should be preserved as such, only for self-determination by people to promote their cultural survival, identity, welfare, and rights. The moral and political issue is the right and power of the state to dominate indigenes or others and to implement ethnocide. Advocacy attempts to intervene in this asymmetry through demystifying the process, exposing injustices, and offering political resistance (Bodley 1999).

3. Historical Sketch

Advocacy has a long history. Bartolome de las Casas (1474–1566)—theologian, missionary, and something of a historian and anthropologist—participated in the first decades of European colonialism in the Americas. He chronicled injustice against indigenes and argued in their defense. By the mid-nineteenth century, the Anti-Slavery Society and the Aboriginal Protection Society emerged in the UK as humanitarian organizations campaigning for just policies toward indigenes and others. During this period, the early anthropological societies of London and Paris added similar concerns. In the 1960s, organizations focused on advocacy developed, most notably Cultural Survival in Cambridge, Massachusetts; the International Work Group for Indigenous Affairs in Copenhagen; and the Minority Rights Group and Survival International in London. Each publishes newsletters, journals, and/or documents to expose human rights violations and analyze issues; funds collaborative research with communities; and works to influence national and international governmental and nongovernmental agencies and the public, especially through lobbying, the media, and letter writing (e.g., Solo 1992).

Most of the history of advocacy as well as recent cases and issues can be found in the publications of these advocacy organizations (e.g., *Cultural Survival Quarterly*) and in the journals *Current Anthropology* (especially December 1968, December 1973, June 1990, June 1995, February 1996); *Human Organization* (especially January 1958, Winter 1971) and its predecessor *Applied Anthropology*; and *Practicing Anthropology*. This literature can greatly enrich anthropology courses.

4. Some Cases

Two pioneering projects in action anthropology stand out: the Fox and Vicos projects. These became models for subsequent initiatives worldwide. Action is based on the premise that if a community is adequately informed of the alternatives for change, then it will try to choose what is best. Both action and advocacy pivot on self-determination (see Castile 1975). From 1948 to 1959, Sol Tax and his students from the University of Chicago developed the Fox Project to promote the self-determination of some 600

Mesquakies in Tama, Iowa. The Mesquakies, commonly called Fox Indians, faced cultural extinction. The anthropologists facilitated the identification by the community of their needs, problems, and alternatives (Stanley 1996). From 1952 to 1957, Allan Holmberg of Cornell University led a team, including colleagues from the Indigenous Institute of Peru, in action anthropology for the Quechua community of Vicos in the Andes. About 2250 people gained significant freedom from centuries of oppression, exploitation, and abuse as the project provided technical, economic, and other assistance for community development and a cooperative (Dobyns et al. 1971). Advocacy long predates action anthropology, although the term advocacy is more recent. Action focuses on community directed cultural change and development, advocacy on pleading the case of a community to a government or other agency, especially about human rights violations. However, often advocacy and action are intermeshed.

An exemplary case from the mid-1990s is the Ye'kuana Self-Demarcation Project. Some 4000 Ye'kuana are scattered in 30 communities in the Venezuelan Amazon. Despite factions created by Catholic and Protestant missionization, the Ye'kuana united in this project. They are documenting their history, settlement pattern, resource and land use, and other aspects of their culture for legal title to ancestral land from the government. Nelly Arvelo-Jimenez (Venezuelan Institute for Scientific Investigations and Otro future) and other outsiders provided assistance including the Global Positioning System to help map Ye'kuana territory. Mapping was financed by a grant from the Canadian government through the Assembly of First Nations, the Canadian indigenous organization (Arvelo-Jimenez and Conn 1995).

In such ways advocacy contributes to indigenes, ethnic minorities, and others economic, technical, health, legal, and political assistance as well as helping raise their media savvy, cultural consciousness, and hope. Also it helps promote the global movement of pan-indigenous identity (e.g., Lurie 1999).

5. *Criticisms and Responses*

At least two criticisms contributed to the development of advocacy: first, accusations of genocide and ethnocide of indigenes by colonials and neo-colonials in frontiers like the Amazon (Bodley 1999); and second, from outside and within anthropology criticisms of basic and applied research together with calls for increasing social responsibility and relevance (Biolsi and Zimmerman 1997, Hymes 1972). In the late 1960s, Vine Deloria, Jr., a Sioux lawyer and author, launched a searing critique of anthropologists engaged in either pure research with natives as objects in their private zoo, or applied work for the colonial government, only concerned with advancing their career for status, prestige, and money; and irresponsible and unresponsive to the needs and problems of indigenes. He asserted that anthropologists should obtain informed permission from the host community for research, plan and implement it in close collaboration with them, and focus on their practical needs, problems, and concerns (Biolsi and Zimmerman 1997).

In 1971, a historically important but neglected conference of mostly Latin American anthropologists developed the Declaration of Barbados which, among other things, criticized anthropology for its scientism, hypocrisy, opportunism, and apathy in the face of the oppression, exploitation, ethnocide, and genocide of indigenes by colonials and neo-colonials. For some anthropologists this became a manifesto to join the struggles for liberation and self-determination of indigenes and ethnic minorities through advocacy (Dostal 1972).

There have also been criticisms of advocacy from within the profession, mainly for supposedly abandoning scientific objectivity and reducing or abandoning anthropology to some form of social work or political action. For instance, Elsass (1992) asserts that anthropology rests on criteria of science, objectivity through neutrality, and scholarship for the creation of knowledge; and advocacy on morality and the use of knowledge. He thinks that anthropologists are ill equipped to deal with matters such as the politics of state penetration into indigenous areas. He worries that advocacy may make things worse in the community and jeopardize the credibility and prestige of basic research. Elsass believes that fieldwork, moral commitment, a sense of justice, political observation, and anger on behalf of the community, are all part of the decision to advocate, but that anthropology as science and scholarship does not lead to advocacy (cf. Castile 1975).

Such critics fail to realize four things. First, in a general sense all anthropologists are advocates in some degree and manner. At least since Franz Boas (1858–1942), teaching anthropology advocates the value of the profession and cultural diversity; research publications advocate certain arguments, theories, and methods; and both may challenge racism and ethnocentrism in favor of valuing equality.

Second, no scientist or science is apolitical and amoral; indeed, even the decision not to act involves politics and morality. When ethnocide, genocide, or human rights violations occur, it is simply unprofessional and unconscionable for a knowledgeable anthropologist not to act. This is implicit in the code of professional ethics of organizations like the American Anthropological Association, numerous resolutions at its annual meetings over many decades, and its Committee for Human Rights.

Third, many communities believe that either the anthropologist is part of the solution or part of the problem (Biolsi and Zimmerman 1997). Increasingly host communities are excluding anthropologists unless

they demonstrate social responsibility and relevance. Indeed, if anthropology is not of some relevance to the communities from which research is derived, then some would suspect its credibility. Even when a community can readily speak for itself, it usually helps to have an outsider with some special knowledge speak as well. For instance, this transpired in the USA with numerous cases of land claims by Native Americans in which anthropologists served as expert witnesses in court.

Fourth, many anthropologists are involved in advocacy because they are sincerely concerned with applying knowledge on behalf of the communities who are indispensable for their research, as an expression of genuine reciprocity, and to avoid dehumanizing their hosts and themselves.

6. *Future*

In the future advocacy needs to more explicitly and systematically develop its foundations and operations in terms of its history, philosophy, theory, methods, ethics, practice, and politics. There are many ways to contribute to advocacy, even for those who eschew its complexities, difficulties, and risks in fieldwork (cf. Mahmood 1996). To be effective advocacy must be grounded in basic research, but it also feeds into theory. For example, advocacy should help anthropologists continue critical reflection on fundamental issues such as these problematic dichotomies: science/humanism, objectivity/subjectivity, fact/value, observer/participant, theory/practice, basic/applied, inaction/action, powerful/powerless, modernist/traditionalist, realist/idealist, and universalism/relativism.

Advocacy, action, and other varieties of applied anthropology are most likely to increase in the twenty-first century because of at least three factors: first, growing population and economic pressures on land and resources with ensuing conflicts, violence, and rights violations; second, increasing encroachment of the state, military, business, industry, and other forces into 'undeveloped' zones; and third, insistence by local communities that anthropologists be more responsible and relevant. For example, by the 1990s, most anthropologists working with the Yanomami in the Amazon between Brazil and Venezuela voluntarily shifted their emphasis from salvage ethnography (traditional culture) to advocacy, especially with epidemics and other serious problems from the mining invasion (Ramos 1999). Advocacy is likely to continue developing well into the future as a significant component of the conscience of anthropology. As Sol Tax said, 'If there is something useful I can do, then I have to do it' (Stanley 1996, p. 137).

Aesthetic Education

Having no fixed meaning, the phrase 'aesthetic education' may connote (a) a program of studies intended to develop dispositions to regard things from an

aesthetic point of view, (b) an emphasis on response to art in contrast to its creation, (c) concentration on the common features or the interrelatedness of the arts, (d) the cultivation of sensibility generally, not just in the arts, and (e) a special role for aesthetics as both content and method of inquiry. Given the multiple meanings of the term, definitions of aesthetic education are properly regarded as programmatic interpretations intended to convey desirable end states. Since using 'aesthetic education' as a blanket term to cover all possible relations between the arts and education would necessitate presenting a complete history of the subject, a framework must be imposed that will elicit some of the major themes of modern and contemporary thinking. The scheme discusses theorists in whose writings the cultivation of aesthetic experience plays a key role.

1. Three Generative Thinkers: Schiller, Read, and Dewey

An appropriate starting point are the writings of Friedrich Schiller, an eighteenth-century German dramatic poet and philosopher whose *On the Aesthetic Education of Man in a Series of Letters* (1793–95) (Schiller 1967) is significant for thinking about the role of a man of letters in culture, the function of art in personal and social life, and the wholeness of aesthetic experience. Problems that concerned Schiller were also addressed in different ways by such influential twentieth-century theorists as Sir Herbert Read and John Dewey. All three writers were variously preoccupied with the harmful consequences of political and social dislocation, the alienation inherent in modern productive processes and institutional arrangements, reductionism in values, and disruption of the continuity of nature and human experience. For Schiller, the Reign of Terror of the French Revolution provided the impetus for formulating in the *Letters* an idea of aesthetic education as productive of a humane and democratic society. For Read it was the advent of industrialization and the alienation of the proletariat that prompted his recommending a pedagogy capable of reuniting in human experience what modern life and production methods had sundered. For Dewey the notion of consummatory experience was a response to concerns similar to Schiller's and Read's. He further believed that art, broadly defined as experience, was important not just for the personal satisfaction it provided but for the restoration of a greater sense of community.

1.1 Schiller (1759–1805)

Schiller's career unfolded during the turbulent modern era when the power of the State and privileged classes was coming under attack in the name of Enlightenment principles of reason, freedom, and democracy. Many theorists of the time believed history was evolving in a direction that would provide individuals with greater freedom and control over their lives. Schiller admired the ideals and promise of the French Revolution, but, abhorring most forms of violence, he was dismayed at its cruelty and concluded that Man was not yet prepared for freedom. Consequently, he believed that the proper constitution of the State must be preceded by the proper constitution of individuals themselves. This transformation was to be aided by recourse to the discipline of aesthetics (newly established by Baumgarten) and the philosophical writings of Kant, as well as through energies drawn from Schiller's close association with Goethe—not to mention his own considerable strengths as a dramatic playwright. The aim of the *Letters* was to release in Man what Schiller called the living springs of human life, that is, qualities of life essentially manifested in experiences of Beauty. Such experiences would produce a healthy confluence of conflicting human impulses (the sensuous and the formal impulses) by giving free rein to a third impulse—the play impulse. The experience of Beauty, in other words, was a necessary precondition for the emergence of full humanity. Schiller found the play impulse ideally exemplified in artists' integrations of form and content in great works of art. Although he prescribed no particular curriculum or pedagogy, he was persuaded that the fostering of aesthetic culture was the required next phase in the evolution of civilization. The aesthetic path must be taken, he said, 'because it is through beauty that, man makes his way to freedom' (Schiller 1967, p. 9).

Subsequent philosophic analysis questioned Schiller's metaphysics and psychology as well as his extraordinary faith in aesthetic education's ability to advance the cause of human freedom and morality. But the inspirational force of Schiller's message was not lost on writers who have either appealed directly to his belief in the civilizing power of the arts or expressed affinity for the value he placed on art's role in the integration of the human personality. Above all, Schiller provided a significant justification for aesthetic education—the promotion of aesthetic culture—and described its potential for achieving increased social and political stability. Schiller's dated psychology notwithstanding, his discussion of the need to harmonize conflicting human drives has been of continuing interest to later theorists.

1.2 Read (1893–1968)

A poet, critic, art historian, editor, philosopher, pacifist, anarchist, and educational theorist, Read is perhaps best characterized as a humanist who was immersed in the art, culture, and politics of his time. As a humanist he was at odds with the received

cultural, intellectual, and educational traditions he believed inhibited the full realization of individuals' potentialities. And he was appalled by living and working conditions in the burgeoning factory towns of the industrial revolution. The specialization and division of labor consequent upon the triumph of technical rationality were fracturing the sense of community that had pervaded his rural upbringing. His experiences in World War I as well as his early literary training had endowed him with a poetic sensibility reminiscent of Schiller's. In his educational writings Read appeals directly to Schiller, and he evokes echoes of him when he both characterizes the kind of education that might meliorate the effects of dehumanization and prescribes a fitting instrument, model, and method for it—art and aesthetic education. But there were differences.

The materials from which Read composed his theory of education were largely of his own time. If the ideas of Marx, Morris, and Ruskin influenced his social analysis, the psychoanalytical theories of Freud and Jung, especially their notions about the structure and dynamics of the unconscious, played a significant part in his thinking about the nature of the artistic process and aesthetic education. The operations of the unconscious being essentially sensuous and sexual in character—Read called his philosophy of education a salutation to Eros—they stood in opposition to the constraints placed on human behavior by religious and moral codes. He believed that dipping into the unconscious, especially into its potent image-making powers, opened the way to greater self-realization. The crucible of the unconscious—a cauldron of memory images, feelings, and inherited attributes called archetypes—supplied source material for the creative imagination. Whatever hindered access to unconscious processes was to be discouraged, for only by utilizing them as resources could the individual benefit from their creative energies. Since Read thought that modern artists were particularly adept at exploiting the unconscious, he devoted a major portion of his career to championing their efforts.

Read's thought and career contain several complexities that cannot be dealt with here. Suffice it to say that from his social and political philosophy, conception of psychological processes, and interpretation of modern art, it was but a natural step to an educational aesthetics aimed at liberating mind and sensibility from the repressive tendencies of contemporary life and schooling. In contrast to Schiller's emphasis on studying the great works of the tradition, Read's pedagogy demoted the art object in the belief that conventional modes of art appreciation encouraged passiveness on the part of the learner and perpetuated a conception of knowledge as inert. What was wanted instead was what Dewey called learning by doing. Read also envisioned aesthetic education broadly enough to encompass the creation of a more aesthetically satisfying environment, which meant paying greater attention to the arts of everyday life. It comes as no surprise then that Read favored a pedagogy grounded in process, one that stressed the creative self-expression of the child. Given the idiosyncrasies of learners and the dispositions of teachers, the method of aesthetic education Read often referred to was less a single procedure than a collection of practices—whatever seemed to work for a particular student or situation was acceptable.

Read's impact was literally global, as witnessed by his influence on the International Society for Education through Art, which periodically confers an award in his name. But as in Schiller's case, it was the spirit of Read's message that counted more than his theoretical formulations. Few teachers were prepared to comprehend the intricacies of his major theoretical work *Education Through Art* (Read 1956). *The Redemption of the Robot* (Read 1966), in which Read recalls his encounters with education through art, is a more helpful introduction to his thought.

1.3 Dewey (1859–1952)

Dewey's roots and preoccupations resemble Read's: early childhood in a rural environment, concern about dislocations wrought by social change, impatience with educational traditions and institutions hostile to reform, compatible pedagogical ideas, and a belief in art as both a means of personal satisfaction and an instrument for reconstructing experience.

Dewey's distaste for separations and dualisms of all kinds and his almost religious feeling for the unity of human experience reflect the strong influence of Hegel, though in the course of evolving a naturalistic empiricism Dewey abandoned Hegel's metaphysics in favor of a Darwinian bio-social conception of human development. Dewey conceived experience as the interaction between organism and environment, as a doing and undergoing. Among the numerous dichotomies that worried Dewey (1958), of particular relevance to this discussion, was the separation of art from everyday life as epitomized in the museum conception of art. The theoretical task of reintegrating art into common experience that Dewey set himself required, first, defining everyday experiences in a way that revealed their inherently dramatic character and, second, claiming that whenever experience possesses certain features or qualities it may be spoken of as *an* experience—or *art*. This meant that all forms of inquiry and experience—intellectual, social, political, and practical—could under certain conditions qualify as art. Even the activities of the world of work, ordinarily characterized by a dehumanizing disjunction between means and ends, might aspire to the status of art.

Dewey tended to alternate, somewhat confusingly and not without unhappy consequences for his aesthetic theory, between two views of art and the work of

art. The first was art as the quality of *an* experience regardless of context. The second was art as commonly understood, that is, as a physical object. What is important is that in both interpretations Dewey thought art capable of endowing life with consummatory value and hence of contributing to his effort to find a philosophical justification for the reconstruction of human experience. Such reconstruction would be one of the preconditions for social reform—for Dewey was nothing if not a reformer—and was to be brought about within a framework based on liberal, democratic principles. Being the outgrowth of his theories, Dewey's educational recommendations and experiments—for example, at the University of Chicago—stressed continuity between the activities of school and society and placed reliance on learning by doing, with an emphasis on the designing of problem-solving situations.

2. *Further Developments*

Commentators have observed that subsequent theories of aesthetic education reflect attempts to escape the shadow of Dewey. This is true but requires some qualification. The educational philosophy of Arnstine (1967) is rooted in Dewey's concept of experience in that Arnstine equates learning with aesthetic experience. Dewey's analysis of qualitative thinking also influenced Eisner's (1991) notions of qualitative intelligence and educational criticism, and Dewey's pedagogy still enjoys favor among many theorists and teachers of art. His broad conception of the aesthetic is perpetuated in Howard's (1992) discussion of the role of sensibility in human life generally. Beardsley, in his several writings on the topic (Beardsley 1982), attempted to preserve what is valuable in Dewey's characterization of aesthetic experience while clearing up some of its ambiguities.

Although contemporary theorists of aesthetic education acknowledge that the compass of the field extends beyond the study of artworks, they still tend to emphasize the study of the fine arts. Another thread running through much current thinking is the idea that aesthetic experience should be cultivated for the sake of a variety of values. Broudy (1994) argues that aesthetic experiences of works of serious art serve individuals well in their quest for the good life and help them build a rich imagic store that tacitly informs their interpretations not only of artworks but of other phenomena as well. Greene's (1981) understanding of aesthetic literacy relies on the propensity of aesthetic experience to sharpen perception, expand the imagination, create a sense of freedom, and deflate stereotypes. Kaelin (1989) attributes similar benefits to art and describes how aesthetic education contributes to the effective operations of the art world, an institution that functions as guardian of aesthetic value. Since aesthetic situations are presumed to encourage open-mindedness and tolerance, aesthetic education may also help produce personality traits valued by democracies. In his interpretation of aesthetic education from a humanities point of view, Smith (1989) highlights the constitutive and revelatory values of art, the humanizing potential of aesthetic experiences, and the capacity of aesthetic studies to refine discrimination, stretch the imagination, and provide ideals for human life. Aesthetic education further prepares the young to traverse the world of art with sensitivity and percipience. Swanger (1990), who places emphasis on creative activities, thinks art's radical and destabilizing powers derives from its freshness, creativity, efficacy in the transfer of learning, and promise for transforming a materialistic consumer society into one more protective of the environment. The volume by Parsons and Blocker (1993) is noteworthy for featuring a cognitive developmental theory of aesthetic experience, a description of benefits conventionally associated with the study of art (especially the education of feeling), and a balanced account of modernism and postmodernism.

The pervasiveness of the notion of aesthetic experience in contemporary theories having been discussed, it must be mentioned that the concept has been subjected to criticism in recent aesthetic theory. Critiques tend to center on doubts about the existence of a distinctive experience or attitude called aesthetic. But the debate is hardly closed and theorists continue to argue persuasively that aesthetic encounters inspire and vitalize human experience and are therefore part of any worthwhile life. But regardless of the fate of the aesthetic in philosophical analysis, it remains indisputable that efforts by theorists to identify an aesthetic strand in human experience have contributed importantly to the depth of understanding and the quality of the experience of art and nature.

3. *The Unity of Aesthetic Education*

The diversity of aims and emphases in theories of aesthetic education raises the question of whether it has any unity as a field of study. Assuming the word 'aesthetic' sustains a more than casual relationship to 'education,' the field can be said to be unified by a solicitude for aesthetic value. No other area of study can be said to be as preoccupied with this particular value, a fact that argues for aesthetic education's occupying a singular territory within the philosophy of education. Concomitantly, the purpose of aesthetic education could be interpreted as initiating the young into a unique realm of value—the value afforded by aesthetic experience. Such an interpretation of aesthetic education's aims prompts a few further observations. First, it necessitates appropriate adjustments in teacher preparation. Second, goal achievement presupposes the mastery of relevant aesthetic concepts and the acquisition of aesthetic dispositions—which,

however, are unlikely to be attained if, as some theorists advocate, the arts should be used primarily in furtherance of the objectives of other subject areas. Third, since all the arts possess the capacity to induce aesthetic experience, it seems reasonable to organize aesthetic studies according to one of the educational schemes that recommend grouping the arts together.

Prospects for the future of aesthetic education however, would appear to be clouded. On the one hand, analytical critiques question the viability of the concept of the aesthetic, while ideology-driven theories of art and arts education often exhibit an antiaesthetic bias. On the other hand, the endurance of the American *Journal of Aesthetic Education* (1966–), evidence of increased cooperation between aestheticians and educators (Moore 1995), the founding of a committee on education within the American Society for Aesthetics, and two essays on aesthetic education in the first English-language *Encyclopedia of Aesthetics* (Vol. 2, Oxford University Press, New York, 1998) suggest continuing interest in the subject.

4. Definitions of Key Terms

Aesthetics. A branch of philosophy that inquires into the nature, meaning, and value of art; or any critical reflection about art, culture, and nature.

Aesthetic point of view. A distinctive stance taken toward phenomena, e.g., works of art and nature, for the purpose of inducing aesthetic experience.

Aesthetic experience. A type of experience that manifests the savoring of phenomena for their inherent values, in contrast to practical activities and values.

Aesthetic value. A type of value, in contrast, e.g., to economic value, etc.; also the capacity of something by virtue of its manifold of qualities to induce aesthetic experience.

Aesthetic literacy. A cluster of capacities that enables engagements of phenomena, especially works of art, with prerequisite percipience.

Aesthetic culture. A distinctive domain of society, in contrast, e.g., to its political culture, and, normatively, sensitivity in matters of art and culture, as in a person's aesthetic culture.

Interrelatedness of the arts. Implies features that different kinds of art have in common; or programs that group the arts together for purposes of study.

Affirmative Action: Comparative Policies and Controversies

1. Introduction

Although the phrase 'affirmative action' apparently originated in the United States in 1961, the practice of providing benefits or preferential treatment to individuals based on their membership in a disadvantaged group can be found in a wide variety of forms in many other countries. For example, India developed affirmative programs as early as 1927, and was probably the first country in the world to create a specific constitutional provision authorizing affirmative action in government employment. Other countries with more recently developed affirmative action programs include Australia, Israel, and South Africa.

2. Comparative Issues in Designing Affirmative Action Programs

Galanter (1992) identifies several issues that are critical to a comparative study of affirmative action programs: justifications, program designers, selection of bene-

ficiary groups, distribution of benefits within a group, relations between multiple beneficiary groups, determination of individual eligibility, resources to be devoted, monitoring, and termination. This section will provide a comparative analysis of three of these issues; justifications, selection of groups, and individual eligibility.

2.1 Justifications for Affirmative Action

Affirmative action programs for racial minorities in the US typically seek to remedy harm caused to specific individuals by 'cognitive bias,' that is, harm caused by an actor who is aware of the person's race, sex, national origin, or other legally-protected status and who is motivated (consciously or unconsciously) by that awareness. Much of the current skepticism in the US about affirmative action may result from this narrow focus: many white people seem to believe themselves free of such cognitive bias and thus doubt that it is a continuing problem of sufficient magnitude to justify affirmative action. Such a focus makes affirmative action particularly vulnerable in settings like university admission, where decisions based on grades and test scores seem, to many, to be immune cognitive bias (see *Race and the Law*; *Gender and the Law*).

Although cognitive bias-type discrimination based on caste status is treated as a serious, continuing problem in India, affirmative action there is focused more on eradicating the enduring effects of centuries of oppression and segregation. There appears to be a more conscious commitment than in the US to change the basic social structure of the country. The Indian approach perhaps can be understood best using the economic theory pioneered by Glenn Loury, which distinguishes between human capital and social capital (Loury 1995). Human capital refers to an individual's own characteristics that are valued by the labor market; social capital refers to value an individual receives from membership in a community, such as access to information networks, mentoring, and reciprocal favors. Potential human capital can be augmented or stunted depending on available social capital. Economic models demonstrate how labor market discrimination, even several generations in the past, when combined with ongoing segregated social structure, can perpetuate indefinitely huge differences in social capital between ethnic communities. Since the landmark case of State of Kerala vs. Thomas (1976), decisions of the Indian Supreme Court have recognized the need for affirmative action to redress systemic inequality. Even though the constitutional provisions authorizing affirmative action are written as exceptions to guarantees of equality, the Court has characterized these provisions as providing instead a right to substantive equality rather than a simply formal equality.

Sunstein (1994) foreshadowed the potential value to the US of learning from India's differing justifications for affirmative action. The author proposed an anticaste principle in order to reconceptualize the American post-Civil War 14th Amendment (that no law may be enacted that abridges the rights of citizens of the USA), which was a source of both civil rights legislation and reverse discrimination attacks on affirmative action. Under Sunstein's anticaste principle, affirmative action would not be seen as a limited exception to the constitutional guarantee of equality, but rather as a logical, perhaps necessary, method of correcting the effects of caste, which interfere with equality. '(T)he inquiry into caste has a large empirical dimension … focus(ing) on whether one group is systematically below others along important dimensions of social welfare.' For Sunstein the key dimensions are income level, rate of employment, level of education, longevity, crime victimization, and ratio of elected political representatives to percentage of population. The range of persons who can make 14th Amendment claims would be drastically reduced from the entire population (all of whom have a race) to those who are members of a low caste. Thus, reverse discrimination claims by whites affected by affirmative action would disappear. Further, it would not be necessary to prove discrimination, either contemporaneous discrimination against an individual plaintiff or historical discrimination against that person's group, since the purpose of the 14th Amendment would no longer be interpreted as preventing or remedying discrimination but rather alleviating systemic social disadvantage. (See also Cunningham and Menon 1999, Sunstein 1999.)

India's justification of affirmative action (altering systemic inequality) can be seen as well as in several other countries' efforts to address the problems of diverse populations. Israel has developed affirmative action programs for Sephardi Jews, who typically have immigrated to Israel from Middle Eastern and North African countries, and have been socially and economically disadvantaged in comparison to Ashkenazi Jews, who typically have emigrated from Europe. These Israeli programs do not aim to combat current discrimination or to compensate for past discrimination. There is no history of Ashkenazi dominance and exploitation of the Sephardim comparable to the treatment of African-Americans in the US or the lower castes in India. Rather the programs have been justified in terms similar to the current constitutional discourse in India, recognizing that the combination of initial socioeconomic disadvantage with the continuing influence of informal networks would perpetuate a society divided along the Sephardi/Ashkenazi line, thus requiring affirmative action to counteract these social forces (see Shetreet 1987).

The new constitution of the Republic of South Africa takes the Indian approach one step further. The

very concept of equality is defined so that only unfair discrimination is prohibited. Properly designed affirmative action is thus fair discrimination. The constitution also explicitly states that 'to promote the achievement of equality, legislative and other measures designed to protect or advance persons, or categories of persons, disadvantaged by unfair discrimination may be taken.' (See Cunningham 1997, pp. 1624–28.)

Australia, in contrast, attempts to preserve principles of formal equality in its legislation designed to increase female participation throughout private-sector employment, by justifying programs as simply a 'fair go' for women and as consistent with 'best business practices.' The legislation specifically states that hiring and promotion on the basis of merit is not affected by affirmative action, which intended instead to facilitate the accurate recognition of merit among female as well as male employees (see Braithwaite and Bush 1998).

2.2 Selection of Beneficiary Groups

India appears to be unique among the countries of the world in the degree to which its affirmative action programs have wrestled with the problem of selecting beneficiary groups. The constitutional provisions authorizing affirmative action identify three general categories: (a) Scheduled Castes (descendants of the former 'untouchables'), (b) Scheduled Tribes (ethnic groups generally living in remote and hilly regions), and (c) other 'socially and educationally backward classes of citizens.' The greatest difficulty and controversy has focused on selection of groups for this third category, generally termed the OBCs (Other Backward Classes). In the first three decades after adoption of the Indian constitution, selection of groups for OBC designation was left largely to state governments within India's federal system of government. As a result, the Indian Supreme Court repeatedly struck down plans that seemed primarily to benefit politically powerful groups, or that were based on traditional assumptions of caste-based prejudice without knowing which groups were truly in greatest need.

In 1980 a Presidential Commission (known as the Mandal Commission after the name of its Chairperson) issued a comprehensive report and set of recommendations for national standards for OBC designation. Responding to the Supreme Court's concern about objective and transparent processes, the Mandal Commission conducted a national survey that started with generally recognized group categories (typically based on caste name or hereditary occupation) and tested each group using standardized criteria of 'backwardness' (such as comparing the percentage of group members who married before the age of 17, or who did not complete high school, with other groups in the same state). Eleven numerical factors, given varying weights, were assigned to each group based on the survey results and those groups with total scores below a specified cut-off point appeared in a list of OBCs. The Commission then recommended that a percentage of new hires for most central government jobs be reserved for OBC members under a quota system.

The Mandal Report generated lively debate but it was not until 1990 that the national government actually proposed implementation of the Report. This announcement, by then-Prime Minister V. P. Singh, prompted widespread civil disturbance, instances of self-immolation by high-caste Hindus in protest, and litigation leading to three months of oral argument before the Supreme Court. In 1992 the Supreme Court reached a 6–3 decision, largely approving the Report and its recommendations. A majority of the Supreme Court justices approved the following basic principles: (a) Traditional caste categories can be used as a starting point for identifying OBCs but selection criteria must include empirical factors beyond conventional assumptions that certain castes are 'backward.' (b) Identification of a group as an OBC can not be based on economic criteria alone (Indra Sawhney vs. Union of India 1993).

In contrast to India, affirmative action programs in the US have not used consistent criteria for defining group boundaries or for selecting eligible groups. For example, one US federal court struck down a law school admission program at the University of Texas, in part because only blacks and Mexican Americans were eligible for affirmative action consideration; Hispanic Americans, Asian Americans and Native Americans were excluded (Hopwood vs. State of Texas 1996). Many people who oppose affirmative action programs in the United States because they use racial categories such as black, African American, or Latino claim that equally effective and more equitable programs can be developed using only class categories, such as low-income (see Malamud 1996). Economist Glenn Loury, who is African American, has suggested that affirmative action is not needed by all African Americans but instead should be focused on a distinct group whose members share the following characteristics: (a) slave ancestry, (b) rural and Southern origins, (c) current residence in northern cities, (d) current residence in ghettos. He uses the term 'caste' to describe this group (Loury 1997).

In South Africa current affirmative action programs are haunted by the categorization systems of the apartheid regime that distinguished between black Africans, coloreds (mixed European and African ancestry), and Indians (some ancestry from the Indian subcontinent). The ruling party, the African National Congress, in its earlier role as the leading opponent to apartheid, sought political solidarity among all peoples oppressed by apartheid; it used 'black' to refer to Africans, coloreds, and Indians. The 1998 Employment Equity Act, implementing affirmative action in both the public and private sector, continued this

tradition by targeting 'Black people' (combining the three Apartheid-era categories) as well as women and people with disabilities. However, this selection system exists in tension with the recognition that coloreds and Indians were differently disadvantaged compared to those designated by apartheid as 'black Africans.' For example, a South African court has upheld a medical school admission program that gave greater preference to black African applicants than to Indian applicants (Motala vs. University of Natal 1995).

2.3 Determination of Individual Eligibility

In the US, individual eligibility for affirmative action is usually based solely on membership in one of the selected beneficiary groups. An apparent exception is the federal Disadvantaged Business Enterprise (DBE) program, an affirmative action program affecting federally-funded contracts, in which membership of one of the designated beneficiary groups only creates a presumption of eligibility (see Adarand Constructors vs. Pena 1995). However, a minority-owned business is not required to provide additional evidence of disadvantage beyond group membership to be eligible; instead the presumption is conclusive unless a third party (typically a disappointed competing bidder) asserts that the individual beneficiary is not personally disadvantaged.

In India, an individual eligibility test is being implemented pursuant to the decision of the Indian Supreme Court in Indra Sawhney vs. Union of India 1993. This 'creamy layer' approach—as it is termed in India—addresses two different but related concerns: (a) that the benefits of affirmative action are not distributed evenly throughout a backward group but instead are monopolized by persons at the socio-economic top of the group: and (b) that benefits are going to persons who do not in fact need them, because they have been raised in privileged circumstances due to parental success in overcoming the disadvantaged status of the backward group. Interestingly, the criteria proposed by the national government after the court's decision focus more on the wealth and occupation of the individual's parents than of the individual, reflecting perhaps continuing sensitivity to the role of social capital in perpetuating disadvantage (see *Class and Law*).

3. Comparative Studies of Affirmative Action

Clearly there is a need for more comparative scholarship on affirmative action, although the last years of the 1990s saw a significant increase in published work in this area. Galanter (1984), a classic in this area, points out the need to be cautious about the comparative lessons that the United States and other countries could learn from India. Thomas Sowell, a US economist critical of affirmative action policies in the United States, has frequently made use of comparative materials, most extensively in Sowell (1990) which includes sections of India, Malaysia, Nigeria, and Sri Lanka. In 1991, during the transition period that led to the abolition of apartheid and the founding of the new Republic of South Africa, the Constitutional Committee of the African National Congress convened a conference on 'Affirmative Action in the New South Africa' that included subsequently published studies of affirmative action in India and Malaysia as well as the United States Centre for Development Studies (1992). A set of conference proceedings published in 1997 includes cross-national and interdisciplinary perspectives on affirmative action by public officials and social scientists from India, South Africa, and the United States (Cunningham 1997); the same year also saw the publication of Parikh (1997). An extensive section on affirmative action in India may be found in Jackson and Tushnet's law text on comparative constitutionalism (Jackson and Tushnet 1999), and Andrews (1999) includes studies of affirmative action in Australia, India, South Africa, and the United States.

Affirmative Action, Empirical Work on its Effectiveness

1. Introduction

Affirmative action generally refers to a set of public policies meant to redress the effects of past or present discrimination. Affirmative action connotes active measures to level the playing field for access to education, to jobs, and to government contracts. While a wide variety of affirmative action policies have been implemented in different countries, much of the existing research concerns experience with the affirmative action directed at expanding employment opportunities for women and minorities in the United States, the focus here.

One defining characteristic of the policy in the United States is its ambiguity. The closest the US Congress has come to explicitly requiring affirmative action in employment is in the Americans with Disabilities Act of 1990, which explicitly requires that employers make 'reasonable accommodations' to hire the disabled. This requires that employers must do more than be blind to differences between the disabled and the able, but must actively invest to overcome these differences. It is worth noting that during a period when affirmative action policies were contentiously debated, a law explicitly requiring affirmative action in employment was swiftly enacted without mention of affirmative action. Affirmative action has long been a political lightning rod. To its critics, it is symbolic of quotas unfairly and rigidly imposed. To its proponents, it is symbolic of redressing past wrongs and of leveling the current playing field. An empirical basis for policies to counterbalance current employment discrimination can be sought in (a) continuing judicial findings of systematic employment discrimination, (b) statistical evidence of wage disparities across demographic groups, and (c) audit studies of employers' hiring behavior. For reviews of this evidence, see Altonji and Blank (2000), Blau (1998) Heckman (1998), and Fix and Struyk (1993).

2. Affirmative Action in the Shadow of Title VII of the Civil Rights Act of 1964

Affirmative action in the United States has been implicitly encouraged by judicial interpretation of Title VII of the Civil Rights Act of 1964 (CRA), and explicitly required, but not defined, by Executive Order 11246 applied to federal contractors. From its inception, the CRA has embodied a tension between words that bar employment discrimination, and a Congressional intent to promote voluntary efforts to redress discrimination. The courts have struggled with making room for what they sometimes saw as the intent of Congress within the language of the CRA. In later cases, the Supreme Court read Section 703(J)'s bald statement that 'Nothing in the act shall require numerical balancing' as allowing numerical balancing as a remedy. In other cases, the court held that the act should not be read to bar voluntary acts to end discrimination. These cases left considerable if ambiguous room for affirmative action. The threat of costly disparate impact litigation under Title VII following the Griggs v. Duke Power case created considerable incentive to undertake affirmative action.

The extent of 'voluntary' (or at least non-judicially directed) affirmative action taken in response to Title VII can be roughly estimated from existing work on the overall impact of Title VII. Because firms directly subjected to litigation under Title VII represent such a small share of employment, the bulk of the black economic advance credited to Title VII must be due to its indirect effect in promoting 'voluntary' affirmative action. For example, Freeman (1973) shows the overall impact of Title VII in the time series of black–white earnings differentials. From this, the direct impact of Title VII litigation at companies sued for racial discrimination could be subtracted. While these impacts are substantial at the companies incurring litigation, employment at such companies makes up only a small fraction of employment. The impact on market wages from the outward shift in the demand curve for blacks at these companies can only be small

given their small share of the market. Most charges of discrimination never result in litigation, and much litigation never reaches a judicial decision, leaving ambiguous interpretation and little trail. It is likely that the bulk of the changes attributed to Title VII are in a broad sense the result of affirmative action taken in response to the indirect threat, rather than the direct act, of litigation. Since the impact of Title VII is at least an order of magnitude greater than that of the contract compliance program, and only a small share of this could have occurred at companies directly litigated against, the biggest impact of affirmative action, broadly defined, very likely took place in the shadow of Title VII. To date, no one has filled in the blanks in the calculation just outlined.

One difficulty in evaluating the impact of a national law such as the 1964 CRA is that a contemporaneous group unaffected by the law is usually lacking for comparison. In the case of Title VII, Chay (1998) overcomes this problem by examining the impact of the Equal Employment Act of 1972, which extended the reach of Title VII to smaller establishments. Chay finds that once smaller establishments came under Title VII's coverage, the relative employment and pay of blacks improved at these small establishments. Again, very little of this can be the direct result of litigation against small establishments.

3. *Affirmative Action Through Contract Compliance*

In the US, Federal contractors and first-tier subcontractors are required by Executive Order to pursue affirmative action. Because the Executive Order does not apply to all companies, it sets up a contrast that under some assumptions allows us to discern the impact of affirmative action under the contract compliance program by comparing the change in demographics at contractors with that at non-contractors. The interpretation of these comparisons would be complicated if each employer's demographics or anticipated change in demographics affected its selection or self-selection into contractor status. However, there is no evidence of this. To the contrary, initial demographics are generally not used as a prerequisite to becoming a contractor. And, as will be explained further below, because of peculiarities in the enforcement targeting procedures in use during much of the programs, existence, firms with unusually low proportions of minorities or females were not likely to come under greater regulatory pressure. So given the regulations as implemented, there was little reason for firms with low representation of minorities or females to avoid becoming a contractor. Since firms were not held rigidly to whatever promises they may have made to increase the employment of minorities or females, there was also no reason for firms that did not anticipate an increase in female or minority share to avoid contractor status. Given that enforcement creates a generalized pressure rather than a tight link from a firm's demographics to the targeting of enforcement, reverse causation is less of a concern. We can be more confident that the differences in changing demographics between contractor and non-contractor establishments firms are not an artifact of selection or self-selection into or out of contractor status. The research on the contract compliance program allows somewhat stronger conclusions about a weaker program because it relies not just on time-series variation but on a comparison of establishments with and without the affirmative action obligation.

Two mutually inconsistent criticisms of affirmative action have found prominent voice. The first criticism is that affirmative action goals without measurable results invite sham efforts; because these programs do not work very well, the argument goes, they should be disposed of. The second criticism is that an affirmative action 'goal' is really a polite word for a quota; in other words, that affirmative action works too well, and therefore should be disposed of. Empirical research into affirmative action programs contradicts both these criticisms. Affirmative action goals have played a statistically significant role in improving opportunities for minorities. At the same time, those goals have not resulted in 'quotas' (Leonard 1985b).

Federal Contract Compliance Program Regulations require that every contractor maintain an affirmative action plan consisting in part of a utilization analysis indicating areas of minority and female employment in which the employer is deficient, along with goals and timetables for good-faith efforts to correct deficiencies. To put this program in perspective, it is important to understand that, through most of its history, between 400 and 100 investigative officers have been responsible for enforcing compliance. The ultimate sanction available to the government is debarment, in which a firm is barred from holding federal contracts. In the history of the program, there have been fewer than 60 debarments. The other sanction typically used is a back-pay award. This sanction too is used infrequently (Leonard 1985a).

There have been several studies of the impact of the Contractor Compliance Program (Ashenfelter and Heckman 1976, Goldstein and Smith 1976, Heckman and Wolpin 1976, Smith and Welch 1984, Leonard, 1984c, Rodgers and Spriggs 1996). These studies have consistently found that employment of black males increases faster at establishments that are federal contractors than at those that are not, with the possible exception of the period during which the Reagan Administration undercut enforcement. While significant, this effect has always been found to be modest in magnitude. In general, the impact on females and on non-black minorities has been less marked than that on blacks.

Between 1974 and 1980, black male and female employment shares increased significantly faster in

contractor establishments than in noncontractor establishments. These positive results are especially noteworthy, in view of the relatively small size of the agency and its limited enforcement tools. First consider differences between contractors and noncontractors in the change in female and minority employment share without controlling for other possibly confounding variables. A summary measure, white males mean employment share, declined by 5 percent among contractors compared to 3.5 percent among noncontractors. In other words, the contractors subject to affirmative action reduced white males' employment share by an additional 1.5 percent over six years. For other groups, the comparable difference between contractors and noncontractors in the change in employment share is 0.6 percent for white females, 0.3 percent for black females, 0.0 for other minority females, 0.3 for black males, and 0.1 for other minority males (Leonard 1984c).

Controlling for establishment size, growth region, industry, occupational, and corporate structure, the annual growth rate of black male employment grew 0.62 percent faster in the contractor sector, and the annual growth rate of white males grew 0.2 percent slower. Contractor status shifted the demand for black males relative to white males by 0.82 percent per year. This is less than 1 percent per year, not a dramatic change although it can cumulate over time. Studies of earlier and later periods by Ashenfelter and Heckman (1976), Heckman and Wolpin (1976), and Rodgers and Spriggs (1996), find effects on black males of the same order of magnitude. Not surprisingly, growing establishments are better able to accommodate the regulatory pressures. Minority and female employment share increased significantly faster in growing establishments.

In addition to increasing the sheer numbers of minorities employed, the program also has had some success in helping move them up the career ladder. Affirmative action appears to increase the demand for poorly educated minority males as well as for the highly educated. Black males' share of employment increased faster in contractor establishments in every occupational group except laborers and white-collar trainees. Black females in contractor establishments increased their employment share in all occupations except technical, craft, and white-collar trainee. The positive impact of the contract program is even more marked when the position of black females is compared with that of white females (Leonard 1984b). While some part of this improvement appears to reflect title inflation by employers upgrading detailed occupational categories with a relatively high representation of minorities or females (Smith and Welch 1984), the occupational advance is accompanied by wage increases incompatible with pure title inflation (Leonard 1986). The evidence does not support the contention that this is just a program for blacks with skills. To the contrary, it helps blacks across the board. Thus, affirmative action does not appear to have contributed to the economic bifurcation of the black community.

The employment goals to which firms agree under affirmative action are not vacuous; neither are they adhered to as strictly as quotas. Affirmative action 'goals' are often considered to be a euphemism for quota. This appears to overstate what the regulatory authorities actually require: good faith efforts to meet goals that are in the first instance chosen by the employer and may subsequently be negotiated with the OFCCP. Under the Contract Compliance Program, firms agree to set goals and timetables. Firms that agree to increase minority employment by 10 percent will, on average, increase minority employment by about 1 percent. Employers are not sanctioned for failing to meet their goals. A good-faith effort toward compliance in practice means that firms make it about one-tenth of the way toward the stated goal. This falls well short of the rigidity expected of quotas (Leonard 1985b).

Both the contract compliance program and Title VII have been criticized for inducing firms simply to hire a 'safe number' of minorities and women, irrespective of qualifications. According to this argument, whatever 'quota' is imposed should be the same for firms in the same industry and region. Application of such quotas would mean that firms in the same industry hiring out of the same labor market should, over time, start to look more and more like each other in terms of the percent of women and minorities. This does not generally happen, either under Title VII or as a result of affirmative action programs, Leonard (1990).

There is some evidence that the general pressures of affirmative action have succeeded in prompting employers to search more widely, but at the same time have been flexible enough not to impinge upon the economic performance of these firms. Holzer and Neumark (1999) find that although affirmative action employers tend to hire women and minorities with lower educational qualifications, these hires do not exhibit reduced job performance.

To summarize, contractor goals do have a measurable and significant correlation with improvements in the employment of minorities and females at the reviewed establishments. At the same time, these goals are not being fulfilled with the rigidity one would expect of quotas.

4. *Future Research*

Classic economic models of discrimination recognize that discrimination is not only unfair, but also inefficient. The available evidence suggests that affirmative action has helped to promote black employment, and to a lesser degree that of females and of non-black minorities. But by themselves, these employment gains

do not tell us whether affirmative action has reduced discrimination or gone beyond that point to induce reverse discrimination. Two fundamental questions remain: has affirmative action reduced discrimination, and has it helped integrate society?

One method of answering the first question is to ask whether workers of various demographic groups subject to labor market discrimination are more likely under affirmative action to be employed and paid in proportion to their productivity without regard to their race or sex. Productivity is difficult to measure, but a model for this approach appears in recent papers by Hellerstein et al. (1999) for the US, and Hellerstein and Neumark (1999) for Israel.

Whether the employment gains associated with affirmative action and Title VII have reduced discrimination or gone beyond that to induce reverse discrimination can be addressed by asking whether industries that had come under the most pressure from Title VII or affirmative action, or industries that had increased their employment of minorities and women, had suffered in terms of productivity. The earliest paper to use this approach (of comparing relative earnings to relative wages) relied on highly aggregated data and found that minority and female employment gains under affirmative action had not reduced productivity (Leonard 1984a). Direct testing of the impact of affirmative action on productivity finds no significant evidence of productivity decline, which implies a lack of substantial reverse discrimination. However, these results at the industry-State level are too imprecise to answer this question with great confidence.

Hellerstein et al. (1999) refine this approach of comparing wage differentials to estimated productivity differentials, and develop much more persuasive results with a detailed study of establishments. They find that pay premiums for older workers are roughly matched by productivity increases, but that the female pay penalty in the US is generally not a reflection of lower productivity. The latter result suggests that far from imposing pervasive reverse discrimination against men, affirmative action for women has not yet succeeded in eliminating labor market discrimination. This direction of research holds great promise to move us beyond the formulaic debates over whether the wage differences that remain between groups after controlling for observable differences in qualifications and preferences are due to omitted human capital or discrimination.

A second approach to this question uses stock-market returns to ask whether investors consider Title VII litigation good for companies because it forces them to use labor more efficiently. Hersch (1991) finds a negative effect on investment returns. This might mean that investors do not believe that litigation will force the firms to become more efficient. Alternatively, investors might take the litigation as news that management is more inept than they thought.

The political question of whether affirmative action has served to unify or divide is of continuing concern. Sniderman and Piazza (1993) conduct survey based experiments in the US and report that just using the term affirmative action is enough to provoke more discriminatory responses.

Studies of affirmative action type policies in education and government contracting are in their infancy. Analysis of both education and public contracting face the challenge of measuring the impact of heterogeneous policies with substantial local variation that is difficult to pin down. For higher education, see Datcher-Loury and Garman (1993) in contrast to Kane (1998). Even less is known about set-aside programs at the federal, state, and local level, (see Bates and Williams 1996), although anecdotal evidence suggests that gains under these programs quickly evaporate when set-asides are suspended. The open questions include whether there is evidence of systematic discrimination in public or private contracting, as well as how discrimination and set-asides programs affect the profitability and growth of firms. Given the context of laws designed to limit discretion in public contracting, evidence of discrimination in contracting can be thought of as a miner's canary signaling loopholes in public contracting laws (see *Discrimination*).

5. *Other Mechanisms, Other Countries*

One of the most interesting mechanisms for pursuing affirmative action can be found in the German policy to promote employment of the disabled. It is a play or pay policy. Employers face an explicit quota for employment of the disabled. The German government has drawn a bright line clearly stating minimum employment share for the disabled. However, together with this clear standard is a buy out provision; firms that do not meet their quota, for whatever reason, pay into a special government fund. This mechanism is remarkably different from those used in the US. First, the quota is explicit and stated in terms of numerical standards rather than abstract rights. This reduces the uncertainty, risks, delays, and costs of enforcement through the courts. There is also little opportunity to argue over the existence of a hidden quota. At the same time, the buy-out provision defuses complaints about the costly burdens imposed by rigid quotas, because employers experiencing the greatest difficulty meeting the quota can buy their way out. The nearest example of a US policy using a similar mechanism is the creation of tradable pollution rights under US environmental law. Both mechanisms are desirable on efficiency grounds. Firms that face the greatest difficulty reaching the legal standard can buy the right to pollute (or to hire fewer disabled) from firms that can more easily meet the standard. The aggregate level of disabled employment can be adjusted by changing the

overall standard, leaving to a decentralized market mechanism the question of which firms will employ the disabled and which will pay a fine. One additional benefit is that the penalty paid by firms below quota goes into a fund used to support the training and rehabilitation of the disabled.

Whatever its desirability on efficiency grounds, this mechanism appears to be politically impractical in the context of race and sex discrimination in the US. Explicitly setting quotas and putting a price on the right to employ fewer minorities or women raises political conflicts. The current policy places only an implicit price on discrimination. But it is apparently politically advantageous to frame the discussion in terms of absolute human rights, rather than to explicitly highlight the relative price society is willing to put on these rights through enforcement budgets and employment standards.

Affirmative Action Programs (India): Cultural Concerns

Affirmative action in the USA has come to mean the selection of candidates from among the blacks, Hispanics and other backward communities for appoint-

ment in preference to candidates who figure higher in the merit list. In India this procedure is described as 'reservation,' that is, reserving certain posts and places in educational and professional institutions for backward communities. The objective in all such cases is to equalize opportunity in an unequal world. However, the term 'affirmative action' is being increasingly used to conform to international practice.

1. *Affirmative Action Prescribed in Constitutions*

There are two notable cases in which the idea of affirmative action is enshrined in the constitution of modern states. The first is independent India, whose constitution came into force on January 26, 1951. The second is South Africa, whose first constitution based on adult franchise was adopted in 1996.

1.1 *Indian Constitution*

In the Indian Constitution, Articles 14, 15, and 16 guarantee the fundamental rights of equality under the law: equal protection of the law and no discrimination against any person on grounds of race, religion, caste, creed, place of birth, gender, or any of these, to positions in the state or to educational institutions in the state.

Article 16 guarantees equality of opportunity, which would appear to be another way of looking at discrimination. However, clause 4 of this Article asserts that 'nothing in this Article shall prevent the state from making any provision for the reservation of appointments or posts in favor of any backward class of citizens which, in the opinion of the state, is not adequately represented in the services under the state.' The implication of this provision is that there are some groups of persons who do not in fact have equal opportunity because of financial or social deprivation: then the state is empowered to assist them by reserving posts and positions in educational institutions for them to help them catch up with the rest of society. This proviso takes note of the fact that there cannot be equal opportunity when large sections of the populace have been held down by poverty and social discrimination.

1.2 *Fundamental Rights and Directive Principles*

Prime Minister Nehru, while addressing the Constituent Assembly (First Amendment Bill, 1951), defended the notion of affirmative action, then called reverse discrimination, by distinguishing between the claims of Fundamental Rights on the one hand, and Directive Principles on the other. 'Fundamental Rights are conceived of as static and Directive Principles represent a dynamic move towards certain objectives. If in the protection of individual liberty you protect also individual or group inequality, then you come into conflict with that Directive Principle which wants … an advance, to a state where there is less and less inequality and more and more equality. Then you become static … and cannot realize the ideal of an egalitarian society which we all desire.'

1.3 *Three Classes of Deprived Citizens*

The Constitution recognizes three classes of deprived citizens.

Scheduled Tribes (S/T) and Scheduled Castes (S/C) as laid out in relevant schedules are two classes of citizens for whom reservation was to be made when the Constitution came into operation. The extent of reservation was 27 percent, and it was to last for a period of 15 years, by which time it would have fulfilled its purpose. The third class was described as Other Backward Classes.

2. *Backward Classes Commissions*

Regarding the third category, the Other Backward Classes (OBC) Commission was set up in January 1953 and submitted its report on March 31, 1955. It listed 2,399 castes as socially and educationally backward. The Commission, which consisted of 11 members under the Chairmanship of Kaka Kalelkar, was a dead letter. Five members submitted notes of dissent. The Chairman, who did not submit a note of dissent, repudiated it, saying that reservation would deprive the country of its best talent and would lower standards. It was shelved.

The Second Backward Classes Commission was set up in December 1978 under the Chairmanship of Mr. R. P. Mandal, Member of Parliament, hereafter to be known as the Mandal Commission. The Commission consisted originally of five members and a Secretary, Mr. S. S. Gill from the Indian Administrative Service. A sixth member, Mr. L. R. Naik, was added at a later date. The Commission submitted its report on the last day of 1980. A point to be noted is that all members belonged to the OBC, which led to some critical comments from the press, alleging that the Commission was a 'packed house' and therefore could not be objective. However, the Commission was appointed by the Janata government. In the last 20 years of the twentieth century the Congress Party declined in power. It was replaced by parties which defined themselves as 'Janata' or peoples' parties. An extreme right-wing Hindu fundamentalist group called themselves the Bharatiya Janata Party (BJP). The others, which comprised many splinter groups based on personal loyalties, were also called Janata parties. The common link between these parties was their alleged adherence to secularism. However, secularism in India

does not mean separation of church from state. It means equidistance and, as a corollary, equal closeness to all religions. The Commission was given extension by the Congress government under Mrs. Indira Gandhi.

2.1 Determining Criteria

The Mandal Commission faced two major issues. The first was to decide on the extent of the population which comprised Other Backward Classes and on what bases. This narrowed itself down to the question of whether the determining factor was poverty or caste. It was argued by some, including the Congress Party, that the criterion should be poverty and not caste. They based themselves on the fact that the relevant Article of the Constitution speaks of *classes*. However, noting that poverty is not necessarily an indicator of backwardness, the Commission decided on the caste indicator. After going through a complicated calculation, the Commission came to the conclusion that the OBC constitute 52 percent of the population.

2.2 Reference to Supreme Court

The question regarding the extent of reservation a society is prepared to tolerate is a matter of negotiation between political parties. At this stage, several controversial issues in the Mandal Commission's recommendations were referred to the Supreme Court by government. The Supreme Court ruled that reservation for the OBC should be pegged at 22 percent; thus the total reservation amounted to 49 percent of the whole population. The balance of 51 percent was available for open competition. The Supreme Court also ruled that reservation should only apply at the initial state of entry into service. In addition, the Court decided that conversion does not remove the stigma of caste. It had been the policy of the government to assume that if a person is converted to a religion, which does not recognize caste, such as Christianity, Islam or Sikhism, he or she no longer stands in need of reservation.

2.3 Lack of Follow-up

It is extraordinary that nearly 20 years after its publication, the Mandal Commission Report has not been discussed in parliament. Perhaps this is because it has become an election issue. On the eve of a General Election the party in power declares its intention to implement the Report as a bait for getting the vote from the lower castes. The result has been violence, rioting, arson and self-immolation on an unprecedented scale. This happened for the first time in the capital Delhi in 1981 and in Ahmedabad and Baroda in 1985. The reaction of the upper classes was immediate and extreme. Academics, professionals, and students came out on to the streets. The self-immolation deaths which were triggered off by the Delhi riots spread to all parts of India. The overall result has been that reservation quotas have been fixed for Central Government and corporate employees, and for admission to professional institutions, but other aspects of the ways and means to create a better environment for equalizing opportunity have not been examined.

3. Moral Justification

The question arises of what justification there is to penalize some persons and appoint others to certain jobs although the former have been rated superior according to the merit criteria. Kaka Kalelkar, Chairman of the First Backward Classes Commission, a noted educationist and disciple of Gandhi, argued that it is necessary for the upper castes to atone for keeping the lower castes in a state of deprivation. To this there are at least two objections: first, those guilty of discrimination are long since dead and gone. (However, discrimination is still being practiced by the upper castes to a considerable extent.) To this the reply is that dominant groups exist and persist over time, and own responsibility. The Brahmins form such a group. This argument does have loopholes: is it fair to apply the moral notions of today to events which took place centuries ago when social structures were very different? Political and religious beliefs held by the community as a whole upheld certain types of inequality which are not compatible with liberal democratic regimes. Nevertheless, the contention is not without force.

The second argument against reservation is that it is contrary to a sense of justice and fairness that a person of greater merit should be overlooked in place of one rated as less meritorious. This objection is based on the supposition that the criteria for testing merit are objective. It has been argued that criteria are only 'facially' objective; they have a hidden bias which tilts them in favor of the dominant class or classes. Thus in India it has been a long-standing practice to rate merit on a standardized written test followed by an interview. As is well known, the upper castes, especially the Brahmins, have a long tradition of rote learning, and success in such examinations depends on memory. The interview boards at the highest level are manned by members of the august Union Public Service Commission and of similar bodies at lower levels. The Commission would certainly be the embodiment of upper class and upper caste values.

One justification for rating intellectual ability as a criterion for selecting civil servants is the supposition that it can be objectively tested. However, there are other qualities which are essential for a good civil

servant, such as honesty, integrity, incorruptibility, and persistence. To test these may not be easy, but it should not be impossible to devise such tests.

3.1 Towards Greater Equality

Regarding the steps to be taken to create a better society in which there is near equality of opportunity, one has to turn back to the Mandal Report. As a result of reservation, a few of the deprived classes will get into prestigious educational and technical institutions and into Class I jobs. However, by and large, the Commission points out, these communities can only hope to compete if special schools are set up to train them. Education in the rural areas is very poor, and it is here that the bulk of the deprived classes live. Again, the multiplicity of languages in India raises serious problems. English is the first language of a very small minority. A knowledge of English is necessary for interstate communication and is the window on the world. The latest report (1998–99) of the Ministry of Human resources informs us of several steps which have been taken to improve education in the rural areas.

3.2 Reservation and Aspiration

It has been contended that a fuss is being made about reservation of posts in government because it provides at best a mere three million jobs, a minute percentage of the workforce in the open market where reservation does not apply. But against this there are two objections: first, employment in government is important because it is these officers who determine national policies and, moreover, all sections of society have a right to participate in the framing and implementation of national policies. Second, it has been pointed out that since reservation applies to a caste, the chances are that its benefits will be acquired by a limited number of powerful caste groups. The benefits will not trickle down to the weaker castes. The Mandal Report defends this probability by asserting, 'But is this not a universal phenomenon? All reformist remedies have to contend with a slow recovery along the hierarchical gradient; … human nature being what it is, a "new class" ultimately does emerge, even in classless societies.' To say this is, in effect, to negate the entire policy of reservation. Mandal was replying to a point made by L. K. Naik that the vast majority of reservations should be distributed among the lowliest and most deprived classes, and only the remainder should be kept for the more advanced. Interestingly, this move was welcomed by the current dominant classes. It would mean that for the foreseeable future the advanced OBC would be in no position to challenge them. Hence the power structure would not change unless the already emerging deprived sections are given more and more reserved positions. Then we could expect a shift from one power group to another.

4. South Africa

South Africa's constitution guaranteed equality to all citizens; equality before the law and equal protection of the law irrespective of color, race, gender, ethnic or social origin, religion, language, belief, culture, or birth. It sought to provide free education to children up to the age of 14 years, development of the several languages of the Republic, free movement within its territory, and freedom of expression. Affirmative action is prescribed.

Article 2 of its Bill of Rights reads, 'Equality includes the full and equal enjoyment of all rights and freedoms. To promote the achievement of equality, legislative and other measures designed to protect or advance persons, or categories of persons, disadvantaged by unfair discrimination, may be taken.'

Two points are worth noting. First, reservation in India is confined to government posts and educational and professional institutions. However, demands are now being made that reservation should be extended to the private sector. In South Africa it covers the whole gamut of institutions in the country. Second, no fixed percentage has been laid down for the allocation of posts or places in institutions for underprivileged persons. The number of places to be filled by the deprived will depend on the number of qualified persons available for the posts—and the degree of discrimination practiced in the past.

4.1 Measures Initiated in White Paper 1997

However, a White Paper outlining new affirmative action targets was released on November 6, 1997. It spells out practical steps that departments must follow in implementing broad affirmative action goals set out in other policy documents and statutes. Programs must focus on three main areas, namely, achieving representation, redressing disadvantages, and developing a more diverse management culture. Two of the targets, which had to be achieved by 1999, are an increase in black management by 50 percent and more than doubling of the number of women in middle and senior management from 11 percent to 30 percent. By 2005, at least 2 percent of public servants must be disabled people. Compulsory affirmative action quotas will not be introduced for the private sector, but there will be incentives for companies that promote employment equity. Employers will be required by law to implement affirmative action at their workplaces by December 1999. The government would begin implementing the Employment Equity Act in four phases from May 1999.

Affirmative Action Programs (United States): Cultural Concerns

Even the term itself—'affirmative action'—is hotly contested in the United States today. Opponents generally refer to race-conscious policies designed to benefit nonwhites as 'racial preferences.' Thus, they distinguish 'affirmative action' in the form of aggressive nondiscrimination (its original meaning) from contemporary practices that involve racial double standards: admitting students, for instance, to selective institutions of higher education by different standards depending on their racial or ethnic identity. This article examines the issue from the perspective of two such critics. It reviews the history, and the arguments on both sides of what has become an ugly debate. Although preferential policies have provoked serious controversy in a number of countries, the focus here is exclusively on the United States.

1. The Original Conception

The term 'affirmative action' first entered American public discourse in executive order 10925, issued by President John F. Kennedy shortly after he took office in 1961. The president's order created a new watchdog committee to secure 'equal opportunity in employment by the government or its contractors,' and it demanded that employers engage in 'affirmative action' to secure that end.

The president's directive that companies and the government should treat their employees 'without regard to race, creed, color, or national origin' simply restated the central moral principle that had animated the civil rights movement from before the Civil War to the 1960s. The Constitution is 'color-blind,' John Marshall Harlan had declared in his famous dissent in *Plessy vs. Ferguson*, the 1896 Supreme Court decision that upheld 'separate but equal' railroad accommodations. The Rev. Martin Luther King, Jr., had dreamed of the day when Americans would be judged solely by the 'content of their character,' not 'the color of their skin.' Plaintiffs' attorneys in the 1954 landmark case, *Brown vs. Board of Education* (striking down segregated schooling in the South) had argued that the Constitution 'stripped the state of power to make race or color the basis for governmental action.' Kennedy's executive order seven years later thus reiterated a noble idea that had long been conventional civil rights wisdom.

2. An Altered Vision

Three years later, under the presidency of Lyndon B. Johnson, Congress passed the Civil Rights Act of 1964, which banned discrimination in employment, education, and public accommodations. The act did not include the phrase 'affirmative action'; it rested on the vision earlier articulated by President Kennedy who declared that 'race has no place in American life or law.'

Within a few years, however, the clarity of that moral stance was lost. Civil rights advocates adopted the view most famously stated by Supreme Court Justice Harry Blackmun in 1978. 'In order to get beyond racism we must first take account of race. There is no other way. And in order to treat some persons equally, we must treat them differently.' By the late 1970s, the vaguely Orwellian notion that some persons must be treated 'differently' in order to treat

them 'equally' had become civil rights orthodoxy, and it remains so today.

The revised view sanctioned racial double standards. If established selection procedures resulted in a statistical 'underrepresentation' of blacks, Hispanics, or American Indians in a particular business, profession, or college, they should be revised to remedy the 'imbalance.' Equal opportunity thus became synonymous with equal group results—proportionate racial and ethnic representation in selective schools, in places of employment (public and private), and in the awarding of governmental contracts.

Blackmun's idea was not new. 'You do not take a person who, for years, has been hobbled by chains and liberate him, bring him up to the starting line in a race and then say, "you are free to compete with all the others,"' President Johnson had said in 1965. Opening 'the gates of opportunity' would not suffice; racial 'equality as a fact and as a result' had to be the nation's goal. Although the president did not use the term 'affirmative action,' his image of blacks as crippled by racism laid the foundation for a generation of race-conscious measures designed to ensure 'equality as a fact.' Handicapped citizens were entitled to compete under different rules.

Perhaps this radical departure from the color-blind conception of fairness that had been advocated by liberals for many decades would have met with greater resistance if it had not been proposed on the eve of riots that erupted in the nation's cities in the summer of 1965. The looting, burning, and fighting sent tremors of fear and guilt through white America, and a subsequent official (Kerner Commission) report that purported to explain the disorders set the tone for subsequent civil rights discourse and policy. America was in grave danger of becoming 'two societies—separate and unequal'—the report concluded. It was an invitation to aggressive race-conscious action to ensure equality and thus close the divide.

Given the long and ugly history of American apartheid, the demand for equal results—blacks in the workplace and other settings in proportion to their numbers—was understandable. But it was impossible to square race-conscious measures (amounting inevitably to preferences) with the antidiscrimination language of the 1964 act and the Fourteenth Amendment to the Constitution, which guaranteed 'equal protection' to all Americans. Civil rights warriors in the 1950s and early 1960s had marched and died to rid the country of discriminatory policies; now, in revised form, they were back. Preferences involve discrimination against members of nonfavored groups.

3. *Preferences in Higher Education*

The Supreme Court played an important role in redefining the nation's commitment to civil rights. A series of decisions starting in 1973 tell a startling story of judicial creativity and confusion, culminating in *Regents of the University of California vs. Bakke* five years later. Allan Bakke had been denied admission to the medical school of the University of California at Davis, despite having had an academic record that was vastly superior to those of blacks and Hispanics accepted through a separate race-based admissions process. A deeply divided Court held for Bakke, but allowed the use of race in university admissions as only *one* factor in the equation.

It was a legal standard that was, in effect, a Rorschach test, open to a variety of interpretations. Claiming conformity to the *Bakke* rule, most schools proceeded to admit minority students whose academic records were so weak that they would never have had a chance of admission if they had been white or Asian. At the University of California at Berkeley throughout the 1980s and early 1990s, for example, the whites and Asians who were admitted fell in the top tenth of all test-takers on the SATs, the exam usually taken by high school graduates who hope to be admitted to a selective college or university. The typical black student, on the other hand, had much lower high school grades, and SAT scores at about the national average.

Berkeley was not unique. Starting in the early 1970s, all of the most selective colleges began accepting students by racial double standards. Indeed some places, like the University of Texas Law School, continued to use a separate admissions committee to read color-coded folders for members of different racial and ethnic groups. The picture was kept from public view, however. Tantalizing fragments of evidence only began to trickle out in the 1990s, as a consequence of legal and political challenges to preferential programs, inquiries under state freedom-of-information-act lawsuits, and studies by investigators with special access to the evidence.

For instance, the Center for Equal Opportunity's analysis of data from the University of Virginia reveal black applicants to the college to have had more than a hundred times better chance of admission than white candidates with the same qualifications. In three states (Texas, California, and Washington) a popular referendum or a court ruling has banned racial double standards in public institutions, but they continue to thrive across the nation in other publicly funded settings, as well as in almost all selective private colleges and universities. Thus, such preferences are now deeply embedded in the educational culture.

The fullest empirical study of racial preferences in admissions to elite colleges and universities is a volume by William G. Bowen and Derek Bok(1998), former presidents of Princeton and Harvard respectively. *The Shape of the River* was greeted with uncritical enthusiasm in the liberal press, but its arguments in favor of preferences were deeply flawed. Although the authors claimed to have shown that race was just 'one factor' in admissions decisions, their tables revealed

that affirmative action meant glaring racial double standards, not just a small bonus for belonging to an 'underrepresented' group.

The evidence in *The Shape of the River* supported rather than refuted the criticism that such programs did nothing to benefit the most disadvantaged blacks and Hispanics, whose educational development had been held back by the poor inner-city public schools they attended. The beneficiaries of preferences at the top colleges were from middle-class, often suburban, families.

Bowen and Bok's evidence also punctures the wishful argument that attending an elite school will erase the academic deficits of students admitted under lower standards. The average black student attending schools like Yale and Swarthmore performed well below average in the classroom, ranking in only the 23rd percentile in grade point averages. Even that low figure is deceptively rosy, because it is for all African-American students, although half of those admitted had credentials that merited admission without preferences. The failure to distinguish regular and preferential admits is an astonishing methodological blunder in a study purporting to assess the effects of race-conscious admissions policies.

Bowen and Bok (1998) cite the large numbers of black students accepted to the best law, medical, and other graduate schools as evidence of the success of affirmative action admissions. But a high proportion of those students were again the beneficiaries of lower standards for blacks and Hispanics. The authors ignore a wealth of evidence suggesting that preferentially-admitted black graduate students, like their counterparts in college, rank at the bottom of the class and are much more likely to leave school without a degree.

Most disturbing, those in fields that require passing external competency tests tend to perform dismally. A dismaying 43 percent of all the preferentially-admitted black students who entered an American law school in the Fall of 1991 either failed to earn their degrees or, worse yet, graduated but failed to pass the bar examination within three years of graduating. After costly years of effort, they were thus unable to engage in the practice of law. A study of 1975 medical school graduates found that less than one-third of the minority students who were given heavy preferences in admissions had earned certification in their specialty from the National Board of Medical Examiners seven years after graduation, as compared with 80 percent of Asians and whites and 83 percent of minority graduates with high college grades and good scores on the Medical College Admissions Test.

Preferential admissions to competitive schools were a failure by these objective measures. We lack careful studies of other possible negative effects, but some may be suggested. The common idea that students admitted through affirmative action will have enhanced self-esteem because they are attending an elite school seems highly dubious. Students who do poorly academically do not usually feel good about themselves. Moreover, when most black students have low grade-point averages, racial stereotypes may be reinforced, and all members of the group—whatever their academic talent—may find themselves stigmatized. Perhaps a sense of this danger explains the results of a national survey of college students conducted in 2000. While 84 percent of the respondents said that ethnic diversity on campus was important, 77 percent opposed giving admissions preferences to minority applicants.

4. *Contracting, Employment, and Voting Too*

Preferences are equally embedded in the world of contracting and employment. For instance, since the early 1970s the federal government has given a decided leg-up to minority-owned businesses who submit bids for government contracts to provide goods and services (ranging from paper clips to major construction). A 'small disadvantaged business' (which presumptively means minority-owned) will get the work even if the taxpayers end up footing a bill 10 percent higher than it would have been if a low bid from a white-owned company had been accepted. In theory, only 'small' companies qualify, but the cap on wealth is sufficiently high as to make eligible between 80 and 90 percent of business-owning families in the United States.

In recent years, the US Supreme Court has raised serious questions about such bidding preferences, but those rulings have had little impact. Bill Clinton, as well as many state and municipal governments, have worked hard to circumvent federal court decisions. In 1995 the President promised to 'mend' affirmative action, but in 1998 his administration actually extended to all federal agencies the 10 percent preference given minority firms that had previously been confined to Department of Defense contracts. The Republican-controlled Congress with which he had to work posed no obstacle; it frequently reauthorized preference programs built into legislation governing federal contracts. The rationale behind such preferences is of course a history of discrimination against minority-owned enterprises, but US government spokespersons have, by their own admission, found no discrimination by a federal procurement officer. In any case, the logical sanction is to fire such officers from their jobs.

Employers (private and public) routinely engage in race-conscious decision making, too. The 1964 Civil Rights Act (as amended in 1972) covers all private employers with at least 15 workers. With discrimination redefined to mean disparate impact, employers are vulnerable to government-initiated suits if the process of selecting employees ends up with 'too few' blacks and 'too many' whites (or perhaps Asians).

Litigation is extremely expensive; most businesses would rather create a statistically balanced workforce through the use of racial preferences (when necessary), than tangle with lawyers. Race-based hiring is a means of self-defense.

The Fourteenth Amendment also protects against employment discrimination in the public sector, but neither it nor the 1964 act allows the government to order race-conscious hiring directly. Preferences are explicitly mandated only as remedies upon a finding of discrimination. On the other hand, employers who do business with the federal government—roughly a quarter of the total American workforce—are under quite a different obligation. They are governed by an order issued by President Richard Nixon in 1970 that forthrightly demands race-conscious hiring as a condition of supplying goods and services to federal agencies.

Thus, companies like Raytheon and IBM are expected to assess the availability of black employees and file with the Department of Labor a written affirmative action plan that includes minority hiring goals and a timetable. They must show 'good faith' efforts to reach those targets. If the effort seems insufficient, the department has the power to cancel federal contracts and permanently keep a business (or educational institution) off the list of those eligible to submit bids for government work. It can also recommend further legal action.

The imposition of affirmative action policies upon these employers does not require a judicial finding of unlawful employment practices, nor does the definition of what constitutes appropriate affirmative action depend upon a court. Of course, employers can escape the coercive nature of the executive order by avoiding government contracts altogether, but that is a steep price to pay. For many companies, in fact, the federal government is their best—or only—buyer.

Almost everyone understands that racial preferences have become widespread in contracting, employment, and selective institutions of higher education. Less understood is the degree to which race-conscious policies also affect the enforcement of voting rights. In 1965 Congress passed a landmark Voting Rights Act aimed at enfranchising southern blacks, still denied their basic right to vote. Through the process of implementation, and with congressional acquiescence, that unambiguous aim of enfranchisement was soon altered. The right to vote became an entitlement to black officeholding in proportion to the black population. States became obligated to draw race-conscious districting lines to create a maximum number of safe black seats—in state legislatures, on city councils, school boards, and other elected bodies. Those race-conscious lines would protect black candidates for public office from white competition in much the same way as race-conscious admissions protected black applicants to elite colleges from white and Asian competitors.

Large employers and universities, as well as most members of Congress and other public officials, have either acquiesced or positively embraced the notion that race-conscious policies are good for business and good for America. Indeed, they have gone far beyond the demands of the law in instituting racial preferences. But a majority of the public, surveys indicate, opposes sorting and labeling Americans on the basis of skin color, and beginning in 1989 a majority of justices on the US Supreme Court began to have second thoughts about racial classifications.

Such classifications, the Court said, carry 'the danger of stigmatic harm' and 'may … promote notions of racial inferiority and lead to a politics of racial hostility.' Today, race-conscious public policies are held to a tough constitutional test. They must be narrowly tailored to serve a compelling state interest. What the Court's rulings will mean for the future of race-conscious policies is impossible to predict, however. In three states, the government can no longer discriminate—for good or invidious ends—on the basis of race; in the other 47, preferences are ubiquitous. Moreover, private companies, colleges, and other institutions in every corner of American society still favor blacks and Hispanics over Asians and whites in the interest of a more 'diverse' workforce or student body. And they are likely to continue doing so until, perhaps, demographic change—the lines of race and ethnicity blurred as a consequence of intermarriage—makes all such classifications obsolete.

5. *Arguments For and Against*

Racial preferences are one of the most polarizing issues on the American political scene, and thus few politicians discuss them. But civil rights spokespersons and numerous academics have long exchanged fire in an often ugly war.

The arguments on each side have become familiar. Supporters see race-conscious employment and other policies as essential to keeping rampant white racism in check. In fact, racism is so deeply imbedded in the nation's institutions, they assert, that individual attitudes are quite irrelevant. Thus they view affirmative action as an essential life raft—the means by which blacks and Hispanics stay afloat, the antipoverty, empowerment program that really works. In addition, they believe race-conscious programs are morally just, given the nation's history of slavery, segregation, and rampant discrimination.

Critics, on the other hand, argue that the past cannot be rectified by perpetuating color-conscious policies. There is, in fact, no way of making up for America's terrible racial history. But the past contains a lesson: judging people on the basis of the color of their skin is incompatible with racial equality. If citizens are classified by race and ethnicity, they will not view each other as equal individuals. Pasting racial and ethnic labels on everyone—assuming individuals

are defined first and foremost by the color of their skin—is no way to get beyond race. Racial classifications never worked, and never will. They are as American as apple pie, but today, as in the segregated Jim Crow South, they perpetuate terrible habits of mind. Americans are still viewed as fungible members of a group defined by race—not as unique individuals. And they are treated differently, depending on their group membership. Moreover, blacks, Hispanics, and Asians qualify for group membership on the basis of one drop of blood; the children of a black–white intermarriage are still 'black.'

Critics make a further argument. The notion that groups will be proportionately represented in all walks of life in a racially fair society is fundamentally misguided. Most doughnut shops in Los Angeles are run by Cambodians; East Indian immigrants operate a high percentage of American motels; the stereotype of the Jewish doctor has become a standing ethnic joke. The division of labor along ethnic lines is a common phenomenon in all ethnically diverse settings.

Racial inequality in America remains real, but most beneficiaries of racial preferences are already on the road to success. They are not from the black underclass, and admitting middle-class black students to Yale or Berkeley under lower standards does not address the problem of a disproportionately high percentage of black males still unemployed in a full-employment economy. Inner-city students generally lack the academic skills to compete for classroom seats in elite schools, or for well-paying middle-class jobs—only better education in the earlier years can address that problem. Indeed, poorly educated students do not make up for their lack of academic skills by being placed in a highly competitive environment; black students at elite schools, on average, end up in the bottom quarter of their class. That fact alone carries the danger of perpetuating a pernicious racial stereotype.

Racist Americans have long said to blacks, the single most important thing about you is the color of your skin. In recent years, black and white Americans of seeming good will have joined together in saying, we agree. It has been—and is—exactly the wrong foundation, these authors believe, on which to come together for a better future. Ultimately, black social and economic progress largely depend on the sense that we are one nation—that we sink or swim together, that black poverty impoverishes us all, that black alienation eats at the nation's soul, and that black isolation simply cannot work.

Affirmative Action, Sociology of

The phrase 'affirmative action' first became firmly associated with civil rights enforcement in 1961, the year President Kennedy directed federal contractors to take 'affirmative action' to ensure nondiscrimination in hiring, promotions, and all other areas of private employment. Over time, federal goals began to shift away from 'soft' affirmative action programs that merely required equal opportunity for members of previously excluded groups towards stronger policies mandating preferential treatment of women and minorities in order to obtain equal (or proportional) results. The shift in emphasis from 'weak' to 'strong' methods of policy enforcement emerged as many policy makers concluded that nondiscrimination alone was not sufficient to address the deep racial divisions

and inequalities that beset American society. The many different meanings and forms that affirmative action has taken on through the years create difficulties in measuring its public support and explain, in part, its tortured legal standing and questionable future.

1. *Defining the Concept of Affirmative Action*

Affirmative action involves a range of governmental and private initiatives that offer preferential treatment to members of designated racial or ethnic minority groups (or to other groups thought to be disadvantaged), usually as a means of compensating them for the effects of past and present discrimination. Justification for affirmative action programs typically rests on a compensatory rationale, i.e., members of groups previously disadvantaged are now to receive the just compensation which is their due in order to make it easier for them to get along in the world. However, other useful definitions and characterizations of affirmative action de-emphasize the retrospective, compensatory, and ameliorative nature of such programs and focus instead on the current value of such programs in enhancing diversity, particularly in educational institutions and in the workforce.

The actual programs that come under the general heading of affirmative action are a diverse lot, and can include policies affecting: (a) admissions to educational institutions; (b) public and private employment; (c) government contracting; (d) the disbursement of scholarships and grants; (e) legislative districting; and (f) jury selection. Innumerable affirmative action programs have been enacted into law at the federal, state, and local level, and many private corporations and universities have developed affirmative action programs on their own voluntary initiative. Methods of implementing affirmative action policies are similarly diverse and in the past have ranged from 'hard quotas' to softer methods of outreach, recruitment, and enforcement of anti-discrimination norms.

2. *Measuring Public Support for Affirmation Action Policy*

After years of focusing on polarization between white Americans and African-Americans, survey researchers have begun to realize that public opinion on affirmative action is highly sensitive to question wording and question context in addition to being plagued by respondent misinformation. As a result, respondents' answers to direct questions about their support or opposition to affirmative action tells us very little about the types of public policies that a given individual will endorse. In fact, one researcher has observed that respondents who say that they oppose affirmative action policies may actually support more types of affirmative action programs than a person who identifies as an affirmative action supporter. Greater awareness of the sensitivity of affirmative action questions to question context and question wording has led some researchers to conclude that validity of survey results could be greatly improved if the use of the term 'affirmative action' was abandoned and instead the content of specific policies described. When a range of survey questions is examined carefully, it is found that Americans seem to be moving towards greater on consensus on affirmative action related issues. This consensus includes a shared unease with racial preference programs coupled with a willingness to support outreach programs that benefit the economically disadvantaged regardless of race

3. *The Legal Standing of Affirmative Action*

While the shift from weak to strong methods of policy enforcement occurred in the late 1960s and was largely the result of decisions made in the executive branch of the federal government, the Supreme Court has played a crucial, if somewhat more equivocal, role in the period which followed by legitimating some of these policy changes and restricting others.

3.1 *Preferences in Hiring*

Title VII of the Civil Rights Act of 1964 is a statutory measure designed to combat racial discrimination in employment situations. Charges of 'reverse discrimination' became common during the 1970s as more and more corporations and private businesses, often under pressure from federal enforcement agencies, began more aggressive hiring of minorities and women. The Court ruled unanimously in *McDonald vs. Sante Fe Transportation Company*, 427 US 273 (1976), that whites as well as blacks are protected from racial discrimination under the antidiscrimination provisions of Title VII. Despite this ruling, a number of subsequent court decisions have held that Title VII permits the preferential treatment of minorities and women in hiring and promotion decisions (but not in decisions affecting layoffs) if such treatment is part of an affirmative action plan designed to increase the employment of previously excluded or under-represented groups (see *United Steelworkers of America vs. Weber*, 443 US 193 (1976), *Local 28 Sheet Metal Workers International Association vs. Equal Employment Opportunity Commission*, 478 US 421 (1986), *United States vs. Paradise*, 480 US 149 (1987), and *Johnson vs. Transportation Agency, Santa Clara County*, 480 US 616 (1987)). Justice Brennan writing for the majority in Weber explained 'It would be ironic indeed if a law triggered by a nation's concern over centuries of racial injustice and intended to improve

the lot of those who had been excluded from the American dream for so long constituted the first legislative prohibition of all voluntary, private, race-conscious efforts to abolish traditional patterns of racial segregation and hierarchy.' However, the Court's subsequent support for affirmative action is quite fragile as shown by the many 5:4 decisions, the restrictions placed on affirmative action programs with regard to layoffs in *Firefighters Local Union No. 1794 vs. Stotts*, 467 US 561 (1984), and *Wygant vs. Jackson Board of Education*, 476 US 267 (1986), and the changing composition of the Court.

3.2 Set-asides

One form of affirmative action preference that became very popular among state and municipal governments in the second half of the 1970s was the minority contracting set-aside. Set-aside programs usually involve the reservation of a fixed proportion of public contracting dollars that by law must be spent on the purchase of goods and services provided by minority-owned businesses. Like preferences in hiring, set-asides have been enormously controversial and cries of reverse discrimination abound. The Supreme Court first took up the issue of set-asides in the case of *Fullilove vs. Klutznick*, 448 US 448 (1980), in which it held that a federal set-aside law did not violate the equal protection provisions of the federal Constitution because it was a legitimate remedy for the present competitive disadvantages of minority firms resulting from past illegal discrimination. However, nine years later and again reflecting the influence of the Reagan-era appointees, the Court held in *Richmond City vs. J. A. Croson Co.*, 488 US 469 (1989), that racial classifications within state and local set-aside programs were inherently suspect and were to be subject to the most searching standard of constitutional review ('strict scrutiny') under the equal protection provisions of the Fourteenth Amendment. Six years after Croson, the Court extended strict scrutiny review to federal affirmative action programs that draw racial classifications (see *Adarand Contractors Inc. vs. Pena* 115 S.Ct. 2097 (1995)). These Court decisions have curtailed minority set-aside and led to greater efforts to address concerns about over-inclusiveness in the protected categories.

3.3 Preferences Higher Education

Equally important—and equally controversial—have been affirmative action policies adopted by educational institutions. Beginning in the late 1960s, many universities and professional schools began admitting minority students, particularly African-Americans and Hispanics, with substantially lower grades and lower scores on standardized tests than white students. Some nonadmitted white students charged reverse discrimination and a few brought suit in federal court claiming that affirmative action in higher education was a violation of Title VI of the 1964 Civil Rights Act, as well as of the equal protection provisions of the US Constitution. In *Regents of the University of California vs. Bakke*, 438 US 265 (1978), the Supreme Court ruled against an explicit quota system but allowed admissions officers to take race into account as one of many 'plus' factors designed to enhance the diversity of a school's student body. Affirmative action in higher education has come under increasing attack in the 1990s. In *Hopwood vs. Texas*, 78 F.3d 932 (5th Cir. 1995), the Fifth Circuit questioned the vitality of the Bakke decision and upheld a claim of racial discrimination brought by nonadmitted white students who had higher test scores and grades than admitted minority students. Two challenges to the University of Michigan's admissions policy, which takes the applicant's race into account as one of many factors bearing on admissibility, are currently working their way through the legal system and are likely to provide the vehicle for the Supreme Court to revisit the Bakke decision. In 1998, *Gratz and Hamacher vs. University of Michigan and Grutter vs. Michigan*, were combined into a class-action suit which is awaiting resolution (www.wdn.com/cir/mich1.html). These higher education cases are expected to reach the Supreme Court sometime during the twenty-first century.

4. The Outlook for the Future of Affirmative Action

Affirmative action in the US faces an uncertain future. Changes are occurring at the state and local level, as well as in the federal court system. Two states have voted to ban state-supported affirmative action programs. In November 1996, California voters approved Proposition 209, by a vote of 54 to 46 percent. This initiative provided that the state 'shall not discriminate against or grant preferences to any individual or group on the basis of race, sex, color, ethnicity or national origin in the operation of public employment, public education, or public contracting.' Similarly, in 1998 voters of Washington State, by a vote of 59 to 41 percent, passed an initiative also banning affirmative action in state-supported programs. Nevertheless, a ballot initiative in Houston, Texas failed after pro-affirmative action forces were able to control the wording of the initiative so that voters voted against dismantling affirmative action programs and for banning state supported 'discrimination.' The language used in these three initiatives seems to have been a factor in explaining the different political outcomes. Affirmative action, therefore, appears to be a vul-

nerable public policy. Changing demographic patterns could further decrease its public support, since racial and ethnic minorities are expected to reach majority status sometime during the twenty-first century. Already, a racial divide exists in the perception of the extent and nature of racial discrimination and this seems to be an important factor in explaining contemporary attitudes towards the policy. Perhaps, the perceptual gap could be narrowed by studies that identify and expose hidden racism and discrimination in housing, employment, police actions, and college admissions. Such studies could serve to heighten public awareness of the pervasiveness of discrimination and lead to greater acceptance of public policy remedies designed to help ameliorate the kinds of disparities that affirmative action was originally designed to address. It is race-based and not class-based affirmative action that seems to be most vulnerable to constitutional based challenges.

African Legal Systems

'African legal systems' means here the bodies of interrelated legal norms and accompanying institutions of norm-creation, norm-finding, and norm-enforcement which have a social existence in Africa. Legal norms are taken to be those social norms which are enforced by a relatively strong degree of coercion.

1. Customary and Religious (Non-state) Legal Systems

Customary legal systems are those systems which exist by virtue of the social observance of their norms, and not by the creation of their norms through state institutional processes such as the enactment of legislation. Customary legal norms are observed because of a continuing but usually tacit agreement among a population to accept them as obligatory. For the present purpose a practice need not have been observed for a very long period to be 'customary'. (See also: *Folk, Indigenous, and Customary Law*.)

Religious legal systems are for the present purpose a variety of customary legal systems, their distinctive feature being their derivation from a system of religious belief. In Africa the primary systems of religious law are varieties of Islamic law. There are many communities, especially in North Africa and in the Sahel region, where the predominant law is Shari'a, sometimes modified under the influence of other local customary norms.

These non-state African legal systems vary widely, and almost any generalization about them is subject to exceptions.

Perhaps the most distinctive feature of African customary legal systems is the frequency with which the parties to legal relations are communities of ascribed membership, especially membership by descent, not individuals or other corporate persons as in Western legal systems. Thus, for example, substantial interests in land are often vested in lineages or communities comprised of several lineages. Marriage is generally contracted by agreement between the lineages to which the bride and groom belong, and creates legal relations between them. A customary law community often has an individual leader, instances of which range from the 'head of family' of the relatively small lineage to the 'chief' or 'king' of a large polity such as Asante or Buganda, although there are also many acephalous communities (Middleton and Tait 1958). Leaders are determined according to customary legal norms. Although in some circumstances a charismatic leader may temporarily acquire personal authority and wield great discretionary power, generally customary law imposes strict limits on the powers of leaders: the rule of customary law prevails widely.

Another common feature of customary legal systems is the nature of the procedures and principles concerning conflicts of interests and disputes. These are directed to the achievement of social peace and harmony within the community rather than the determination of legal rights. Dispute processes are less frequently instances of adjudication than of

mediation or negotiation, in which there are social pressures on the parties to compromise.

2. *State Legal Systems*

The modern African state with its governmental and legal institutions is a product of colonization. In most parts of Africa there was relatively little immigration from the colonizing countries, and everywhere the indigenous inhabitants remained in the majority. Nevertheless the colonial powers set up systems of government which resembled those of the metropolitan states, except that they did not provide for public participation in government. The English common law was imported into the British colonies. Codes largely identical with those of France and Portugal were enacted in their colonies. (Allott 1960, 1970; see also: *Law: Imposition, Reception, and Colonial.*)

The received laws shaped the institutions of the state legal systems, such as the courts, and provided bodies of legal norms law in fields such as contract, property transactions, and personal injuries. The technical and social knowledge necessary to administer this law in such roles as those of judge, legal advisor, legislator, and police officer were initially lacking in the indigenous populations. The lacuna was filled by colonial officers brought from the metropolis, some of them members of the professional legal community and others with some training and socialization in the ways of that community. Members of indigenous communities later obtained the training and assumed the social practices which enabled them to take over these roles. Thus the laws of the colonial powers became African legal systems. At Independence (between the late 1950s and the end of the 1970s) African rulers and administrators saw their aspirations and material interests as dependent on the continued effectiveness of these legal systems.

Those customary and religious institutions and practices which the colonial powers perceived to be inconsistent with colonial domination, such as primary allegiance to chiefs, they attempted to destroy or transform. Their policy towards other components of these legal systems was to tolerate or even encourage their continuance as alternatives to those of received law. In consequence, in the social field of each colony both the state legal system and one or more customary or religious legal systems were observed. In this form of legal pluralism there was no unified hierarchy of norms. Individuals differed according to whether they gave general priority to the observance of state law rather than a non-state law, or gave priority to each on different occasions.

Within state law a further type of legal pluralism was formed. State legal systems gave recognition to African indigenous customary and religious legal systems. 'Recognition' here designates the policy whereby state legal systems treat the institutions or norms of customary and religious law as parts of the law of the state, giving effect to them and enforcing them in the same way as the institutions and norms of received law. Policies of recognition were adopted in some British colonies from the beginning, and eventually adopted everywhere.

Institutional recognition of a customary or religious legal system occurred when institutions of that system were incorporated into a state legal system, as for example when chiefs became administrative officials or judges of the state. This frequently happened in British colonies, in accordance with the policy of indirect rule which sought to govern colonies through native forms of government. With the abandonment of the policy from the 1940s this recognition became less significant, but it has continued in a limited form. In other colonies it was adopted as a concession to local opinion, as well as for practical reasons; there also it has continued since Independence.

Normative recognition of a customary or religious legal system occurred when norms of that system were incorporated into the body of norms of the state legal system. State law might provide, for example, that rights in land could be transferred by procedures specified by norms of customary law, or that the inheritance of property might be determined by customary and religious norms. The incorporated norms then became enforceable in state courts. This also occurred in most African colonial legal systems, and also has continued to the present.

Customary and religious laws were not and indeed could not be 'incorporated' into state law without radical changes to their nature and content. The state has always excluded from incorporation some portions of customary laws, such as those providing for slavery, which were contrary to the fundamental values of the state. Moreover, the acceptable elements of customary and religious legal systems could not be accommodated without reformulation. The institution of chieftaincy, for example, is transformed when its authority ceases to be derived from respect for tradition and communal identity, and becomes based upon the threat of coercion by state institutions. The forms of coercion of state institutions, such as the threat of imprisonment supporting an adjudicative decision, differ from the social pressure traditionally exerted upon disputing parties to agree to a compromise. Consequently the effect of normative recognition has generally been to compel behavior of a different type from that which would otherwise have occurred. Finally, the personnel of state institutions are frequently unfamiliar with customary or religious law and have 'recognized' norms which differed from those socially observed. Thus state institutions create new bodies of norms, 'official,' 'judicial,' or 'lawyers,' customary laws,' which differ from the 'people's,' 'folk,' 'indigenous,' or 'practiced customary laws' which have continued to be observed outside state

administrations. Some legal historians consider lawyers' customary law to be an 'invention,' bearing no significant relationship to pre-existing social norms (e.g., Chanock 1985), although others consider this extreme conclusion to be unrealistic (e.g., Woodman 1985).

3. *Past and Present Trends in Legal Development*

Legal development since the institution of the colonial state has reflected the considerable political and social change in Africa.

Changes in state public law, that is, those branches of the state legal system which regulate government, have generally been directed towards strengthening the state and elaborating the functions and powers of state executive bodies. From the late 1940s they also provided for increasing public participation in government. The Independence constitutions contained rules for democracy and constitutional government. In the immediately following decades many states instituted one-party government, or experienced the violent overthrow of their constitutions followed by military rule. More recently internal developments and external, globalizing pressures seem to have produced trends towards constitutionalism, more democracy and accountability in government, and emphasis on environmental protection. These forces, and notably the formation of the African Charter on Human and People's Rights in 1986, have produced constitutional recognition of a wide range of human rights through judicially enforceable legal provisions.

Nation-building has been a major objective of constitutional orders. The boundaries of modern African states, inherited from the colonial powers, contain different ethnic and religious groups, each with its own culture, customary law, and language. The individual citizen's loyalty and sense of belonging often refers primarily to the ethnic or religious group. Constitutional provisions, in an effort to create a sense of national identity, have prohibited discrimination on the ground of ethnicity, language, or religion in many activities, including the selection of members of state institutions and political organisations. This has been seen as necessary to economic and social development, as has the principle of indigenization of positions of economic or social power. There have been increasingly determined attempts to improve the legal position of women, who are seen as seriously disadvantaged by traditional laws and practices, and of children.

Recognition in state criminal law of customary law has never been extensive. Today the criminal law is contained exclusively in state criminal codes, together with other written laws specifying minor offences.

Generally developments in public law have increased the function of state law as a regulator of social behavior. All of the trends just noted, and the long-term tendency towards Western-style governmental systems have been accompanied by a decline in the African state's use of customary institutions such as chieftaincy, and so in the strength of these institutions. Nevertheless, the state is still not the sole, unchallenged legal authority. It remains notoriously ineffective in regulating the daily lives of its citizens outside its own bureaucratic institutions. Even within these, instances of corruption and abuse of power show that state officials are not punctilious observers of state law. One global policy may even have reduced the scope of state law. The structural adjustment policies which the World Bank and International Monetary Fund have set as conditions for economic aid have tended to reduce state involvement in economic activity in favor of private business institutions.

In the fields of private law changes are visible in the content of received law, practiced customary law, and lawyers' customary law, and in the relationships between them.

Received private law has been continuously changing both in the European countries of origin and in African states. State laws required received law to be adapted to local circumstances by the courts and legislatures. But decision makers have also asserted the value of transnational uniformity in the principles of the common law and civil law. Decisions and textbooks from the source countries of received laws have been followed in African jurisdictions. Even in the legislative reform of received law the best legislative model is often held to be the latest legislation in the country of origin, in fields as diverse as company law and divorce law. Only in some of the legislation concerned with economic development, such as that regulating foreign investment, has there been significant innovation.

Some aspects of social change have increased the extent to which received law is observed. Policies of 'modernization' have been accompanied by a general official belief that the application of Western laws gives effect to the principles of the market economy. (See *Law and Development*.) To the same effect has been the growing involvement in the global economy of private individuals and businesses through the export-oriented development of cash crops and extractive industries. There has been much expansion in the education and technology derived from the West. The same tendencies have produced and are in turn reinforced by the emergence and growth of national legal professions. Nevertheless, in activities such as the contracting of marriage, the acquisition and use of lineage assets, and land use, most people still choose to act under customary law, especially when the parties involved all observe the same customary law, or have relatively little Western education.

Non-state African legal systems have never been static. Systems of practiced customary law have changed considerably since colonization. The individual has gained more autonomy, having today the

capacity to hold extensive property and enter into weighty transactions independently of the lineage. Legal transactions are more often governed today by market forces, rather than by standard customary terms. Written records are more commonly used, and more norms have been developed to guide relations between members of communities and outsiders. New bodies of customary law have been formed, especially in the vastly expanded urban areas where religious, professional, welfare, and self-help communities with their own customary laws have been created.

Lawyers' customary law has also changed, in that norms which the state will recognize and enforce as customary law have been progressively elucidated and embodied in judicial decisions, restatements, and textbooks. To some degree, the reformulation entailed in these processes has been in the same direction as changes in practiced customary laws. However, the processes have also had a conservative effect, because a norm embodied in an authoritative pronouncement is not easily changed thereafter in response to changes in social circumstances. The gap between lawyers' customary law and practiced customary law could thus grow. Another major development in lawyers' customary law has been the extensive amendment to some areas by legislation. Land laws in particular have been amended in attempts to balance competing claims to land use while also promoting economic development and inhibiting environmental damage. Here the extent to which practiced customary law diverges from state law is a function of the extent to which the state is able to make its legislation effective.

4. *Current and Future Issues in Legal Development, Theory, and Research*

Current law-making by states is directed towards a number of practical problems. Everywhere there is a search for constitutional forms which will maintain stability against interethnic and interreligious conflict, and armed uprisings. The relationship between customary and religious legal systems and state law has become an even more acute issue since the constitutional entrenchment of human rights, since these appear incompatible with some non-state laws. Globalization intensifies certain issues. State law may be developed to protect national economic independence against the power of international businesses and institutions such as the World Trade Organisation. It may also assist economic development in the face of new threats from natural disasters such as climatic change and the AIDS epidemic.

Research into African legal systems has in the past been carried on within several disciplines. The study of customary law has used the methods of anthropology and sociology, of state law those of legal analysis, and of Islamic law those established specifically within that scholarly tradition. Today there is more interdisciplinary understanding. One consequence is renewed concern with fundamental questions about the concept of law, especially that as to whether customary and religious normative orders are truly law. These debates may also raise doubts as to whether it is appropriate to speak of 'systems' of law.

With indigenization and expansion of the African civil service and academia, most research into African legal systems will in future be conducted in Africa by African scholars. It will be closely concerned with the practical problems just mentioned. However, it is likely that the more fundamental theoretical issues will continue to inspire and to be investigated by an international community of scholars.

African Studies: Culture

1. Introduction

1.1 Introductory Paragraph

The concept of culture is one of the most disputed in the social sciences, and nowhere more so than in African studies. The classic study of culture rested on the study of the main media of expression: music, art, material forms, and (above all) language and the written expression of thought in literature, philosophy, and theology. Texts were central. In the foundational era of African Studies, in the nineteenth century in Europe, Africa was assumed to have no texts at all. Its arts of music, performance, and oral poetics were thought to be different in kind from text-based culture. They were performative and multimedia rather than abstract and specialized. Hence their designation as 'primitive,' which survives in many museums and art galleries. The basic collections were, therefore, of sculptural art and material culture, which were relatively accessible even to amateur collectors, and which were assembled during the competitive rush for acquisitions by museums in the late nineteenth and early twentieth centuries. Even for specialists in the study of 'primitive cultures,' however, techniques for reproducing their nonwritten cultural forms—such as tape-recording, photography, and film—were still too clumsy and fragile at that time to produce a solid and reliable corpus for study. The analysis of African cultures has grown and changed, therefore, with changes in thinking about culture in general, in the technologies of scholarship, and in the place of Africa in the world. These changes are discussed in general and then their enduring contributions are summarized.

1.2 Historical Overview

Since the late nineteenth century in the systematic study of African culture, scholars and artists have struggled to rework the foundational legacy as new study techniques, approaches, and colleagues appeared on the scene. Three major changes have erased the categorical distinction between literate and oral/performative culture. First, new recording technologies have made performative culture amenable to the kinds of analysis given to texts in the past, and have made primary sources more widely available for secondary analyses. Second, and at the same time, modern Cultural Studies in Europe has moved closer to African Studies by embracing a much wider range of arts and performance than in the past, including multimedia work, and by looking at how different media can draw on the same forms and themes. Still using textual methods, they now include popular culture, film, clothing, and other expressive forms, and they link style, substance, and concepts of authorship to social context far more than was done in the classical mode. Finally, the African library of written texts has expanded greatly in the twentieth century. Far more written forms from the past are now recognized than were acknowledged in the classic period, including voluminous sources written in Arabic script and certain sculptural, geometric, and musical forms that are now realized to encode verbal content (e.g., Roberts and Roberts 1996). The other source is current artistic production. There is a new corpus of literature, music, and the arts that is not 'traditional,' but rather responds to the situation of modern life, including the global marketplace. The new expansion in Africa includes African scholars' studies of their own past and present art forms, working from their own languages, and this has contributed new expertise and a new set of ideas to the international arena.

These changes from the classic, classificatory, study of culture to the current expansive incorporation of varied and linked forms are still being worked out and they are still contentious. At the same time, the sheer enormity of the task of adequate study of African cultures is realized increasingly. Only in the European view of the confident, progressive industrial era could the whole continent and its millennia of history be grouped together into a single category as 'Africa.' Africa is the cradle of humanity; its cultures have very deep histories. Its population is also highly diverse. There are about 1,000 African languages spoken. More than was originally understood also benefit from written works. Even the popular icons of Africa that have been studied for decades—such as masks, body decoration, 'fetishes,' and drumming—are far richer as traditions than the scholarship can yet do justice to.

With these provisos about the completeness of the record, the history of cultural study can be divided schematically into four broad successive phases. The first comprises the early missionary and traveler documentation, up to the mid-nineteenth century. The first systematic efforts at documentation (a second phase, from the late nineteenth century up to World War I) were carried out in the natural history style. Nonliterate cultures were studied by collecting cultural items, and describing and classifying them according to the taxonomy of the collector. The third phase was anthropological, and lasted more or less unchallenged from about 1920 to about 1960 (the time of political independence from European colonial rule). It was devoted to the idea of cultures as coherent systems of thought and representation, where all the elements of

the life ways of a community (judged either by their common language or common membership in a political community) could be related to each other. The fourth and present phase (from about 1960 and continuing) illuminates cultural themes and techniques by drawing on the classic and modern humanities. Here culture is seen from within, as a field of imagination and debate. There have been major achievements in all four phases, each of which has posed key questions for comparative knowledge, general theory, and public debate.

2. Phases in African Cultural Studies

2.1 Missionary Understandings and Older Sources

The idea that Africa and Europe 'framed' the human experience—initiated and culminated it, expressed two ends of a spectrum of biological and cultural experience—predates the disciplinary study of the continent and has been extremely persistent in Western thought. Evidence about Africa from before the nineteenth century is both sparse and problematic. Nevertheless, these sources set agendas. Writings from that period, by Europeans in their own languages, are now seen as having 'invented' (Mudimbe 1988) an Africa that is fundamentally contrastive with the West. This conceptualization still informs the general Western lexicon about Africa, but it has been repeatedly challenged by scholars.

African philosophers and scholars outside of the European mainstream have insisted on a return to older sources, to question the basis for the contrastive model. Most prominent has been the Senegalese thinker Diop (1955), who argued for the Egyptian origins, pan-African connections and historical unity of African cultures, as against a 'primitive' and racialized conception. Painstaking scholarship in several disciplines continues, linking evidence from the old sources to new findings on, for example, the long history of urban cultures, monies, and trade, and the use of Arabic script. Archaeology and paleontology examine yet earlier traces of cultural life, not only through fossil remains (for the very distant past) but also in rock paintings, house and burial sites, the remains of iron and copper works, and so on.

It was, however, the prevailing contrastive model that was pushed in new directions by the first disciplinary scholarship about African culture.

2.2 Culture and Natural History

A passion for creating encompassing classifications of all of life gained momentum in European intellectual circles during the nineteenth century. Other cultures and their attributes were seen as part of the phenomenal world, to be treated similarly to other life forms. The actual process of collecting involved human and political encounters of a depth, complexity, and problematic nature that is still being studied (Fabian 2000). Some objects were seized during the punitive expeditions of colonial conquest from the 1880s until about 1910; some were accumulated during Christian conversion and the outlawing of the ritual cycles in which they were used; others were acquired by organized museum expeditions, where the items were bargained over and paid for. Hundreds of thousands of pieces—some of great artistic value in the West and religious value to the populations themselves, and others of technical interest only—arrived by one or other of these routes in American and European museums, where the vast majority remain. Some pieces have been missed gravely; one or two have been returned. To their lasting credit, however, some of the collectors were attuned to the breadth and completeness of their collections and to the originality of the material so that they remain a spectacular resource for scholars from all nations and fields. Some collectors also kept acquisition records, which can still be gleaned for contextual understanding of both the collecting and the objects themselves (Schildkrout and Keim 1998). And a few, such as the missionaries George Schwab (1947) with George Harley, wrote books about the cultural lives of the people who created and used the objects.

The emphasis was on material culture, with some notable photography of items in use and of daily life in general. It would be hard to exaggerate the amount and the variety of the African material culture in Western museums: everything from divination trays to fishtraps, enough spears to arm small militias, carved spoons, blacksmiths' tools, indigenous currencies, cloth, talismans, and 'fetishes.' Culture, in the natural history mode of thinking, was everything that people produced by virtue of learning, from the most intricately symbolic to the most pragmatically functional. The very large number of works that could be classified as 'art' had a further destination than the natural history museum. Some went into an art market that made its own selective choices of value. There are African works from this period that are now considered masterpieces, valued in the hundreds of thousands of dollars. The asymmetric geometry, the nonnatural figurative representations, the brilliant colors, and the general vitality of these pieces were a major influence on modernism in European art. The power of modernism, in turn, fixed these particular pieces in the mind of the public as icons of African aesthetics.

The recognizability of African icons has turned out to be a very mixed legacy because it has made innovation more of a struggle. During the museum era, the icon of African music became drumming, of art became figurative sculpture and especially masks, of architecture became what is still referred to in popular parlance as the 'hut,' of body decoration,

scarification, and so on. The following phase of cultural study involved an effort to break out of this straightjacket, and above all to place the elements back into the context of life-as-lived. Culture was not just a product of learning, but a means of articulating a world view.

2.3 Culture in Anthropology

The era between World War I and political independence, about 1920 to 1960, was the period of effective colonial rule in Africa. During this time, conditions were settled enough for scientists to stay for long phases of their careers, in some places setting up permanent research institutions. By this time, anthropology had become committed to studying societies and cultures as wholes. Where political and cultural lives were lived through oral and performative media, this meant long-term residence with them: to collect the texts, case studies, genealogies, maps, calendrics, and so on from which such an integrated model could be deduced. Political and medical conditions allowed, and intellectual aspirations promoted, the practice of field research, usually carried out for at least a year.

If cultures are conceptualized as integrated wholes then the key to their understanding must be the general concepts that animate and link the separate elements, domains, and performances. So this era of cultural study moved away from the objects, to place greater emphasis on ideas, symbols, and general principles. Particular emphasis was given to the ideas that motivate social life rather than those expressing aesthetic values: the concepts underlying kinship and political identity, religious symbols and practices, and philosophies of the composition of the life-world. In fact, cultural studies in European scholarship about Africa moved away from materiality altogether. The key works were about concepts of causation (Evans-Pritchard's eternal classic entitled *Witchcraft, Oracles and Magic Among the Azande* 1937), symbolic power (Turner 1968), kin relations (Fortes 1945), cosmology (Griaule 1948), and philosophy (Tempels 1946). Scholars of Africa such as Douglas (1966) made major contributions to general culture theory, by linking conceptions of what is pure and what is dangerous to specific ambiguities in social structures. In a sense, this period replaced a notion that African cultural 'genius' lay in the figurative arts with an 'African Genius' (Davidson 1969) that lay in the capacity to organize complex social life without the state domination characteristic of Europe. African cultural studies illuminated the study of society in general.

2.4 Culture Today

The rebellion against this approach, both within anthropology and beyond, was a rejection of the implication that any cultures could be studied as if they were 'traditional,' in the sense of closed, unchanging, and unchallenged from within. The arts resumed center-stage, not as iconic objects but as active creativity: emergent novelty, specific authorship, audience reception, and constant revision and re-creation. This was culture as a field of imagination and its students included its creators: the new novelists and artists of independent Africa, commenting on the present. The humanities became prominent again. Greenberg (1972) suggested a highly persuasive language classification, which changed the history of the modern peopling of the continent. Vansina (1961) innovated in historiography by promoting oral history, which helped to open up a new effort on orature in general. Scholars of their own languages, such as Abimbola (1976) of Yoruba and Kunene (1979) of Zulu, worked on their own language creativity. Novelists, poets, and film-makers—such as Achebe (1958), Soyinka (1964), and Sembene (1960)—used modern media to express the challenges of modernity as well as writing very influential critical works about culture and national life. New popular art forms such as juju and highlife music, the Yoruba traveling theater, textile fashion, and hair-dressing animated local engagement with the future and became subjects of study in the academy. Hountondji's (1977) attack on 'ethno-philosophy' both opened a new era of African philosophy and symbolized the break in cultural studies from the community-based traditionality of earlier anthropology. The center of gravity moved away from communities and towards the study of expertise and innovation.

In the 1990s, the cultural scene in Africa is yet more diverse, including new architecture, jazz, video, and new versions of Christian thought and expression. The vast African diasporas in the Americas and elsewhere, from both the era of the slave trade and recent global mobility, are now considered to be part of an African cultural ecumene. In turn, African history is being revisited to show how long and how widely Africa has been connected to the rest of the world, with lasting effects on many aspects of life—from cultigens to religious expression (Blier 1995)—that were once thought to express the very 'nature' of Africanity. These social geographical observations are matched by a new appreciation of the openness of cultures within Africa to novelty and originality, whether developed from within or borrowed from without. In a world era when dynamism is in full play, amongst ordinary people as well as cultural elites, this makes the study of Africa's long history, popular ebullience, and varied multiplicity the unique contribution of African Studies to the study of culture: to an understanding of cultural hybridity, memory, and power.

Diaspora Studies have been pioneered by peoples of African descent: in Brazil, the Caribbean, Europe, and undoubtedly in a growing crescendo elsewhere in the world. The 'retentions' and reconstitutions of African

culture by the continent's descendants who had been utterly stripped of every object, every community relationship, and any common African language during the era of the slave trade has remained a challenge to understanding. Herskovits's (1941) pioneering work in the 1930s stood for a long time at a tangent to cultural scholarship, which remained continent-based. In the 1990s, these themes are being reopened, and in the process African cultural studies are trailblazing in the study of global networks in artistic and intellectual life, and of memory and continuing creativity in diaspora cultures.

African Studies: Environment

The environment, defined as biophysical landscapes and their natural resources (forests, wildlife, grasslands, water, and so on), has always figured prominently in public and scholarly images of Africa (Anderson and Grove 1987). The continent hosts a wealth of the world's biodiversity, especially its share of large mammal and bird species, and has attracted intellectual interest since at least the early nineteenth century. However, with the exception of geography, social science interest in environmental issues in Africa was minimal until the 1970s. The recent concern with environmental issues is motivated by a strong recognition that social and political forces increasingly shape the environment (Little et al. 1987). These complex relationships provide a significant empirical arena ('laboratory') for testing social science theories and methods and define a field that addresses the social and political dimensions of the physical environment. This article summarizes some of the major paradigms and topics that have influenced this field of study.

1. Theories and Approaches

Interest in the social dimensions of the African environment was provoked by a series of environmental events. The first, and perhaps most important, was the Sahelian drought of the early 1970s that instigated cries of environmental degradation and 'desertification.' Considerable doubts about whether or not desertification actually existed were voiced almost immediately, and picked up considerable momentum in the 1980s when the results of several long-term studies became available. Other events, such as the Ethiopian droughts and famines of 1971–1974 and

1984, conflicts surrounding the management of the continent's major river basins (Waterbury 1979), and West African deforestation evoked concerns of environmental catastrophes and resulted in simplistic causal statements about their origins. As early as the 1970s, social scientists were skeptical about many of the explanations for environmental degradation in Africa. Perhaps the most publicized of the social science debates concerned land tenure and the extent to which common or communal property ownership, a prevalent form of tenure in Africa, fosters natural resource abuse. Characterizing certain situations as a so-called tragedy of the commons, some researchers speculated that much of the degradation in Africa's dry regions results from the contradictions inherent when animals are owned privately, but land and other resources are held in common (see Anderson and Grove 1987). While the evidence against a tragedy of the commons is overwhelming, the position still has support among certain scholars and policymakers and still underlies current debates about land reform in Africa.

The complexity of recent environmental events challenges social scientists to rethink their methods and theories. During the 1980s and 1990s, interdisciplinary research programs on land use and environmental change in Sub-Saharan Africa continued to increase in number. Empirical findings from this collective work challenged orthodox assumptions about the relationship between population growth and environmental change, the resilience of African ecologies, and the capacity of local institutions to regulate resource use. They also pointed to concerns about the fundamental politics of natural resource use, an issue that had emerged in the early 1980s. In terms of theory, two broad bodies of work became especially appealing to social scientists and to a small number of ecologists. These are the 'ecology of disequilibrium' and the 'political ecology' approaches.

Recent theoretical advances in the 'ecology of disequilibrium (disturbance)' school are relevant to understandings of the complex relationships between human agency and African habitats. For example, the dryer portions of the African continent, including savannas, are subject to large rainfall fluctuations and sustained droughts (disequilibrium) from one year to the next. Climatic data collected since the 1980s reveal that many ecosystems of Africa are inherently unstable and, therefore, attempts to adjust conditions to some notion of stability violate the natural order and in themselves are destabilizing. Because of the higher variability of African ecosystems, many of the ecological concepts developed in the temperate zones (USA and Europe) fail to explain the dynamics of these highly variable ecosystems. Ecologists in Africa and Australia have designated these highly variable environments as disequilibrium ecosystems to distinguish them from ecosystems where climate patterns are generally reliable enough for resident plant and animal populations to reach some sort of equilibrium (Behnke et al. 1993). Most plans for preserving biodiversity in Africa (for example, national parks and biosphere reserves), however, are still based on equilibrium theory and invoke notions of carrying capacity and average stocking rates to preserve an 'undisturbed wilderness.'

Recent theoretical advances in the ecology of disequilibrium school are relevant to understandings of the complex relationships between politics, human agency, and African habitats. The approach is also more consistent with indigenous models of the African environment, which have never excluded anthropogenic disturbances nor pursued ecological equilibrium as an objective. For example, herd management strategies of East African pastoralists—which have always been the bane of conservationists—assume drought, some degree of range degradation, and fire (burning) as norms, and have never tried to pursue ideas of carrying capacity or equilibrium.

The political ecology approach, in turn, is relevant to this discussion; indeed, often the same Africanist social scientists have intellectual stakes in both schools (for example, Bassett, Behnke, Horowitz, Leach, Scoones, and Swift). Political ecology can be a useful framework for weaving together different disciplines and has contributed considerably toward understandings of the social and political processes underlying resource use in Africa and elsewhere. There are three elements that define political ecology: resource access, resource management, and ecological impacts. Political ecology starts with the political question of access to resources, but also addresses how resources are managed and the environmental effects of this. Particular areas of political ecology research in Africa include studies of: (1) forestry (Fairhead and Leach 1996); (2) wildlife conservation (Neumann 1998); and (3) pastoralism (Little 1992).

2. *Other Topics of Research*

Social science research on the African environment covers a range of significant topics, some of which have been discussed earlier: colonial history, land tenure, and pastoralism. While it is not possible to cover the breadth of research issues, there are at least four themes that require special attention.

2.1 *Gender and the Environment*

Recent studies highlight the gendered nature of the environment, whereby resources and their value are perceived differently along gender lines (Moore and Vaughan 1994). The increased dependence on wage labor markets in Africa creates additional pressures for women. They have been compelled to absorb tasks normally carried out by men, many of whom have

migrated to towns and other areas of employment. The increased workload of females in agrarian economies is at least partially a response to this loss of labor. As Sperling (1987, p. 179) shows for the Samburu pastoralists of northern Kenya, 'Male emigration intensifies the female workload … They become more directly involved in many aspects of herd care, such as fencing, watering, curative regimes, and forage collection.' These additional demands, however, are not always accepted passively. In some areas, pastoral women have refused to contribute to certain tasks (e.g., moving animals to remote pastures) that require excessive labor beyond their already heavy burdens and long absences.

Women of poor households are most seriously impacted by labor shortages and the environmental problems that ensue. Not only do they absorb additional tasks, but because of the localized degradation resulting from decreased mobility, they must search further from their homes for firewood and other natural products (e.g., wild plants) required for cooking and other domestic chores. Anthropological studies in northern Kenya estimate that because of sedentarization by pastoral groups, some women now allocate considerably more labor for collecting fuel wood than in the past (Ensminger 1987).

Very little is known about how environmental degradation in Africa is perceived by different gender groups or how their perceptions are translated into action. For example, a woman may define degradation by declining yields from dairy herds since women often control income from milk sales, or by the amount of time spent in collecting fuel wood. A male, in turn, who might control income from tree crops, may define environmental degradation in terms of how it affects coffee or tea production. Recent efforts highlight the importance of incorporating political ecology into feminist research on the African environment (Rocheleau et al. 1996). By making this linkage it is possible to show how resource access by women is shaped by power relations and policies that often disadvantage them, and force them on to marginal lands where their only option may be overexploiting the environment. The emergence of women-led environmental groups as significant political forces, such as the Green Belt Movement in Kenya, demonstrates the ways in which gender meshes with politics and environmental concerns.

2.2 Indigenous Environmental Knowledge

African farmers and herders control a wealth of sophisticated knowledge about the environment. Studies by anthropologists throughout Africa highlight the importance of understanding how local knowledge systems affect the use of environmental resources. These systems are expressed through elaborate local terminologies and classification systems, which rarely are acknowledged by governments and policy makers. Instead, outside agencies and development 'experts' often advocate new technologies and practices that may actually contradict or conflict with these local knowledge systems. Social science research in this area has emphasized the documentation of local vegetation and resources, local environmental practices, and the development potential of indigenous knowledge. As indicated earlier, these knowledge systems can have important gender components.

A few examples from Kenya demonstrate the critical role of local knowledge systems and practices in natural resource use. In the Baringo area of Kenya, for instance, many community-based irrigation schemes have achieved considerable success in a region noted for land degradation and food shortages; and where large-scale irrigation systems have failed miserably (Little 1992). Based on local councils of elders (*lamaal*), low-cost irrigation systems have been developed that conserve the fragile soils and transport water through intricate canal systems over kilometers of dry barren lands. Land and water disputes are resolved locally and, unlike neighboring villages, food-aid distribution is minimal in these areas. Because local irrigators maintain trees in their fields and do not drain or extend irrigation into local wetlands, they help to maintain some of the richest diversity of bird populations in East Africa (in excess of 700 species in an area of less than 70 square kilometers). By contrast, the mechanized, clear-cutting techniques of large-scale, government irrigation projects in the area threaten this rich diversity by transforming valuable habitats.

In the nearby Kerio Valley of northern Kenya, irrigation is managed on the basis of clans, and in some cases sub-clans. As Soper (1983, p. 91) notes, 'the water ownership unit is the clan section or, in some cases, sub-section, which is also the land-holding and the basic residential unit.' A clan or a group of clans will own a particular furrow, which they are responsible for managing and maintaining. Water from the furrows is allocated on a rotating basis to members of the clan, usually based on a 12-hour watering unit or fractions of the unit. Most agriculturalists who have surveyed the furrow system note its efficiency in conserving water and soil. They also indicate the community's commitment to maintaining it. In an area that is prone to drought and environmental problems, the system stands as a notable achievement.

2.3 Environmental 'Narratives'

Important environmental work in Africa is currently focused on how particular narratives or discourses emerge, are 'scientifically legitimized,' and are then incorporated into environmental policies. Both Fairhead's and Leach's (1996) work on deforestation in West Africa and Tiffen et al.'s (1994) treatise on soil erosion in East Africa skilfully show how flawed assumptions about population growth, local practices, and environmental degradation stem from a set of

narratives dating back to the early colonial period. These discourses, however, are still reflected in environmental policies that shape the ways in which Africans interact with their habitats.

The debate about desertification in Africa represents another environmental narrative that dates back to the colonial period but has contemporary implications. An entire book easily could be devoted to how the desertification debate was constructed, how political and institutional factors contributed to its production and reproduction, and how 'science' was invoked to justify the excessive funds and projects allocated to such an elusive issue. Concerns about this phenomenon stem from the 1930s when colonial officers pointed to the creeping deserts of West Africa and to the terrible dust storms of East Africa. The colonial soil erosion and conservation campaigns of the 1930s, a favorite theme of Africanist historians, stemmed in part from official beliefs in the desertification narrative. In the post-colonial period, elaborate sets of projects and techniques were established to measure desertification, even though climatic and aerial photos showed that the extent of the Sahara's advance had been greatly exaggerated. Similar to other narratives about environmental degradation in Africa, the 'scientific' arguments about desertification and its causes are reinforced by environmental policies, often supported by outside agencies, which blame human agency for environmental problems. Fortunately, there is a growing body of social science wisdom in Africa that challenges these truisms, as well as defines an important area of social science research.

2.4 Environment and Development

The relationship between economic development and a sustainable environment is among the most important research issues in Africa today. Questions of food security, sustainable development, and environmental welfare are imbedded in this topic. However, the tension between strategies for increasing rural incomes and development in Africa and for preserving the natural resource base remains unresolved; nor is there a good consensus on how to measure and monitor these processes. Most social scientists acknowledge the overwhelming importance that local economic incentives and benefits assume in conservation efforts in Africa, but most have not been successful in documenting the social and economic variables that facilitate effective environmental programs.

Recently, development practitioners have emphasized local participation as a possible means for achieving environmental goals, especially in villages surrounding important parks and protected areas. While it is difficult to achieve meaningful local participation in development activities, the challenges are even greater when environmental goals are pursued. Social science research shows how the recent emphases on local participation and community-based conservation are a reaction to earlier, highly centralized programs. The case of national parks, backed by restrictive legislation and heavy-handed sanctions that carved out large chunks of indigenous lands without local involvement, are classic examples of the earlier approach. This top-down approach to conservation was especially characteristic of many wildlife and forestry departments in colonial Africa.

The reality that biodiversity programs could not be limited to national parks because of migratory animal species also provoked a concern with community conservation programs. A proliferation of such activities was initiated in the 1980s and 1990s by many of the major international environmental organizations (for example, the World Wildlife Fund (WWF) and the International Union for the Conservation of Nature (IUCN)).

What has social science research in Africa told us about the relationships between development and environmental conservation? First, it has shown that local participation and conservation cannot be delinked from development concerns if environmental programs are to be sustainable. The CAMPFIRE (Communal Areas Management Programme for Indigenous Resources) program of Zimbabwe is a good example of a community conservation program with a biodiversity goal that also has a development outcome. In the CAMPFIRE effort, the local community participated in the identification of the conservation problem—in this case, better management and regulation of wildlife resources (Metcalfe 1994). Although international and national organizations were instrumental in heightening local awareness of conservation problems, the communities themselves saw the linkages between economic benefits and sustainable management of wildlife. The CAMPFIRE program was first initiated in a very poor region of Zimbabwe, and it took on the appearance of a rural development rather than a conservation project. This effort contrasts sharply with other wildlife/park schemes in Africa where wildlife conservation—as defined by external parties—has been the overriding objective, and local populations have been alienated. The Zimbabwe case, however, has proven to be a better model for promoting wildlife conservation, and has not confronted many of the social problems and conflicts that have marred wildlife conservation in Africa (Anderson and Grove 1987). In Zimbabwe, low-income producers saw the economic benefits that could accrue from tourism and hunting, while recognizing the threat that poaching posed to these activities. While there are still massive poaching problems in eastern and southern Africa, the CAMPFIRE approach demonstrates that community participation can slow down rates of resource depletion.

Other studies of environment and development in Africa point to the importance of national and

international political processes, including a renewed interest in the management of Africa's major waterways. Research shows that macro processes affecting access to natural resources vary considerably among different African countries, reflecting the varied political structures and leadership of different states. In addition, the extent to which particular states allow sufficient political space for local participation will also vary by country. With widespread political changes and turbulence in Africa, a future area for research will address the effects of collapsed states and liberation movements on natural resources and the environment (Salih 1999). In those few instances where strong states exist, however, the national political structure may prove more significant than any other variable in determining local participation. Some successful local conservation programs in Kenya and Uganda have taken place without conducive policy environments and without large amounts of external funding. In the well-documented Machakos case (Kenya), for example, local households and communities have responded to land shortages and severe soil erosion by shortening fallow periods and improving the quality and maintenance of hillside terraces (Tiffen et al. 1994). While the macro political environment has not been particularly conducive to local participation, population and land pressures motivated local communities to address environmental problems. More cases like this need to be documented by social scientists and their results disseminated to policy makers.

To conclude, environmental issues will increasingly shape social science research agendas in Africa during the twenty-first century. Scholars will be challenged even more to confront flawed and overly simplistic interpretations of ecological problems on the continent. Pressing needs to sustain adequate food production and incomes without degrading natural resources will also occupy farmers, herders, and governments, while opening space for innovative interdisciplinary programs that actively engage policy and policy makers. The success of these initiatives during the next decade will cast the critical intellectual questions about the environment, as well as contribute to improved local livelihoods.

African Studies: Geography

1. Geography

Geography is an integrative discipline that studies the location of phenomena on the earth's surface and the reasons for their location. Most people think that geography consists of memorizing countries and their capitals, or photographic essays of exotic places in popular magazines. However, these are only a small part of contemporary geography. Within the past 30 years the discipline of geography has undergone an unparalleled technological revolution in the spatial analysis of data. First, the personal computer has

greatly enhanced measurement technologies including remote sensing and global positioning systems, which have rapidly expanded the quantity and types of spatially referenced data about the human habitat and the physical environment. Second, the development of computer-based Geographical Information Systems (GIS) has greatly facilitated the ingestion, management, and analysis of the rapidly increasing spatially referenced data. This has allowed geographers to evaluate spatial processes and patterns, and to display the results and products of such analyses at the touch of a button. The word geography was coined by the ancient scholar Eratosthenes based on two Greek words, *geo*—meaning 'Earth,'—and *-graphy*—meaning 'to write.' Geographers ask three basic questions, where do people and environments occur on the Earth's surface? Why are they located in particular places? What are the underlying explanatory factors for the spatial patterns? This entry briefly reviews how geographers have studied the continent of Africa with reference to the past 30 years.

2. Geographic Approaches on Africa

During the 1970s and 1980s research on Africa dwelt on the many crises. While Africa has had its fair share of problems such as the collapse of the state in Sierra Leone, Liberia, Somalia, Rwanda, Zaire, Burundi and a few others, and economic shocks engendered by the continuing failure of structural adjustment programs, the 1990s witnessed momentous positive changes. For example, South Africa experienced remarkable and unprecedented social and political change and moved toward majority rule faster than previously anticipated. Dictatorial regimes in Zaire, Malawi, and Zambia as well as elsewhere in Africa crumbled and were replaced by emerging democratic systems. Gratifyingly, geographical research on Africa in the 1990s began to move away from sensationalism and over-generalization to more pragmatic and pertinent micro-level perspectives that reflected the diversity and richness of the African continent. In contrast to the gloom and doom of the 1970s and 1980s, some scholars have begun to highlight some of the positive new developments.

Most geographic work in the 1970s and 1980s concentrated on regional geography with an emphasis on country surveys, descriptions and compilation of geographic data at country or regional level. The late 1980s and 1990s saw the rise of new paradigms in the study of African geography. While the empirical subject matter may be agriculture, health, gender issues, development, etc., the theoretical paradigm guiding the geographic research during the 1990s was often about issues such as representation, discourse, resistance, and indigenous development within broader frameworks influenced by the ideas of prominent social science scholars such as Foucault (1977), Said (1978), and Sen (1981). Broadly speaking, the works fall into the three main subdisciplines of geography, namely, human geography (by far the most dominant), physical geography, now commonly referred to as earth systems science and/or global change studies, and geographic information systems (GIS). Within these three main sub-disciplines, various theoretical perspectives overlap to characterize the growing body of research by geographers on Africa.

During the 1990s geographers came to realize that the rapid and complex changes that Africa was undergoing could not be adequately explained by the conventional narrowly focused disciplinary perspectives and approaches. Geographers embraced and, in some cases, devised more complex and integrated interdisciplinary approaches. The most important of these transitions or developments in African geographical research during the 1990s include: (a) post colonial–poststructuralist–postmodern approaches; (b) political ecology championed by the works of Blaikie and Brookfield (1987); (c) Boserupian perspectives on population and environment promoted by the hotly debated book by Tiffen et al. (1994); (d) challenging environmental orthodoxies, particularly a reassessment of 'taken-for-granted' ideas about the environment championed by Fairhead and Leach (1996); (e) development from below/grassroots initiatives; (f) recognition of the importance of indigenous knowledge; (g) the impact of globalization on economic development particularly in agriculture and industrial restructuring; (h) policy-oriented studies; (i) social geographies pertaining to gender and other issues; and (j) global environmental change research involving climatologists, geomorphologists, hydrologists and biogeographers using an integrative–systems framework. The following two sections briefly highlight some of the major areas of research by geographers working on Africa.

3. Human Geography

In the subdiscipline of human geography, a number of research themes were explored by geographers. These include population, resources and the environment, population dynamics, development discourse, policy-oriented or impact-analysis studies, urban and regional development, and the geography of disease and healthcare. Theoretical orientations included the Boserupian perspective, political ecology, political economy, post-colonialism, post-structural, feminist perspectives, sustainable–green development approaches, globalization, disease ecology, and location–allocation models. For example, research on population issues moved away from neo-Malthusian approaches. Couched within the Malthusian tradition, it was commonplace for analyses of Africa over the 1980s to bemoan the combination of rapid population growth and economic and environmental decline.

Indeed, many geographers continue to be convinced that ecological degradation is a human-induced problem with a strong element of neo-Malthusian thinking. However, recent works have moved away from the neo-Malthusian trap and have concentrated on exploring the role of population growth on agrarian transformation, the role of land tenure in agrarian change, farmer–pastoral conflicts, the environment, and issues of gender and resource contestation. This literature stresses the good aspects of increasing population densities with respect to agricultural transformation. Perhaps the most influential work in the Boserupian tradition is by Tiffen et al. (1994). Their work argues that even as population densities have increased, agropastoral productivities have increased and a degraded landscape has flourished with trees, terraces, and productive farms.

The debates on indigenous land tenure systems versus privatization intensified during the 1990s. Several works questioned the traditional thought that indigenous tenure systems are an obstacle to increasing agricultural productivity. Fairhead and Leach (1996) challenge 100 years of received wisdom on the degradation of the African environment and their numerous works continue to dramatically influence 'environment' research in geography with reference to Africa. Little and Watts (1994) examine the impact of globalization on agrarian change in Africa under the rubric of contract farming. The book focuses on the genesis, growth, and form of contract farming in sub-Saharan Africa. In many geographic works that use the political economy, political ecology and liberation ecology frameworks have tackled the perplexing issues of multinational corporations versus local resources, common property rights and indigenous knowledge, land for agricultural extensification versus wildlife conservation, and afforestation–deforestation issues. The rise of post-structuralist, post-colonial, post-modern, and feminist critiques of development discourse has spawned an interesting set of case studies that examine the complex intersections among gender, agrarian change, environmental discourse, access to resources, and indigenous knowledge. Other scholars have explored the role of women in development and the changing conditions of women in rural and urban Africa.

Geographers have also been prominent in development discourse, a term which refers to the language, words, and images used by development experts in development texts to construct the world in a way that legitimates their intervention in the name of development. Geographers have contributed significantly in critiquing development discourse, particularly its characteristic language of crisis and disintegration, which gives justification for intervention. The works which critique this approach arose out of old suspicion of a hidden agenda behind the introduction and abandonment of development strategies in Africa, as well as the perpetuation of development strategies and notions that are detrimental to Africa's development, particularly structural adjustment programs. A number of influential books have fruitfully engaged and critiqued this perspective (see, for example, Corbridge 1995, Godlewska and Smith 1994). An important issue raised in some of the articles contained in these volumes and others is the persistent (mis)representation of development and of Africa itself. For example, a chapter in Godlewska and Smith's (1994) offers a critique of images in the *National Geographic* as the complicity of geography as a discipline in perpetuating colonial and post-colonial myth-making about Africa and about development.

During the 1990s, scholars from North America, Africa, and Europe collaborated to examine issues concerning urban development, industrial restructuring, the informal sector, labor, and regional development, with particular focus to the South African transition. Many geographers have been grappling with the question of what does a post-apartheid geography of this country and the southern African region look like. Thus geographers working on this issue have examined it from many perspectives, particularly the (dis)continuities between the geographies of apartheid and post-apartheid in the social and economic realms which shaped South Africa's economy, cities, and social relations under apartheid, and continue to do so in the post-apartheid era.

Medical geography research on Africa continued along the traditional lines of disease ecology and geography of health care with a clear trend toward linking health with its political and economic context. A number of scholars continued work in disease ecology focusing on specific diseases such as filariasis (elephantiasis) and dracunculiasis (guinea worm). Geographers, using a political economy or structuralist theoretical perspectives have examined the diffusion of HIV–AIDS pandemic and have typically recommended education with empowerment arguing against intervention strategies that ignore poverty.

4. *Global Change and Earth Systems Science*

This is an area in which an old disciplinary category is becoming obsolete as physical geographers increasingly refer to their subject matter as earth systems science or global change instead of physical geography. Physical geographers are examining the causes and impacts of climate change in the Sahel, rainfall patterns, and El Niño effects in Africa. Some of their work challenges conventional wisdom that the Sahara desert is expanding at a phenomenal rate. Instead they demonstrate that there has been no progressive change of either the Saharan boundary or vegetation cover in the Sahel during the last 16 years, nor has there been a systematic reduction of 'productivity' as assessed by the water-use efficiency of the vegetation cover. Some areas of study include sand transport and dune

formation, desert landscapes, soil degradation, and river morphology.

European geographers, particularly British and African geo-scientists, have been extremely active in conducting research broadly defined as physical geography. There are many hydrologists and ecologists studying wetland ecology–hydrology. The Cambridge group led by Grove and Adams is very active in examining the multifaceted physical geography processes on the African continent. Their recent book (Adams et al. 1996) is a testament to their productivity. In this book, the authors weave together biophysical and human induced processes and recognize the multitude of environmental conditions at the local, regional, and continent-wide scales. The work contains detailed discussions of the physical geography of Africa, the geomorphologic and biogeographical aspects of the continent, and the impact of human agency on African environments.

There is a tremendous amount of work on the African physical environment by geo-scientists. Geographers have had a significant role to play in this work, although this work is often 'hidden' in non-geographical journals and multidisciplinary team projects. The emerging idea of earth systems science as an integrative science has made the old-fashioned term 'physical geography' obsolete so that people who used to call themselves physical geographers are now able to cross traditional disciplinary boundaries with ease. One important development is the growing importance of remote sensing and geographic information systems (GIS) as a research tool, as well as the importance of large-scale modeling to generate global climatic models. These techniques have grown in their importance as tools for studying environmental change on the continent. Many geographic studies of Africa use these tools. Such tools have made it possible to monitor and analyze variations in, for example, grazing intensity associated with rural land practices. Other studies have used satellite imagery to study short- and long-term variability in climate within Southern Africa by determining trends in variability of vegetation greenness for evidence of climatic trends.

5. *Conclusion*

Geographic research on Africa is multifaceted and interdisciplinary in its methodological and theoretical approaches. Within the past 30 years the discipline has embraced or devised new approaches in its study of the continent. The bulk of the work has been on human geography. A number of insufficiently developed substantive areas include physical geography (geomorphology and biogeography), historical cartography, political and cultural geography, and regional geography. However, several excellent and comprehensive textbooks that address these underdeveloped areas, particularly cultural and regional geography, seem to have bridged the gap. Some of these books do an excellent job of putting together the regional geography of Africa in a systematic fashion with a coherent thematic interpretation of the regional, cultural, and development status of the continent.

One important neglected area by human geographers is the political and electoral geography of the continent. Transitions such as democratization in quite a few countries and the collapse of organized authority in others (Liberia, Somalia, Democratic Republic of the Congo, Rwanda, etc.) have received precious little in the way of attention by geographers. Another neglected area by geographers is that of population geography. Perhaps due to overreaction against the neo-Malthusian debacle, demographic factors have been completely ignored in recent research. Indeed, the major weakness of the literature that uses political ecology as its guiding framework is its muteness on dynamics of population change and demographic factors. It is apparent in reading this body of work that most of the authors, constrained by the political economy and political ecology frameworks, ignore population in their analyses. However, it should be obvious that excluding demographic factors in these important debates may result in shortsighted policy formulations.

In conclusion, the rich geographic literature on Africa reveals the adoption of newer methodological and theoretical perspectives during the late 1980s and 1990s. For example, several prominent geographers embraced and/or helped to advance the post colonial–post structuralist studies of representation and resistance and critiques of development discourse. As we move into the twenty-first century, we predict that geographical research on Africa will intensify the adoption of these newer interdisciplinary approaches, and perhaps, develop new ones in the process of discarding old and static methodologies.

African Studies: Health

Health has been defined by the World Health Organization as a condition of complete physical and psychological wellbeing. In common usage the term 'good health' is employed to mean that there is present no major manifestation of ill-health, and this is also the most satisfactory way of scientifically determining the situation. The most clearly defined outcome of ill-health (or morbidity) is death (or mortality) because it can be most certainly defined and measured, and because in its irreversibility it is an index of the most extreme ill-health. This entry will focus on mainland sub-Saharan Africa plus the large island nation, Madagascar, omitting the smaller islands of the Indian and Atlantic oceans with their mixed historical, ethnic, and cultural backgrounds. All of these have lower mortality than any mainland African country and most are richer. The advances in health research since the mid-twentieth century are outlined.

1. *Researching Africa's Health Levels*

At mid-twentieth century sub-Saharan Africa was assumed to be the unhealthiest region in the world, in spite of an almost complete lack of data to confirm this view. That confirmation was to be achieved later by reconstructing the situation with data from subsequent research, which showed that as late as 1950–5 the region was characterized by a life expectancy at birth of only 37 years (United Nations Population Division 1999). The problem in making such estimates was a complete lack of vital registration, and of usable mortality and morbidity information in censuses and demographic surveys. Comprehensive national counts of deaths or illness are still not available anywhere in the region.

This problem of inadequate data has been overcome in three ways:

(a) The so-called 'indirect methods' of estimating mortality (and fertility) levels from inadequate data have been invented by William Brass and colleagues associated in later years with the London School of Hygiene and Tropical Medicine, while the stable and quasi-stable population model approach was developed by Ansley Coale and colleagues at the Office of Population Research, Princeton University. At first the 'Brass' methods provided estimates only of child mortality, but later techniques were developed for adult mortality, although the latter results were usually less secure.

(b) Censuses and national sample surveys with questions allowing indirect or even direct estimates of vital rates were developed. The first censuses with questions on births and deaths were those in British East Africa in 1948. From the 1960 census round, the United Nations assisted African censuses. From 1954, demographic sample surveys were conducted in most francophone African countries. Subsequently, many African countries participated in the great international survey programs: the World Fertility Survey (WFS) (which contained mortality questions) from 1975 and its successor, the Demographic and Health Surveys (DHS) from 1985. Nevertheless, by the year 2000 there still had been no adequate censuses or surveys of the Congo (Democratic Republic) or Angola, and only preliminary reports had been issued for the DHS surveys of South Africa and Ethiopia.

(c) High-intensity surveillance projects had been established in a range of areas. These provided demographic and health information and were often the sites for intervention projects. They included largely demographic projects such as the Sine-Saloum (1962–6) and later studies in Senegal, and those with greater attempts to investigate health: Pare-Taveta, Kenya and Tanzania (1954–6), Keneba, Gambia (1956 onward), Danfa, Ghana (1969–74), Malumfashi, northern Nigeria (1974–9), Machakos, Kenya (1974–81), Kilombera, Tanzania (1982–8) and Navrongo, Ghana (1993 onward). All programs measured health, mostly by mortality or survival measures, and all involved collaboration between African and outside institutions. African demographic estimation was the most challenging in the world, and the new techniques developed to meet that challenge were employed subsequently in other parts of the developing world and by historical demographers.

The data released from these investigations were employed by a succession of research programs:

(a) The African project of Princeton's Office of Population Research analyzed the results from predominantly francophone African demographic surveys and anglophone African censuses from 1961, and published *The Demography of Tropical Africa* in 1968. Its major contribution was its fertility estimates, and those on mortality were largely confined to infancy.

(b) The International Union for the Scientific Study of Population (IUSSP) in the mid-1980s commissioned papers on African mortality change for a 1987 conference and published *Mortality and Society in Sub-Saharan Africa* in 1992.

(c) The American National Research Council's Committee on Population established a program on the population dynamics of sub-Saharan Africa in 1989 and published *Demographic Change in Sub-Saharan Africa* and five other volumes in 1993.

(d) From the late 1980s the World Bank commissioned studies of the health of sub-Saharan Africa and in 1991 published *Disease and Mortality in Sub-Saharan Africa*. The first part of the book was constituted by studies of child and adult mortality and child malnutrition drawn from WFS and DHS data, the second part by studies of specific ailments from miscellaneous sources, and the third part by reports on morbidity and mortality from the various surveillance projects.

(e) A collaborative analytical program of persons working in African universities and institutions on West and Middle Africa resulted in 1975 in the publication of *Population Growth and Socioeconomic Change in West Africa*. In it, Cantrelle developed his thesis on tropical mortality (discussed below).

Some African research themes have a strong behavioral component. Studies of the impact of parental education, especially maternal education on child survival began in the region (Orubuloye and Caldwell 1975, Caldwell 1979, Farah and Preston 1982), and have since become numerous elsewhere. The AIDS epidemic has brought demographers and other social scientists to the study both of AIDS mortality and of sexual relations and other aspects of HIV transmission (Cleland and Way 1994, Awusabo-Asare et al. 1997).

Health in sub-Saharan Africa has not been a major feature of social science literature, probably because the data have been elusive and difficult to interpret. It has constituted 7.8 percent of all articles in *Social Science and Medicine*, 2.5 percent in *Population and Development Review* and, except for anthropological accounts of traditional healing practices, none in *Africa*. The latter point underscores the fact that the major social science input into African health research has been by demographers. Biomedical researchers have undertaken research on specific diseases. The balance of this article summarizes what the research reveals about African health.

2. The Health Situation

The first reliable estimates of sub-Saharan mortality were for the late 1940s and early 1950s, and were for infants, and then young children, made by adjusting mothers' reports of their children's deaths. These revealed infant mortality rates (deaths per 1000 births during the first year of life) ranging in most of francophone Africa between 200 and 275 (and probably equivalent to life expectancies ranging from 25 to 35 years). At the district level, Mopti in Mali and Luanda in Angola recorded infant mortality rates of 350 and 329, respectively, showing that one-third of all births resulted in deaths during the first year of life. In contrast, Kenya recorded an infant mortality rate of only 132 (a life expectancy around 45 years) and two of its districts, Central and Rift Valley Provinces, registered rates under 100. Subsequent studies increasingly involving life histories, many summarized by Althea Hill, showed infant and child survival improving nearly everywhere until at least the 1980s. West African mortality was higher than that of East and Southern Africa, but convergence was taking place. As appropriate questions were added to surveys, advances were also made in the study of adult mortality, which fell consistently until the 1980s. Thereafter, the decline became much slower in West Africa, and halted or reversed in East and Southern Africa (Timaeus 1999).

At the end of the twentieth century (1999) sub-Saharan Africa's life expectancy was 49 years, with male expectancy around 48 years and female 50 years. This compared with 61 years in South Asia, 64 years in North Africa, 65 years in Southeast Asia, 69 years in Latin America, 72 years in East Asia, 73 years in Southwest Asia, and 75 years in industrialized countries. With 9 percent of sub-Saharan African babies dying in the first year of life, and 15 percent in the first five years, the region's infant and child mortality was also the world's highest. Sub-Saharan Africa's life expectancy compares with that in Western Europe at the beginning of the twentieth century, suggesting a health lag of about 100 years. Within sub-Saharan Africa, Southern Africa recorded a life expectancy of 56 years, West Africa 52 years, Central Africa 49 years, and East Africa 44 years, the latter's poor performance being a recent product of the AIDS epidemic. National levels ranged from 55 or more years in Ghana, Liberia, South Africa, and Cameroon to 42 years or less in Malawi, Swaziland, Botswana, Zimbabwe, Niger, and Ethiopia. Such low levels as those for the last-mentioned countries are no longer found anywhere else in the world.

2.1 Past Mortality Trends

If tropical African population growth was almost stationary before the European partition of the region in the 1880s, then stable population calculations suggest that life expectancy was around 20 years. Alternatively, if, as has been suggested, the European presence on the coast had allowed the adoption of new foodstuffs permitting the denser settlement of the forest and other wetter lands, thus leading to a population growth rate as high as 0.5 percent per annum, life expectancy may have risen to around 23 years. In any case, mortality was, as traders on the west coast knew, the highest in the world, with malaria, yellow fever and other insect-borne diseases protecting the land from European settlement of the type that had occurred in Latin America. These mortality levels

Table 1
Life expectancy at birth (in years), 1950–2000 and per capita income (in US$), 1997

	Sub-Saharan Africa	North Africa	Asia	South Asia	Latin America	World
1950–55	37	42	41	39	51	46
1960–65	41	46	48	45	57	52
1970–75	45	51	56	50	61	58
1980–85	49	57	60	55	65	61
1990–95	49	62	64	60	68	64
1995–2000	49	65	66	62	69	65
Per capita income 1997	$520	$1160	$2450	$470	$3950	$5170
Adult female literacy 1995	47%	41%	50%	36%	85%	62%

are not much greater than the demographic surveys of the 1950s and early 1960s found persisting in some remote rural areas of the West African savanna.

2.2 The Second Half of the Twentieth Century

Mortality estimates spanning the second half of the twentieth century, constructed by the United Nations Population Division (1999) from the research findings described above, are shown in Table 1. Such estimates can hardly be exact but they are probably reasonably close to the truth. They are compared with estimates for the world and selected other developing regions.

What emerges from Table 1 is that sub-Saharan Africa is a healthier place than it was half a century ago. By the end of the twentieth century its life expectancy was above that of the world as a whole at mid-century, and only a little behind that of Latin America at that time. Nevertheless, it had fallen further behind every other world region. The most appropriate comparison is with south Asia, which has a somewhat lower per capita income than sub-Saharan Africa (and, taking purchasing power into account, a lower per capita parity purchasing power) and a slightly higher level of female literacy. In 45 years, Africa's life expectancy rose by 12 years, compared with 23 years in south Asia.

Table 2 explores the African health failure further. Neither sub-Saharan Africa nor North Africa participated to the same extent as Asia and Latin America in the great leap forward in reducing mortality that characterized much of the world during the two decades following World War II. Nevertheless, sub-Saharan Africa's record in health advancement was moderately successful until the 1980s, but since about 1985 there has been little health advance at all.

The relatively limited sub-Saharan African success in health up until the 1980s can be at least partly explained by the fact that ecological and other conditions meant that it was the only major world region that completely failed to reduce the level of malaria. Since the 1980s two other factors have also been important. The first was a slowdown in economic growth that necessitated the acceptance of 'structural adjustment' policies: in many countries, investment in the health sector almost ceased, and charges for government medical services were instituted. The second factor was the arrival of the AIDS epidemic with an intensity experienced nowhere else in the world.

All parts of sub-Saharan Africa have experienced a deceleration in health improvement, but this has been spread unevenly, as Table 3 shows. The health situation in the region had been described as one improving along a diagonal with the lowest levels in the northwest of West Africa and the highest levels in

Table 3
Life expectancies and average increases for the major regions of Africa, 1950–2000

	Life expectancy at birth (years)				Average annual increase in life expectancy since previous period (years)

Southern and East Africa (see Feachem and Jamison 1991, pp. 31–2). Largely as a result of the AIDS epidemic, this situation has been reversing, and by the 2010s West Africa may have the highest regional life expectancy south of the Sahara.

A very similar experience characterized trends in infant and child mortality rates. Sub-Saharan Africa's infant mortality rate in 1950–5 has been estimated as 176 deaths per 1000 births, with the south Asian rate at 186. By 1995–2000 the sub-Saharan African rate was 93 compared with a south Asian rate of 73. The child mortality rate compared even more badly; in 1995–2000 it was 152 in sub-Saharan Africa (i.e., 15.2 percent of births resulted in a death before five years of age) compared with 96, or less than two-thirds the African level, in south Asia. The explanation is what Cantrelle (1975) called the 'tropical pattern,' and others have termed the 'African pattern.' When Cantrelle was writing, not only was infant mortality in tropical Africa high, but almost as many deaths occurred to each cohort of births between their first and fifth birthdays as during the first year of life. That fraction has now fallen to 63 percent (although it is still 73 percent in West Africa) compared with 32 percent in south Asia. The reasons for very high one-to-four-year-old mortality in tropical Africa are probably the high level of infectious disease affecting that age group, poor weaning practices, and unsatisfactory foods available for weaning.

3. *Why Did Health Improve?*

It seems likely that life expectancy climbed by about 15 years between the 1880s and the early 1950s, and then by another 11 years in the next three decades. The reasons are complex, and the use of modern medicine is only part of the story.

Much of the explanation for mortality decline in the first period was probably the organization brought about by colonial governments. Inter-ethnic and individual violence probably declined. People were separated from others when plague struck, and from wild animals to curb sleeping sickness. Roads and railways helped to usher in a market economy which distributed food, and medicine, more widely. Capitalism and education increased individualism and made it likely that greater initiatives would be taken to prevent or cure illness. Immunization, led by smallpox vaccination, eventually brought the great epidemic diseases under control. Yellow fever has almost vanished, and cholera levels have declined. Digging drains and oiling stagnant water reduced malaria in towns, and mosquito nets partly protected colonial and local elites.

There was a slow spread of government and missionary hospitals. Although there is debate about the impact of modern medicine on poor, predominantly rural societies, a comparison of two areas of similar socioeconomic levels in Nigeria showed that the one which had possessed for a generation a small, adequately staffed and supplied hospital offering free services was characterized by a life expectancy 12 years greater than the area with no facilities (Orubuloye and Caldwell 1975). The treatment of water supplies, usually in urban areas and often inadequate, has improved, but is still often woefully bad. Better sanitation and hygiene practices have doubtless also reduced mortality. By the 1990s, Demographic and Health Surveys were reporting that about half of all countries had a majority of children immunized against tetanus, diphtheria, and pertussis (whooping cough), while the coverage against measles (a major killer in the region) was increasing and the incidence of poliomyelitis was declining steeply. But morbidity and mortality from diarrhea and pneumonia were still high. Malaria was almost as bad as ever, although many lives were saved by the use of drugs, and HIV/AIDS was presenting a horrific challenge.

4. *Health at the Dawn of the AIDS Era*

By the early 1980s sub-Saharan African life expectancy was 48 years, having increased by seven years in the previous decade, and seeming to promise similar gains

to come. This was not to be so, because of problems in funding the health system and the emergence of the AIDS epidemic. In contrast to most of Asia and North Africa, female child mortality was as low as that of males. There were significant mortality differentials by region (with mortality lowest in Southern Africa), ethnic group (even when neighbors), parental education (with mother's education being more important for child survival than father's education), by occupation (with farmers' death rates highest), and by residence (with urban health better). Mortality was highest in countries like Ethiopia and Mozambique where civil unrest and war had disorganized the health and other systems. It was also higher in the drought-prone savanna countries, but no higher than would be expected from their relatively low income and educational levels, which were in turn the product of impoverished agricultural resources. Drought still visited these lands regularly but evidence accumulated that, although it caused much distress and livestock loss, excess human mortality was less than might have been anticipated because of the scale of migration to better-off areas and towns.

Information on the nature of illness and the causes of death is still meager because so few people are seen by doctors or die in hospitals. By the 1980s the great epidemic diseases were largely under control. Campaigns, which mostly proved successful, aimed at eradicating onchocerciasis (river blindness), and some progress was being made against schistosomiasis (bilharziasis). Malaria, particularly its worst form, falciparum malaria, was almost universal, moderated only in the highest parts of East and Southern Africa by lower temperatures and in South Africa by a more temperate climate and successful eradication. A Gambian study revealed malaria to be the dominant cause of illness, except among children under three months of age, who were relatively free of it. Research in Tanzania showed that 31 percent of the sick were suffering from malaria, 13 percent respiratory infections and 7 percent diarrhea.

A major World Bank/Harvard University study (Murray and Lopez 1997) of global mortality estimated that 65 percent of the region's mortality was still attributed to communicable, congenital, maternal, and nutritional causes (compared with 51 percent in India, 42 percent in all developing countries, and 6 percent in developed countries), 23 percent by non-communicable disease, mostly cardiovascular and cancer (compared with 40 percent in India, 47 percent in all developing countries, and 86 percent in developed ones), and 12 percent by violence and accident (only a little higher than other areas). A World Bank survey (Feachem and Jamison 1991) found that 47 percent of deaths were from infectious and parasitic causes (malaria and measles being particularly important), which, together with perinatal problems, accounted for nearly all child deaths, and 16 percent from circulatory disease and cancer (but their category of 'other,' including indefinable, was 23 percent). A longitudinal study in Machakos, Kenya (Muller and van Ginneken 1991), an area where altitude renders malaria a minor complaint, ascribed 16 percent of deaths to respiratory infection, 13 percent to congenital factors, 11 percent to intestinal infections, 8 percent to measles, 7 percent to tuberculosis, 7 percent to other infectious and parasitic diseases, 4 percent to nutritional and metabolic causes, 4 percent to problems of the digestive system, 3 percent to malaria, 11 percent to diseases of the circulatory system and cancer, and 6 percent to violence and injuries, while 11 percent could not be determined. Hepatitis B also presents dangers. Maternal mortality has been estimated at 655 per 100,000 births, the world's highest level and 30 times that of Europe. This, together with deaths arising from miscarriages and abortion, translates, because African women still average six live births, into a lifetime chance for females of dying from maternity causes of about 5 percent. It is likely that the lifetime risk will fall substantially in the near future as the result of a fertility decline.

5. *The AIDS Epidemic*

HIV-2, perhaps the more ancient of the two human immunological retrovirus strains, is present in West Africa, Angola and Mozambique, but, because it is not a major cause of mortality, will not be discussed here. The HIV-1/AIDS epidemic began in East Africa in the early 1980s, at much the same time as it appeared elsewhere. By the mid-1990s prevalence rates in Southern Africa were higher than they have ever been in East Africa. UNAIDS/WHO (1998) estimates for the end of 1997 indicate that 9.6 million Africans have already died of AIDS (82 percent of the world total) and a further 21 million are now infected (69 percent of the world total). More startlingly, there are 15 countries, constituting the 'Main AIDS Belt' and stretching from Ethiopia through East Africa to South Africa, which contain 4 percent of the world's population and half the world's HIV/AIDS. All of them have adult HIV prevalence rates of at least 9 percent, but the rate reaches 15 percent in Malawi and Mozambique, around 20 percent in Namibia and Swaziland, and 25 percent in Zimbabwe and Botswana. The latter levels imply more than a doubling of the death rate, with a lifetime expectation of dying of AIDS over 50 percent. United Nations population projections do not anticipate Zimbabwe regaining its 1985 life expectancy without a gap of 35 years, or Botswana with a smaller gap than 50 years. Sub-Saharan Africa's epidemic is almost entirely heterosexual in primary transmission, with the result that at least as many women as men are infected. Thus, although the region contains only 59 percent of the infected men in the world, it has 81 percent of infected women, and, because of higher birthrates, probably at

least 85 percent of infected children. Thus, almost uniquely in the world, all parts of the community are affected. The AIDS epidemic is also catalyzing an increase in tuberculosis levels. There is growing evidence that HIV-positive women are likely to be rendered infertile or subfertile. Campaigns to contain the epidemic have been less intensive than the crisis demands, and largely ineffective.

6. *The African Health System*

Government hospitals are found chiefly in towns, with teaching or specialist referral hospitals in the capitals or other large cities. In most countries there are also missionary hospitals, often in rural areas. Nevertheless, most rural people depend on primary health services in the form of village health posts, clinics or dispensaries, and health centers. This system is developed to very different degrees across the region, and the health facilities often have insufficient drugs. Most have now moved to a 'user-pays' system, often characterized by declining attendances and by women losing their ability to take their children straight to the facilities without consulting male relatives (Orubuloye et al. 1991). Research has shown that most clients of health centers come from no further away than the village in which the center is located.

The system is supplemented by private pharmacies and medical stores. A Nigerian study showed that in rural areas the majority of drugs sold are malaria suppressants, worm syrups, and analgesics, although antibiotics are usually also in stock. Private doctors and nurses are becoming of increasing significance in most countries. Traditional practitioners remain important. They do not have an agreed-upon pharmacopeia as in various Asian medical systems, and their medicines are derived from animals as well as herbs. Many also identify evil forces and reveal how they can be nullified.

The great campaigns which eliminated smallpox and contained sleeping sickness, yellow fever, and cholera are largely things of the past, although watch is kept for outbreaks. Efforts continue to reduce the incidence of leprosy and tuberculosis, and to ensure that those people with malarial fever do not die. Immunization of children is now a major health weapon, and recent years have seen sustained attempts to control measles. Public health efforts continue to ensure safe drinking water and sanitation, but it is unlikely that the levels of safety are as high as respondents report to the international survey programs.

7. *Trends in the Research Literature*

More articles on the social and behavioral aspects of health are published in the journal *Social Science and Medicine* than anywhere else. In the last quarter of the twentieth century 865 of these papers were on sub-Saharan Africa. Their numbers rose rapidly at first from an annual average of nine during the late 1970s to 24 in the early 1980s and then reached a plateau at just under 50 per year. Many of the articles were derived from empirical studies of specific locations or diseases. The major topics were access to health services (132 papers), the interaction of traditional and modern health beliefs and services (75 papers), HIV/AIDS (68 papers, nearly all in the 1990s), maternal and child health (55 papers), the political economy of health (48 papers), and health economics (39 papers). Some trends were noticeable. The number of papers published on the interaction between traditional and modern health services declined after the 1980s, those on the political economy of health peaked in the late 1980s as economic structural adjustment policies were applied, and HIV/AIDS papers mostly appeared in the 1990s, with no clear trend during the decade.

8. *The Future*

The immediate future is not reassuring. In contrast to the rest of the world, the regional life expectancy is stalled at under 50 years. Most sub-Saharan African countries are unable to do more than maintain their present public health systems. The impact of such systems depends on their level of use, which is largely determined by the population's ability to pay, and by their level of education, which raises the priority given to successful treatment and the skill with which it is administered. The fee-for-service principle is limiting the expansion of use of both the health and education systems. On the other hand, the likelihood of accessing the health system is probably increasing with the transition from subsistence to market agriculture. Fertility decline has now begun in a range of African countries. Smaller families will mean fewer women dying from maternal causes, and probably greater concentration on the education and health of children.

It is now likely that no country in mainland sub-Saharan Africa will, by the year 2000, have attained any of the three criteria established by the World Health Organization to certify the attainment of the 1978 Alma Ata Declaration of 'Good Health for All' by the year 2000: a life expectancy of at least 60 years, and a survival level of 95 percent of births to one year of age and 93 percent to five years of age. Indeed, most of East and Southern Africa will probably by that date be slipping further away from these criteria.

African Studies: History

Central to the origins of African history as a field of inquiry is the quest to demonstrate that such a subject actually existed. Opinion leaders and intellectuals in Europe and North America had long treated Africa as the embodiment of the primitive. Nineteenth and early twentieth century science marked it a place where earlier stages of evolution could still be observed or else (as in structural–functional anthropology) as a laboratory of social specificity, where forms of social organization could be compared as if each were bounded and timeless. The decolonization of Africa shook up intellectual understandings as well as political arrangements, and from the late 1940s, some intellectuals inside and outside Africa began to argue that rethinking Africa's past was a necessary part of its future. Asserting that history could be studied scientifically was part of a new politics of intellectual inquiry. Pioneering studies stressed the dynamism of precolonial societies; resistance to conquest was a harbinger of nationalist movements. But by the 1970s, a more complicated present was leading to a more complicated past, above all to new ways of thinking about Africa's relationship to the rest of the world and the implications of this relationship for historical writing itself. Yet the time frame for considering the emergence of African history needs to be pushed back even further, and its spatial dimension—the definition of Africa, the relationship of its constituent social and political units, and the significance of the continent to Africans in the Americas—needs examination as well.

1. *Africa and the World*

Africa was in part an invention of its diaspora, a unit that became of world–historical significance because slave traders—from the sixteenth century—defined it as a place where one could legitimately develop a commerce in human beings. Over time, enslaved Africans and their descendants in the Americas began to appreciate the commonality of their fate and many looked to 'Africa' as an almost mythic symbol that they were not mere chattel who could only serve their

owners. Certain nineteenth-century African–American religious leaders looked toward 'Africa' and 'Ethiopia' (although few slaves came from that kingdom), and through such language asserted Africans' important place in a universal history—in the unfolding of Christian civilization. As some people of African descent returned to the continent in the nineteenth century—repatriated ex-slaves to the British colony of Sierra Leone, Brazilian traders in the Bight of Benin or Angola—some saw themselves as part of broad, translantic 'nations,' sharing ancestry and culture but needing Christianity to link a torn-apart past to a reintegrated future (Matory 1999).

By the late nineteenth century, Africans from coastal societies—Christian, Western-educated, but thoroughly integrated into regional social organizations—began to write about their own regions in terms that linked different historical sensibilities. Africanus Horton and Edmund Wilmot Blyden countered the primitivizing ideologies of the eras of the slave trade and colonization by writing about African societies as complex entities whose traditions of origin defined commonality, whose ideas about kingship and social hierarchy defined political order, and whose interest in commerce with the outside world, in Christianity and Islam, and in Western education marked an open, adaptable attitude to interaction. Africans, they thought, had much to learn from Muslims and Christians, but they brought something to the encounter as well.

The period of escalating European exploration and eventual conquest (from the 1870s to 1910s) brought to African contradictory regards. Some explorers encountered powerful kingdoms whose dimensions they sought to understand; others recognized in the impressive mosques of the West African desert edge or the East African coast a history of a long encounter of Africans with the outside world; but many chose to see an unchanging landscape of different peoples ensconsed in their particular cultures. The culturally mixed inhabitants of West Africa coastal region were marginalized by colonization; the worldwide connections of African Muslims were played down in favor of their 'tribal' characteristics.

After some efforts toward remaking African societies in a European image—the 'civilizing mission'—colonial regimes began to hitch their legitimacy to the chiefs whose authority toward their subjects colonial rulers needed. With that, the idea of 'tradition' as the essential quality of African life acquired a new salience in colonial ideologies. Colonial regimes—and scholars and intellectuals of that era—were interested in 'customary law,' in 'folklore,' in 'primitive art.' The growth of African ethnography in the 1920s brought to the continent foreign scholars curious about the diversity of social forms and sympathetic to victims of colonial oppression, but their emphasis on the bounded integrity of each African 'society' was ahistorical.

2. *A New Past for a New Future*

Even within the ethnic cages of colonial polities, consciousness of the past did not necessarily remain static. Some early mission converts used their literacy in French or English to record genealogies and traditions of 'their' people—using the legitimacy of 'European' writing to articulate indigenous views of the past and to emphasize the integrity of local society. Such histories were invoked to make claims for collective representation in state-sanctioned councils. Meanwhile, pan-Africanists like W. E. B. duBois countered the belittling conceptions of colonial ideology by emphasizing the importance of long history of oppression shared by Africans and African–Americans, a history which underscored the importance of the liberation movements.

The burst of interest in African history after World War II thus has a deeper context. The break, however, was fundamental. In the aftermath of a devastating war against Naziism and conquest, European states needed simultaneously to justify their rule over African peoples and to intensify their use of African resources. The dilemmas posed by challenges to legitimacy and control—from within and outside African colonies—and the increased intrusiveness of regimes into African social and economic life has made this a fascinating period for historical investigation (Marseille 1984, Cooper 1996). Even at the time, scholars and intellectuals wondered whether the conception of bounded and static units made sense of the Africa they were observing. Although a few anthropologists had seen in the 1930s that migration, for example, was redefining the nature of social connections, by the 1950s, population movement, cross-cultural interaction, and cultural adaptation demanded scholarly analysis. Meanwhile, the anthropologist Melville Herskovits (1958), had not only seen the importance of historical analysis to political anthropology but had become interested in the transmission of African culture to the new world via the slave trade, and he asked what Africans' experience of governing indigenous kingdoms had to offer to Africa's political future.

The last question was one most African political elites—and almost all social scientists—did not want to think about; the 1950s witnessed the escalation of claims from African social movements to be considered part of the 'modern' world and to enjoy the possibilities it entailed, irrespective of race or a past of colonization or enslavement. Social scientists took more interest in where history was supposed to end—'modernity'—than where people had been.

Academic historians, the professional custodians of the past, were part of the postwar political and intellectual ferment. The first African Ph.D. in history K. O. Dike of Nigeria, was trained by historians of imperial expansion, and turned their archival methodology into a means of legitimizing the telling of a

different sort of story, one of the interaction among traders, rulers, and warriors, both African and European, in the Niger Delta, and of the adaptation of African social institutions to new forms of competition in the nineteenth century. Dike (1956) insisted that oral sources could be used alongside written ones, although most of his own work was archival. At one level, his work staked itself on extending the methodological canons of history; at another his insistence that the locus of history could be found in Africa itself—that interaction was more important than transmission—was a charter for nationalist history.

The next generation of European-trained African historians went further in this direction, and many stressed explicitly that the preconquest past was a precedent for the postindependence future, showing how Africans had brought diverse populations into larger political units, how African initiative in agriculture and commerce had linked ecologically distinct regions with each other and with the outside world, how indigenous religious leaders had built networks that transcended ethnic frontiers, and how Africans had adapted Islam to particular political and cultural purposes.

The quest for a usable past—and a useable national past at that—was both African history's strength and its weakness in the 1960s. A strength, because it attracted a younger generation of Africans to believe that they could combine international scholarship with a sense of the past they had learned in their own communities and because it allowed Americans and Europeans to come to grips with the way in which the end of colonial empires had forced a reordering of intellectual categories. A weakness, for the political context privileged 'state building' over the diverse strategies of women and men, traders and religious figures to live their lives in different ways, and this both diminished a varied past and ratified an increasingly authoritarian present. The only aspect of colonial history that fitted the bill was 'resistance'; indeed, some African historians saw the 'colonial episode' as a short and not particularly important interval between an autonomous past and a promising future. A consequence of the new historiography, whatever its limitations, was a heightened interest in methodology, to solve the problem of how to reconstruct historical patterns with a paucity of written documentation, much of that from visitors and conquerors. Vansina helped to develop rigorous criteria for analyzing oral texts with the same critical eye as employed on written ones, and other scholars explored the use of linguistic and archeological material to chart the movements of people, the evolution of material culture, and the spatial configuration of state-building (Vansina 1965, Vansina et al. 1964).

African historical scholarship was vibrant in the 1960s and 1970s, and the core of the action was in Africa. Every nation had to have a university, every university a history department. Associations and journals were founded; international congresses were held; and UNESCO brought together African authors to write a comprehensive history of the continent (UNESCO 1981–93).

3. *Reconnecting Africa and the World*

Since the 1970s, African historians have become increasingly conscious of the different ways of rethinking the relationship of Africa and the rest of the world. They no longer had to prove that Africa had a history; the mounting evidence that decolonization did not free Africa from its problematic relationship to the world economy raised questions about pasts before and during colonization. Why African polities became caught up in the Atlantic slave trade, how the African presence in the Americas contributed to European wealth, and how African societies coped with unequal trade and unequal politics became topics of increasing interest (Rodney 1972). In addition, French Marxist anthropologists (Meillassoux 1975) argued that such institutions as kinship systems were not so much the product of a peculiarly African culture but of the logic of reproduction of agricultural societies, and they went from there to posit that the resulting modes of production interacted in particular ways with the expanding capitalist system. Other scholars saw that the question appeared differently if instead of asking how a 'society' responded to European traders or rulers one asked how ruling elites reacted. They showed that the strength of internal social groups made rulers look to the manipulation of external relations for power and wealth, and that this made African kingdoms and chiefdoms especially open to external relationships, most disastrously those of the slave trade and later of colonial economies (Peel 1983).

Historical research allowed not just the use of 'informants' to gain information, but the juxtaposition of different kinds of historical sensibilities and the elucidation of how thinking about the past affects and is affected by political processes in the present (Cohen 1994). Oral history revealed different lines of cleavage within African societies, including gender, age, and status. It described not the actions of fixed social groups against each other, but the flexibility of social arrangements, such as the tendency of people detached from kinship groups—through war or efforts to escape patriarchal authority—to form important but unstable groups of clients of 'big men.' Both oral sources and more nuanced reading of documents reopened the colonial era to historical investigation, not as a history of what white people did for or to Africans but as a dynamic process, in which the limited power of colonizing regimes left numerous fissures where women tried to establish autonomy even as male elders tried to contain it, where labor migrants developed networks linking distant regions, where Christians built independent churches and cults, and

where cash-crop producers used their incomes to enhance their kinship groups and chieftaincies. Such histories stand alongside those of expropriation of resources, especially in southern Africa, of segregation and discrimination against the most 'Westernized' of Africans, of arbitrary authority and daily oppression under colonial regimes, in their late, 'reformist' phases as well as brutal early ones.

Studying African history has offered the possibility of thinking about 'world' histories in a different way. Rather than seeing Africa as a peculiar place that somehow lacks what made other regions develop more rapidly, one can ask what is particular about each region of the world, what in the process of interaction produced inequalities of wealth and power. African historians have been in dialogue with historians of Latin America over economic history and with historians of India over the analysis of colonialism. World history can no longer be seen as a single narrative, but this recognition leaves in place the more difficult question of how is one then to analyze large-scale historical processes. The challenge is to chart the multiple pathways without losing sight of the development of highly unequal political and economic relations on a global scale. In the eighteenth century, European countries were perhaps five times as wealthy as African regions; now the gap is as high as 400 to 1. Such an historical change requires analysis that is about neither 'Africa,' nor 'Europe,' but their relationship in the last 200 years.

4. *The Pecularities of Disciplinary Divisions of Labor*

In the 1930s, Africa not only had no history; it held no interest for political scientists or sociologists either, and for economists only in the sense the colonial economies had spawned 'modern' sectors with certain measurable characteristics. Africa was the domain of anthropologists, the custodians of human particularity, while what was putatively 'European' was assimilated to the universal, and that was where social science found its glory. The dramatic challenges to European power in the 1940s and 1950s shook up this division of labor (Pletsch 1981). The idea of modernization was espoused within colonial bureaucracies before 'modernization theory'—in the style of the Committee on Comparative Politics of the Social Science Research Council—came into vogue. It allowed officials to think that even if African colonies became independent, they would invariably follow a road charted out to them by the early developers. However much modernization reinscribed global hierarchy, eurocentrism, and teleology, it offered African intellectuals and policy-makers a chance to position themselves as mediators between a perceived Euro–American modernity and diverse African particularities; it gave a language to leaders with which to ask industrial countries for the resources they needed to 'develop' and it allowed outsiders to see themselves as forging a world in which people of all races could advance.

American and European political scientists and sociologists flocked for a time to Africa—and their standards of empirical research deserve some of the credit for deflating modernization theory. But after that time, the interest of political scientists, sociologists, and economists in Africa has waned. Anthropologists remain the custodians of African particularity, but now this embraces the complexities of innovation and interaction more than unchanging specificities. Historians, from the 1950s, were the new element in the division of labor, and their work, despite temptations to the contrary, can offer a vision of Africa that stresses change—economic, political, social, and cultural—without confining it to a predetermined route.

Some historians have their version of the modernizing vision. The narrative of African state-building from the empire of Sundiata to the empire of Shaka was indeed a selective reading that linked a modernizing future to a modernized past. One British historian (Wrigley 1971) accused another (Fage 1969) of missing the moral and political significance of the slave trade by putting it inside a narrative of centralizing of power by successful slave-exporting West African kingdoms. Even the 'underdevelopment' school of the 1970s is as a variant of modernizing themes, for its emphasis on how over the long-term European exploitation retarded growth and transformation in African economies presumes a global narrative of capitalist development which Africa is then held to fall *under*. That Europe's oppression, not Africa's backwardness, is held culpable does not negate the inattention to the myriad innovations, struggles, and changes that have occurred within particular parts of Africa, the importance of regional, not just overseas, mechanisms of exchange and communication, and the ways in which the actions of Africans limited the actions of Europeans, whatever their intentions (Cooper et al. 1993). Much recent social and economic history bounced off the arguments of the underdevelopment school to develop more varied and more interactive views of change in various periods of African history, including those when European power was seemingly at its height (Berry 1993).

5. *Multiple Perspectives on a Varied Continent*

If Africa is neither a homogeneous space reduced into abject poverty by imperialism nor a series of autonomous societies with their own internal logics, getting a grip on units of analysis is not simple. Rather than take present-day ethnicity as a starting point, some scholars have used concepts of region, of network, and of patron–client relations to see how people in the

nineteenth and twentieth centuries constituted actual patterns of relationships, which only sometimes crystallized into groups that maintained boundaries (Ambler 1988, Glassman 1995, Barry 1998). Others have emphasized how pioneers of urban migration shaped patterns that linked particular villages with African cities (and Parisian suburbs), how religious pilgrimages and circuits of Koranic scholars created linkages across inland West Africa with further connections to Egypt and Saudi Arabia, how networks of shrines and spirit mediums shaped cross-ethnic affiliations in a large belt of Central Africa, how African American missionaries from the 1890s influenced Christianity in South Africa, and how in the 1920s African ports became nodal points in the spread of Garveyite movements across the Atlantic to large parts of Africa (Manchuelle 1997, Campbell 1995).

From there, scholars can examine the different visions of sociability held by women and men, by young and old, by elites and ordinary people. They can study not only the differential experience, say, of men and women in agriculture under precolonial and colonial regimes, but the ways in which the categories of gender and age—and the affinities and conflicts they entailed—were created and struggled over (Mandala 1990, Grosz-Ngaté and Kokole 1997). They can look at different forms of imagination and communication (White 2000).

6. Conclusion

The Senegalese novelist and film-maker Ousmanne Sembene has accused historians of being 'chronophages'—eaters of time. They impose, he insists, a one-dimensional, progressive view of time on the unruliness of people's experience. Yet the idea that other notions of past give more a more varied picture than professional history depends on aggregating different visions of the past—a quintessentially 'academic' operation. The griot or the lineage elder may also recount the past to serve narrow, presentist concerns. Historical scholarship has complicated unilinear narratives as well as imposed them.

Reflecting on historical processes confronts us with the tension between the contingency of processes and the fact of outcomes, that multiple possibilities narrowed into singular resolutions, yet led to new configurations of possibilities. The doing of history introduces a tension between an historian's imagination rooted in the present and the fragments of the past that appear in all their elusive vigor, in interviews, letters, newspaper articles, and court records. The data of history are not created neutral or equal: archives preserve certain documents but not others, and the tellers of oral tradition remember some narratives and forget others (Mudimbe 1988).

African history has offered a glorious national past that points to a national future, and it has offered an ethnicized past projected backward in time. But history can also be read as process, choice, contingency, and explanation. Since World War II, historical scholarship has provided a sense of the possibilities which mobilization can open up—and an awareness of the constraints that have made and make it so difficult for African states and societies to make their way in the world.

African Studies: Politics

1. Introduction

African politics, as a distinct field of inquiry, essentially begins in the 1950s, at a moment when the rise of African nationalism and foreshortening timetables for decolonization created the prospect of an early entry into the world system of more than 50 new states. The initial focus was African nationalism and the political parties through which it found expression. The rapid succession of dominant political forms and preoccupations brought corresponding shifts in analytical focus: transitions to independence; single-party systems; military intervention; ideological radicalization; patrimonial rule; state crisis and decline; economic and political liberalization. Interactively, a series of paradigmatic orientations shaped the study of African politics: modernization, dependency and neo-Marxism, rational choice, democratic transition and consolidation.

2. Scope and Nature of Field

Officially, the African state system defines itself as coincident with the geographic continent and its offshore islands, symbolized in the membership of the Organization of African Unity (OAU). As a corpus of knowledge, however, African politics most frequently refers to the sub-Saharan states, which share a large range of cultural, sociological, and political traits. South African politics represents a distinct sphere, rendered exceptional until the 1990s by that country's apartheid regime. Africa has an extraordinary number of sovereign units (53 in 1999); however, comparative understandings of African political dynamics derive from a much smaller number of states that, by reason of their size, accessibility for research, or attractiveness as models, received disproportionate attention (for example, Nigeria, Tanzania, Kenya, Senegal, and Congo–Kinshasa).

Some particular aspects of the sociology of Africanist political knowledge merit note. There is a singular preponderance of external scholarship, North American and European, which only recently began to be balanced by African contributions. At first the paucity of African academics explained this phenomenon; subsequently, until the 1990s, most regimes had low tolerance for critical scholarship from their nationals, and by the 1970s the severe material deterioration of many African universities inhibited research from within. Methodologically, most scholarship relied upon qualitative approaches, which sharpened the debate around contending broad theoretical paradigms shaping such inquiry.

3. Decolonization and the Origins of African Politics as a Field

Until the 1950s, there were two distinct domains within African politics. At the summit lay the colonial apparatus, whose study was restricted to an administrative science conducted largely by colonial practitioners. At the base lay subordinated African societies, whose study was confined to anthropologists, missionaries, and administrators. Knowledge thus generated influenced anthropological theory and the practice of 'native administration,' but was outside the realm of comparative politics.

African nationalism emerged as a potent political force in the 1950s; its leading students (for example, Coleman 1958) are the foundational generation of the African politics field. The defining attribute of African nationalism was its autonomy from the colonial state it sought to challenge, thus constituting an authentic field of African politics. In its rendering of nationalism as a doctrine of liberation, its African form offered a dual summons to solidarity: as African, whether understood racially or continentally, and as territorial subject of the unit of colonial administration. The sources and content of nationalist thought, and the organizations through which it found expression, animated a first generation of scholars deeply sympathetic to its ends.

With the approach of independence, focus shifted to political parties. In the transitional arrangements, parties were the first institution of representative government to operate in African hands. Their in-

ternal dynamics and competitive struggle best captured the essence of African politics, well before states were 'African.' As well, their capacity to reach and mobilize urban and rural mass audiences seemed a measure of the potential for genuinely representative and hence legitimate postcolonial rule. One particularly influential school held that the prospects for stable, effective, and democratic rule were best fulfilled by mass movements successful in winning support spanning all ethnic and social groups, and thus enjoying a universal mandate as a single party (Morgenthau 1964).

4. *Modernization Theory and the Early Independence Years*

4.1 *The Single-party System*

With independence achieved, analysis shifted to the political development of new states, along with a substantial infusion of comparative political theory, greatly influenced by the Social Science Research Council Committee on Comparative Politics. The various strands of modernization theory, rooted in the premise of duality of tradition and modernity, privileged the state as indispensable central instrument of progress. Apter (1955), drawing upon Weberian theories of legitimacy, saw the key to effective modernization in the ability of the nationalist leader to transform the personal charisma achieved in this role into a routinized form of state legitimation. The nationalist parties, once in power, flowed into the state apparatus and soon lost their organizational distinctiveness; Zolberg, in a prescient study (1966), identified the party-state as dominant form, and pointed to emergent trends towards political monopolies.

With rare exceptions, the dominant parties which assumed power with independence sought to consolidate their exclusive hold on power, and to co-opt, circumscribe, or often proscribe opposition. Development, political and economic, required the undivided exercise of state power. Open opposition was likely to play upon ethnic or religious divisions, and to politicize cultural identities. Tradition resided at the periphery, the agencies of modernity at the center. Thus the widespread choice of African rulers for centralization and unification of the state, represented as nation in formation, was largely shared in the first years of independence by academic observers.

4.2 *Military Intervention*

The limitations of the first formulas for postcolonial rule stood exposed in 1965–6 when within a few months a wave of military coups occurred (Ghana, Algeria, Nigeria, Congo-Kinshasa, Benin, Central African Republic, Burkina Faso). At the time, comparative political sociology of military regimes in the developing areas supplied an unintended brief in support of such interventions. Armies, ran the argument, could serve as positive managers of modernization. The rationality and hierarchy of their internal structures, their technocratic skills, the merit basis of promotion, and their dedication to the nation equipped them for a beneficial developmental role.

Though military coups were generally justified as transitional cleansing operations, to be followed soon by restoration of civilian rule, almost invariably the new rulers concluded that national interests were best served by the permanence of their rule. To legitimate this consolidation of their rule, they adopted the political instruments fashioned by the nationalist movements in power: the single party, accompanied by co-option of prominent civilian politicians. Actual performance of such regimes proved indistinguishable from that of other party-states, deflating the military-as-modernizer theories. Closely inspected, military intervention motives bore little relation to public interest notions (Decalo 1976).

5. *The Authoritarian State Interrogated*

5.1 *The Demise of Modernization Theory*

Virtually apace, the cluster of approaches labeled 'modernization theory' lost their hold on political inquiry, and the nature of rule predominant in Africa found its credibility beginning to erode. The master concept of modernization encountered sharp criticism for its linear notions of change, its insensitivity to social cleavage and conflict, and its teleological concept of progress. A silent shift in focus took place with respect to perspectives concerning African regimes: from custodians of development to authoritarian states. In developmental perspective, the core analytic was state action in overcoming a crisis of development: integration, legitimation, penetration, distribution. Influential studies in Latin America and Asia pointed in a different direction: the nature of the state itself, and the mechanisms by which it assured the reproduction of its power. Although Latin American notions of 'bureaucratic-authoritarian' or 'national security' states did not apply, save possibly to South Africa, new currents of reflection on authoritarianism itself altered the problematic of African political inquiry.

In turn, the 1970s were a period of expanding state ambitions and further reinforcement of the centralizing and unitary state impulses. For a number, radical ideological impulses surfaced; for seven countries, these took the form of officially proclaimed Marxist–Leninist state doctrine. For others, sweeping nationalization or indigenization projects vastly enlarged the domain of state economic control. Elsewhere, the 1973 Algerian 'agrarian revolution' or the 1976 Tanzanian venture in enforced rural resettlement

in villages exemplified a mood of enlarging state aspirations for accelerated development under its control and management. But the reach far exceeded its grasp.

5.2 Dependency and Neo-Marxist Theories

The newly critical perspective towards the postcolonial state, as well as modernization theory, found potent expression in a family of conceptual approaches drawing in one way or another on Marxism. Dependency theory, which enjoyed virtual ascendancy for an extended period in Latin America, crossed the Atlantic and achieved broad influence in Africa, not only amongst scholars and intellectuals but also in ruling circles. From the dependency perspective, the issue was less the authoritarian character of the state than the class dynamics and international capitalist system which made it so. The extroverted nature of African economies, the control of the international exchanges by capital in the imperial centers, and the subordination of the domestic ruling class to the requirements of international capitalism led ineluctably to an authoritarian state to repress and control popular forces. In dependency theory's most sophisticated formulation, Leys (1974) employed a dependency perspective to question the character of development in Kenya, then still viewed as a narrative of success.

Beyond dependency theory, various currents of Marxism enjoyed intellectual influence, particularly amongst the African intellectual community in French-speaking Africa. An important revival of Western Marxism in the 1960s transcended the doctrinaire rigidities of Marxism–Leninism, and shaped an unfolding quest to resolve the riddle of the nature of class relations in Africa, a prerequisite to grasping the character of the state. Particularly interesting, though ultimately abandoned as unproductive, was the search for a 'lineage mode of production,' which could deduce class dynamics from the descent-based small-scale structures of rural society. Other hands sought to employ the ornate abstractions of the structural Marxism of Louis Althusser and Nicos Poulantzas. In the end, the schema supplied by dependency theory and neo-Marxism lost ground over the course of the 1980s. The sudden collapse of the Soviet Union in 1991 was a shattering blow in Africa as elsewhere to the credibility of Marxism, whether as regime doctrine or analytical instrument.

6. State Decline and Crisis

By the 1980s, patterns of decay became apparent in a number of states, and the notion of state crisis entered the analytical vocabulary. Corruption on a large, sometimes colossal scale became apparent; a prime example being that perpetrated by Mobutu Sese Seko, the ruler of Congo/Zaire. The rents extracted from power by ruling groups reached a magnitude which transformed citizen perceptions of states from provider to predator.

Another concept drawn from Weber, patrimonial rule, emerged as the key to understanding political practice. 'The politics of the belly,' wrote Bayart (1993), produced a 'rhizome state,' whose tangled underground root system of patron–client networks rather than its formal structure governed its operation. Office was a prebend, whose rents rewarded the occupant for service to the prince. The essence of African politics was 'big man' personal rule, or neopatrimonialism, rather than authoritanianism.

The inevitable consequence of the tentacular expansion of state ownership and control of the formal economy, and decline of government effectiveness, was a deepening economic crisis. The per capita GNP of Ghana comfortably exceeded that of South Korea at the time of independence; by 1995, that of South Korea was 25 times greater, a pattern found across much of the continent. Employing rational choice theory, Bates (1981) showed how the political logic of state operation systematically disfavored the rural sector, main source of wealth for all but a handful of oil rentier states. Hyden (1981) pointed toward the peasant response, in recourse to the exit option of the informal economy and secure reciprocities of the local kinship matrix.

7. Economic and Political Liberalization

The unmistakable economic stagnation and symptoms of state crisis drew the international financial institutions into the fray, at a moment when newly dominant political economy perspectives in the Western world called for far-reaching curtailment of the orbit of state action: privatization, deregulation, budgetary austerity, and rigor. Although a need for economic reform was acknowledged on all sides, deep divergences existed on the diagnosis of the core causes, and appropriate remedies. The 'Washington consensus' held that the explanations lay mainly in flawed domestic policies, while much African opinion, both official and scholarly, believed the root causes lay in the unjust operation of the international economy. The international financial institutions developed a standard package of 'structural adjustment programs,' holding the upper hand in the bargaining. However, these formulas were only fitfully applied, producing uneven results and strong domestic disapproval for what critics argued were their negative social consequences. The dilemmas of structural adjustment define an important fraction of African political studies of the 1980s and 1990s (Callaghy and Ravenhill 1993).

The failure of reform to reverse economic decline in the 1980s led a growing number of voices to suggest that the underlying flaw lay in the patrimonial auto-

cracies which continued to rule. Only political liberalization could empower an awakening civil society to discipline the state; accountability, transparency, and responsiveness necessitated democratization. The evaporating legitimacy of aging incumbents, and their shrinking capacity to sustain prebendal rule from declining state resources, reduced their capacity to resist political opening. The remarkable spectacle of the fall of the Berlin wall in 1989, and collapse of the Soviet Union in 1991, resonated powerfully. Leading Western donors now insisted on political reform as a condition for additional economic assistance.

The powerful interaction of internal and external pressures, and the contagious effects of the strongly interactive African regional political arena, proved irresistible. Democratization dominated the political scene in the 1990s, both on the ground and in the realm of African political study. Political opening in Africa formed part of a much larger 'third wave' of democracy, affecting Latin America, the former state socialist world, and parts of Asia as well. Initially, comparative political analysis focused upon the dynamics of transition itself, in a veritable moment of enthusiasm for the changes in course.

The initial impact was important; in at least a dozen states, long-incumbent rulers were driven from office by electoral means. However, in a larger number of other cases rulers developed the skills of managing competitive elections in a way to retain power. When attention turned to democratic consolidation in the later 1990s, the analytical mood was more somber. In the greater number of cases, only a partial political liberalization had occurred, captured in the analytical characterizations which emerged: 'illiberal democracy,' 'semi-democracy,' 'virtual democracy.' But now-dominant norms in the international system required a minimum of democratic presentability. Further, important changes had occurred in expanding political space for civil society, enlarging freedom of expression and media, and better observation of human rights. Democracy, however, was far from consolidated at the turn of the century (Bratton and van de Walle 1997, Joseph 1998).

Disconcerting new patterns appeared contemporaneous with the wave of democratization. A complete collapse of state authority occurred in Somalia and Liberia in 1991, and spread to some other countries. In a quarter of the states, significant zones of the country were in the hands of diverse militia, opening an era of 'warlord politics' (Reno 1998). In other countries such as Uganda, Ethiopia, and both Congos, insurgent bands from the periphery seized power. These events testified to a weakening of the fabric of governing, even a loss of statehood for some.

This enfeebled condition of numerous states, many if not most African scholars argued, emptied democratization of its meaning (e.g., Ake 1996). The externally imposed measures of structural adjustment had so compromised the effectiveness of states and their capacity to deliver valued services to the populace that the possibility of electoral competition had little value to the citizen. Democracy, in this view, was choiceless.

8. *African Political Study and Comparative Politics*

From the first application of modernization theories of largely extra-African derivation to African political study, a succession of conceptual perspectives drawn from comparative politics broadly defined have shaped political inquiry (dependency, neo-Marxism, rational choice, economic and political liberalism). In turn, African political study has made an important contribution to comparative politics. Instrumentalist and constructivist theories of ethnicity in their initial phases were strongly influenced by African studies (Young 1976); these modes of interpretation added important new dimensions to the comparative study of nationalism, which took on new life in the 1980s and 1990s (Rothschild 1980, Anderson 1983). The rebirth of the concept of civil society began in Africa and the former Soviet camp in the 1980s. Africa was a critical site of the late-century democratization experiments, which fed into the comparative study of democratic transitions (Diamond et al. 1995).

Africanists are prominent in the field of gender political studies. Analytical recognition of the political economy of the 'informal sector' or underground economy in good part originates in Africa-based studies. Understandings of the politics of patrimonialism rest heavily on African evidence. The collapse of some African states and the failure of others in the 1990s injected novel themes of state crisis into comparative politics (Zartman 1995). Sustained patterns of civil conflict and violence in some parts of Africa had counterparts in some regions of the former Soviet Union, suggesting the emergence of new kinds of political pathologies requiring analysis.

The singular trajectory of the African state generates multiple challenges to understanding, and divergent responses. The odyssey of independence began with high hopes and unrestrained optimism in the capacity of the state to manage rapid development and build an expanding political order from the center. Overdeveloped states and parastatalized economies ran into crisis, requiring far-reaching adjustments, economic retrenchment in the 1980s and political liberalization in the 1990s. An earlier apprehension of excessive state strength gave way to fears of state decline and weakness; analysts differed as to whether the prime cause was the inner logic of colonial autocracy embedded in the postcolonial polity (Mamdani 1996, Young 1994), or reflected a continuous pattern of underlying state weakness dating to precolonial times (Herbst 2000). The quest continues for forms of rule which could bring sustainable

development, accountable and effective governance, and also be authenticated and legitimated by a rooting in the African cultural heritage.

In sum, African politics as a field rests upon a dual dialectic. On the one hand, the rapid succession of distinctive political moments within Africa engages and defines the interpretive priorities of students of African politics. In turn, African political study remains firmly embedded in the larger field of comparative politics, whose evolving conceptual persuasions shape the orientations of its practitioners.

African Studies: Religion

Most African languages lack an indigenous word for that sphere of belief and practice that is termed 'religion' in the West; their closest terms usually convey something more like 'usage' or 'custom.' So the study of African religion has tended to embrace a wide range of topics, extending to magic, witchcraft, divination, healing, cosmology and philosophy, as well as spilling over into virtually all other areas of social life and cultural endeavor. Yet still, defined as systems of belief and practice relating to the posited existence of spirits or personalized forces normally unseen by humans, African religions are not only analytically comparable in many respects to world religions such as Islam and Christianity, but have been compared in practice by the millions of Africans who over the past hundred years have converted to such religions. Scholars of African religion have thus been concerned, not just with 'traditional' religion, but with the far-reaching processes of religious change, stimulated above all by colonialism, that Africa has undergone since the late nineteenth century. African religion is thus a plural phenomenon and its study is multidisciplinary.

1. Missionary Origins

The earliest serious works on African religions were by missionary authors, many of whom also pioneered the study of African languages. Their agendas, of course, were far from disinterested: not just to explore the complexities of belief systems that many had dismissed as mere idolatry, but to find cultural leverage within them to promote the Gospel or to yield evidence for an original monotheism. Still, the best of them were serious ethnographies, grounded in long familiarity and a good command of the local language, such as Henry Callaway's study of the Zulu, Henri Junod's of the Thonga or Edwin W. Smith's of the Ila, all from Southern Africa. German scholarship was especially impressive, such as that of Diedrich Westermann on the Ewe of Togo or Bruno Gutmann on the Chagga in Tanganyika, among Protestants, or on the Catholic

side the work of several missionaries of the Society of the Divine Word (SVD), which was linked to Pater Schmidt and the journal *Anthropos* in Vienna. Sir James Frazer made use of missionary correspondents, such as John Roscoe, who dedicated his study of the Baganda to him.

After 1945, when the growing nationalist movement cast both missionaries and anthropologists under a cloud—the former for their disparagement of traditional beliefs as idolatrous, the latter as practicing a colonialist science of 'primitive' societies—the missionary tradition evolved into one of 'African theology.' A generic category of 'African traditional religion', homologous to the great scriptural religions, was first proposed by a former missionary, Geoffrey Parrinder, who was the first professor of religious studies at the University of Ibadan in Nigeria, and was taken up by a new generation of African scholars of religion, who were concerned to valorize traditional culture and to see Christianity fully 'inculturated' (to use the term that would come to be used in Catholic circles). Their theological contentions typically rested on 'ethnographic' accounts of traditional religions, whether these focused on contrasts between them and Christianity (as in the Kenyan J. S. Mbiti's comparison of eschatological concepts in the New Testament and among the Akamba) or on affinities (as in E. B. Idowu's *Olodumare: God in Yoruba Belief*). The irony of these works was that their nationalist appreciation of traditional religion often depended on their being able to write Judeo–Christian notions into it; for by now Christianity itself was fast becoming the largest religion of sub-Saharan Africa.

2. *From Administrators to Anthropologists*

The contrasting (but not wholly distinct) secular tradition of research on traditional religions had its roots in works by colonial administrators, some employed as 'government anthropologists,' such as R. S. Rattray's *Religion and Art in Ashanti* (1927) or B. Maupoil's *La Géomancie à l'ancienne Côte des Esclaves* (1944). Free from evangelistic concerns (and therefore less constrained by the category of 'religion'), they were more able to explore themes such as the mundane, practical dimensions of magical charms, or of techniques of divination, and of the cognitive or cosmological principles underlying them. The greatest figure was E. E. Evans-Pritchard, who produced two classic studies of African belief and practice, quite different from one another. The first, *Magic, Witchcraft and Oracles among the Azande* (1937) was in the mold of his teacher Bronislav Malinowski (who, though not himself an Africanist, played an important role as research director of the International African Institute). Its chief aim was to show how seemingly irrational beliefs were in their context both reasonable and effective; and its distinction between witchcraft and sorcery (made by the Azande themselves) was highly influential in subsequent studies of African witchcraft.

Most British anthropologists over the next two decades, drawing their theoretical inspiration from A. R. Radcliffe-Brown, made social structure, rather than culture, their cardinal concept. Religion (or, as preferred, 'ritual') was seen as an aspect of political and social organization, the expression of social values (like the cult of ancestors in lineage-based societies, or sacred kinship in some centralized polities, or rites of passage everywhere).

A focus on religion as culture did, however, continue elsewhere, as in the work of Melville J. Herskovits, the *doyen* of American Africanists, on the religion of Dahomey (1938); and the many essays of the French school around Marcel Griaule on the religion and cosmology of the Dogon and Bambara peoples of Mali from the late 1930s into the 1960s. But the opposition between sociological and cultural approaches was bridged in Daryll Forde's collection of essays, *African Worlds* (1954), and altogether abandoned in the fine run of studies that appeared in the ensuing decade: Evans-Pritchard's second great book, *Nuer Religion* (1956); monographs by his pupils John Middleton on the Lugbara (1960) and Godfrey Lienhardt on the Dinka (1961); Meyer Fortes's *Oedipus and Job in West African Religion* (1959), and other essays on ideas of morality and personhood among the Tallensi; and Victor Turner's studies of Ndembu rituals and symbolism (1960s and 1970s). With this body of work, the study of 'traditional' religions may be said to have reached its zenith. Essentially structural–functionalist in approach, these monographs treated systems of belief and ritual practice as distinctive wholes, expressed though the categories of a particular culture and adapted to the social and ecological setting in which they existed. Only marginally—and that mostly in the analysis of topics like witchcraft and spirit possession—did these studies address those issues of social change that were then starting to become insistent in Africa itself.

3. *Historical Perspectives*

A historical perspective—in the sense both of attention to the past, and of the analysis of change in the present—became widespread in the 1960s, with a large measure of convergence between anthropology and history. Missions, as major agents of more than just religious change, now began to attract study, first by historians for their contribution to the establishment of colonial society, as with Roland Oliver's *Missionary Factor in East Africa* (1952), or to the emergence of the educated African elite and hence, ultimately, of nationalism itself, as with the work of J. F. Ade Ajayi and E. A. Ayandele in Nigeria. T. O. Ranger probably did most to establish the historical study of African

religion, with an emphasis on the relations between religion and politics—as with the role of spirit mediums in the 1898 Rhodesia uprising—and on the specific ways on which mission Christianity became localized in East and Central Africa.

Prophetist or syncretic religious movements and independent churches attracted much attention. The seminal work was written by a Swedish missionary, Bengt Sundkler: *Bantu Prophets in South Africa* (1949/1961), which showed how independent Christian churches provided a means for the black population of South Africa to sustain alternative values to the regime of racial oppression then being imposed on them. Some Marxist-inclined analysts of nationalism in the 1950s, such as Thomas Hodgkin or Georges Balandier, saw its early precursors in religious leaders going back to just before World War I—figures such as Prophet Harris in the Ivory Coast, John Chilembwe in Nyasaland, Simon Kimbangu and his successors in the Congo. But their accounts were too reductionist, and too prone to assume that such religious movements would necessarily yield, with development, to more secular forms of politics. Most studies of contemporary movements and churches in the 1960s and 1970s—such as those by H. W. Turner and J. D. Y. Peel of the Aladura ('praying') churches among the Yoruba, Wyatt MacGaffey on Kongo prophets, M. Daneel or B. Jules Rosette on Shona independent churches, and (the richest of all in its analysis of ritual and symbolism) James W. Fernandez's *Bwiti: An Ethnography of the Religious Imagination in Africa* (1982)—laid more emphasis on the extension of African ideas of spiritual power and social renewal into Christianity.

As the tally of monographs grew, so did the demand for a theoretical synthesis. D. B. Barrett attempted in his 1968 work *Schism and Renewal in Africa* an overarching explanation for the rise of independent Christian movements, but it did not rise above the empirical identification of some rather obvious predisposing conditions, such as the depth of Christian (especially Protestant) penetration or the intensity of colonial pressure. De Craemer, Vansina and Fox (1976) proposed for Bantu Central Africa that recent religious episodes, though largely Christian in idiom, belonged to a long-established pattern, whereby phases of social malaise led communities to look for social renewal through eradicating evil (typically in the form of witches) and adopting new ritual means to ensure security and wellbeing—until things again ran down, and the cycle was repeated. The anthropologist Robin Horton, who had earlier formulated a much-debated 'intellectualist' interpretation of African cosmologies (Horton 1967), drew on it to propose the most influential general theory in a series of articles in the journal *Africa* between 1971 and 1975. This explained African conversion to the monotheist faiths as a cognitive adaptation to a basic change in social experience, from living in a 'microcosm' of confined, small-scale settings, to one in a 'macrocosm' of mobile, large-scale relations. The symbolic correlate of this was the declining relevance of local spirits and ancestors, and a new interest in the Supreme Being—relatively otiose in traditional belief, but given central position in Islam and Christianity. Horton's theory was much applied and critiqued in subsequent studies of religious change all over Africa. It had particular value in that, by placing Islam and Christianity in the same frame, it bridged the gap that had tended to develop between the study of the two world religions. Its spatial emphasis was echoed in work on regional cults and oracles, particularly by Richard Werbner on western Zimbabwe; and was combined with a Marxist perspective by Wim van Binsbergen in a bold attempt to link levels of religious development in Zambia with successive modes of production. Horton's theory was criticized on various grounds: for ignoring other kinds of religious change than the growth of monotheism; for neglecting the role of power in conversion; and (a criticism made especially by Humphrey Fisher, a historian of Islam) for laying so much emphasis on the interplay of the indigenous religious framework and Africans' experience of social change that the cultural dynamics of the world religions themselves were underplayed.

4. *Islam*

With the exception of Ethiopia, Islam's presence in sub-Saharan Africa long predated Christianity, and there is a historical and textual depth to its study not shared by the other two sectors of the African religious field. Yet the modern study of African Islam by outsiders goes back to similar missionary and administrator origins, as with traditional religion.

The French, having added a large area of Sudanic West Africa, where Islam was the hegemonic religion, to their earlier occupation of the Maghreb, were particularly concerned to gauge the political import of '*Islam noir*.' Among a notable series of scholar–administrators, the most prolific was Paul Marty, who produced no fewer than 12 volumes on Islam in different territories of French West Africa between 1913 and 1926. In English the most comparable *oeuvre* was that of an ex-missionary, J. S. Trimingham, who between 1949 and 1964 produced a series of works surveying Islam in different regions—East and West Africa, Sudan and Ethiopia—with a cultural rather than a political focus.

With the growth of a more systematic research tradition after 1950, in African universities 'Islamic Studies' was often placed with Arabic in a separate academic department from 'Religious Studies', where scholars of Islam and Muslim scholars might work together. The vital long-term project of locating and cataloging the Arabic documentation on which Islam's historical, as well as theological and legal, study

depended was begun. For centuries, the growth of Islam in Africa had been linked closely with long-distance trade and with state formation. In East Africa, the balance between external Islamic influences and internal Bantu ones in the shaping of the Afro–Islamic culture of the mercantile city-states of the Swahili coast excited debate between Islamicists, historians, archeologists and anthropologists. In West Africa a contrast was drawn between a militant Islam associated with an alliance of Fulani pastoralists and holy men, which produced, in the eighteenth and nineteenth centuries, a sequence of jihadist states, and a more accommodative Islam promoted by Dyula traders. Classic works like Murray Last's *The Sokoto Caliphate* (1967) and Yves Person's *Samori: une revolution dyula* (1969–71), still shed much light on politics in their respective modern countries, northern Nigeria and Guinea. Such institutions as Sufism, clerical lineages, and especially the religious brotherhoods that have been such a prominent feature of African Islam also received attention. Two notable studies by political scientists have examined the political and economic roles of brotherhoods in modern times: D. B. Cruise O'Brien's *The Mourides of Senegal* (1971) and John Paden's *Religion and Political Culture in Kano* (1973).

Anthropologists who worked in Muslim areas inevitably had much to say about Islam, though the initial impetus had sometimes been to marginalize it, as S. F. Nadel did in his *Nupe Religion* (1954). While historians and Islamicists tended to emphasize the long-term advance of orthodox Islam through reformist movements, the inclination of anthropology, privileging the local over the global, was to explore the substrate of indigenous practices which lie 'under' or alongside the official face of Islam. There was always *adat* ('custom') in contrast to *sharia* (Islamic law), and also a variety of less orthodox ritual practices, such as divination, charms, *sadaqa* ('alms') as sacrifice, and belief in djinns. The relation between Islam and spirit possession cults has been the subject of some fine ethnographies, such as Janice Boddy's *Wombs and Alien Spirits* (1989), on religion and gender in the northern Sudan. The label 'popular Islam,' though sometimes applied to such phenomena, misleads both because they deeply involve the religious elite and because they reach back into the past of mainline Islam. But anthropology did succeed in bringing the study of Islam and Christianity closer together, drawing parallels (for example) between patterns of conversion and the content of mundane religious practice in the two religions (Lewis 1980).

5. *African Religion at the Turn of the Millennium*

Since the mid-1980s, the study of African religion has both become more of a unified field in itself and become less compartmentalized from the rest of African studies. Two works which show this conspicuously are David Lan's *Guns and Rain* (1985), on the role of spirit mediums in the guerrilla war which won Zimbabwe's independence, and Stephen Ellis's *The Mask of Anarchy* (1999), which incorporates the 'mystical' factor into an account of the civil war in Liberia. More generally, religion—especially Islam and Christianity—came to play a larger role in public life. As the capacity of African states declined, the major churches (and the Catholic Church above all) stood out more as the most effective institutions of civil society, and by the early 1990s were playing a significant role in movements of democratization (though with fitful success), in development initiatives, and, in South Africa, in the process of post-apartheid reconciliation. At the same time, the churches had been not been able to stop the atrocities in Rwanda and religion emerged more strongly as a source of political conflict in countries such as Nigeria and the Sudan. In his *African Christianity* (1998) Paul Gifford compares Ghana, Cameroon, Uganda, and Zambia to give a nuanced picture of the public role of the churches, concluding that they reflect, at least as much as they transcend, the political values of the wider society.

New militant movements came to the fore in both Christianity and Islam, mirroring one another in their strongly global orientations. The Islamic movement might be seen as another surge of the long-term reformist trajectory, in that it is oriented to the normative standards of the Middle East, generally hostile to Sufism and the influence of the brotherhoods, and concerned to promote Islamic education, *sharia* law, and a more universal Muslim identity. However, there is still much variation from one country to another (Brenner 1993, Westerlund and Rosander 1997). In contrast, the rise of neo-Pentecostal, charismatic or 'born-again' Christianity, represents (at least on the surface) a reversal of the earlier trajectory of 'Africanization' or local inculturation, in that what attracted its youthful adherents was precisely its transnational quality, its use of electronic media, and its evocation of American modernity.

Some of the best work of the 1990s on Pentecostalism—David Maxwell on eastern Zimbabwe or Birgit Meyer on the Ghanaian Ewe, for example—shows how necessary it is to relate modern developments to earlier mission activity in its particular localized forms. The prime example of such a two-way integration of anthropology and history appears in the *oeuvre* of Jean and John Comaroff, whose massive work *Of Revelation and Revolution* (vols. 1–2, 1991, 1997) explores how Protestant missions contributed to 'the colonization of consciousness' of the southern Tswana through their many-sided impact on daily life. In contrast, Paul Landau's *The Realm of the Word* (1995), on the northern Tswana, Donald Donham's *Marxist Modern* (1999), on the contribution of missions to revolution in southern Ethiopia, and J. D. Y. Peel's

Religious Encounter and the Making of the Yoruba (2000) all give more attention to the import of the religious content of mission for new local and national identities. The forms of religion in Africa transmute with great rapidity, yet its centrality to social relations shows little sign of secular attenuation. While Christianity and Islam are now formally predominant, with 'African traditional religion' largely a thing of the past, the focus of religious concern still shows much continuity with the 'pagan': empowerment, guidance and deliverance from mundane evil are what Africans continue to ask of their gods. Moreover, many recent studies from all over Africa have drawn attention to *The Modernity of Witchcraft*, as Peter Geschiere put it in the title of his 1995 book, mainly about Cameroon. Despite its seemingly radical emphasis on renewal and its global connections, Pentecostalism maintains and even extends older discourses of witchcraft and the demonic. This social reality underscores the need for the closest interdependence between the present and the past in African religion. For just as studies of contemporary religion or those concerned with the 'advance' of the world religions must acknowledge the durability of values and ontologies grounded in the indigenous religions of Africa, so also must historical studies of religion be oriented towards those dynamics of change which have eventuated in the present complex religious disposition. A principal theoretical outcome of the study of African religion over the past century is that one of its main conceptual instruments—the distinction between the 'traditional' and the 'modern'—finally needs to be abandoned.

Age: Anthropological Aspects

Age is a product of the process of aging, which is partly determined by the social environment. Recognition of this social component has led to some initial attempts to identify features of the life course that are unique to Western civilization. However, the ethnographic literature reveals a considerable blurring of some of these stereotypes. Thus Philippe Ariès's (1962) influential argument that 'childhood' as opposed to 'adulthood' is essentially a product of the industrial revolution may be challenged with reference to the widespread practice of initiation in other cultures, which frequently marks a transitional point in the life course, distinguishing distinct stages, and is associated with a range of beliefs associated with childhood and development (La Fontaine 1985). Again, G. Stanley Hall (1904) is credited with 'discovering' adolescence as a further category that arose out of the industrial cities in America, leading to a developing interest in this topic; yet deviant subcultures associated with dispossessed youth have been noted in some traditional rural settings and extend even to studies of primate behavior (Spencer 1965, Pereira and Fairbanks 1993). Again, Leo Simmons' (1945) early survey of the role of the aged in 'primitive' societies is often cited, suggesting that this category was highly respected as compared with the West, where the family has diminishing importance in the process of urbanization (Cowgill and Holmes 1972); yet the data on this topic reveals a varied response to the problem of reconciling respect for the age and experience of older people with the frustrations of their overbearing power within the family on the one hand, or the liability of caring for them on the other, especially in impoverished situations where the family often does not survive beyond two generations.

The complexity of the problem has led to the development of more refined concepts among sociologists, focusing on particular stages of the life course as prime topics for investigation by specialized subdisciplines. In contrast to this, anthropological studies

aim to be holistic, and within a culture, any role or status associated with age has to be viewed in the context of the life course as a whole.

1. The Family and Ambivalence Towards Aging

Thus, the marginalization of certain age categories—perhaps adolescence or old age—forms part of a wider pattern involving a complex of relations between young and old. Adolescent subcultures, for instance, may be viewed as an alternative to the authoritarian structure of the family, and a milieu where the more open-ended bonds between age peers sharpen their awareness of an alternative experience involving a more creative lifestyle, preparing them for future possibilities within the wider community. Again, some studies have indicated that stress and hardship during adulthood, perhaps a midlife crisis, appears to reinforce people's ability to cope with the social discomforts of old age in due course. Conversely, a more cushioned life career appears to leave people more vulnerable to the sense of loss and isolation as they grow old.

Very broadly, ambivalent regard for old age is especially associated with the elaboration of the family as a corporate unit in preliterate agricultural societies. The evolution of the family, reaching a peak in such societies, is entwined with the evolution of age relations and the concept of 'status' coined by Henry Maine (1861), where social position is ascribed by being a member of a family. This is closely associated with power in the hands of the most senior members by age as the legitimate custodians of family tradition. In this milieu, cultural knowledge itself may be treated as a form of property, to be imparted or withheld. In a very pertinent sense, property relations within the family are age relations, creating bonds and tensions within the family (Foner 1984). A common factor underlying the urban stereotypes of old age and adolescence is the demise of the family as a dominant institution (Maine's 'status to contract').

The premise of respect and even fear for older people is especially widespread in rural Africa, where it is often associated with strong patrilineal families and polygyny. This highlights the notion that children are the property of the family in 'status-dominated' societies, giving the senior generation the power to marry off their daughters early and to delay the marriage of sons for perhaps a decade or more. As long as this regime can be maintained, extended bachelorhood facilitates widespread polygyny among older men. The array of life-stages is illustrated in Fig. 1 with reference to the Samburu of Kenya, who provide a clear-cut example of a more general phenomenon, with no dispensation for younger men to marry early or for widows to remarry. The concave shape of the age distribution is characteristic of preliterate societies, where mortality rates are especially high among the young.

The figure also indicates the contrasting life trajectories of women who are married young to much older men. The depressed status of women in such societies has to be viewed in relation to their total life-course.

Figure 1
Age, status, and the demographic profile of a polygynous society (Samburu 1960)

Whereas a boy tends to take the first step from the obscurity of childhood towards a promising adulthood with his initiation, the marriage of a girl transforms her from the obscurity of childhood to an initially obscure role as a young wife with very restricted opportunities and a stranger in her new home. A view of women as the victims of male exploitation is particularly apt at this low point in their careers, and especially in societies where there is a sharp separation between male and female domains. An alternative viewpoint portrays women as agents who can manipulate their depressed situation to their own advantage. This becomes increasingly apt as her life course develops and notably once she surmounts the restrictions of her reproductive years and is increasingly independent of her aging husband. In the prime of middle age, the advantage still rests with men. However, this tends to be reversed beyond this point as they lose the will to assert themselves against younger, more competitive successors and are edged to the margins of activity in community affairs. Women are less hampered by aging until they are too frail to play an active role. The process of growing old for women in these circumstances is to free themselves from the domestic routine, but not from their personal networks which focus on their growing family with a freedom to choose how they wish to involve themselves (Amoss and Harrell 1981).

2. *The Experience of Maturation and Aging*

The social experience of maturation and aging shapes the perception of time and hence its meaning in a quite fundamental sense. This may be analyzed in several ways. The first involves an autobiographical approach, viewing each major event of the life course as a uniquely personal experience that may form a pattern retrospectively, but can only be anticipated within limits. The personal experience of aging coincides with the shared experience of historical change, and any analysis of one of these has to disentangle it from the other (Mannheim 1952). Thus, when older people suggest that policemen are getting younger, this may be a sign that they are getting older; but when they suggest that bank managers are getting younger, this may accurately reflect a historical trend. Correspondingly, in anthropological studies, the extent to which younger people are seen to subvert tradition may be an aspect of a continuous process of adaptation to new opportunities; and 'tradition' itself may be adapted by the new generation as they mature and take over as its custodians. Or youthful subversion may be in part a response to their subordination—an adolescent rebellion that is mounted by each successive generation. In the absence of written records, only longitudinal studies, monitoring the process of change over a period of decades, can distinguish between irreversible historical trends and the tenacity of family structures perpetuated by the recycling of vested interests and intergenerational strains. To the extent that a popular awareness of social change draws attention to recent innovations and gives an impression of the contemporary scene as a watershed between tradition and modernization, the persistence of age relations embedded in resilient family structures is less evident in short-term studies. Underpinning this resilience is the cumulative nature of privilege associated with age in 'status-dominated' societies. Those who react against traditional restrictions in their youth become the new custodians as they age.

A more interactive approach to the experience of aging, especially in tight-knit communities, focuses on the accommodation of major life transitions as a discontinuous process; a life-crisis theory of aging. The significance of rites of passage is that they involve the wider community, even beyond the family, in a shared experience of irreversible change. In the space between these events or other critical episodes, people age physically, but the configuration of social relations remains unchanged and there is a sense of timelessness as trends leading to the next critical change unfold. When this occurs or is precipitated, the configuration of roles adjusts to a new status quo and there is a distinct step in time. In dialectical terms, there is a mounting contradiction between inflexible social relations and the unstoppable process of maturation and decay, undermining the array of power relations. From this point of view, the anxieties that accompany these transitions and shifting roles are also anxieties of aging. Critical life events and transitions are key points, both in the experience of aging for the individual and with regard to adaptation and regeneration within the community.

3. *Age Systems and Hidden Knowledge*

A third approach to the experience of aging has coined the analogy of a 'cultural clock' that prescribes the appropriate ages for major life transitions within any society, facilitating adjustment, and heightening the awareness of those who forestall or lag the norm (Neugarten 1968). While this expresses an essentially conformist approach towards aging, it is a particularly appropriate model for societies with age systems. And because members of such societies are very aware of age, they provide an ideal type for examining a range of issues associated with the process of aging. In an age system, those of a similar age are grouped together as an age set (or age group), maturing and aging together. Their position at any stage may be termed as age grade, consisting of an array of expectations and privileges. In effect, the age set passes up an age ladder, rung by rung, through successive age grades in a defined progression, like children passing through school but over a more extensive period in a process

that persists into old age. The left-hand side of Fig. 1 illustrates a society with such a system, indicating the extent to which the transitions from boyhood at initiation and to elderhood with marriage are closely associated with age. Each step in the demographic profile broadly represents an age set, and the successive statuses for married elders could be elaborated to provide a more detailed set of aged grades. In general, age sets tend to involve males only, but they may also define critical aspects of men's relations with or through women, giving women a distinctive role within the age system. Thus, the position of a woman may be highlighted in relation to the age set of her husband or father or sons, but women are only rarely grouped together by age, except sometimes during the brief period leading up to their marriages.

Age systems institutionalize the cultural premise of respect for age through a form of stratification that in effect inverts stratification by caste. In contrast with the total immobility of a caste system, where status is determined by birth and persists throughout life, age systems guarantee total mobility: a young man is initiated onto the lowest rung of the age ladder as a member of the most junior age set, and is systematically promoted with his age set from one age grade to the next towards the top. The nuances of each age system relate to the process of promotion, involving certain pressures from below and resistance from above. It is these pressures, arising from the interplay between a concern for status and the physical process of aging, that provide the mainspring for the 'cultural clock,' which is perceived frequently as a recurring cycle of promotions and delays, spanning the interval between successive age sets.

Elaborate age systems are associated primarily with the pastoralist peoples of East Africa. The relevance of nomadic pastoralism appears to stem from the equality of opportunity in a setting where a mixture of acumen, commitment, and sheer luck determine the success of each stock owner. Unequal fortunes tend to even out as the more successful convert their surplus into further wives as an investment for the herding enterprise, leading to larger families and the dispersal of this wealth among the sons of the next generation. Correspondingly, the ideals underpinning age-based systems are of equality among age peers associated with the mobility of wealth rather than the inheritance of privilege based on birth and accumulated capital. This is complemented by the premise of inequality up the age ladder, regardless of family or wealth, again endowing ultimate moral authority and ritual initiative on the senior generation. Age systems were more widespread historically, but have become outmoded by the gathering complexity and inequalities in the process of urbanization.

The position of older men as the repositors of traditions has an affinity with secret societies in West Africa and Papua New Guinea, where esoteric knowledge is acquired by stages and is only fully understood in later life by those that are eventually initiated into the higher levels of the organization. It is the hiding of this secret rather than the elusive knowledge as such that displays power, impeding the progress of individuals up the career ladder towards the privileges at the top. Among East African societies with age systems, there is a similar mystique and hierarchy of power, where careers are controlled by the ritual authority ascribed to those higher up. However, it is as age sets rather than as individuals that promotion takes place; and to the extent that the pace of these is controlled by older men, manipulating the 'cultural clock' to their own advantage, they are playing for time against the inevitability of their own aging. Older women, middle-aged and even relatively young men may conspire in this, resisting the advancement of their juniors by age. For those that live long enough, the frailty of their aging does not diminish the awe for their great age.

The antithesis of the power of older men is the physical virility of youth, often associated with an alternative lifestyle in 'warrior societies.' This poses a contradiction between the moral advantage that lies with older men and the more immediate interests of younger men, who may react against traditional restrictions. Historically, situations of political turbulence offered opportunities that favored youth, overriding the constraints of the age system. However, it is also characteristic of the periodic age cycle that certain phases may be associated with greater or lesser gerontocratic control over a new age set. These are paradoxically an aspect of the system where privilege is vested heavily in the hands of older men, notably over women and marriage, and this creates a certain power vacuum on the lower rungs of the age ladder, encouraging youthful rebellion. By viewing age systems as interactive enterprises concerned with the distribution of power with age, rather than in terms of 'gerontocracies' or 'warrior societies' as such, their apparent resilience to change relates to involvement in the system at all ages. Those who can claim certain privileges of youth also have a stake in their future as elders.

A holistic approach towards age systems leads one to examine the relationship between principles of age organization and aspects of the family. As in other polygynous societies, competition for wives can give rise to rivalry between brothers, and the delayed marriage of younger men to tension between generations. Age systems can serve to diffuse these strains by imposing the restrictions on younger men from beyond the family (Samburu), by creating an alternative and prized niche for younger men (Maasai, Nyakyusa), or by maintaining a disciplined queue towards marriage (Jie, Karimojong). A variation of this general pattern occurs among the Cushitic-speaking peoples in Ethiopia and Kenya, where the age system underpins the privileges of first-born sons within the family.

A clear link between age systems and family structures is illustrated by the extent to which recruitment to an age set is often complicated by restrictions of generation: the position of the son within the system is determined in part by that of his father, giving rise to a hybrid 'age/generation' system, rather than one based solely on age (Stewart 1977). The rules can be highly elaborate, leading to speculation that they either are spurious or have been misunderstood. However, their implications for the distribution of power and authority with age are very specific, and understanding in each instance derives from a wider analysis of relations between old and young within the family and the wider community (Baxter and Almagor 1978). Younger men have the advantage of physical virility and the rapid accumulation of practical experience. Age systems, and indeed any institutions that endow older people with power, may be viewed in terms of their ability to impose a moral superstructure with a higher authority. The claim of older people to be the true custodians of tradition, and perhaps to have the closest rapport with the ancestors, places society above the brutish forces of nature and inverts the natural process of aging in a hidden display of power.

Age Policy

As government interventions in the society and economy have diversified and expanded, what can be called 'age policy' has developed for organizing and regulating phases in the life course. Age policy centers around the state for two reasons. First of all, it has come out of state interventions: constructing the welfare state cannot be separated from the task of forming and categorizing phases of life on the basis of age-based norms. Secondly, age has been a major policy tool for public authorities. Dividing the population into age groups has been the easiest way to distribute individuals to socially assigned activities (see *Age Stratification*). These two dimensions of age policy will be discussed, and a few concrete examples of the implementation of policies regarding youth and old age will be examined.

1. Age Policy, the Product of Government Interventions

Along with the building of the modern state has emerged a social and legal construction of the individual. At stake in this process is the creation of conditions 'that single out the individual' so as to enable each person to stand apart from family and community bonds. The individual has thus been taken 'as the prime holder of rights and duties and as the prime target of bureaucratic and administrative acts' (Mayer and Schoepflin 1989, p. 193). This construction of the individual has been grounded in a set of age-

based norms that have marked the chronological continuum of life with significant thresholds and organized it into successive phases.

Increasingly strict laws have been adopted about the age for working (specifically for regulating child labor and, more recently, for setting the retirement age) and the age of compulsory schooling. These laws have laid the very foundations for social constructing and institutionalizing the life course (see *Life Course: Sociological Aspects*). The life span has thus been divided into three distinct phases. Owing to its increased interventions in the economy and society, the state has regulated the ages of life. By 'policing ages' (Percheron 1991), it has become the major actor in constructing the life course. In particular, it has distributed social duties and activities by organizing the triangular relations between family, work, and school (Smelser and Halpern 1978) into an orderly model of successive phases. Each phase has thus been identified with an activity that, setting it apart from the other phases, endows it with meaning and identity. Childhood is the time for education and of dependence on the family; adulthood is defined by work; and old age is a period of rest after a life of work. This threefold organization of the life course has become an institution as the welfare state has expanded and as age norms have been enacted in law.

The invention and generalization of old-age pensions—one example of age policy—has played a decisive role in constructing and consolidating this 'tripartition' of the life course (Kohli 1987). First of all, retirement systems have been a major factor in determining the order and hierarchy between the three principal phases of the life course—with, at the center, work as the social contents of adulthood. This phase lies in between youth (devoted to education for a life of work) and old age (associated with inactivity). These systems have helped stake out a life course where the individual's contribution during adulthood to the world of work conditions the right to rest, placed at the end of life. Secondly, retirement systems, along with other social policies (such as education), have given more weight to chronological criteria for marking the transitions from one phase to another. Old-age pensions have thus chronologized the life course, marked as it is by the legal ages for starting and leaving school (the latter separating childhood from adolescence) and for going on to retirement with a full pension (an event marking the threshold of old age).

This division of the life span into three chronological phases has produced a standardized life course. At the same age, everyone moves quite predictably from one phase to the next. At an equivalent level of education, entering the world of work occurs at the same age for nearly everyone. And the retirement age sets the date when everyone will stop working. Long-term trends in the ages of exit from the labor force provide evidence of this standardization of behaviors. As retirement systems have expanded to cover more and more of the population, the moment when individuals stop working has gradually approached the age of entitlement to a full old-age pension.

Old-age pensions have fostered new expectations about the future. The individual no longer has the same prospects as in preindustrial societies, where the family and private wealth determined the timing of phases in life and where individuals had no future as such: they died young. The development of old-age pensions, along with a much longer life expectancy, has individualized the life course even as it has 'chronologized' it. Thanks to pensions, the individual is endowed with a future. As a consequence, retirement has furthered the change from a society where the person was ascribed a status through membership in a family or local group to a society of achieved statuses and, thus, of mobility. In this new society, the individual has prospects. Security is now based on the person's work and no longer on belongings, or a local or family status. To insure this security, retirement involves successive generations in forms of reciprocity and statistical, long-term solidarity. It thus contributed to erecting and developing a new social order in line with the requirements of a society undergoing industrialization. This example illustrates the state's regulatory interventions that have instituted age-based norms for 'policing ages.'

This social construction of the life course by the state, in particular through welfare policies, is an ongoing process. During the 1980s and 1990s, all sorts of early exit schemes were worked out to enable aging workers to withdraw from the labor force before the normal retirement age. This can be interpreted as a factor in deinstitutionalizing the threefold organization of the life course (Guillemard and Van Gunsteren 1991), since these schemes undermine the regulated transition from work to retirement. Early exit schemes wreak havoc in the orderly succession of the three phases in the life course. Appearances suggest that early exit is a mere event on the retirement calendar entailing no other noteworthy change. But looking beyond appearances, the impact of these new age-based measures advises interpreting early exit and preretirement schemes in terms of increased flexibility in reorganizing the end of the life course (Guillemard 1997).

The most frequently used early exit schemes have been, not old-age pension funds, but rather disability and unemployment insurance funds. These schemes have proven extremely malleable. In all countries, they have continuously evolved as a function of the employment situation. This can be interpreted as a detemporalization of the life course: the individual can no longer imagine a continuous, foreseeable life. The order of phases and activities is no longer precise, and is even contingent. The timing of definitive exit from the labor market is unforeseeable. No one working in the private sector knows when (at what age) or how (under what conditions) they will defin-

itively stop working. As a result, the end of the life course is becoming destandardized as well. Since chronological thresholds are no longer clearly set, the work inability (real or alleged) of older wage-earners is becoming a criterion more important than chronological age. Given the reforms now under way or under study, retirement tends to be timed later in life. In any case, definitive exit from the labor market has been fully separated from admission into retirement. There is now a long transition as persons move out of work and toward retirement.

The hierarchical, orderly succession of phases in the life course is coming undone. Sociologists who study youth have described this as a 'tourniquet' on young people's lives. A period of unemployment often follows education, as young people enroll in government-sponsored training programs or take up odd jobs that, instead of leading to integration in the world of work, often end in further 'mixes' of training programs with unemployment compensation. Entrance into the labor market is uncertain. A similar pattern can be detected in exit from the labor market. Arrangements in between a full-time job, full retirement, and outright unemployment now punctuate the end of careers. These changes have set off an identity crisis among economically inactive, aging persons, who do not see themselves as being retired or jobless but, instead, as being 'discouraged workers' who have given up looking for a job (Casey and Laczko 1989).

2. *Age Policy, a Major Policy Tool for Public Authorities*

As a neutral, universal criterion, age has been an especially useful tool for constructing the social security system. This system of social insurance needed to lay down universal conditions for eligibility; and age was retained as the most relevant criterion. Insurance against the risks of disability or unemployment only cover persons in the 'age of work.' And old-age funds only serve pensions after a regulatory age threshold. The welfare state has thus developed out of increasingly strict norms about the timing of phases in life. Systems of education and social (security) insurance funds have laid down clearly marked thresholds: a person is either a child in school (with life regulated by policies concerning childhood and parenthood) or else an adult at work (with risks covered by insurance funds) or else a retiree (entitled to a pension).

Entitlement under universal rules contrasts with the situation in societies before the creation of the welfare state. There, the passage from one phase to another (from childhood to work, for example) could be gradual and reversible, since families responded to needs in an occasional, particularistic way (Hareven 1986). The state has used this single criterion of age to perform its principal duties: redistributing revenue between age-groups and generations; maintaining order by assigning roles, statuses, activities and identities to each age-group and individual; and managing human resources.

As regards this management of human resources, Graebner (1980), in his history of retirement in the USA, has shown that the invention of old-age funds represented more than just a means for insuring older workers who could no longer work: firms used these funds to control the flow of labor. Companies could thus rationalize the withdrawal of older workers from the work force and replace them with young people—after all, the recently developed Taylorist Scientific Management had proven that older workers were less efficient. With respect to public policies in the UK since 1945, Phillipson (1982) has shown that the incentives offered to older workers to either keep or stop working have fluctuated depending on labor market needs. Older workers form a reserve army to be mobilized when there is a labor shortage. Or, on the contrary, they can be pushed out of the workforce during economic downturns, as unemployment rises.

As the state and and its bureaucracy have developed, age has become a major tool in government interventions in the society and economy. Dividing the population into age groups and adopting age-based programs now constitute the prevalent response to social problems. As a result, occupations, customers, and other targeted groups are segmented by age. Health care, for instance, is increasingly based on occupations specialized in handling age groups, such as childhood (Heyns 1988) and old age (Haber 1986), and as much can be said about social work.

3. *Implementing Age Policies: Childhood and Old Age*

3.1 *From Policing Ages to Working out a Fully-fledged Age Policy*

Childhood, as well as old age, has been identified as such only in modern times. During the Middle Ages, childhood did not exist as an autonomous phase in life; it emerged during the eighteenth century, when children were 'placed apart and reasoned' inside institutions specialized in educating them (Aries 1973). Likewise, the invention of old age owes much to retirement systems, which, by setting the age of entitlement to a pension, have established a threshold and thus assigned old age the socially uniform meaning of 'pensioned inactivity' (Guillemard 1983).

For each of these two phases, a variety of 'social laws' have been passed. In the case of childhood, laws regulate maternity and childcare, schooling, family

allocations, health, and child labor. Two major policies have defined old age. First of all, job and retirement policies have regulated the relation between age and work, and set the threshold for entrance into old age. Secondly, welfare policies for the elderly, which provide services to those who have physical disabilities or experience financial hardship, have assigned an identity and 'way of life' to old age (Guillemard 2000). These heterogeneous measures are more than a means of using age-based norms to police ages; they form a coherent, public policy for managing ages and the phases of life.

Once the phases of life had been clearly distinguished, broad, coherent social programs gradually emerged for managing them. In France during the 1960s, major public reports on youth and old age were published; and public interventions, coherently programmed with the clearly formulated aim of improving the management of these age-groups. French public authorities published in 1962 the first major report on age policy; its title, 'Old age policy,' clearly signaled a shift in government priorities. The USA adopted the Older American Act (Estes 1979). Meanwhile, several age policies have been programmed in Europe: for the social and vocational integration of young people, for infancy and for the frail elderly (Olson 1994).

3.2 *The Perverse Effects of Age Policies*

By implementing these various age-based policies, public authorities have invented and now regulate infancy, childhood, adolescence, old age, and advanced old age. They have assigned social contents and identities to these phases in life. These policies have not, however, always had effects in line with their initial objectives.

As studies of the old age policies implemented in the USA or Europe since the late 1960s have shown, the measures for providing social services and facilities to help the elderly continue living at home and avoid institutional custody (with the consequences of 'marginalization' and lessened autonomy) have made these persons dependent (Guillemard 1983, Walker 1980). The central argument in studies of these perverse effects is that, despite the good intentions underlying public interventions and despite tangible results for beneficiaries, these programs have, in general, not maintained or developed the autonomy of targeted age groups. The new arrangements for providing home services have perversely turned any physical or social disability into a form of 'dependence.' Thus has arisen a new definition of the senior citizen as the 'recipient of services whose extent and nature is decided by others' (Townsend 1981, p.19). Furthermore, the fragmented provision of home services have tended to define the beneficiary as a long list of needs for: health care, social ties, home helpers, cleaning services, etc. As a consequence, a category of 'professionals' has been assigned to satisfy each need.

4. *Conclusion: The Rise and Fall of Age Policy*

By imposing public education, by making decisions about health, social services, and the family, by creating retirement and then supporting preretirement, the state has, for more than a century now, regulated the relations between age groups and generations. But this 'age-management' has reached its limits, as several studies have shown.

In his pioneering book, Neugarten (1982) questioned both the pertinence of age-based policies to the lives of the elderly and the efficiency of public policies targeting age groups. In a call for an 'age-neutral society' she suggested organizing government interventions on the basis of needs instead of age. Extending this approach with the concept of 'structural lag,' Riley et al. (1994) has emphasized that using age-based criteria has considerably reduced the 'opportunity structures' that shape people's lives at every age. Despite longer life expectancies as well as improvements in health and ways of life, social structures are lagging behind. Because of this lag, there is a need for a new formula for combining work, family, and leisure so as to create an 'age-integrated society' where social activities are interwoven through all phases of life. The relevance of age policy has thus come under severe questioning, as proven by the European Commmission's call for a 'society for all ages' and by new interest shown for fighting against age barriers and age-based discrimination in employment (European Foundation 1997).

Age, Race, and Gender in Organizations

From the psychological perspective, an organization is *about* organization. It is the organization of people, time, resources, and activities. This article will consider the organization of people in two ways: how are they identified and brought into the organization, and once they enter the organization, how do individuals and the organization adapt to each other? In particular, it will consider the impact of the demographic characteristics of age, gender, and race on these two human resource processes.

1. *Relational Demography*

Pfeffer (1983) has characterized organizations as relational entities and introduced the concept of 'relational demography' (Mowday and Sutton 1993). The implication of this concept is that work group composition, and attempts to maintain or change that composition (formally or informally), may in turn influence recruiting, hiring, leadership, motivation, satisfaction, productivity, communication, and turnover. In a partial test of these propositions, it was found that as work groups increased in racial and gender diversity, absenteeism and turnover also increased (Tsui et al. 1991, Tsui and O'Reilly 1989).

Schneider (1987) introduced a similar concept, which he labeled the attraction-selection-attrition model (ASA) that emphasized the similarity of attitudes, values, personality characteristics, and interests rather than demographic characteristics *per se*. Like Pfeffer, Schneider proposed that individuals seek to limit work-group access to those most like them. Further, individuals will attempt to drive out those most unlike them. Both Pfeffer and Schneider hypothesize that group member similarity (demographic similarity for Pfeffer, and intrapersonal and interpersonal similarities for Schneider) creates trust and enhances communication, resulting in commitment, satisfaction, and effectiveness.

Jackson et al. (1991) studied management teams in the banking industry and found support for the models of both Pfeffer and Schneider. These models and the preliminary findings are critically important for two reasons: (a) team work is becoming the standard in many industries, requiring more worker interaction than ever before; and (b) most countries are undergoing a 'demographic revolution' either as a function of anticipated workforce population changes (e.g., the 'aging' workforce) or because of externally precipitated shifts (e.g., legislation inhibiting occupational segregation by race or gender, the creation of new sociopolitical entities such as the European Union, or the elimination of longstanding sociopolitical barriers such as the collection of 'Warsaw Pact' nations. As a result of many and interacting forces, race, gender, and age restrictions in the workplace are disappearing. If Pfeffer and Schneider are correct (as the data of Tsui et al. and Jackson et al. suggest they are), diversity becomes less a goal and more a challenge.

2. *Demographic Comparisons*

In considering differences that may be noted between any two demographic groups (e.g., men vs. women, old vs. young, ethnic minority vs. ethnic majority), it is useful to consider alternative explanatory models. Cleveland et al. (2000) have proposed three such models. The *biological model* assumes genetic, hormonal, and/or physical differences between groups

being contrasted. The *socialization model* assumes that any observed differences are learned. The *structural/cultural model* assumes that observed differences are the result of social structures and systems that work to maintain the status quo of a power hierarchy. As we consider the issue of relational demographics in organizations, elements of each of these models will become apparent.

3. Selection of Group Members

In the selection or promotion of employees, various attributes may be considered. These attributes include training and experience (e.g., educational accomplishments), abilities (cognitive and physical), personality, and skills (i.e., practiced acts). Further, these attributes may be used to predict a wide range of employee behaviors and outcomes including productivity, absenteeism, turnover, and satisfaction (Landy 1989).

3.1 Age

With respect to life-span development, it seems clear that the differences *within* any age stratum are exceeded by the differences *between* strata. Thus, while one might describe mean differences between any two age groups on tests of cognitive function, these differences are modest when considered in the context of their respective group standard deviations (Schaie 1982). Further, it is clear that job-relevant experience more than offsets any modest decline that might occur in job-related abilities (Schmidt et al. 1992). The same tradeoff between ability and experience is true, but to a somewhat lesser extent, with respect to the decline of physical abilities with age (Landy et al. 1992). For a wide range of jobs from managerial to unskilled labor positions, the age of the applicant should be largely irrelevant.

Recent meta-analyses have demonstrated that there are no differences in either the objective performance or the judged performance of older workers (Arvey and Murphy 1998, McEvoy and Casio 1989, Waldman and Avolio 1986). It does appear that older workers experience greater satisfaction and less absenteeism, but this may be more a function of increasing experience, skill development, and organizational position than age *per se* (Bedeian et al. 1992). When experience and job title are held constant, there seem, to be few differences in satisfaction between younger and older workers (Mangione and Quinn 1975). This confound is exaggerated by full-time/part-time status since part-time jobs tend to be more mundane and are most often held by younger workers. Once again, when part-time vs. full-time status is held constant, there are no differences in satisfaction between older and younger workers (Hollinger 1991).

3.2 Gender

There appears to be little difference between males and females with respect to general mental abilities. Although, on the average, females tend to do somewhat more poorly on tests of mathematical abilities (Feingold 1995), and are underrepresented in many scientific and engineering specialties, these differences may be the result of stereotypes held by employers, academic advisors, or by women themselves (Cleveland et al. 2000). With respect to personality differences, there are no clear-cut gender-based differences in either personality structure, or assessed personality dimensions (Hough 1998, Hough and Oswald 2000). Nevertheless, there are some substantial differences in physical abilities (Hogan 1991, Salvendy 1997), particularly in cardiovascular endurance and upper body strength. These differences need not be prohibitive, however, for physically demanding jobs since most jobs may be performed in a variety of ways that permit task accommodation as well as allow experience to offset lower levels of physical abilities (Landy 1989). As an example, several studies have suggested that women seek different work situations from men. Men tend to value compensation and opportunities for advancement to a greater extent than women; women, on the other hand, place a greater emphasis on hours of work and opportunity for social interaction. (Betz and O'Connell 1989, Chelte et al. 1982, Konrad and Mangel 2000, Tolbert and Moen 1998). These findings suggest that there may be male/female job satisfaction differences that result from the differential availability of rewards that each values. When job title and experience are held constant, there are no data to suggest systematic differences in the overall job satisfaction of males and females.

3.3 Race

It is not uncommon to find a mean score difference of as much as one standard deviation between whites and blacks on standardized multiple-choice cognitive ability tests (with blacks scoring lower) (Dubois et al. 1993). Hispanic test-takers usually fall midway between white and black test-takers, scoring approximately 0.5 standard deviations below whites and above blacks (Hartigan and Wigdor 1989, Jensen 1980, Sackett and Wilk 1994). But there is considerable overlap among the score distributions, suggesting the strong influence of cultural or structural issues. A debate has raged for decades with respect to the reason for these observed differences (Gottfredson 1994; Helms 1997) but there is no clear explanation at this point—just several intriguing hypotheses. The organizational reality, however, is that if standardized cognitive ability tests are used as the sole screening device for employment, blacks, and to a lesser extent Hispanic applicants, will be at a distinct disadvantage

when competing against white applicants. No such differences appear in physical abilities, personality tests, or structured interviews (Hough and Oswald 2000).

Since many, if not most, jobs depend on communication skills and personality characteristics, in addition to cognitive ability, it would seem obvious that assessment should cover a wide range of job-related attributes and not simply cognitive abilities. In expanding the comprehensiveness of the assessment process, nonwhite applicants can compete more favorably with their white counterparts, at the same time enhancing validity or job relatedness and diminishing the test score gap between applicant groups. With respect to outcomes such as job satisfaction, turnover, and absenteeism as was the case in other demographic groupings, there are no reliable differences between whites and nonwhites when job title and experience are held constant.

4. *Issues of Adaptation*

Assuming that women, older workers, and members of ethnic minority groups are employed by an organization, what are the issues of adaptation that need to be addressed? The adaptation challenges would seem to be similar for each of these demographic groups. The concept of a 'traditional' job is of value here (Cleveland et al. 2000, Sterns and Miklos 1995). Women and ethnic minorities are seeking access to occupations and organizational levels where they are historically underrepresented. Older workers are seeking entry to nontraditional occupations/job titles or to maintain an organizational position in spite of age-based stereotypes. In that sense, each group is 'dissimilar' to those already holding positions that group members seek.

If, as both Pfeffer and Schneider predict, 'dissimilar' members will be marginalized or forced out of the organization, what is the psychological mechanism by which such marginalization may occur? The most likely mechanism is a stereotype that is used as a heuristic for determining how women, older workers, and ethnic minority group members will be perceived. A stereotype is a set of beliefs and/or assumptions about a particular group of people. Stereotyping assumes that (a) the beliefs or assumptions are veridical, and (b) that all members of the group can be accurately characterized by that stereotype (Hilton and von Hippel 1996). The existence of race, gender, and age stereotypes has been well established (e.g., Cleveland et al. 2000, Sterns and Miklos 1995). Stereotypes can operate to the disadvantage of demographic subgroups in several different ways. The most obvious is by influencing the decisions of individual managers. Such decisions could involve access to training, promotion or job transfer, occupational segregation (Cleveland et al. 2000), compensation decisions or layoff decisions. In addition to the behavior of managers, stereotypes can be held by the stereotyped individuals themselves. This leads to individual decisions regarding 'appropriate' or 'expected' behavior. Thus, individuals may actually limit their own opportunities by accepting the assumptions and beliefs consistent with the stereotype. This results in a self-fulfilling prophecy that provides further support for the maintenance of the stereotype.

It is often assumed that stereotypes influence not only personnel decisions through the data used to support those decisions. One such data source is performance evaluation information provided through supervisory ratings. In spite of the intuitive appeal of this hypothesis, meta-analyses do not support it (Sackett and Dubois 1991, Pulakos 1989). Thus, it does not appear that performance ratings are being used to force 'dissimilar' members out of the organization. Recent research on stereotypes (Glick et al. 1988, Hilton and von Hippel 1996, Kunda and Thagard 1996) suggests that stereotypes are more likely to operate in the absence of individualized information about a particular individual. Thus, a manager may be opposed to the idea of 'older' engineers or female engineers in a department but feel very differently about a particular older or female engineer. This could account for the fact that even though there are no differences between the performance ratings of majority vs. minority, or male vs. female, or older vs. younger employees, there are still differences in occupational outcomes such as salary levels, progression to upper-level management ranks, or access to advanced training programs (Cleveland et al. 2000, Sterns and Miklos 1995, Borman et al. 1997).

Since it is clear that workgroup diversity will increase in the furure, the question remains with respect to what effect such diversity will have. As indicated above, prevailing theory (Pfeffer 1983, Schneider 1987) and data (Jackson et al. 1991, Tsui et al. 1991) suggests that efforts will be made by the 'in group' to exclude the 'out group.' This suggests lower levels of group satisfaction, group stability, and possibly group effectiveness. Some recent data suggest, however, that the dynamics are a good deal more complicated than they might appear. Jackson et al. (1995) conclude that group heterogeneity (broadly defined to include not only demographic characteristics but also background, experience, and personality) may actually enhance creative efforts of the group by widening the variety of approaches taken to a problem area. Watson et al. (1993) found that culturally homogeneous task groups performed better than heterogeneous groups initially, but that these differences were reversed after 15 weeks.

Taken as a whole, the following inferences might be drawn about the literature on workgroup or team diversity: (a) initially, there will be some tension and lowered effectiveness in demographically heterogeneous groups, (b) if the groups remain intact,

effectiveness will increase, and (c) the fewer the number of 'out group' members, the greater the initial tension and efforts to drive 'dissimilar' members out of the group. The general areas of group or team performance and group composition are only now receiving careful empirical attention (Guzzo and Dickson 1996, Landy et al. 1994). Given the inevitable diversification of workforces worldwide, the results of this research will prove valuable for organizational psychologists and managers alike.

Age, Sociology of

The sociology of age is currently developing as a broad, multifaceted approach to research, theory, and policy on age in society. It is concerned with: (a) people as they grow older and as cohorts succeed one another; (b) age-related social structures and institutions; and (c) the dynamic interplay between people and structures as each influences the other. These concerns reflect the hallmark of sociology itself which, unique among the sciences, emphasizes (a) people, (b) structures, and (c) the relationships among them. Thus the sociology of age, although it has so far paid more attention to (a) than to (b) and (c), provides a potential focal point for diverse multidisciplinary contributions to sociology as a whole (see *Age Stratification*).

As an emerging specialty, it will be described in this article in terms of its complex history, its consolidation of work in related fields, its developing working principles and research findings, and its promise to stand beside class, ethnicity, and gender in the sociology of the future.

1. An Emergent Field of Sociology

The sociology of age is comparatively new. It has been taking shape as a special field of sociology only since the 1970s. In 1972 Riley et al.'s *Sociology of Age Stratification* established an analytical framework for understanding the age-related dynamic interplay between people (actors) and roles (social structures). Similarly, in 1982 the Max Planck Institute for Human Development organized a center on life-course sociology and social-historical change. By 1988 the field was given separate status in a *Handbook of Sociology* (Smelser 1988). Attention to age began to crystallize at this time with the general recognition of the unprecedented increases in longevity, coupled with dawning awareness of the long-term impact of the 'baby boom cohorts.'

Though not a central focus, age—always a topic of primordial interest—had long been in the sociological air. Among the classical forerunners, Pitirim Sorokin, Talcott Parsons, S. N. Eisenstadt, and Leonard Cain wrote on age as an aspect of social structure; W. I. Thomas and Florian Znaniecki, as well as Bernice Neugarten, examined aging (growing older) as a social process; and Karl Mannheim tied the characteristics of successive generations—or 'cohorts' of people born at the same period of time—to historical and cultural change. Thus the meaning of 'age' was marked early by the distinction between the noun 'age,' as both a component of people's lives and a structural criterion for occupying and performing in roles, and the verb 'aging,' as interacting biological, psychological, and social processes from birth to death. However, this early work largely failed to explicate the irreducible reciprocity between human development and the changing society.

2. Convergences and Ramifications

As the sociology of age has been emerging as a special field, it is enriched by consolidating fragmentary work on the stages of people's lives and, at the same time, by reaching out toward multiple related disciplines.

2.1 Convergence of Life Stages

The sociology of age has gradually encompassed several subfields which have appeared sporadically, often with little awareness of each other. Paramount among these subfields is *old age*, which in the 1990s has seen a staggering rise in popular and policy attention

to the problems of older people, along with substantial scientific work supported by many agencies (notably, in the United States, by the National Institute on Aging). Forerunners include the epoch-making *Handbook of Social Gerontology* (Tibbitts 1960) that ranged over societal aspects of old age from population to values to technological and social change; it initiated a continuing series of handbooks. Back in 1950, Kingsley Davis (Davis and Combs 1950; see also Cowgill 1974) foretold that the growing numbers of older people and the rapid pace of social change would contribute to the isolation of older people and make them 'useless'—a social problem of falsely perceived uselessness which still requires correction today.

Starting even earlier, work on *childhood and adolescence* has also been proliferating, supported professionally and financially by its own organizations and agencies (notably, in the United States, by the National Institute of Child Health and Human Development). A variety of sociological studies have complemented psychological models by relating individual development to social structure and social change, for example, Glick (1947) to the 'family cycle' within which children and parents influence each other; Smelser (1968) to the movement of families into factories and mines during the Industrial Revolution; Elder (1974) to the hardships of families during the Great Depression, Vygotsky (see Cole et al. 1978) to the adult world through communal processes of sharing; and Corsaro (1997) to childhood as a structural form within which children are active agents. Meanwhile, Hernandez (1993) has analyzed in extraordinary detail the impact of several societal revolutions on the life course of children and adolescents over the past 150 years in the United States, and also in other countries. Family size plummeted. One-parent family living jumped. Family farms became rare. Formal schooling and nonparental care for children increased greatly. Unlike early longitudinal studies of aging (as by George Maddox and Gordon Streib), Hernandez, like other modern analysts, could benefit from the computer revolution and availability of data banks.

Perhaps because most work centers on adulthood as a generic category, less specific attention has been paid to the middle years *per se*, save for promised sociological reports from one of the MacArthur Foundation Networks.

Overarching these subfields is the focus on the life course as it extends from birth (or conception) to death (e.g., Marshall 1980). Intellectual progress in this area is reflected in the work of John Clausen, who corrected his limited masculine and cohort-centric 1972 analysis by his well-rounded 1986 account of both stability and change in the lives of individuals traced longitudinally over a 50 year period. Major theories of the 'institutionalization of the life course' assert that Western societies have actually been constructed to fit the 'three-box' pattern of education for the young, work and family responsibilities for the middle-aged, and leisure reserved for the old (see Meyer 1986, Kohli et al. 1991). At the same time, marked *diversity* in individual lives has been emphasized (Neugarten 1968, Dannefer 1987). Today, important as life-course studies are (see Giele and Elder 1998), the broader sociology of age awaits development of the complementary dynamics of social structures.

2.2 Multidisciplinary Ramifications

In addition to simplifying complexities in its own field, the sociology of age has been incorporating and in turn enriching relevant work in other disciplines (e.g., Bengtson and Schaie 1999). From the outset it was recognized that age-related structures cannot be understood without reference to all the social sciences—as, for example, history shows how age criteria for entering or retiring from work were institutionalized through industrialization, or anthropology shows how attitudes and feelings develop in nursing home care. Even more impressive, because aging consists of biological and psychological as well as social processes, the sociology of age has been a forerunner in the rapprochement with psychology and the life sciences (e.g. Hess 1976)—as in studies of genetic predispositions or age-related stress. Moreover, the dynamic character of aging has suggested revisions of earlier static models of age because, while people are growing older, society is recognized as changing around them, affecting both structures and the very process of aging.

3. Working Principles and Findings

Underlying such convergences and ramifications, certain common assumptions and working principles have been identified in the sociology of age, as they relate to the accumulating research findings—and also recapture the dual emphasis on structures and lives. Some principles have departed from accepted usage (for example, that intelligence declines after a peak at age 20), and some findings were demonstrably fallacious (for example, cross-sectional age differences were often erroneously interpreted as describing the process of aging). Gleaned from decades of work, the central theme of the sociology of age is that, against the backdrop of history, *changes in people's lives influence and are influenced by changes in social structures and institutions*. Linked to these reciprocal changes, just three sets of inter-related principles and findings can be illustrated in this article.

3.1 Inevitability of Change

Neither lives nor structures are entirely fixed or immutable, but vary in complex ways (Foner 1975). In the sociology of age they are conceived as 'two dynamisms'—changing lives and changing structures—that are interdependent yet distinct sets of processes. Study of the interplay between these dynamisms has succeeded in freeing the meaning of age from its early dependence on biological determinants, and has begun to suggest new meanings in a society undergoing fundamental change.

3.2 Import of Cohort Differences

Seeking to explain how lives are influenced by social as well as biological factors led sociologists to examine cohort differences (Ryder 1965, Uhlenberg and Riley 1996). The principle was formulated that: *because society changes, members of different cohorts age in different ways*. Over their lives from birth to death people move through structures that are continually altered with the course of history, thus the life patterns of those who are growing old today *cannot* be the same as the lives of those who grew old in the past or of those who will grow old in the future. Indeed, large cohort differences have been found in the aggregates of people's standard of living, educational level and technical skills, health and functioning, attitudes toward other people, and views of the world. Cohort differences characterize even the very young: newborns now weigh more than their predecessors, and children now become sexually active much earlier. Such changed characteristics of cohort members now young are bound to have predictable consequences for their later lives—their occupational trajectories, gender relationships, health and functioning.

3.3 Imbalances Between Lives and Structures

As such cohort differences were observed, it became apparent that the interplay with the dynamism of changing structures does not run smoothly. Although the two dynamisms are interdependent, *differences in timing—or asynchrony—are inherent in the interplay*. The biological lifetime of people has a definite (though variable) rhythm from birth to death. The timing of structural processes has no comparable rhythm or periodicity, but is going through entirely different historical transformations. Thus 'imbalances' arise between what people of given ages need and expect in their lives and what structures have to offer. These *imbalances exert strains on both the people and the social institutions* involved, creating pressures for further change. A current example of imbalance is 'structural lag,' as society has failed to provide opportunities in education, family, or work for the growing numbers of competent older people whose longevity is unprecedented in all history (Riley et al. 1994).

4. Future Prospects

Such intertwined principles and findings are laying the groundwork for future continuities, as the sociology of age has already begun to broaden its reach across concepts and countries.

4.1 Conceptual Reach

As one possible response to structural lag, the concept of *age integration* has been postulated as an extreme type of structure, in opposition to the extreme 'age differentiated' type of the well-known three boxes. Though originally defined as 'ideal' in Max Weber's classic sense, age integration is in some respects becoming real. Thus, the *age barriers* dividing education, work and family, and retirement are becoming more flexible (noted in the 1970s by Gusta Rehn); and incentives are sometimes advocated for interspersing these activities over people's extended lives (Riley and Loscocco 1994). Moreover, as the barriers are reduced, age integration *brings people of different ages together*. Any future shift toward age integration would challenge both the constraints placed by age on the familiar rigid structures, and also the age-related norms of 'success' and materialism now institutionalized in those structures and incorporated into people's lives.

4.2 Cross-national Reach

Future work in the sociology of age will certainly also extend to all ages its international reach. This reach dates back to the major studies of three countries by Shanas and her collaborators (1968), which showed that older people's living apart from children does not necessarily mean abandonment. The internationalism long nourished by various research committees of the International Sociological Association was updated by a 1998 discussion of age integration by scholars from seven countries. Alan Walker, speaking there about grass roots movements among older people, opined that Europeans themselves are beginning to seize the initiative in thinking that aging should not be defined as 'a simple matter of adjustment and peaceful retirement but that older people should be fully integrated citizens.' With the increasing globalization of science in the future, the multidisciplinary sociology of age should continue throughout the industrialized world as a focal point for sociology as a whole.

Age Stratification

In the human sciences, stratification generally refers to those forms of differentiation that entail ordinal ranking along a defined dimension. Age is an inherently ordinal phenomenon, anchored in the intersection of time and the event of birth. Those individuals born within a given time period comprise a cohort. The defining cohort feature of lived time, or age, defines age difference. Age strata, however defined, are thus comprised of the continuous succession of living cohorts, glimpsed at a single point in time.

1. *Age Stratification as a Feature of Populations*

Figure 1 depicts the age composition of the US population in 1880 and the projected pattern for 2020. The ranked difference is determined by different dates of birth, and succeeding cohorts are essentially piled on top of each other at a single point in time to form a 'snapshot' of the age composition of the population. A comparison of these two figures reflects the dramatic changes that occurred in the intervening 140 years, including population growth, increased life expectancy, and the shift of the societal burden of dependency away from youth and toward age. The bulge produced by the maturing baby-boom cohorts (b. 1946–64) is also clearly visible.

Such changes in age composition are explained by fertility, mortality, and migration. Changes in these processes, in turn, can result from a diverse array of technological and other social forces; the shape of the age distribution also has an independent impact on society more generally. Scholars of age recognize immediately the consequences of such shifts in age

Figure 1
US population in millions by five-year age categories, 1880 and 2020 (projected) (source: Population Reference Bureau 1994, Thompson and Whelpton 1933 (adapted))

distribution of a population, which can affect aspects of society as diverse as employment prospects for graduating students, the meaning of old age, marriage markets, and one's economic life chances.

Taken alone, however, such figures reveal nothing about how age is implicated in the overall structure of society. The effects of age are always contingent on specific institutionalized regimes. For example, a shift in the aged dependency ratio might seem a very different kind of problem in modern welfare states than in present-day Russia, where economic decline has produced acute deprivation which especially affects the aged. Thus, analysis of age strata inevitably requires a consideration of stratification as a component of social structure.

2. *Age Stratification as a Feature of Social Structure*

2.1 *The Cultural Significance of Age*

As a feature of social structure, the boundaries and character of age strata are anchored in the broader social meaning and definition of age and time. The manner in which societies define age and cohort membership is, of course, not universal but variable. Indeed, the very awareness of age and cohort membership is variable and, ultimately, socially constituted as a more or less integral feature of the larger social order. Societies vary in how they count, in how they measure the passage of time, and in how they identify time of birth. In some societies, the age set—a group of individuals spanning several years—is the central social unit defining life stage and role transition processes (Foner and Kertzer 1978). In others, age is defined in remarkably descriptive terms. For example, Rwandans traditionally have not thought of individual age in metric terms, but only in relation to memorable events, such as political transitions or natural disasters. The taken-for-granted modern practices of defining age and time by precisely quantified calibrations are not essential elements of human nature, but are products of historically and socially specific systems of language and ideas.

2.2 *Age and Bureaucratic Rationality*

Within a single society, the significance of age may undergo dramatic alteration in response to changes in other aspects of social structure. An obvious prototypical case is the transformation to modernity, which generally meant the emergence of age-graded strata supported by newly identified life stages, the legal-bureaucratic reliance on age as an eligibility criterion, and an increase in age consciousness (Chudacoff 1989). The result has been the institutionalization of the life course (Kohli 1986). Viewed as a contemporaneous societal cross-section, this same phenomenon comprises the institutionalization of age strata in which the everyday experience of members of the several age strata are differentially organized by legal, governmental, and corporate policies and broader social practices that are explicitly age-graded. In age-graded societies such as modern welfare states, stratum membership is a basis for strong predictions of one's likelihood of being socially engaged or 'significant' (Uhlenberg 1988).

Standard sociological wisdom declares that modern states assign roles based on universalistic criteria that reflect individual abilities rather than sponsorship or ascription. It is thus ironic that these societies have developed criteria (both formal and informal) to govern access to and exclusion from valued social positions based on the ascribed characteristic of age. 'Children,' 'adolescents,' and 'retirees' are examples of life-stage constructs that authoritatively define capabilities based on age, even though these 'life stages' were largely unheard of 150 years ago.

Age has proven to be a useful criterion for bureaucracies faced with the task of managing and processing large populations. It has been used to regulate access to scarce roles and resources, and for attributing competence (or its lack) to individuals based on generalized assumptions of age-related capacities rather than actual abilities. Just as ageism is a social bias that often goes unrecognized by the most passionate activists for social justice in other areas, the rationality of age as an exclusionary criterion is seldom questioned by the rational-bureaucratic logic of the systems that rely upon it.

3. *Age Stratification and Social Theory*

3.1 *The Age Stratification Paradigm*

The organization of society in terms of an age-stratified social structure must be analytically dis-

tinguished from the composition of the population of individuals of different ages who occupy positions in the social structure, and who move through a sequence of age-graded roles as they age. This fundamental sociological distinction between actors and structure, persons and roles, was articulated for gerontology by Matilda Riley and associates three decades ago, but is still often overlooked (Riley et al. 1972). Confusion can arise if this analytical distinction is not recognized (e.g., when normative age-graded roles become taken for granted and assumed to be part of human nature.) The importance of this distinction was thus, from the beginning, a key premise of what Riley initially termed the age stratification perspective, a framework that crystallized a number of related theoretical principles.

One such principle is what Riley and associates term structural lag—'society's failure to provide meaningful roles...,' for people of all ages (1994). A contemporary, archetypal example is the incongruity of (a) a dramatic growth in longevity and late-life vitality among aged individuals, and (b) social institutions and policies that are premised on entrenched ageist beliefs in the incompetence and obsolescence of the aged. Riley's work thus has given a rigorous sociological foundation that supported or anticipated other scholarly (and popular and activist as well) efforts to question the prevailing social organization of age roles.

Some have criticized the age stratification approach for its reliance on terminology associated with functionalism. In fact, her approach mobilized classical concepts to highlight the crucially important distinction between structural (e.g., roles, norms) and personal (e.g., attitudes, abilities) characteristics, with the intent of challenging conventional views that prevailed within as well as beyond the social sciences. It is only by making clear, for example, that men and women in their forties are not *naturally* supposed to remain in a single career throughout their working life and old people must not *inevitably* 'retire,' that it becomes possible to have a basis for a critical analysis of the social organization of age. Allocation implies the existence of an age-stratified opportunity structure with a finite number of roles, within which individuals must find meaningful social engagement. Given the limited elasticity in the number of available age-graded roles, there is considerable potential for an 'imbalance between persons and roles' which can mean an exclusion from desired social participation that is costly for both the individual and society. Since the cohorts that populate strata are constantly aging, this is especially true when there are sharp discontinuities in the size of adjacent strata (or changes in the aspiration or abilities of stratum members). In stratification terms, such a situation may be called a disordered age structure, a cross-sectional 'snapshot' perspective on Waring's (1975) important concept of disordered cohort flow. In sum, the age stratification perspective has explicated the issue of whether the potentials of individuals can be realized within an insitutionalized role structure imposed by governmental and corporate practices and the resultant norms that regulate access to roles on the basis of age. The systems that produce allocation problems also legitimate and sustain age norms.

Thus, the age stratification framework has been used to develop a critique of the prevailing age-stratified role structure, often called the 'three boxes of life'—school, work, and retirement (Riley and Riley 1999). Using this framework, Riley proposed, alternatively, an age-integrated society, where control of the design of the individual life course shifts away from an institutional regime that has tended to stratify individual opportunities and normative possibilities according to age stratum boundaries, and toward an arrangement that affords a greater voice for self-expression.

Beyond this general perspective of social critique, the age stratification perspective has contributed to several substantive lines of research and theory, at the same time that work in related historical, demographic, economic, and sociological traditions have generated ideas that are relevant to age stratification. As examples, two general lines of theorizing will be briefly discussed: (a) the effects of cohort size and composition, and (b) the potentials for intergenerational conflict.

3.2 *Effects of Stratum Size*

Several scholars have argued that cohort size (and hence, stratum size) has a range of consequences for the lives of cohort/stratum members, including psychological (Waring 1975) and socioeconomic (Easterlin 1987) effects. The general argument is that the large cohorts (which constitute densely populated age strata) are disadvantaged relative to smaller ones, since they must compete for scarce, age-graded roles and resources. Such ideas have found support in analyses of education and work careers (Dannefer 1988). Of course, all such notions rest on the premise of a rigidly stratified age-role structure: of age as a normative if not legal qualification for occupying desirable educational and occupational positions. To the extent that this is true, the movement of unusually large cohorts through the age structure should mean that the status and resources of the various strata will change over time as the size of strata changes.

The rapid demographic change of the past century has provided a natural laboratory for exploring hypotheses about the relation of the age structure of the population and individual lives. The dramatic and still continuing increase in life expectancy has produced a population explosion in the most aged strata. Here, too, the principle of being disadvantaged by being in a large cohort has been advanced.

In preindustrial USA, the very old were often seen as the experts regarding health and longevity (cf.

Achenbaum 1979). They were few, and with no prestigious medical profession, many of these survivors carried a mystique that seemed to imply expertise. Nevertheless, the status of the aged in nineteenth century USA as in other premodern societies derived from much more than the rarity of nonagenarians. It was broadly rooted in the control of resources by the aged, and the limited options open to young people —circumstances fixed by laws of inheritance and other customary practices that organized the distribution of power in society.

3.3 Interstratum Inequality: The Intersection of Age and Other Bases of Stratification

As an ordinally ranked characteristic, age itself is an analytically distinguishable basis of stratification. Yet its significance typically involves its intersection with other dimensions of stratification, especially those involving control of economic, political, or cultural resources. However, the interpretation of interstratum age differences becomes a central concern. Stratum differences in any measurable characteristic (e.g. wealth, political attitudes; intrastratum inequality) may represent life-course, cohort, or period effects (Riley et al. 1972, Dannefer 1988). Partly because of the potential confusion that arises from issues related to discussing age and such other bases of stratification together, Riley (Riley and Riley 1999) recently renamed her analytic framework the 'Aging and Society' paradigm.

In a cross-cultural analysis of age inequality and conflict, Nancy Foner (1983) identified several factors that privilege senior age strata in many societies: control over human and material resources; knowledge, expertise and experience; prestige and positions of authority; community influence; wisdom or mystical power.

Many of these factors also appeared to operate in preindustrial Western societies. With the transformation to modernity, the aged lost both status and economic power, as the venerated characteristics of experience, skill, and wisdom were supplanted by physical strength and endurance, youthful beauty, up-to-date knowledge, and willingness to deal with rapid change.

Some scholars have argued that this structural transformation brought relief to strong intergenerational tensions that were present in many traditional agrarian families in New England and in Europe as, for example, when senior landholders survived until their children were well into or past middle age. When the family was replaced by the firm as the primary unit of economic production, the central familial relationship of economic dependency was removed (Kertzer and Laslett 1995). A hypothesized result is that the relations of adult children and aging parents were premised on volition and sentiment, rather than economic issues.

By contrast, others have proposed that the rapid pace of technological and educational change characterizing modernity tended to create cleavages between cohorts in worldview and values, dramatically increasing the likelihood of interstratum conflict.

The characterization of modernity as removing the issue of intergenerational economic strain places the entire topic of the prospect of interstratum conflict on subjective grounds. Both arguments focus on values and sentiments; in neither case is economics central to predictions about conflict. Nevertheless, the possibility of interstratum conflict based on the alignment of age and economic interest re-emerged in the late twentieth century as concern over the cost of entitlements for the age became a widespread public concern in most modern and postindustrial societies.

3.4 Economics and Generational Equity

The politicized Generational Equity controversy that has developed since 1980 in the USA returns economic issues to the foreground of potential age conflict, and illustrates the potential for age to become a basis of interest group politics. The forces underlying the debate were deeper than political opportunism. Dramatic shifts in resources among age groups, especially from children to old people, occurred, traceable to the success of policies that award special economic consideration to the senior age strata, mostly as a result of age-qualified pensions and transfer payments (Preston 1984). If being in a large cohort/stratum is disadvantageous for educational and employment opportunities, it may be the reverse for interest group politics, where the senior strata are recognized as comprising an active and growing segment of the electorate. The apparent failure of the Generational Equity campaign to polarize age strata was predicted by theoretical principles set forth by Foner. One such principle, age mobility, sees the inevitability of aging as producing an anticipation on the part of midlife adults of their own certain movement into more senior age strata (Foner 1974). A second principle involves the insulation from direct responsibility for dependent parents that Social Security and Medicare/Medicaid provide to adult offspring. Although intergenerational resource transfers may be more likely to go from parents to children than the reverse, the protection that many midlife adults are afforded by public subsidy of seniors is very real. Indeed, 'downward' resource transfers may depend, in many cases, on the public benefits afforded the senior generations.

Other sources of resistance to the so-called 'generational equity' movement may include a belief in intergenerational economic continuity within families, which implies a relatively stable intergenerational

reproduction of the structure of economic inequality along familial lines. For example, it may be the affluent neighbors or overpaid supervisor who become a focus of a sense of economic deprivation and limited life chances, and not one's comfortably situated parents.

3.5 Interstratum Variation in Intrastratum Inequality

Awareness of nonaged-related economic inequalities that are based on stratification of the general opportunity structures is made even more likely since intrastratum economic disparities appear to be greater in aged strata than in younger ones, as economic inequalities appear to cumulate across the life course of each succeeding cohort (Dannefer 1988, O'Rand 1996), creating a picture of an age structure in which inequality is higher in older age strata than in younger ones.

Despite characterizations of many traditional societies in gerontocratic terms, it appears that many aged in such societies enjoyed neither wealth nor status. Evidence for this comes from studies of the preindustrial US (e.g., Demos 1978) as well as from traditional societies (Foner 1983). If the most powerful members of traditional societies occupied the senior age strata, it does not follow that most members of those age strata were affluent or particularly respected. Just as intercohort differences in patterns of intracohort inequality has been a neglected area of life course research, interstratum differences in intrastratum inequality is a neglected question in analyses of age structure.

4. Summary

Age stratification brings together the deceptively elusive individual characteristic of age, and the complex and dynamic social phenomenon of stratification. A grasp of society as a systemic structural reality that shapes many aspects of aging has been slow to develop among those who focus on the individual-level characteristics of age and development. Conversely, a grasp that individual social actors—whether citizens, students, parents or workers—are arrayed in continuously aging and changing cohorts has been underappreciated by sociologists. The study of age stratification has contributed a clear and forceful message concerning the importance of distinguishing age and age-specific subpopulations on the one hand from normatively age-graded social practices and structures on the other. It has contributed principles helpful in understanding how population and social structure jointly impact individual life chances, and has begun to consider the conditions governing the form of the relation of age and other bases of stratification. As issues such as the impact upon individuals of age-graded structures and the question of how socioeconomic stratification and age may interact, new research agendas have begun to take shape around questions of stratification and age.

Age Structure

Age is a ubiquitous and fundamental ascribed status concept within the social sciences, along with sex to which it is often linked. In spite of this distinction, age structure, the distribution of persons by age in a social unit, is often the subject of neglect as being too obvious to gain serious consideration as a theoretical concept or negative comment as a biological category without social phenomenological content. Nonetheless, consideration of age has given rise to a distinct field of study, gerontology, and remains a crucial determining variable, both distal and proximal, in empirical analyses of a wide range of phenomena and behavioral outcomes (Myers 1996a). It also serves as a defining categorization for collectivities and social groups that gives rise to specialized roles and expectations. Moreover, derived age structures, such as cohorts and generations, have achieved wide attention in studies of societal transformations and life course analyses. In short, age structure is arguably one of the most important concepts in the field of sociology.

An effective way of examining age structure is to consider it as both an outcome and an explanatory mechanism in social science investigations. At the same time, it is useful to distinguish between macro and micro levels.

1. *Macrolevel Determinants*

In the field of demography, age structure is an imbedded concept. Nonetheless, it is surprising to learn that in the eighteenth and nineteenth century there was virtually nothing written about age *per se* or age structure, although considerable attention was devoted to population size and the determinants of population change—fertility, mortality, and migration. In fact, it is not until the beginning of the twentieth century that the Swedish statistician, Gustav Sundbarg (1900), introduced a classification of countries based on the proportions of population under age 15, 15 to 49, and 50 and over. He observed that the proportions in the working ages for a number of European countries appeared to remain constant over time (roughly 50 percent), while the relative share of young and older persons shifted in magnitude from the former to the latter. Thus, he proposed that countries undergo transitions from youthful population structures (that he termed progressive) to stationary and eventually to old structures (regressive), developments largely determined by declining fertility and mortality. This remarkable insight, although subsequently found somewhat inadequate, nonetheless gave important impetus to studies of the determinants of population change, especially mortality and fertility, the possibility of transitions in these vital rates and their systematic impact on population structure, and time-series cross-national research.

Attention to the determinants of age structure benefited from the original mathematical contributions of Lotka in the early twentieth century and later at midcentury in the development of stable population and demographic accounting models by Coale, Bourgeois-Pichat, and others (Myers 1996b). The important role played by the succession of cohorts (usually determined by year/s of birth) over time has been recognized in transforming age structures. This has brought attention to the notion of disordered cohorts, in which catastrophic events (e.g., wars, famines, etc.) have produced large deficits in the numbers of persons at subsequent ages.

2. *Macrolevel Outcomes*

Although the dynamics of fertility, mortality, and migration rates determine the age composition of a population, it is important to note that the actual number of these events depend on age composition interacting with the rates. In this respect, age structure can play an important role in determining the number of births, deaths, and moves in a population. In the process of demographic transitions to lower levels of fertility and mortality, age structures have become older and overall population growth levels have declined or become negative.

Interest in the effects of declining population size emerged in the 1930s in several European countries (most notably the UK and France), but it was not until midcentury that concerted attention was drawn to potential population aging and its societal implications. A notable exception was found in the work of Maurice Halbwachs ([1938] 1960), that elaborated on the notion of social morphology, following the inspiration of his mentor Emile Durkheim. Ironically, it was his compatriot, the noted demographer Alfred Sauvy, who stressed that population aging had grave consequences on the evolution of French culture and national social structure. Scientific examination of how population aging evolves and its broad societal impact gained momentum in the 1950s, especially with the publication by the United Nations (1956) of the volume *The Aging of Populations and Its Economic and*

Social Implications. Today, aging or gerontology has become an important subdisciplinary field within sociology and the other social sciences.

Aggregate age structures have important implications for the institutions in a society—educational (schools, teachers); labor force (demand, productivity, retirement); economic (housing, savings, consumption, income); religious (attendance, volunteerism); and political (voting, government policies). This is true on both the demand and supply side in considering personnel and infrastructure to fulfill institutional functions. For example, Pampel and Stryker (1990) carried on an exchange over the relative importance of changing age structures and state corporatism effects on social welfare expenditures. Their comparative time series study demonstrated the major role that population aging played in overall welfare spending.

3. *Microlevel Perspectives*

The most ambitious treatment of age in sociological thinking can be attributed to Matilda White Riley and her associates (most notably John Riley and Anne Foner) since the early 1970s. In their view, age structure is viewed as one important component of 'age stratification.' Citing important early sociologists, such as Sorokin, Mannheim, Eisenstadt, and Parsons, the team pointed out that age is basically involved in 'group formation and intergroup relations, as a basis for social inequality, and as an intrinsic source of social change as new cohorts because of their particular historical experiences make unique contributions to social structures' (Riley et al. (1988, p. 243). Nonetheless, the basic aspects of age structures involve people and roles stratified by age, which puts a microlevel focus on the individual and normative behavioral characteristics.

This perspective owes a great debt to earlier social anthropologists who emphasized that age groups and age grading are prominent features of many traditional societies. Eisenstadt (1956), in his pioneering work on age groups, observed that age groupings also are important in more complex societies. Indeed, youth, working, and aged groups fulfill important functions in delineating roles, creating group identification, and shaping interactions with other age groups. It is interesting to note that many age groupings formed at younger ages maintain bonding throughout the life course, as is the case with so-called generational groups.

4. *Microlevel Outcomes*

In recent works, Riley and associates place great emphasis on 'structural lags' in which social institutions, such as the family, work, and so forth, have not adapted to collective individual wishes for less rigid age segmented roles (Riley et al. 1994). At the core of this framework is a social psychological perspective in which persons volitionally chose to follow certain behaviors that are in their best interest. The goal is to create a more age-integrated society. In a somewhat similar vein, O'Rand and Henretta (1999) have pointed out that recent processes of age structuring in many industrial societies have produced 'mixed patterns of uniformity and diversity in life course schedules … and decreasing importance of age for the conduct of more and more social roles' (p. 1). The increased variability in the life course, they argue, is associated with increased economic inequality.

Nonetheless, there is strong evidence that formal definitions of age continue to strongly influence behavioral outcomes. For example, expenditures on housing, utilities, and transportation in the USA are strongly affected by the varying consumption behaviors of people at different ages (Pebley 1998). Expenditures for housing rise from nearly $6,000 for persons under 25 to over $12,000 at ages 45–54 and decline to about $7,000 at ages 75 years and over. Expenditures on utilities and transportation vary less, but still follow an inverted U-shaped distribution.

5. *Measurement*

Population pyramids have been widely used to reflect the absolute (numerical) or relative (proportions) age and sex distributions in diverse population, community, and social groups. As a descriptive device, the population pyramid is unparalleled in providing a view of overall population structure at a particular point in time and the magnitude of different age and sex cohorts. Viewed in time series, these displays provide a convenient means of assessing development with regard to demographic transitions and discontinuities in cohort size and composition that can be useful in explaining emerging societal changes.

In multivariate analyses, age is frequently measured as a continuous independent variable (e.g., in ordinary least square regression) or a discrete variable defined by age groups (e.g., in logistic regression). Not uncommonly, the explanatory power of age is very strong and absorbs a considerable amount of variance. Nonetheless, it should be acknowledged that age is a variable that usually reflects other more obtuse or difficult to measure characteristics.

6. *Future Directions*

Several scholars, as we have noted, feel that age structure has or should become less salient in shaping roles and role expectations over the life course. Moreover, some have argued 'the measurement of

age, age structuring, and the life course has become more problematic as the study of human lives has moved away from global images and theoretical categories toward more detailed analyses and explanation' (Settersten and Mayer 1997, p. 234). While heterogeneity, discontinuity, and contingency always exist in considering age structures, it is important to note that age structures are but snapshots of ever-changing distributions. From a societal perspective, however, the continuing extension of life and the concomitant rectangularization and stretching of age distributions suggest that attention to age structures will persist as a major force shaping future sociological research of social structures, the life course, and individual roles and status.

Agenda-setting

Agenda-setting theory develops the observations of Walter Lippmann (1922) in *Public Opinion* that the mass media act as a bridge between 'the world outside and the pictures in our heads.' The central idea is that elements emphasized by the mass media come to be regarded as important by the public. In agenda-setting research, news content is conceptualized as an agenda of items, most frequently an agenda of the major public issues of the day, and agenda-setting theory describes and explains the transfer of salience from this media agenda to the public agenda.

1. Comparing Media and Public Agendas

The media agenda is defined by the pattern of news coverage over several weeks or more, and the public agenda most often is determined by the venerable Gallup Poll question, 'What is the most important problem facing this country today?' First verified during the 1968 US Presidential election, there are now more than 300 empirical studies worldwide documenting agenda-setting effects. These studies have examined the presentation of a wide variety of public issues—and a handful of other objects—by various combinations of newspapers, television, and other mass media and the public response to these media agendas in both election and nonelection settings in Asia, Europe, Australia, and South America, as well as in the USA. Agenda-setting effects also have been produced in controlled laboratory experiments.

The seminal 1968 Chapel Hill study (McCombs and Shaw 1972), which compared the salience of five major issues defining the media agenda with the public agenda among undecided voters, found a near-perfect match in their rank-order ($+0.97$, where the maximum value of this correlation coefficient used to index the strength of agenda-setting effects is $+1.0$). The empirical correlations among general populations are somewhat lower. A year-long study during the 1976 US Presidential campaign found a peak correlation of $+0.63$ between the television agenda and the public agenda during the spring primaries (Weaver et al. 1981). In the 1995 local elections in Pamplona, Spain (McCombs in press), there were substantial matches between the public agenda and the agendas of both local newspapers ($+0.90$ and $+0.72$) and television news ($+0.66$).

2. Explaining Agenda-setting Effects

News reports are a limited portrait of our environment and create a pseudoenvironment to which the public responds. Often there is little correspondence between news coverage and underlying historical trends, in-

cluding rising trends in news coverage and public concern about situations that are unchanged or that actually have improved. These agenda-setting effects of the mass media occur worldwide wherever there are reasonably open political and media systems. Under these circumstances, the public turns to the mass media for orientation on the major issues of the day, especially those issues beyond the ken of personal experience. Even in many cases where personal experience creates high salience for an issue, people turn to the media for additional information and perspective. The concept in agenda-setting theory explaining this behavior is need for orientation, the cognitive equivalent of the physical science principle that nature abhors a vacuum. People are psychologically uncomfortable in unfamiliar situations, such as elections with a plethora of candidates and issues, and frequently turn to the media to satisfy their need for orientation. This psychological concept, which is defined in terms of relevance and uncertainty, explains, for example, the strong agenda-setting effects found in 1968 among Chapel Hill undecided voters. Obviously, both relevance and uncertainty were high for these voters, the condition defining the highest level of need for orientation.

With increased levels of media use, there also is increased agreement about the most important issues of the day among disparate demographic groups, such as men and women or those with high and low education. These patterns of social consensus have been found in Spain, Taiwan, and the USA. Consensus also is facilitated by the limited capacity of the aggregate public agenda. Typically, no more than three to five issues are able individually to garner a constituency of 10 percent or more of the public who regard that single issue as the most important issue of the day, and the public agenda is best characterized as a zero-sum game (McCombs and Bell 1996).

3. *Two Levels of Agenda-setting Effects*

Initially, agenda-setting theory focused on the objects defining the media and public agendas. However, mass media messages about public issues and other objects, such as political candidates, include descriptions of these objects. In abstract terms, objects have attributes. Just as these objects vary in salience, so do the attributes of these objects. When the mass media present an object—and when the public thinks about and talks about an object—some attributes are emphasized. Others are mentioned less frequently, some only in passing. Just as there is an agenda of objects, there is an agenda of attributes for each of these objects. The influence of the media on the relative salience of these objects among the public is the first level of agenda-setting. The influence of the media on the relative salience of these objects' attributes is the second level of agenda-setting.

Images of political leaders among the public afford examples of attribute agenda-setting (McCombs et al. 1997). In the 1994 mayoral election in Taipei, Taiwan, the median value of the comparisons between voters' images of three candidates and news coverage in two major daily newspapers was +0.68. In the 1996 Spanish general election there was substantial correspondence between the news coverage of the major candidates and their images among Pamplona voters. For six comparisons of the voters' images of the three candidates with the coverage in two local newspapers, the median correlation was +0.70. For six comparisons with two national newspapers, the median correlation was +0.81, and for six comparisons with two national TV news services it was +0.52.

Attribute agenda-setting also occurs with public issues (McCombs in press). Some aspects of issues are emphasized in the news and in how people think about and talk about issues. Other aspects are less salient. News coverage in Japanese newspapers about global environmental problems in the months prior to the 1992 United Nations Rio de Janeiro conference resulted in a steady increase in public agreement with the media agenda. By February the match was +0.68 and by April +0.78. A similar pattern was found during a three-week period prior to a local tax election in the USA. Correspondence between the voters' attribute agenda, the relative salience of various aspects of the issue, and the local newspaper's framing of the local tax increased from +0.40 to +0.65. The match with the political advertising on the issue increased from +0.80 to +0.95.

4. *Sources of the Media Agenda*

Although the majority of empirical research on agenda-setting has examined the relationship between the media agenda and the public agenda, scholars also have asked 'Who sets the media agenda?' Influences shaping the media agenda range from the external activities of major news sources to the internal dynamics of the media system (Dearing and Rogers 1996, McCombs and Bell 1996, McCombs in press). Examination of the *New York Times* and *Washington Post* across a 20-year period found that nearly half of the news stories were based substantially on press releases and other direct inputs by news sources, such as press conferences and background briefings. News coverage of Louisiana government agencies was based substantially on information provided by their public information officers to the state's major newspapers. Across an eight-week period the correspondence between the agenda originating with the press information offices and all news stories on those agencies was +0.57.

Political campaigns make a concerted effort to influence the news agenda. In the 1993 British general election, a series of comparisons between the three

major parties' agendas and seven news media, both newspapers and television, found a median correlation of +0.70. American political parties do not fare as well at the national level. A comparison of television news coverage during the 1996 New Hampshire Presidential primary, the inaugural primary in the lengthy US election year, with the candidates' speeches found only a moderate correspondence (+0.40) in their agendas. However, at the local level, in an election for Governor of Texas the combined agendas of the Democrat and Republican candidates shaped the issue agenda of both the local newspaper (+0.64) and the local television stations (+0.52) in the state capital.

The Texas election also reflected intermedia agenda-setting, the influence that one news medium has on another. In Austin, the correspondence between the local newspaper agenda and subsequent television news coverage of public issues was +0.73. A similar comparison in Pamplona, Spain, of two local newspapers with local television news found correlations of +0.66 and +0.70. In the USA, the *New York Times* is regarded as a major agenda-setter among the news media. A case study of the drug issue during the 1980s found that the *New York Times* influenced subsequent coverage by the national television networks, news magazines, and major regional newspapers.

5. *Consequences of Agenda-setting*

The agenda-setting role of the media has consequences beyond the focusing of public attention (McCombs in press). Public opinion during 1992 and 1993 about the overall performance in office by Hong Kong's last British Governor was significantly 'primed' by the pattern of news coverage on his proposals to broaden public participation in local elections. Exposure to this news coverage significantly increased the importance of these proposals in Hong Kong residents' overall approval of the Governor's performance. By calling attention to some matters while ignoring others, the news media influence the criteria by which public officials subsequently are judged, noted Iyengar and Kinder (1987). Priming represents a special case of agenda-setting in which the salience of an issue among the public becomes a significant factor in opinions about a public figure associated with that issue.

The tone of news reports as well as their content can affect subsequent attitudes and behavior. In Germany, shifts in the tone of news stories about Helmut Kohl preceded shifts in public opinion from 1975 to 1984. Daily observations during the final three months of the 1992 and 1996 US Presidential campaigns found that the positive and negative tone of television news about key campaign events influenced voters' opinions about the candidates. The pattern of negative headlines about the US economy over a 13-year period influenced both subsequent measures of consumer sentiment and major statistical measures of the actual economy.

These consequences of agenda-setting for attitudes and opinions require the revision of Bernard Cohen's (1963) seminal observation that the media may not tell us what to think, but are stunningly successful in telling us what to think about. His distinction between affective and cognitive effects of the media was an important precedent for research on first-level agenda-setting effects. At the second level, attribute agenda-setting and its consequences reinvigorate the consideration of media effects on attitudes and opinions. This expanding perspective also is a response to criticism that agenda-setting has focused narrowly on the initial stages of the mass communication and public opinion process.

Agenda-setting theory details a range of effects on the public that result from the mass media's inadvertent focus on a small number of topics and their attributes. To the extent that the news agenda is set by social forces external to the news media, the role of news institutions is important, but neutral as a transmission belt. To the extent that the news media exercise autonomy in defining the public's news diet, they are in themselves a powerful social force.

Agendas: Political

The political agenda is the set of issues that are the subject of decision making and debate within a given political system at any one time. Significant research specifically on the topic of agenda setting, as opposed to decision making, dates mostly from the 1960s. Early studies of agenda setting were quite controversial because they were often presented as critiques of the pluralist studies of the 1950s and 1960s. Truman (1951) mostly ignored the issue of who set the agenda of political debate. Dahl (1956) discusses the matter in mentioning that ensuring that no group have control over the range of alternatives discussed within the political system is a requisite for democracy. In his study of New Haven he explicitly raises the question of agenda setting, noting that with a permeable political system virtually all significant issues would likely come to the attention of the elites. 'Because of the ease with which the political stratum can be penetrated, whenever dissatisfaction builds up in some segment of the electorate party politicians will probably learn of the discontent and calculate whether it might be converted into a political issue with an electoral pay-off' (Dahl 1961, p. 93). In Dahl's view, then, any issue with a significant potential following in the public would likely find an elite-level champion, though he also notes that issues with no large-scale electoral pay-off might never enter the agenda.

1. *Conflict Expansion*

E. E. Schattschneider (1960) focused attention on how political debates often grow from the conflict of two actors, the more disadvantaged of whom may have an incentive to 'socialize' the conflict to a broader political arena. Of course, the more advantaged disputant strives to 'privatize' the conflict. Schattschneider was one of the first to note that the composition of the political agenda was itself a fundamental part of the political process, and he was the first to give it a prominent role in his view of the political system. By around 1960, then, scholars had firmly noted the importance of the study of the political agenda as an important area of research.

After the critique of Schattschneider (1960), scholars were less willing to take the composition of the agenda for granted. Peter Bachrach and Morton Baratz (1962) provided one of the most telling critiques of pluralism when they noted that studies of decision-making, power, and influence were misleading. Their aptly titled article, 'The two faces of power,' noted that the 'first face' of power, the authority to choose between alternatives, may be less important than the 'second face' of power, the ability to control what alternatives are under discussion in the first place. Whereas Dahl and others saw this as a relatively open process, where any social group with a legitimate problem that could potentially be converted into votes in an election could gain access to the political agenda, others saw the process in a decidedly more negative light. Following Bachrach and Baratz, many scholars attempted to study not just governmental decision making, as the pluralists had done, but also non-decisions, or agenda control, as well. For example, Matthew Crenson (1971) noted that air pollution was rarely discussed in public or government in one city despite a very serious pollution problem. In another similar city with much less pollution, however, public and governmental leaders discussed it often and took steps to combat it. The reason behind the difference in the behavior between the two cities appeared to be the ability of powerful economic interests to control the agenda. John Gaventa (1980) followed this study with an analysis of poverty-stricken Appalachian towns and the 'quiescence' characterizing the demobilized populations there. These agenda theorists argued that power was most evident when objective conditions of suffering were not the subject of debate. Bachrach and Baratz (1962), Crenson (1971), and Gaventa (1980) raised important issues and directly challenged the relatively optimistic views of the pluralists but did not convince, all because of the difficulty of discerning exactly what would be a neutral political agenda. In other words, it was hard to know what findings would demonstrate elite control and what findings would demonstrate democratic openness; in this situation two scholars looking at the same findings could disagree forever (and they did; see Baumgartner and Leech 1998, chap. 3, for a discussion of these issues relating to the community power studies of the 1950s and 1960s; see also Polsby's (1980) treatment of these methodological issues).

2. *The Development of a Literature*

Roger Cobb and Charles Elder (1972), in the first book-length treatment of the political agenda, noted the difference between the systemic agenda, defined as the group of issues that were under discussion in society, and the institutional agenda, or the set of issues being discussed in a particular government institution (see also Cobb et al. 1976). Since then, scholars have variously written about the public agenda, the media agenda, the legislative agenda, and any number of other agendas as they have focused on different political institutions.

More recent studies of agenda setting have moved away from the concepts of nondecisions and power because of the difficulties inherent in designing rigorous research on the topic. Instead, scholars have

focused on the rise and fall of issues on the public or institutional agendas and how decision making during high salience periods differs from the more routine decision making that takes place when an issue is low on an agenda. Jack Walker (1977) provided one of the first statistically based studies in the area with his analysis of the US Senate's agenda. He noted that issues often rose on the Senate's agenda following heightened levels of discussion within professional communities.

John Kingdon's (1984) treatment of the public agenda set the stage for much of our current understanding of where issues come from. He emphasized the separate sources of policy problems from the solutions that may be offered to them. Government programs, he noted, come about when a given solution is attached to a particular problem, and his analysis of health care and transportation policies in the USA showed just how unpredictable these couplings can be. Political actors' search for popular issues, windows of opportunity open and close, stochastic events such as natural disasters or airplane crashes momentarily focus public attention on an issue. The confluence of many unrelated factors, often serendipitous, helps explain why a given policy is adopted, according to his study. Kingdon's (1984) was the first major book-length study on the topic since Cobb and Elder's (1972), and it was based on hundreds of interviews with government and other policymakers in the 1970s and 1980s. (Polsby 1984 also reached many of these conclusion in a book appearing in the same year as Kingdon's.)

Frank Baumgartner and Bryan Jones (1993) provided the next major treatment of political agendas in their analysis of nine different policy areas over a 40-year period. Utilizing publicly available sources such as media indices and records of congressional hearings, they noted how particular issues rose and fell on the agenda over the entire post-World War II period. They developed a punctuated equilibrium model of policy change in which episodic periods of high agenda status typically were related to dramatic and long-lasting policy changes. During these high-salience periods, institutional procedures were often created or altered. The subsequent ebbing of the issue from the public agenda enabled the newly empowered political institutions and policymakers to settle into stable routines of behavior persisting for decades at a time. Agenda setting was related to dramatic changes, often upsetting long-standing routines of behavior and power by replacing them with new ones.

3. *Issue Definition*

Studies of agenda setting have often focused on the question of issue definition. Echoing a major theme in Baumgartner and Jones (1993), David Rochefort and Roger Cobb (1994) brought together a number of essays showing how public understanding and media discussion of a given issue can change over time, often quite dramatically. Deborah Stone (1988) also discussed this in her analysis of 'causal stories.' Policy entrepreneurs frame issues by explaining the causes of a given problem with a narrative justifying a particular governmental response. Book-length studies of the issues of child abuse (Nelson 1984), pesticides (Bosso 1987), health care reform (Hacker 1997), and various natural and human-made disasters (Birkland 1997) have shown the impact of changing issue definitions and of focusing events in pushing an issue on to the public agenda. Roger Cobb and Marc Howard Ross (1997) brought together a series of essays on the rarely studied topic of 'agenda denial,' whereby political actors keep threatening issues off the agenda.

William Riker (1986, 1988, 1993, 1996) showed the importance of two related issues: the ability of strategically minded politicians to alter the terms of debate by skillfully manipulating issue definitions, and the power of formal agenda control. A voluminous literature in formal and game theory suggests that the controller of a formal agenda can affect the outcomes in a voting situation by altering the order in which alternatives are considered. Riker used game theory to illustrate how formal agenda control can affect such things as votes in a parliamentary setting, and case studies and historical illustrations to show how political leadership could be even more powerful through the means of altering issue definitions. Political leaders can utilize a combination of formal agenda control and informal debating skills to achieve their ends, according to Riker.

4. *Social Movements and the Media*

A number of scholars have noted that social movements have often successfully brought new issues onto the public agenda. Thomas Rochon's (1998) analysis of the peace movement in various Western countries fits in this tradition, as does the work of Douglas McAdam (1988), whose study of the Mississippi Freedom Summer documented the success of civil rights activists in putting the issue of racial equality on the national political agenda during the mid-1960s.

Studies of the media agenda have been legion, largely following from the early work of Max McCombs and Donald Shaw (1972); for a review of this literature, see Rogers and Dearing (1988). Bernard Cohen (1963) noted famously that while the media cannot tell the public what to think, they can have a great impact on what the public think about. Within political science, several authors have picked up on the issue of media effects on public opinion (Iyengar 1991, Iyengar and Kinder 1987). James Stimson (1991) noted the changes in a broadly measured national mood based on public opinion surveys; John Kingdon (1984) also put considerable emphasis on the national mood in his study of agenda setting in government. As

policymakers consider what issues to spend their time on, Kingdon (1984) noted they often make reference to the idea of a national mood.

Studies of the political agenda have been remarkable in political science for their integrative character: rather than focusing on any particular institution of government, scholars have traced the sources of agenda setting in the public, in the roles of interest groups and social movements, by noting the roles of policy entrepreneurs, and by looking at the government in very broad terms. Of course this does not mean that political leaders play an insignificant role. From the work of Richard Neustadt (1960) onwards students of the US Presidency have noted the need for presidents to focus their energy on a few issues (see Light 1982; for a similar study of congressional leadership see Bader 1996). Studies of the Supreme Court have noted the extremely tight control that the Court maintains over its agenda, as well as the characteristics of the cases that it is most likely to take. The Court, of course, is unusual among political institutions in that its agenda is reactive rather than proactive. Congress or the President can reach out to discuss whatever issues appeal to them; the Court can only choose from the issues that are presented for its decision (see Perry 1984, Caldeira and Wright 1988).

5. *Conclusion*

In sharp contrast to two generations ago, research on political agendas is vibrant and promising today. Though much of the work has been done within the context of US politics, comparative studies have become more common (see Hogwood 1987, Baumgartner 1989, Reich 1991, Zahariadis 1995, John 1998). New sources of quantitative data on public attitudes, government archives, and media coverage promise more systematic studies covering a greater range of issues over a longer time period than was typically possible in the past. Studies of political agendas are now firmly established as an important part of the field of political science now some 40 years after the concept was first discussed.

F. R. Baumgartner

Aggregation: Methodology

Aggregation is a technique that is utilized in various disciplines in the social sciences. A basic definition of aggregation is combining data from members or subordinate units of a larger, superordinate category in order to describe the superordinate category. In the social sciences aggregation typically involves obtaining data from or about individuals and combining these data into a summary statistic that would serve to characterize a larger, well-defined, socially meaningful unit that contains a large number of individuals. This summary statistic may then be used as a data point in a data set consisting of larger units for comparative purposes. Common examples of larger units with multiple members involve a social group, an organization, or geographical or administrative units—a census tract, a county, a school district, a city, or a country. Information collected from individuals is called 'individual-level' data; when these data are aggregated statistically to describe the superordinate category, the resulting data are at the 'superordinate-level' or 'aggregate-level' and called 'aggregate data' or 'aggregated data.'

When individuals are nested (i.e., located) under intact and meaningful units, a 'nested structure' is obtained. A nested structure may involve multiple levels: individuals may be nested in classrooms and classrooms may be nested under schools, schools may be nested under school districts, and so on. When there are multiple levels and the nesting is clear and hierarchical, a 'hierarchical multi-level model' is obtained.

A typical example for the process and significance of aggregation is the census where often detailed information is collected from individuals and households, and this information is used to describe census tracts, counties, zones, cities, regions, and so on. Such information is clearly important—that is why so much money and effort are put into conducting censuses all around the world—and important social policy decisions are often based on such aggregated data. More funding may be provided, for instance, for job opportunity programs in cities where unemployment rates are high.

However, census data are also a good example to illustrate the basic limitations of aggregated data. For multiple reasons, particularly for protecting privacy, census data about individuals and households are never disclosed. Instead, data about city blocks or census tracts (defined by the US Census Bureau as a group of city blocks having a total population of more than 4,000 people) are made available to the public. Statements about average household size (e.g., a household has 4.5 members on average), average number of children (e.g., an average family has 1.5 children), average number of cars, average number of jobs worked in a calendar year, etc. are clearly not about an actual household (a household cannot have 4.5 members) or an actual family (a family cannot have 1.5 children). Aggregated data describe average households or families—the typical patterns in a given census unit—but never an actual household or family. With aggregation information about actual households and the heterogeneity they may present is lost. Aggregation is often useful to characterize superordinate categories—that is, working upwards from individuals to larger social units. The reverse, however, is not true: working backwards from aggregated data to subordinate units can be very misleading.

1. *The Technique*

Aggregation is a technique that cuts across disciplines, but is most commonly utilized in disciplines that deal with collective systems, such as groups, neighborhoods, schools, markets, or organizations. Aggregation is less common in disciplines that focus on individual human beings. Aggregation is particularly important in disciplines that deal with issues where individual-level data cannot be disclosed, as in voting behavior or in household income, and data are collected or made available to the public at the aggregate level. In other cases, collecting individual-level data may be particularly difficult, time-consuming or even impossible. For instance, in criminal justice research, a researcher may have data reported by the

police department about specific crime rates in a given, well-defined area but the perpetrators of these crimes may not be known and collecting data about the motives of the perpetrators may be almost impossible.

Aggregation is not limited to the social sciences. In daily life, too, aggregation is very common. It is commonly used in various areas of life primarily for the practicality of aggregated data. For instance, households that use natural gas for cooking and heating are often provided with no information regarding daily consumption rates. Rather, monthly consumption is reported and billed. For detailed information about gas usage, information regarding daily consumption would have to be monitored and recorded. In most cases, neither the consumers nor the utility industry would be interested in such detailed information. Rather, a summary measure, total amount of gas used per month, which is based on data aggregated over time, is sufficient. Similarly most people do not monitor their calorie intake until they start a diet regimen. In daily life an aggregate perception of how much food is consumed would be sufficient. When the goal is to lose weight—that is, intervene and change the current calorie intake—each source of calorie intake may have to be monitored.

From a practical standpoint, aggregated data are very desirable. Except for those who are interested in understanding the nature of the process, such as scientists, and those who would like to intervene and change the current situation, such as policy makers and reformers, most people would be interested in what the average is or whether the average is at a desired level. For instance, when data on how much fuel it takes each car to travel a given distance is available, almost everyone would prefer to know the average fuel consumption—rather than a list of how much fuel it took each car to travel the given distance.

Basic types of aggregation or aggregate data are very easy to understand and easy to come across in daily life. Total amount of car accidents in a given geographical area per day, the average number of cars crossing a busy intersection per day, the percentange of car crashes that result in fatalities per day are such examples of aggregation. All one needs to do is to count, to take an average or to calculate the percentage of the event of interest. This is called aggregation 'across units.' For events that may show fluctuation or systematic variation over time, it is very important to specify the time period. Sometimes it may be useful to calculate an average across time to obtain more reliable estimates. If the number of cars crossing a busy intersection varies from day to day and the goal is to identify a good estimate of the average number, it would be useful to count the totals per day and then average across five days of the working week. This type of aggregation is called aggregation 'over time.' It is obvious that, depending on the question at hand, aggregation can involve aggregating data across individuals within a larger unit (e.g., a school), schools within a larger unit (e.g., a school district), districts within a large unit (e.g., a city). When time is important, it may be desirable to aggregate data across time points within a time period (e.g., a year) or to even aggregate across time points within an individual, as in monitoring health status over several months.

2. *Problems Associated with the use of Aggregated Data*

When data from individuals are obtained and aggregated to describe a socially meaningful unit, under which these individuals are nested, aggregation is often not problematic. When, however, aggregated data are used to analyze larger units, problems may arise. The most serious problem associated with aggregated data involves generalizing relationships at the aggregate level to individuals as though these relationships necessarily hold at the individual level.

Robinson (1950) is often credited with the discovery of a fundamental problem with applications of aggregation in the social sciences: the behavior of an aggregate often gives no clues to the behavior of an individual belonging to that aggregate. A relationship at the aggregate level (what Robinson called an 'ecological correlation') between two variables (e.g., crime and unemployment) does not reliably lead to an association between these two variables at the individual level (e.g., committing a crime and being unemployed). This is known as the 'ecological fallacy,' which involves deducing individual behavior from the the behavior of aggregates (Weisberg et al. 1996).

An oft-cited example comes from the political science literature, where individual-level data concerning voting behavior are rarely available. The question is simple: If the election results indicate that a voting district that consists of 90 percent ethnic minority voters and 10 percent ethnic majority voters voted 90 percent for Party A, and Party A is known to be generally supported by this ethnic minority, could we safely conclude that each minority voter actually voted for Party A—based on the aggregate data available? It may be tempting to do so, but the answer is negative. It may be the case that very few voters from the minority voted and every member of the majority voted for Party A. It is obvious from this example that a perfect match between numbers (90 percent minority—90 percent vote for Party A) can be very misleading. At the least, other data, if available, should be considered: What percentage of the minority and the majority voted? Is there any individual level data available that can shed light on this issue?

Drawing 'ecological inferences,' which involves arriving at conclusions about individual behavior using aggregate data reported for the superordinate category, is considered a very unreliable method in the social sciences. It has been noted that this problem, the

'ecological inference problem,' hinders substantive work in almost every empirical field of political science and in other disciplines where there is restricted access to individual-level data. Attempts to make ecological inferences more reliable (e.g., King 1997) have been met with strong suspicion. In general none of these attempts have yielded a satisfactory solution. Today the ecological inference problem remains a bottleneck for disciplines that have limited access to individual-level data.

In psychology and related disciplines, there is a second, historically common and much less problematic application of aggregation. This type of aggregation involves combining data across situations or time points to obtain more reliable data. This is known to reduce measurement error, which consists of random fluctuations in data. Random fluctuations often result from imperfect measurement tools, hence the name measurement error. Measurement error creates 'noise' in the data and makes it difficult to observe the true relationships. Reducing measurement error via aggregation, for instance over time, may increase the strength of the relationship (e.g., Harris 1998). In these applications, no ecological fallacy is involved. The observations are being aggregated across situations or time to describe the superordinate unit: in psychology, this unit is often the person and multiple observations are aggregated to better describe this person. This type of aggregation is suitable for situations where the process under observation is not changing, the fluctuations are not immense and the data are relatively homogenous and the fluctuations are due, not to change in the person's behavior, but to measurement error.

Aggregating data to reduce measurement error, however, should not be taken as a shortcut to reliable data and hence reliable relationships. Reliable measures are the key to capturing reliable relationships and aggregation cannot compensate for unreliable measurement. When aggregation involves aggregating observations that are very different, aggregation will yield a misleading picture: the picture will consist of an average that simply does not exist. For instance, when aggression is measured across situations and in some situations environmental factors (e.g., police presence) hinder the display of aggression, the amount of aggression will vary widely across situations. It is better to pick situations that are similar in most respects and aggregate across situations only to reduce random errors (e.g., videotape coding errors). Therefore, the long-standing notion that the use of aggregated data necessarily yields stronger relationships is not true (Ostroff 1993).

A more serious problem that arises when data are aggregated across time points, situations, or persons is the loss of information on variability or heterogeneity. When data are aggregated to obtain an average across observations, the result is a 'homogeneity bias': the average that is obtained contains no information about the degree of heterogeneity in the original data set. The homogeneity bias is a serious consideration when aggregation is done both within-persons and across-persons. When a person's behavior varies across situations, this variability may indicate underlying relationships rather than measurement error and the origins of variability across situations needs to be carefully considered.

The homogeneity bias is most serious when aggregation involves combining data across persons nested under a larger group. First, individual differences are pervasive and often quite large in almost all types of behavior that social scientists are interested in. Therefore, some degree of heterogeneity is inevitable and aggregation loses this information. When the heterogeneity is extreme, the aggregate picture (e.g., the average of the group) may be meaningless.

Second the degree of heterogeneity within a unit offers a window to social phenomena at a descriptive level. For example, neighborhoods are often assumed to be homogenous and when only aggregated data, such as census data are available, this assumption cannot be challenged. When data from individuals are obtained and within-unit heterogeneity is examined using intraclass correlations, which indicate how homogenous individuals are within a unit, neighborhoods appear to be much less homogenous than they were assumed to be (Cook et al. 1997). Finally, individual differences within units may be just what needs explaining. If, for instance, neighborhoods are theoretically powerful influences on residents and yet descriptive evidence indicates that a large degree of heterogeneity within neighborhoods, this heterogeneity needs to be studied. More explicitly, a neighborhood characteristic that is common to all neighborhood residents cannot explain why the residents are varying on a given outcome. What leads to this heterogeneity has to be investigated by focusing on variables not common to all residents. Perhaps the best example for the significance of heterogeneity comes from developmental psychology: a century of research shows that parents have powerful influences on their children and yet heterogeneity within families is always present. Siblings, even genetically identical monozygotic twins, appear to be different in multiple respects. Developmental psychologists are now considering processes that make siblings similar and different simultaneously.

3. *Current Status*

Despite the potential problems associated with the use of aggregated data and the inherent limitations of aggregated data in offering reliable insights into individual's behavior, aggregation is common in the social sciences today and there are advances in the proper utilization of the aggregation and aggregated data. These advances are due primarily to two trends:

As interdisciplinary research becomes more common in the social sciences, it becomes necessary to specify relationships and use data from more than one level. Second, advances in statistical modeling of data from multiple levels, particularly multilevel modeling, allows researchers to utilize statistical tools that match the complexity involved in multilevel research.

There is increased sensitivity in textbooks to problems associated with aggregation, often under sections dealing with the issue of the 'unit of analysis' (e.g., Singleton et al. 1988). With the wide acceptance of structural equation modeling in the social sciences, researchers are urged to specify the theoretical models and the specific relationships these models contain both in their theoretical work, at the outset of their empirical investigations and at the time of statistical analysis. This specificity facilitates specification of the unit of analysis (e.g, individuals, schools, and neighborhoods) and at which level (e.g., individual-level, school-level, and neighborhood-level) data should be collected and analyzed.

There are multiple examples in the recent literature that demonstrate how interdisciplinary research in the social sciences may necessitate working at multiple levels and the proper use of aggregation and aggregated data. When, for instance, the issue is how school reform influences change in a number of measures tapping different aspects of students' lives (e.g., Cook et al. 1999), the question is how a school-level variable (i.e., school reform) influences individual-level variables. This research brings two foci together: the school as an institution, often the focus sociology of education, and individual change, often the focus of developmental psychology. In this study, some variables are measured at the school level (e.g., school size) and outcome measures (e.g., academic performance) are measured at the student level. Several variables are measured at the individual level and then aggregated to the school level to characterize the school. For example, whether or not a student is taking algebra is determined at the individual level (yes or no), and then aggregated to the school level (proportion of students enrolled in algebra class). Such research that brings together two levels is much needed in areas where the construct of interest is collective and the individuals living in or exposed to this collective variable are expected to be influenced by it. Collective climate or organizational culture are prototypical examples of such constructs. By definition, climate or culture is collective and is expected to influence and to be influenced by, individuals living in that culture. Therefore, the issue is a multilevel issue by definition and issues of level in is a key question in organizational research (Morgeson 1999, Rousseau 1985). Often researchers would aggregate individual-level data to be able to capture and describe the collective climate (e.g., Gonzales-Roma et al. 1999) but the richer picture emerges when multilevel analysis is used and both levels are taken into account (Klein 1999).

Multilevel analysis of multilevel questions tends to produce more accurate findings (Bryk and Raudenbush 1992). Multilevel analysis avoids the heterogeneity bias aggregated data often lead to by explicitly allowing for and modeling within-unit heterogeneity. In sociology of neighborhoods, for instance, neighborhoods have often been construed as powerful influences on neighborhood residents. The evidence that supported this view was often based on aggregate data and aggregate relationships between neighborhood variables and variables measured at the individual level and aggregated to the neighborhood level. Recent research employing a two-level model (e.g., Cook et al. 1997) suggests that neighborhoods may have a much smaller influence on individual-level outcomes. When individual-level data are aggregated to the neighborhood level, as was the case before, neighborhoods appear to have stronger influences. Recent research on peer influence suggests a similar picture: when an individual is located in a network of relationships and the multiple levels involved in the network are taken into consideration, long-standing estimates of peer influence appear to be inflated (Urberg et al. 1997).

4. *Future Prospects*

There is a consensus in the social sciences that aggregated data are useful and need not be left behind as a research tool. Aggregated data are widely available through public data collection efforts (e.g., census) and easily accessible at archives, many of which are now online. The increase in the number of interdisciplinary collaborations are making it increasingly more commonplace to use individual-level and aggregate data together. The advances in multilevel modeling are enabling interdisciplinary teams to properly deal with the complexities involved in multilevel data analysis and there is a consensus that multilevel modeling is necessary to overcome the inherent limitations of aggregated data (Jones and Duncan 1998, Klein 1999, Morgeson 1999). These two trends are making it inevitable for researchers to obtain data from individuals and analyze such data at the individual level.

Thus, a third consensus is emerging around the necessity of collecting data from individuals when aggregate-level factors (e.g., economic stagnation) are expected to influence individuals (e.g., depression, job prospects, etc.). Without individual-level data, such relationships cannot be properly examined.

This consensus is bolstered by process-oriented research in the social sciences. Process-oriented research focuses on the linkages or the mediating processes that explain how an outcome may be influenced by various factors. Such research is particularly needed when interventions are necessary to influence the processes leading to negative outcomes. When an intervention is required, aggregated data

offer little or no direction, because most interventions need to target specific individuals and processes. This is particularly true for multilevel models: when global influences, such as economic stagnation, are under investigation, it is often clear from the very outset that global influences do not influence each individual in the same way and different segments of the society experience this influence in different ways. How this influence varies across individuals and social groups needs to be explained with mediating variables and moderating variables. The moderating mechanisms often involve a cross-level interaction between global factors and personal factors (e.g., depression, job prospects, etc.). Without individual-level data, such relationships cannot be properly modeled (Furstenberg et al., Sameroff et al.)

Aggression in Adulthood, Psychology of

1. *Approaches to the Study of Aggression*

Psychological analyses of adult aggression have changed over the twentieth century with the development of the behavioral, biological, and social sciences. Although nearly all of these interpretations view aggression as behavior intended to hurt or destroy some target, the early formulations, including those advanced by traditional psychoanalysts, basically attributed the action largely to endogenous motivation: an internally generated drive continuously seeking expression that supposedly had to be released directly in aggression or indirectly in substitute behavior (see Berkowitz 1993). Contemporary analyses are far more differentiated and recognize the interplay of a large variety of influences in the person's biology (including heredity), past learning, and immediate social context (see Berkowitz 1993, Reiss and Roth 1993). Even so, however, present-day psychological accounts of adult aggression typically concentrate on the psychological processes operating in the instigating situation-to-behavior sequence, although they differ in which aspects of this sequence they emphasize. Some focus on the action's goals, whereas others deal primarily with the cognitive processes promoting the behavior.

Many discussions concerned with the aggressors' goals assume the attackers are mainly motivated to achieve some end other than the victim's injury, such as achieving control or dominance over the victim (e.g., Tedeschi and Felson 1994), status attainment, the repair or enhancement of one's self-concept (e.g., Nisbett and Cohen 1996, Toch 1992), or more generally, the elimination of a noxious state of affairs (Bandura 1973). In contrast, other analyses (e.g., Berkowitz 1993) contend that sometimes the aggressors' primary goal is to harm or destroy. This latter formulation distinguishes between hostile assaults, aimed chiefly at hurting the victim (whatever other benefits might also be achieved), and instrumental aggression that is used as a means to some other, noninjurious objective. As a variation on this theme,

other investigators (e.g., Crick and Dodge 1996) differentiate between reactive and proactive aggression, with the former being a response to a perceived threat and the latter spurred by the anticipation of some gain. Reactive aggression can be regarded as hostile aggression in that both frequently occur in response to externally engendered strong negative feelings (Berkowitz 1993). And similarly, proactive aggression can be seen as instrumental aggression.

Where some discussions of hostile aggression (e.g., Berkowitz 1993) hold that quite a few assaults of this type are carried out impulsively and with little thought, the formulations emphasizing mental processes (e.g., Lindsay and Anderson 2000, Zelli et al. 1999) generally assume that the attackers' aggression-related knowledge (or belief?) structures and modes of information processing shape their decision to assault the target. According to Zelli et al. (1999), those people who believe it is proper to assault a perceived offender are also apt to make hostile attributions about ambiguous interactions with others, and these attributions then determine what behavior is enacted.

People's appraisals of an aversive situation undoubtedly can affect what they feel and do in response. Although emotion researchers do not agree in detail as to what specific interpretations produce anger and aggression, most appraisal theories insist these particular emotional reactions will not arise unless some external agent is blamed, that is, accused of having deliberately and improperly brought about the negative event. However, there is now evidence that blame appraisals are not always necessary for anger and aggression to occur, and more than this, that anger generated by irrelevant negative experiences can lead to blame being placed on innocent parties (Berkowitz 1993, 2001).

Another cognitive process promoting aggression operates through priming: Events or objects having an aggressive meaning automatically bring to mind a range of aggression-related thoughts and may even activate aggression-related motor reactions. Like other hostile acts, the primed behavior is aimed at the injury of the available target, but unlike most instances of hostile aggression, it is not spurred by intense negative affect.

2. *Internal Influences on Aggression*

2.1 *Violence-prone Personalities*

Even though every attack is not necessarily governed by the same underlying processes, those persons who are highly assaultive in some settings are apt to be also aggressive on other occasions as well, even though their actions may vary in form and target (e.g., Olweus 1979). Research has also shown that violence-prone adults are likely to have been hyperactive, impulsive, and restless as children (Reiss and Roth 1993). Consistent with these findings, Dodge and his colleagues (Zelli et al. 1999), as well as other investigators, such as Spielberger, using aggressive trait inventories (see Berkowitz 1998), indicate that many violence-prone individuals are highly reactive emotionally. These persons are also generally quick to attribute hostile intentions to others, and often react to these perceived threats with intense anger. Their aggressive urge is also apt to be facilitated by their beliefs that aggression is an appropriate and effective way to resolve their interpersonal difficulties (Zelli et al. 1999).

There apparently are also some frequent aggressors, such as the classic psychopaths (Patrick and Zempolich 1998), who are more instrumentally oriented. Sometimes termed proactive aggressors, they characteristically do not attack in the heat of anger but use their aggression as a tactic to further their ends.

Whatever its exact nature, this relatively persistent aggressive disposition is typically part of a general pattern of social deviation. Those who often depart from conventional social standards by deliberately hurting others around them are also likely to violate other traditional social norms such as by being heavy users of alcohol and drugs and engaging in crimes. This readiness to engage in antisocial conduct can continue over the years. Longitudinal investigations have repeatedly demonstrated that people who are highly aggressive as children are more likely than their less combative peers to also be convicted of a criminal offense by the time they enter adulthood (Reiss and Roth 1993).

2.2 *Cultural and Community Influences*

Community, ethnic, national, racial, and socioeconomic groupings can differ in their rates of violent crimes (Reiss and Roth 1993). Psychological accounts of adult violence usually refer to within-the-person psychological processes in explaining this variation. Some of these analyses focus on emotional reactions, proposing, for example, that the relatively high crime rates in impoverished areas (Berkowitz 1993), as well as the high incidence of homicides in the warmer regions of the globe (Anderson and Anderson 1998), stem in part from the negative affect generated by the aversive circumstances. Other interpretations have emphasized the role of widely shared values, knowledge structures, and modes of information processing, generally postulating a culture of violence in these groups and regions. Thus, according to Nisbett and Cohen (1996), among other investigators, many White (not African-American) US southerners are apt to believe they are justified in killing another person in defense of their families or property, or more generally when they are confronted by serious threats to their honor. Nisbett and Cohen (1996) also showed experimentally that southerners were typically more

likely than their northern counterparts to interpret another person's ambiguous encounter with them as an act of hostility and then become angry.

The emotional and cultural perspectives should be regarded as supplementary rather than competing accounts of group differences in the proclivity to violence. It is also clear that the differences in violence rates among a number of community, regional, and national groupings cannot be completely explained by individual-level formulations, whatever their exact nature. Any truly satisfactory analysis of the USA's high homicide rate obviously must recognize the significant contribution made by the ready availability of firearms in the USA. Then too, noting that certain urban areas continue to have high crime rates even when their ethnic or racial composition changes, some writers contend that the social disorganization and weak community controls within these areas is greatly responsible for their high levels of antisocial conduct (Reiss and Roth 1993).

2.3 *Biological Influence*

2.3.1 Heredity. Although we know that antisocial tendencies such as aggression tend to run in families, we cannot say unequivocally whether this family effect is due to the common environment, or the genetic influences shared by the family members, or both (Geen 1998). The few investigations employing behavioral measures have obtained only weak, if any, indications of a hereditary patterning in the disposition to violence. By contrast, the Miles and Carey (1997) meta-analysis found that both heritability and family environment contributed to individual differences in personality measures of aggressive inclinations. This analysis also suggested that the relative importance of genetic influences increases with entry into adulthood.

2.3.2 Gender and hormonal influences. In almost every animal species investigated, including humans, males tend to be more aggressive than females. At the human level, men have been reported to be more aggressive than women in virtually every society for which data are available, and furthermore, crime statistics around the world consistently show that far more males than females are arrested for violent crimes (Berkowitz 1993). Nevertheless, it still is not possible to make a simple, sweeping statement about gender differences in aggressiveness that holds across all situations, provocations, and modes of expression.

For one thing, men and women may differ in what kinds of situations spur them to attack a target. A meta-analysis of experimental studies examining such gender differences (Bettencourt and Miller 1996) suggests that men are more likely than women to become assaultive when their intelligence is cast in doubt or they are frustrated, whereas both genders become aggressively inclined when they are openly insulted. The genders probably also differ in what form of aggression they exhibit when they are provoked. Although men are typically more prone to attack an offender directly than are women, Lagerspetz and her colleagues (see Geen 1998) indicate that the angry males' greater propensity to direct assaults decreases as they go from childhood into late adolescence when they make greater use of indirect and verbal aggression. In sum, much of the research in this area suggests that men have a stronger biological disposition to react with direct physical aggression than do women when they are emotionally aroused, but that learning can lessen, or for that matter, even increase this gender difference in the proclivity to direct assaults.

3. *Situational Influences*

3.1 *Cognitively Primed Aggression*

Although public concern about the heavy dose of violence portrayed on TV and in the movies focuses largely on what children may learn from these frequent depictions, adults can also be affected by what they see and hear in the mass media, even if only for a relatively short time. The witnessed or reported violence can prime aggression-related thoughts and action tendencies in the audience members, especially if they already possess strong hostile dispositions (Berkowitz 1993, Geen 1998). If their restraints against aggression are weak at that time, they are apt to be hostile to others in thought, word, or deed until the priming effect subsides. Widely publicized offenses all too frequently spur 'copycat crimes' in this manner. There can even be a 'contagion' of suicides after a report that a well-known personage has taken his or her own life, as Phillips has noted (see Berkowitz 1993). People in the media audience apparently get ideas from what they have seen or read and, if they are already inclined to the same behavior, may act on these thoughts.

3.2 *Affectively Generated Hostile Aggression*

A very wide variety of aversive occurrences can also promote aggressive responses. The afflicted persons may well have a strong desire to escape from the unpleasant situation, but at the same time, their intense negative affect could also activate aggression-related feelings, ideas, and even motor impulses. Under the right circumstances (such as weak inhibitions at that time, an appropriate target, and strong aggressive dispositions), these aversively generated aggression-associated reactions can be stronger than the urge to escape so that an available target is attacked.

3.2.1 Pain and other physically unpleasant conditions. Experiments with a variety of species have now demonstrated that animals suffering from physical pain are likely to assault a nearby peer, especially when escape from the aversive stimulation is not possible and the aggressor had not previously learned to anticipate punishment for such an attack. Somewhat similarly, people in pain are often angry and even prone to hostile thoughts. Nevertheless, the pain-produced instigation to aggression may not become manifest in humans unless intervening, aggression-related cognitions are also present. As an example, the hostile ideas primed by the sight of weapons heightens the chances that great physical discomfort will lead to open aggression (Lindsay and Anderson 2000).

Other aversive conditions, such as decidedly uncomfortable temperatures, can also promote violence (see Anderson and Anderson 1998). The hottest regions of the USA and Europe typically have higher violent crime rates than the areas usually experiencing more comfortable temperatures. Further, within a specific locality (for example, in Dallas or Minneapolis), generally speaking, more violent crimes are committed on the hotter than cooler days. Still, with all of the empirical support for this temperature–aggression relationship at the area/community level, other influences can operate to mitigate the adverse effects of the unpleasant weather. The discomfort-induced instigation to aggression can at times be masked by an even stronger urge to escape from the heat, if escape is possible. And then too, the aversively generated hostility obviously will not be manifested openly if there are strong restraints against aggression in the situation and suitable targets are not available (Berkowitz 2001).

3.2.2 Frustrations and other social stressors. Frustrations can also be decidedly unpleasant and thus give rise to an aggressive urge. Although the idea that frustrations can breed aggressive inclinations has had a long and controversial history in the social sciences, it undoubtedly is best known in psychology through the monograph 'Frustration and Aggression' by Dollard et al. (1939). These writers argued that a frustration, defined essentially as an obstacle to the attainment of an expected gratification, produces an instigation to harm someone, principally but not only the agent viewed as blocking the goal attainment. This proposition has been criticized as seriously incomplete, but Berkowitz's (1989) survey of the available literature indicates that there is considerable evidence for its basic validity, and that even socially legitimate, non-ego-threatening barriers to goal attainment can produce aggressive reactions. Other, more recent, research indicates that thwartings can lead to aggression even without prior learning. In explaining why frustrations do not always have this effect, Berkowitz has proposed that frustrations will generate an instigation to aggression only to the extent that they evoke intense negative affect (see Berkowitz 1993, 2001).

This reformulation ties the frustration–aggression hypothesis together with the sociological 'social strain' conceptions of antisocial behavior. Both lines of thought basically argue that any greatly unpleasant social condition can promote antisocial conduct, including aggression. Consistent with such a statement, in one study (Catalano et al. 1993) job layoffs led to an increase in self-reported violent behavior if alternative employment was not readily available. In general, barriers to economic success can have criminogenic effects, particularly if the affected persons are not clearly threatened with punishment for any aggression they display and have not become apathetic and resigned to their privations. Social stress can also contribute to domestic violence. In Straus's (1980) survey, the greater the number of stressors the adult respondents reported experiencing, the more likely they were to say they had abused their children (Berkowitz 2001).

4. *Future Directions*

Obviously, a good deal still has to be learned about the influences, such as the mass media, peer groups, and social stressors, that contribute to adult aggression, and also about how these influences might be mitigated. Judging from contemporary trends, much of the future psychological research in these areas will focus on how mental processes operate to bring about, or lessen, the adverse effects. This relatively microanalytic approach will tell us much about aggression, but it is also apparent that complementary research by other social scientists will also be helpful if there is to be a truly comprehensive understanding of violent behavior.

Aging and Education

This article focuses on educational issues in adulthood, particularly in middle adulthood and older age. First, global demographic changes in the age structure of societies are discussed with particular emphasis on implications for education. The second section focuses on change and stability in cognitive development in adulthood, as well as the long-term effects of early education on later life and cognitive training in adulthood. Finally, current and future trends in education for adults and the aged are discussed, including efforts to promote lifespan and global learning and the potential for utilization of scientific and technological advances in adult education.

1. *Demographics of Aging and Education*

Growth in the world's population, as well as changes in the age structure of societies will impact the nature of education as well as the demographic characteristics of the learner. As the proportion of adults in middle and later part of the lifespan increases, the number of adult learners will increase, as will the diversity of this group of learners.

1.1 *The Shifting Age Structure*

During the twentieth century, the population of the world has grown substantially in both developed and developing countries. Developing countries, particularly the regions of Latin America, Asia, and Africa, are increasingly accounting for the vast majority of growth in the world population (US Census Bureau 1999). These countries face the greatest increases in population, yet have substantially fewer resources in terms of health, technology, and education. The population growth witnessed in developing countries is in contrast to many developed nations in Europe which are below population replacement (i.e., the number of deaths is greater than the number of births; US Census Bureau 1999).

In contrast to developed nations, the increase in middle age and aged adults in developing countries is occurring in just a few cohorts (i.e., generations). Developed countries, whose populations have aged more slowly, were able to adjust more gradually to demographic shifts and implement corresponding social agendas. In contrast, developing countries are aging before they have resources and social policies in place, forcing them to make major rapid social and policy changes to take into account population shifts.

1.2 *Implications of Demography Shifts for Education and Aging*

Successive cohorts of adults throughout the twentieth century have attained greater levels of formal education compared to previous cohorts. Gross enrollment ratios (i.e., percentage of the school-age population corresponding to the same level of education in a particular academic year) for participation in primary, secondary, and tertiary levels of education increased from 50 percent in 1970 to 63 percent in 1997

for the world as a whole (UNESCO 2000b). In developing countries this ratio has risen from 47 percent to 63 percent, compared to a shift of 72 percent to 85 percent for developed countries during the same time period (UNESCO 2000b). Country-specific data from the USA, mirrors the general trend for increased educational attainment for successive cohorts: 83 percent of adults over the age of 25 in 1998 had completed high school, and 24 percent had completed four years of college, compared with a rate of 25 percent and 5 percent, respectively, in 1940 (US Census Bureau 1998). Currently, American adults over the age of 64 are less likely than adults aged 35 to 64 years to possess a high school diploma; however, given cohort trends in postsecondary education, future cohorts of elderly will have increasing levels of education. While this trend is promising for future cohorts of elderly, particularly in developed countries, it also implies that current cohorts of elderly are seriously disadvantaged in educational attainment compared to current younger adult cohorts (US Census Bureau 2000).

Although the overall levels of education have risen for successive cohorts throughout the twentieth century, the gross enrollment ratios indicate that universal education is not present, even in the most developed countries. The number of expected years of formal education ranges in regions throughout the world from slightly more than one year in less developed countries to over 16 years in developed countries (UNESCO 1996). Current illiteracy rates throughout the world also indicate disparities between developing and developed countries. Developed countries in Europe and North America have very low rates of illiteracy (i.e., average = 1.4 percent) compared to developing countries (i.e., average = 26 percent); and the least developed countries in regions such as Africa and southern Asia (i.e., average = 49 percent), which are more economically challenged and have higher birth rates (UNESCO 2000a). As demonstrated by these statistics, vast differences in educational attainment exist between countries, as well as between cohorts within a country.

Groups such as older women and ethnic minorities, who are increasingly accounting for a greater proportion of the elderly, will be particularly affected, putting them at an even greater disadvantage. Despite advancements in the equity of educational opportunities, great disparities still exist for women, ethnic minorities, and the economically disadvantaged. Women's education during the twentieth century has improved tremendously, however, worldwide fewer girls attend school than boys and women comprise two-thirds of illiterate adults (UNESCO 1996). Educational equality has also been difficult for ethnic minorities within some countries.

With recent changes in population demographics, efforts to facilitate maintenance of independence and productivity in the elderly are gaining attention. It is projected that the number of elderly and their need for support will steadily increase during the next 25 years throughout the world (US Census Bureau 1999). The shifting demographics will have repercussions on numerous policy initiatives, including length of work life and retirement age. Some countries have or are considering eliminating mandatory retirement, or are raising the standard retirement age. As workers remain the in work force to later ages, maintenance of cognitive abilities and issues of educational updating will gain attention.

2. *Changes in Cognition Across Adulthood*

The changes occurring in cognitive abilities throughout adulthood have important implications for the formal education of adults in middle and older adulthood as well as self-directed learning. The variable trajectories of cognitive ability throughout adulthood, as well as the long-term beneficial effects of early formal education and the potential for cognitive training in later adulthood are discussed below.

2.1 *Age-related Changes in Cognition*

A well-established approach to the study of adult cognitive ability has been the examination of higher-order dimensions of psychometric mental abilities, particularly fluid and crystallized intelligence (Horn and Hofer 1992). Fluid intelligence refers to abilities needed for abstract reasoning and speeded performance whereas crystallized intelligence refers to knowledge acquired through one's culture including verbal ability and social knowledge (Schaie 1996).

Longitudinal research examining cognitive development has revealed that mental abilities vary in their developmental trajectories across adulthood (e.g., the Seattle Longitudinal Study: Schaie 1996, the Berlin Aging Study: Smith and Baltes 1999). A substantial body of research in the USA has demonstrated that fluid abilities, such as inductive reasoning, peak in early middle adulthood rather than in adolescence as previously thought. Fluid abilities remain stable in middle age and first show reliable decline in the mid-sixties. In contrast, crystallized abilities, such as vocabulary, do not peak until middle age and show reliable decline later in the mid-seventies (Schaie 1996). Similar developmental trajectories in abilities have been reported in Canadian and European longitudinal research (Backman 2001).

Decline in cognitive ability prior to age 60 is usually considered to be associated with ensuing pathological changes, and universal decline on all markers of intelligence in normal elderly is not evident even by the eighties (Schaie 1996). Findings from Swedish longitudinal study demonstrate that even the oldest-old (i.e., a sample of individuals aged 84 and older), who do not exhibit cognitive impairment at

baseline assessment, demonstrate relative stability over a two-year period on several markers of cognitive ability (Johansson et al. 1992).

2.2 Cohort Differences in Cognitive Ability and Education

In addition to varying individual developmental trajectories, mental abilities also show different cohort trends as well. Some abilities show positive cohort trends with successive cohorts functioning at higher levels when at the same chronological age. Other abilities exhibit curvilinear or negative cohort trends. The two abilities showing the strongest positive cohort trends are inductive reasoning and verbal memory—both representative of fluid ability. Current cohorts of the elderly are thus at double disadvantage on these abilities due to relative early age-related decline on fluid ability, combined with strong positive cohort trends on these same abilities. More modest positive cohort trends have been shown for spatial and verbal abilities. In contrast, curvilinear cohort trends have been shown for numerical abilities with birth cohorts 1918–1920s showing higher functioning compared to earlier or later cohorts when at the same chronological age. There does however appear to be a slowing of these cohort differences, and it is estimated that during the first part of the twenty-first century the differences between cohorts will become smaller (Schaie 1996).

These cohort trends in abilities are multiply determined; however, increasing levels of education across cohorts as well as medical and health advances appear to have been strong influences. The impact of increases in educational attainment as well as shifts in educational practice toward discovery learning, procedural knowledge and metacognition may have contributed in particular to the strong positive cohort trends for inductive reasoning and verbal memory. A recent reduction in the magnitude of cohort differences in abilities may be related to a plateauing of the dramatic increases in educational attainment that occurred in the later part of the twentieth century. Alternatively, the slowing of cohort trends may reflect the decline in college-entrance exam performance reported for recent cohorts of young adults; these cohorts are now in their late twenties and thirties and are represented in longitudinal studies of adult cognition.

2.3 Lifelong Benefits of Early Formal Education

Some research suggests that the benefits of early formal education extend into adulthood. Although debate exists regarding the extent, as well as the mechanisms (i.e., compensatory vs. protective) by which early educational benefits continue to be manifested in later life, numerous cross-cultural studies have found greater levels of formal education to be associated with decreased risk of cognitive impairment in later life (e.g., Kubzansky et al. 1998). Several scenarios for how early education benefits later cognitive functioning have been offered. First, greater education attainment in adolescence and young adulthood increases opportunities and access to further education through the remainder of the lifespan. Likewise, attainment of certain levels of education provides entry into particular career opportunities. A second less direct influence of early education on later cognition focuses on the increased financial and environmental resources available to those with higher educational attainment. Those with greater financial resources typically have access to better healthcare and social services, which may facilitate maintenance of cognitive functioning in late life. Finally, early educational attainment may result in a higher level of cognitive ability and thus a higher threshold of functioning from which decline occurs in later life. For example, level of education may not delay the onset of dementia; however, it appears that it may be related to a delay in its symptomatology.

2.4 Cognitive Training Research with Adults

Given that fluid abilities show age-related decline beginning in the sixties and also that positive cohort trends for some fluid abilities place current elderly cohorts at a disadvantage, the question arises of whether behavioral interventions might be effective in remediating and/or enhancing cognitive performance in later adulthood. Educational interventions have traditionally focused on the earlier part of the lifespan when children are first developing mental abilities and skills. There has been less research on educational interventions in middle adulthood (except for work-related training) and even less study on cognitive interventions in later life. Outcomes from cognitive interventions later in the lifespan may be qualitatively different from those earlier in the lifespan (Willis and Schaie 1986). For older adults suffering cognitive decline, the intervention focuses on the possibility of remediating prior loss in level of ability. In contrast, for older adults who have not declined on an ability, the question is whether interventions can boost cognitive performance above prior levels. In order to examine these questions, longitudinal data on older adults, cognitive functioning prior to the intervention are needed in order to determine whether elders have declined or not on the abilities to be trained.

Since the 1970s, there has been a growing body of cognitive intervention research in later adulthood focusing on a variety of mental abilities, including memory, reasoning, and speed of processing (Camp 1999). Much of the research has shown that non-demented, healthy older adults can improve their performance as a function of brief educational train-

ing. Researchers have focused on different questions regarding the plasticity of cognitive functioning in later adulthood. A number of researchers have compared training gains for young adults vs. older adults. Due to cohort differences, younger and older adults were performing at different levels prior to training. Significant training effects have typically been found for both young and older adults; however, the cohort differences in level of performance remained after training (Willis and Schaie 1994); that is, older adults gained significantly from the intervention, but the training did not eliminate the cohort differences in level of performance. Baltes and co-workers have focused on a form of training known as 'testing the limits' in which older and younger adults were trained on the method of loci in list learning tasks, and then recall was assessed under increasing levels of speeded performance (Kliegl et al. 1989). Although both young and old showed significant training gains, the old showed less improvement when tested under highly speeded conditions.

In the context of the Seattle Longitudinal Study, Willis and co-workers have examined whether training on fluid abilities is effective for both older adults who have declined on the target ability and for those who have remained stable (Schaie and Willis 1986). Significant training effects have been shown for both stables and decliners on two fluid abilities, inductive reasoning and spatial orientation (Willis and Schaie 1986). Seven years after training older adults trained on the ability were performing at a higher level than adults not given training on a specific ability (Willis and Schaie 1994).

While the cognitive training research appears promising, it is important to consider caveats to these findings. First, training effects have been found only with nondemented, community-dwelling elderly, not with demented patients. Second, while training effects have been demonstrated for multiple measures of the ability trained, training transfer is limited to the particular ability that was the target of training. That is training on a specific ability does not lead to significant enhancement on other primary abilities. Third, much of the training research has been conducted with young–old individuals who are White and of middle to upper socioeconomic status. Further research is needed regarding whether training effects can be demonstrated for the old–old and for minority elderly. One such study is currently being conducted by the US National Institute on Aging and National Institute of Nursing Research, which involves a multisite clinical trial examining the effects of cognitive training for more representative groups of elderly (Jobe et al. 2000).

3. *Trends in Education for Adults and the Aged*

Educational systems are continually changing in response to the political, economic, and social forces that occur in countries throughout the world (UNESCO 1996) and these forces are particularly influential in terms of adult education and vocational training. Two principal broad classes of educational trends relevant to adult learners are expected to continue during the first part of the twenty-first century, including the evolution of education into a system of lifelong learning and increasing utilization of science and technology.

3.1 *Lifespan Learning and Globalization of Education*

Education is continually affected by societal changes, particularly in the work place. These changes have promoted the emergence of lifespan learning and the globalization of education. The current transition from industrial to post-industrial economies occurring in many countries (Beare and Slaughter 1993) and a general increase in economic interdependence has fostered an interdependent, global approach to education. The shift in many countries away from industry-oriented occupations necessitates changes in occupational training, evaluation of students from all countries compared to global criteria of competence, and increased creativity and flexibility in meeting future training needs (e.g., creation of new disciplines, increased interdisciplinarity; Beare and Slaughter 1993). Furthermore, the emergence of a more global consciousness and cohesive worldview has prompted educators across the world to foster global awareness and competence in students (Beare and Slaughter 1993, Miller 2000). Systems of higher education throughout the world have begun to converge as the result of emerging national and international educational organizations and the sharing of educational information, theory, and research. This however, could come at a cost for non-English speaking countries with limited technological availability, as they may not be able to remain up-to-date. As the composition of the adult learner population changes, the challenge for educators in the twenty-first century will be the necessity to strive for universal education especially for under-served populations including ethnic minorities, women, and the economically disadvantaged.

Initial formal education, continuing education throughout adulthood, and the creation of everyday learning environments will grow increasingly intertwined. Recent increases in the length of nonworking life and amount of free time during employment, have resulted in an increasing role for education throughout the lifespan (UNESCO 1996). On-the-job training and general and vocational education are becoming more intermixed due to the growing demands to compete in the world market. Economic prosperity, company viability, and employee productivity have become increasingly interdependent. The uncertainty of the world labor market has also highlighted the need for continuing education. An unmet demand for skilled

workers and rising unemployment of unskilled workers point to the need for adequate training (Pair 1998). Education in the workplace is becoming vital as lifelong learning is required to enable job-sharing among employees with comparable training and to support and promote the growth of new occupations; workers must be prepared for present employment positions as well as positions of the future (Pair 1998). Inequalities in initial training (i.e., early formal education) have great impact on subsequent adult and lifelong learning, highlighting the importance of early education as the time for initial training with increasing amounts of subsequent training and education throughout adulthood.

3.2 Impact of Science and Technology on Adult Education

Another major trend in education has been the pervasiveness of computers and the Internet in the last decade, which have increased both older adults' formal and informal educational opportunities. For example, the use of technology throughout the later part of the twentieth century in distance learning has increased older adults' educational access and opportunity. Although distance education has been available during the past century in a variety of countries (e.g., Thailand, Pakistan, and Venezuela), it is only in the very recent years that more interactive options have been available. Early correspondence study programs relied on communication through the mail (Miller 2000), however, long distance learning has become increasingly interactive as these programs have incorporated television, videos, computers, and in the last decade, e-mail and the Internet (Miller 2000). As a result of the Internet, the classroom has become an international one (Miller 2000). The use of technology promotes flexible learning and has the advantages of decreasing cost, improving quality, and broadening access to educational materials, perhaps leading to virtual universities in the future.

The full impact of science and technology on adult education is not yet fully known. Technology has increased educational opportunities for adult learners and can be used to create a more optimal learning environment (i.e., familiar settings, accommodations such as large print and audio presentation). However, middle-aged and older adults' comfort level and ability to adapt to rapidly changing technological advances may be a challenge. The relative lack of computer experience by middle-aged and older adults and age-related changes in working memory, processing speed, and visuomotor skills can be impediments to adults' computer task performance (Czaja and Sharit 1993). However, relaxation of task pacing constraints, attentive interface design, and training are likely to increase older adults' ease and efficiency with computer-related tasks (Czaja 2001).

3.3 Implications of Trends for Adult Education

The emphases on lifelong and adult learning and the globalization of education, as well as the impact of science and technology have several implications for educators. First, education is increasingly taking place in contexts other than traditional educational institutions. This could be advantageous for adult learners as educational opportunities become more easily accessible and available in familiar environments. Second, education and access of knowledge will increasingly require competence in new technologies, which is likely to place adults and the elderly at a disadvantage compared to younger cohorts who tend to be more familiar with these technologies. Third, cohort differences and age-related change in higher order abilities such as inductive reasoning, working memory, and executive functioning may make older adults' use of new technologies particularly challenging. Finally, the rapidity of knowledge increase will require lifelong learning and adaptation, particularly in relation to work settings.

4. Dynamic Between Aging and Education

The dynamic between aging and education will continue to change as the composition of adults over the age of 60, is transformed, education takes a more global approach and encompasses learning throughout the lifespan, and technological advances continue to impact educational methods. Coming years will see an increase in the number of older women, the very oldest segment of the population (i.e., old–old: adults aged 80 and older), and greater diversity in the ethnicity and needs of the older adult population. Increased attention will be devoted to the maintenance and improvement of functioning in older adulthood, which can be aided by investment in early formal education as well as educational opportunities throughout the lifespan.

As the duration and nature of work and retirement change, the educational needs of current and future cohorts will also continue to change. Given the impact of technology in the workplace and the emergence of second careers and later retirement ages, the traditional conceptualization of the relationship between education, employment, leisure, and retirement is being reevaluated (Krain 1995, UNESCO 1996). In western cultures, individuals have typically received education and career preparation only in early childhood, worked at a career throughout early and middle adulthood, followed by retirement in older adulthood. Educational policies must increasingly address the growing number of work transitions, periods of unemployment, decreased period of transition prior to retirement, and increased part-time work after retirement. Future policies should include expansion of adult education, increased availability of lifelong

career-oriented education and training, and greater leisure-oriented education (Krain 1995).

Aging and Health in Old Age

1. Introduction: Living Longer and Better or Worse?

There are three different models describing how disability may change in the US population. First, with improvements in the treatment of some chronically disabling diseases (e.g., cardiac surgery in children with Down's syndrome so they can survive past age 40, i.e., through reproductive ages), it was hypothesized that the US would enter a period of a 'pandemic' of chronic diseases and disability (Gruenberg 1977, Kramer 1980). That is, it was expected that persons with chronic diseases, and the profound disabilities they can generate, would survive many more years raising the prevalence of chronic disability and the average amount of lifetime that could be expected to be lived in an impaired state (Verbrugge 1984).

A second perspective, due to Fries (1980) and Riley and Bond (1983), was that the time (age) to the occurrence of chronic disability could be increased independently of changes in life expectancy (time to death). Life expectancy was postulated to be able to increase only to 85 years of age (Fries 1980) with the

Figure 1
Pandemic of chronic disease due to prolangation of life of severely disabled persons (Kramer and Gruenberg 1977)

variance of the age at death decreasing—leading to a rectangularization of the survival curve. However, it was suggested that, as the survival curve became rectangular, so could the curve describing the age at occurrence of chronic degenerative disease so that the curves, ideally, could meet so that all life expectancy would be in an unimpaired state.

In the third model it was suggested that the times at which chronic disabilities and diseases onset could be in a dynamic equilibrium with overall survival (Manton 1982). In this case which diseases were modified by interventions, and in what ways, affect the relation of the survival and disability age-dependent onset curves over time. By appropriately selecting disease interventions, that is, by targeting for prevention those with the greatest potential for inducing chronic disability (such as Alzheimer's disease), both total life expectancy and disability-free life expectancy could be increased. This would decrease the average amount of time spent in disabled states. This perspective is referred to as 'dynamic equilibrium.' It will produce moderate decreases in the time-weighted prevalence of chronic disability (Manton 1982).

To visually compare these three theories we use concepts developed in WHO TRS 706 (1984). We define a graph (Fig. 1) where the vertical axis is the probability of surviving from birth to Age X. The horizontal axis is Age. For each of these three graphs we define four points. Two (D_1 and D_2) represent the median (50 percent) age at onset of disability at two dates separated in time (e.g., 1982 and 1999). Two (S_1 and S_2) represent the median age at death at those same two times. In graph one, we show that, although the difference between S_1 and S_2 increased (median lifetime increased), the median age of disability onset did not change ($D_1 = D_2$) so the number of years lived with disability increases. In Fig. 2, S_1 and S_2 change little because the survival curve is nearly 'rectangular.' However, since D_1 is at lower ages relative to D_2, the number of years lived with disability declines. In Fig. 3 the median of both years lived, and years lived without disability, increased over time so that, ultimately, the amount of active life expectancy increased.

The survival curves themselves contain much more information than the four median age estimates (S_1, S_2, D_1, D_2) so that comparisons can be made at any age.

2. *Empirical Evidence of Declining Disability*

Considerable scientific and policy debate has emerged regarding the validity of observations of declines in chronic disability prevalence in the US and European elderly populations (Freedman and Soldo 1994, Waidmann and Manton 1998). The US declines in functional disability were first documented in the 1982 to 1989 National Long Term Care Surveys (NLTCS). The NLTCS are sets of longitudinally related surveys (done again in 1994 and 1999) designed to assess

Figure 2
Compression of morbidity and morality due to the 'rectangularization' of human survival curve and delay of onset of chronic disability (Fries 1980)

changes in functional status, social conditions, and Medicare and LTC service use in the US elderly population. The NLTCS samples of individuals (not households or institutions) were drawn from Medicare enrollment lists so that nearly 100 percent of sampled persons could be followed to conduct detailed interviews, to assess functional status, to be linked to health service use and expenditures, and to document the exact date of death. Results from that longitudinal survey based on a list sample were initially thought to be at variance with estimates made from several national health surveys which were not specifically designed to longitudinally sample events generated by population processes—such as age-related health changes and disablement.

After the 1982 to 1989 results were produced, a fourth survey was done in 1994. The 1994 NLTCS confirmed the presence of the decline in chronic disability prevalence. The results from the 1982 to 1994 NLTCS are presented in Table 1.

The age-standardized rate of decline in the prevalence of chronic disability was about 0.36 percent per annum from 1989 to 1994—higher than the decline of 0.25 percent observed from 1982 to 1989 (Manton et al. 1997). This translates into a percentage point decline of 1.77 percent (25.01 to 23.24) from 1982 to 1989 (seven years) and 1.77 percent from 1989 to 1994 (five years).

Both the external and internal validity of those findings were examined in a number of ways. The declines in disability were consistent with such internal validity tests as: (a) examining whether the decline occurred after eliminating an 'age-in' sample (5,000+ new persons sampled from Medicare enrollment lists ages 65 to 69 in 1984, 1989, and 1994) so the change could be documented in only longitudinally followed population groups (i.e., persons 65+ in 1989 were age 70+ in 1994); (b) controlling for the patterns of change specific to age, race, and sex groups so that changes in demographic composition did not confound the trends; (c) determining whether comparable trends existed in the 'rate' of proxy reporting (a measure of severe disability; the proxy rate did decline in 1982 to 1994); (d) determining whether declines were consistent with changes in other covariates of disability (e.g., disability risk is lower at high levels of education; the education level of the US elderly population increased significantly); and (e) determining whether disability rate declines were consistent with declines in the prevalence of medical conditions known to cause disability (e.g., there was a large decline in the age standardized prevalence of severe cognitive impairment from 5.7 percent in 1982 to 3.8 percent in 1994, an absolute reduction from that expected (based on 1982 rates) of 610,000 cases of severe cognitive impairment in 1994).

Figure 3
Dynamic equilibrium between survival and the age at onset of disability curves (Manton 1982)

Table 1
Sample weighted distribution (age standardized) of disabilities in 1982 to 1994 NLTCS

Year	1982	1984	1989	1994
Nondisabled (%)	76.28	76.28	77.31	78.53
IADL only	5.48	5.84	4.65	4.32
1 ADL	3.93	4.02	3.72	3.54
2 ADLs	2.44	2.43	2.61	2.36
3–4 ADLs	2.79	2.85	3.50	3.21
5–6 ADLs	3.39	3.08	2.75	2.81
Institutional	5.69	5.50	5.46	5.24
Housing units	92.58	93.64	94.08	94.37
Nursing home	6.30[a]	5.33	5.11	4.92
Others	1.12	1.02	0.81	0.70
Total (%) nondisabled standardized by 1994 age population distribution	74.99	75.07	76.76	78.53
Total (%) disabled standardized by 1994 age population distribution	25.01	24.93	23.24	21.47
Standardized decline rates (%) (per year)			(82–89)	(89–94)
Nonstandardized decline rates (%) (per year)			0.15	0.25

a Based on estimate that out of 1992 cases identified as in institutions, 1690 were in nursing homes and alive to potentially receive a detailed interview (only community interviews were conducted in 1982).
ADL, activities of daily living; IADL, instrumental activities of daily living.

The external validity of the disability declines was assessed by whether a decline, on the same measures of function, could be established by its replication in both European countries and in other US longitudinal surveys and historical data. Evidence of long-term (75 years) declines in chronic disease prevalence (Fogel 1994) and disability were found in studies of Civil war veterans (all male) who were aged 65+ in 1910 (birth cohorts of 1824 to 1844) when compared with World War 2 male veterans aged 65+ in the National Health Interview Survey (NHIS) in 1985–8, and to comparable groups in the National Health and Nutrition Examination Surveys. Fogel (1994) attributed the decline to improvements in nutrition. Perutz (1998) came to similar conclusions about British centenarians born after 1840 for which the population growth rate increased from 1 percent to 6 percent. The rate of decline in chronic disease was estimated by Fogel to be 6 percent per decade—or 0.6 percent per year.

Among more recent US population studies, an even larger decline than found in Manton et al. (1997) was noted by Freedman and Martin (1998) using the 1991 to 1996 Survey of Income and Program Participation—a decline which existed at the higher levels of disability and at advanced (85+) ages. Waidmann and Liu (1998) also found confirmation of declines in the 1993 to 1996 Current Medicare Beneficiary Survey. This confirmed findings in an earlier analysis which adjusted for methodological difficulties in the NHIS and which combined data from several other sources. Crimmins et al. (1997) found evidence for declines in the 1984 Supplement on Aging and the LSOA (longitudinal study of aging) from 1986 to 1990. Evidence of declines has been found in the 1985 and 1995 Supplements on Aging to the NHIS. Evidence for declines in European countries, as mentioned above, was found in Waidmann and Manton (1998).

As a consequence of this confirmatory evidence in multiple replications in the US and abroad, the focus has now shifted to questions about what caused the declines in disability, the social context of the declines, the social, economic, and health implications of the declines, and whether those declines should be included as covariates in official projections of both the size of the population by the US Census, and in forecasting the future fiscal status of Medicare and Social Security programs (Manton and Singer 2001).

3. *Consequences of Declining Disability*

A wide range of social and economic factors may be influenced by declines in disability in the elderly populations in the US and other countries. Improvements in functioning may change the ages at which retirement occurs. The trend through the 1970s and 1980s was toward a lower age at retirement. More recently the average age at retirement has tended to be static or slowly increase—at least in the US. This may increase the human capital available to the US economy and could dampen the effects of rapidly declining birth rates in a number of large (Italy) and small (Latvia) European societies.

4. *Causes of Disability Decline*

One set of observations about US disability declines questions the nature of their content and intensity. Specifically, disability is usually measured in terms of some variant of ADLs or physical performance measures. The content of these three scales are presented in Table 2.

The IADLs could have been influenced by changes in the socioeconomic environment which allow changes in socially defined gender roles (e.g., men doing more grocery shopping or laundry) or in providing more devices (e.g., improved telecommunications, better transportation systems) to aid partly impaired persons.

The functions reflected by the ADLs may be more influenced by interventions in biological and chronic disease processes (e.g., dementia). Indeed, while the IADLs were intended to reflect social and assistive device support for impairments in the elderly, the ADLs were argued to reflect a sociobiological model of disablement where functions were lost in the reverse order to which they were gained in socialization of the child. The performance measures directly reflect the ability to perform specific types of physical tasks.

A complete picture of disability requires that all of those scales be used because of their different content. Such analyses require multivariate analytic procedures to disentangle the complex inter-relation of the items and possible changes in the relation of items over time. Analyses of the ADLs, IADLs, and physical performance measures suggest that the basic nature of the underlying dimensions of disability have remained stable over time, that is, from 1982 to 1999 (the fifth and most recent of the NLTCS). From 1994 to 1999 the prevalence of chronic disability declined at an even faster rate than from 1989 to 1994. These dimensions have also shown interesting relations to a series of 29 medical conditions (e.g., severe cognitive impairment, stroke, heart attack) also surveyed in the NLTCS.

Of most interest in these relations is that the risk of Alzheimer's disease (and more generally severe cognitive impairment) declined from 1982 to at least 1994. Specifically the prevalence of severe cognitive impairment declined from 5.7 percent (age standardized to 1994) in 1982 to 3.8 percent in 1994. This change may be due to a number of biological and medical factors (e.g., effects of exogenous estrogen use in females (Tang et al. 1996); increased use of NSAIDs (non-steroidal anti-inflammatory medications) (McGeer et al. 1996)). However, it is also likely strongly linked to changes in education so that a decline in cognitive

6.) Using toilet	9.) Taking medicine	
	10.) Telephoning	

impairment could be related to shifts in education in the elderly population. It is also suggested that the intensive performance of cognitive tasks could stimulate an increased complexity of neuronal connections in the brain. Preston (1992) projected that the proportion of persons aged 85 to 89 who had less than eight years of schooling would decline from 62.1 percent in 1980 to 20 percent in 2015. The prevalence of severe cognitive impairment continued to decline from 1994 to 1999 with there being one million fewer cases than expected based on the 1982 rates.

The risk of disability varies strongly with education and age; with larger declines over age 85 Manton et al. 1997). For persons aged 85+ with at least 12 years of schooling, the risk of disability was 5.8 percent lower than for persons with less than 12 years of schooling. Age standardization reduced the difference to 4.0 percent, that is, 70.2 percent of the difference was attributable to education; only 30 percent was attributable to age.

This is also consistent with major shifts in residence among the elderly where the use of nursing home facilities has declined from 6.3 percent (Table 1) in 1982 to 4.9 percent in 1994 with stays in nursing facilities also becoming shorter in duration (e.g., a median of 84 days in 1985 to a median of 63 days in 1997; Gabrel 2000) as more stays are funded by Medicare as instances of postacute rather than long-term care. More and more elderly persons, instead, are going to facilities called 'assisted living' facilities where a graded level of care is provided. A significant proportion of residents in assisted living facilities appear not to be ADL or IADL disabled in preliminary findings from the most recent (1999) NLTCS.

5. *Conclusions and Future Directions*

The nature and persistence of those declines will be evaluated and studied in several ways. First the NLTCS was repeated in 1999—a 2004 survey is being planned. The 1999 NLTCS is now being analyzed. Preliminary results suggest the rate of decline in chronic disability is accelerating further. Second, the instrumentation and temporal structure of the NLTCS is being replicated in existing (e.g., the Longitudinal Study of Danish Twins) and planned (e.g., in Sweden) European surveys. Third, the use of longitudinal data as social indicators is being exploited in measures of active life expectancy as implemented in the WHO global goals for health improvement and which is now gaining international acceptance as exploited by the efforts of the REVES (Réseau sur l'espérance de vie en sauté) groups. As a conclusion there is beginning to be more global acceptance of disability adjusted measures of demographic changes—an acceptance that has extended to such international organizations as OECD and the G7/8.

Aging Mind: Facets and Levels of Analysis

1. *A Zeitgeist in Search for Interdiscipline Integration*

Throughout most of the twentieth century much of the basic research on cognition has progressed in a rather segregated fashion, with differences in experimental paradigms, methodological, and theoretical orientations together with traditional discipline boundaries setting the dividing lines. Disintegrated research pursuits as such are common, as most endeavors in early stages of research development are first devoted to the discoveries of unique new phenomena and the constructions of competitive theoretical interpretations. As the field progresses with ever increasing empirical data and theories, integration is then necessary to provide a comprehensive understanding of the accumulated information.

1.1 *Proposals to Integrate the Studies of Brain, Cognition, and Behavior*

The need for developing overarching integrations across the many subfields of cognitive psychology and cognitive science became evident in the last decade of the twentieth century. Approaches for integrating the studies of brain, cognition, and behavior have been independently proposed by researchers of different specialization (Fig. 1 shows a summary diagram). For instance, researchers in the area of artificial intelligence have proposed cross-domain integration aiming at constructing comprehensive models to capture different domains of cognitive and behavioral functioning such as perception, memory, learning, decision-making, emotion, and motivation (e.g., Newell 1990). There is also the cognitive and computational neuroscience approach of cross-level integration, which aims at integrating empirical regularities and theories of cognition across the behavior, information-processing, and biological levels (see Gazzaniga 2000 for review). Others, built on Burnswik's and Gibson's earlier emphases on the embeddedness of behavior and cognition in the environmental context, have suggested a human–ecology integration stressing that functional adaptivity arising from the human–environment interaction must be considered en route to discoveries of universal principles of behavior and cognition. (e.g., Gigerenzer et al. 1999, Shepard 1995). In order to better capture dynamic exchanges between environmental support and biological resources across the lifespan, developmental psychologists (e.g., Baltes et al. 1999) have advocated a lifespan integrative approach to study behavior and cognition (see also *Lifespan Theories of Cognitive Development*). Although these approaches differ in the questions they address, they complement, rather than exclude, each other,

Figure 1
A summary diagram of different approaches proposed in the 1990s for integrating the various fields of brain, cognitive, and behavioral sciences

with the first two approaches focusing on different domains and levels of cognition and behavior within a person, and the last two focusing on the person–environment interaction and the evolutionary–ontogenetic dynamics.

1.2 Cognitive Aging Phenomena Studied at Various Levels

Couched within the broader research context, the field of cognitive aging had also gone through a period of disintegrated research and is now orienting towards integration. Since the 1920s when the first studies on adult age differences in mental abilities were published, studies on cognitive aging have mostly been carried out independently by individual difference and cognitive experimental psychologists and neuroscientists at the behavioral, information-processing, and biological levels (Fig. 2 gives an overview). Designs and results from animal neurobiological studies are not always readily testable in human cognitive studies, and vice versa. Therefore, until the recent advances with neuroimaging techniques (Cabeza 2001), data and theories of cognitive aging have been mostly confined within their respective levels. The goal of this article is thus to review evidence of age differences in intelligence and basic cognitive processing in ways that highlight the many facets of the aging mind and point out some recent attempts that have been undertaken since the 1990s to link previously less integrated areas of research.

2. Adult Age Differences in Intelligence

At the behavioral level, psychologists interested in how aging might affect individual differences in intelligence have taken the psychometric approach, which has a long tradition (dating back to classical works by Spearman, Galton, and Binet in the 1880s and early 1900s), and focused on the measurement of age differences in intellectual abilities. The existing psychometric data to date indicate that intellectual

Figure 2
A summary diagram of various issues of aging mind addressed by researchers of different specializations at various levels

aging is multifaceted. Furthermore, aging effects can be observed at three aspects of the behavioral data, namely, performance level, variability, and co-variation.

2.1 Differential Age-gradients of Cognitive Mechanics and Pragmatics

Traditionally, two-component models of intelligence distinguish between fluid intelligence reflecting the operations of neurobiological 'hardware' supporting basic information-processing cognitive mechanics and crystallized intelligence reflecting the culture-based 'software' constituting the experience-dependent cognitive pragmatics (Baltes et al. 1999, Horn 1982; see also *Lifespan Theories of Cognitive Development*). Figure 3 shows that the fluid mechanics such as reasoning, spatial orientation, perceptual speed, and verbal memory show gradual age-related declines starting at about the 40s, while other abilities indicating the crystallized pragmatics such as number and verbal abilities remain relatively stable up until the 60s (e.g., Schaie and Willis, 1993). Furthermore, there have also been some recent ongoing theoretical and empirical efforts devoted towards expending the concepts of cognitive mechanics and pragmatics. In addition to the efficacy of information processing, cognitive mechanics also encompasses the optimal allocation of cognitive resources (e.g., Li et al. in press). Cognitive pragmatics has been expanded to include many other general as well as person-specific bodies of knowledge and expertise associated with the occupational, leisure, and cultural dimensions of life (e.g., Blanchard-Fields and Hess 1996). One example is wisdom, the 'expert knowledge about the world and fundamental pragmatics of life and human affair' that an individual acquires through his or her life history, that also includes an implicit orientation towards maximizing individual and collective well-being (Baltes and Staudinger 2000).

2.2 Age-related Increase in Variability and Co-variation

In addition to age differences in the performance levels of the cognitive mechanics, behavioral data also point to age-related increases of performance variations within a person (e.g., Hultsch et al. 2000) and differences between individuals (for review see Nelson and Dannefer 1992). Furthermore, much cross-sec-

Figure 3
Differential trajectories of fluid (mechanic) and crystallized (pragmatic) intelligence. Abilities were assessed with 3–4 different tests, and were scaled in a T-score metric (data source based on Schaie and Willis 1993; figure adapted from Lindenberger and Baltes, 1994 with permission)

tional data show that as people age, performances of different subscales of intelligence tests become more correlated with each other (e.g., Babcock et al. 1997), which has been taken as indications of less differentiated ability structure in old people.

3. *Deficits in Basic Information-processing Mechanisms*

In the light of age-related declines in psychometrically measured cognitive mechanics, the information-processing approach emerged from the rise of information theory and computers in the 1940s and was advanced to explain age differences in fluid intelligence by identifying age differences in basic information-processing mechanisms. Thus far, age-related declines have been found in three main facets of information processing: people's abilities to keep information in mind, attend to relevant information, and process information promptly are compromised with age.

3.1 *Working Memory*

Working memory (WM) refers to people's ability to simultaneously hold information in immediate memory while operating on the same or other information. Age-related decline in WM capacity has been obtained on a variety of experimental tasks including backward digit span, sentence span, and several types of computational span (e.g., Park et al. 1996; see Fig. 4(A)). Age-related decline in WM capacity plays a role in many other cognitive activities where WM is implicated, ranging from long-term memory encoding and retrieval, syntactic processing, language comprehension and reasoning (for review see Zacks et al. 2000; see also *Memory and Aging, Cognitive Psychology of*).

3.2 *Attentional and Inhibitory Mechanisms*

Empirical data abound showing that old people have more problems attending to relevant information and ignoring irrelevant information. Negative age differences have been found in various selective and focus attention tasks along with the Stroop and proactive interference tasks (see Fig. 4(B)). Age-related declines in attentional and inhibitory mechanisms have functional consequences on language comprehension, memory, problem solving, and other daily activities such as driving (see McDowd and Shaw 2000 for review).

3.3 *Processing Speed*

Speed is a ubiquitous aspect of information processing. All information processing takes time, however, fast it is. There is abundant evidence showing that older people are slower in responding compared to young adults in almost every cognitive task in which processing speed is measured (see Fig. 4(C)). Many correlational analyses showed that the observed age differences in fluid intelligence are greatly reduced or eliminated after controlling for individual differences in processing speed (see Salthouse 1996 for review).

3.4 *Resource-reduction Account*

Given clear age-related declines in these fundamental aspects of information-processing, the most prominent account of cognitive aging deficits thus far has been the general conceptual framework of age-related reduction in processing resources that are indicated by working memory capacity, attention regulation, and processing speed (see Salthouse 1991 for review). However, two major difficulties limit the resource-reduction theory. First, the different aspects of processing resources are not independent of each other. Second, the account itself is circular in nature: old people's lower proficiency in cognitive performance is assumed to be caused by a reduction in processing resources, and at the same time, poor performance is taken to be the indication of reduced processing resources. One way to avoid such circularity is to establish better correspondence between the proposed processing resources and their potential neurobiological underpinnings. Lest this be viewed only as

Figure 4
Negative adult age differences in working memory, proactive interference and processing speed. (A) Working memory was measured by three types span test, and were scaled in Z score metric (Data source based on Park et al., 1996. Copyright © 1996 American Psychological Association. Adapted with permission.) (B) Old adults (mean age = 64.4) required more trials to learn arbitrary word pairs than middle-aged adults (mean age = 38.8), when proactive interference was strong (data source based on Lair et al., 1969. Copyright © 1969 American Psychological Association. Adapted with permission). (C) Processing speed was measured by three perceptual speed tests (i.e., digit symbol substitution, pattern and letter comparison), and were scaled in a Z-score metric (Data source based on Park et al., 1996. Copyright © 1996 American Psychological Association. Adapted with permission.)

reductionistic, it should be mentioned that psychometric data showing stronger trends of age-related decline in biology-based fluid intelligence motivates the search for biological correlates. Experimental evidence of age-related decline in basic facets of information processing helps to focus the studies of brain aging on those aspects relevant to the affected information-processing mechanisms. Recent developments in cognitive and computational neurosciences have opened new avenues for studying the functional relationships between behavioral manifestations of the aging mind and the biology of the aging brain.

4. *The Aging Brain of the Aging Mind*

At the neurobiological level, brain aging involves both neuroanatomical and neurochemical changes. Anatomically, there are structural losses in neurons and

synaptic connections and reductions in brain atrophy (see Raz 2000 for review). Neurochemically, there is evidence for deterioration in various neurotransmitter systems (see Schneider et al. 1996 for review). However, progressive neuroanatomical degeneration resulting from cell death and reduced synaptic density is primarily characteristic of pathological aging such as Alzheimer's disease, and there is now evidence suggesting that milder cognitive problems occurring during normal aging are mostly due to neurochemical shifts in still-intact neural circuitry (Morrison and Hof 1997).

4.1 *Attenuated Neuromodulation*

Among different neurotransmitter systems, the catecholamines, including dopamine (DA) and norepinephrine (NE), are important neurochemical underpinnings of age-related cognitive impairments for several reasons. First, there is consensus for age-related decline in catecholaminergic function in the prefrontal cortex (PFC) and basal ganglia. Across the adult lifespan, dopaminergic function in the basal ganglia decreases by 5–10 percent each decade (see Schneider et al. 1996). Furthermore, many DA pathways in the basal ganglia are interconnected with the frontal cortex through the frontal–striatal circuits (Graybiel 1990), hence are in close functional association with the PFC cognitive processes. Second, research over the last two decades suggests that catecholamines modulate the PFC's utilization of briefly activated cortical representations of external stimuli to circumvent constant reliance on environmental cues and to regulate attention to focus on relevant stimuli and appropriate responses (see Arnsten 1998 for review). Third, there are many findings indicating specific functional relationships between age-related deficits in the dopaminergic system and deficits in various aspects of information processing. For instance, reduced dopamine receptor density in old rats' nigrostriatum decreases response speed and increases reaction time variability (MacRae et al. 1988). Drugs that facilitate dopaminergic modulation alleviate working memory deficits of aged monkeys who suffer from 50 percent dopamine depletion in their PFC (see Arnsten 1998 for review). In humans, age-related attenuation of dopamine D2 receptor's binding mechanism is associated with declines in processing speed and episodic memory (Bäckman et al. 2000).

4.2 *Reduced Hemispheric Asymmetry*

In addition to changes in the aging brain's neurochemical environment, recent neuroimaging evidence suggests that cortical information processing in different regions of the brain becomes less differentiated as people age, phenomena that parallel the behavioral findings of less differentiated ability structure in old people. In comparison to the more clearly lateralized cortical information processing in young adults, people in their 60s and beyond showed bilateralized (bi-hemispheric) activity during retrieval (e.g., Cabeza et al. 1997, Cabeza 2001) and during both verbal and spatial work memory tasks (Reuter-Lorenz et al. 2000).

5. *Outlooks for Integrating the Facets and Levels of the Aging Mind*

Faced with the various facets of the aging mind across the different levels, the various subfields of cognitive aging research are ever more inclined to and in need of overarching frameworks for integration (cf. Stern and Carstensen 2000). Some integrative research undertakings along the four general approaches for integrating the studies of brain, cognition, and behavior sciences are already underway.

With respect to better integrating the human–environment exchange and the evolutionary–ontogenetic dynamics, at a macrolevel some researchers embedded issues of cognitive aging within a metatheoretical framework of biological and cultural coevolution for studying lifespan human development. While the benefits of evolutionary selection and the efficacy of neurobiological implementations of the mind decrease with aging, the need for environmental–cultural support increases. In this systemic functional framework it is important for future research to investigate how declines in cognitive resources may be compensated for by the individual's more selective allocations of these resources to different task domains and by cultural–environmental supports such as cognitive training (e.g., Dixon and Bäckman 1995, Li et al. in press). At a more specific level, other researchers have also suggested an environmental support perspective for understanding age differences in episodic memory and attentional mechanisms. Better environmental stimulus and contextual supports are helpful for overcoming age-related deficits in effortful self-initiated processes implicated in various memory and attentional tasks (e.g., Craik 1986, Park and Shaw 1992).

Regarding better integrating different domains and levels of behavior and cognition within the person, some researchers have started to work towards bridging the gaps between age-related declines in basic memory and attentional processes and higher-level cognitive function such as language comprehension (e.g., Light and Burke 1988, Burke 1997). Regarding cross-level integration, there actually have been a few classical proposals trying to relate individual differences in the performance level, variance, and covariation of intellectual functioning with individual differences in general brain energy (Spearman 1927) and to link age-related cognitive aging deficits with

increased neuronal noise (e.g., Welford 1965). However, these long-range brain–behavior links could not be specified with more details in early research. It has only recently become possible to investigate these links more explicitly in cognitive and computational neurosciences. There is now some consensus for associations between PFC dysfunctions and aging-related cognitive impairments (West 1996). However, details of the functional relationships between PFC impairments, aging attenuated neuromodulation, the distribution of information processing across different neural circuitry, and various behavioral manifestations of cognitive aging deficits await further explications. Recently, one computational neuroscience approach has been undertaken to explore the links between age-related declines in neuromodulatory mechanisms innervating the PFC, noisier neural information processing, and adult age differences in episodic memory, interference susceptibility, performance variability, and co-variation (e.g., Li et al. 2000, Li in press).

These integrative research orientations have different advantages and disadvantages. While theoretical considerations about environmental and evolutionary impacts on the aging mind at the metatheoretical level have the strength in providing overarching organizations, they need to be complemented by more information-processing and neurobiologically oriented approaches to generate predictions that are more amenable for direct empirical validations. In the process of co-evolving a range of related fields, there may not be a 'right' level for integration; rather there is the task to supplement and balance the weaknesses and strengths of different approaches.

6. Conclusion

The average life expectancy in most industrialized countries has been increasing from an average of about 45 years in 1900 to about 75 years in 1995. A major task for cognitive aging research in the twenty-first century is to identify the causes of and methods to minimize or compensate for these cognitive declines, so that the blessings of improved physical health and extended life expectancy in old age could be accompanied by sound aging mind. Attempts to achieve this challenging task require collective contributions of studies from the various subfields of cognitive aging research, ranging from individual-difference based psychometric and behavioral experimental studies to cognitive and computational neurosciences in the future. Furthermore, research on the aging mind necessarily entails an applied orientation; therefore, future research also needs to include more specific focuses on identifying age-relevant knowledge, aging-friendly social and environmental contexts, and aging-rectifying training programs to help old people better allocate and compensate their declining cognitive resources.

Aging, Theories of

Because theories of aging in the behavioral and social sciences have come from a variety of disciplines it is often difficult to distinguish between formal theoretical frameworks and theoretical models that seek to systematize sets of empirical data. This article, therefore, will discuss current thought on theory building in aging, and then summarize exemplars of theoretical frameworks that inform the field origination from biology, psychology and the social sciences.

1. *Theory Building in Aging*

1.1 *Historical Development of Theories of Aging*

Early gerontologists looked for conceptual frameworks that might explain human aging by looking at popular and ancient models, including the bible, Sanskrit, medieval allegories, other ancient texts and even archaeological evidence to explain individual differences in well being and maintaining competence through the various stages of life (e.g., Hall 1922). These early models of aging typically represent broad world views, such as the biblical admonition that obedience to God's commandments would ensure a long life. New historical contexts, however, result in new explanations of aging, whether of the medieval explanation of old women as witches or the modern conception of the biological advantages of female aging. But as in Hall's writings, they may also include critiques of contemporary societal arrangements.

More modern views of the complexity of aging may be found in Cowdry's classical opus *Problems of Aging* (1939). It contains a mixture of assertions that aging

resulted from 'degenerative diseases' to contentions that social context affected the expression of aging and could lead to the difference between what Rowe and Kahn (1997) have referred to as the difference between 'normal' and 'successful' aging. As scientific insights on the aging process have accumulated during the twentieth century, a movement has occurred from broad world views on aging to more circumscribed theoretical models that are driven by disciplinary perspectives but also by the fads and explanatory frameworks that have waxed and waned in the scientific enterprise (cf. Hendricks and Achenbaum 1999).

1.2 Models and Explanation

Distinctions must be made between theories and other aspects of knowledge development. As a first stage, we find statements describing regularities detected in the process of systematic observations. A second stage is represented by prototypical models that attempt to depict how empirical generalizations are related to each other. A third stage may be characterized by the term 'paradigm' which implies a shift in scientific efforts represented by the accumulation of empirical generalizations, models, and theories. In contrast to these terms, which are of course also important for knowledge development, the focus of a theory should be upon the construction of explicit explanations that account for empirical findings (cf. Bengtson et al. 1999).

1.3 Theory Development and Research Design in Aging

Theory development in aging has been impacted markedly by advances in research design. One of the early impacts was the development of the age–period cohort model which required theory development to distinguish between age changes (measured longitudinally) and age differences (measured cross-sectionally). The distinction of within-subject maturational effects and between-subjects cohort differences has also informed theory development. In addition, the advent of restrictive factor analysis and structural equation modeling has made it possible to provide empirical tests of structural relationships in various domains that tend to change across time–age and differ across groups (cf. O'Rand and Campbell 1999, Schaie 1988).

2. Biological Theories of Aging

2.1 Biological Theories of Senescence

Theories explaining the biological basis of human aging are either stochastic theories that postulate senescence to be primarily the result of random damage to the organism, or they are programmed theories that hold that senescence is the result of genetically determined processes. Currently most popular theories include: (a) the free radical theory, which holds that various reactive oxygen metabolites can cause extensive cumulative damage; (b) caloric restriction, which argues that both lifespan and metabolic potential can be modified by caloric restriction (thus far not demonstrated in humans); (c) somatic mutation, arising from genetic damage originally caused by background radiation; (d) hormonal theories, proposing, for example, that elevated levels of steroid hormones produced by the adrenal cortex can cause rapid aging decline; and (e) immunological theories that attribute aging to decline in the immune system. Another prominent view is that the protective and repair mechanisms of cells are insufficient to deal with the cumulative damage occurring over time, limiting the replicative ability of cells (cf. Cristofalo et al. 1999, Hayflick 1994).

2.2 Stress Theories of Aging

These theories argue that excessive physiological activation have pathological consequences. Hence differences in neuroendocrine reactivity might influence patterns of aging. The focus of such theories is not on specific disease outcomes, but rather on the possibility that neuroendocrine reactivity might be related generally to increased risk of disease and disabilities. Stress mechanisms are thought to interact with age changes in the hypothalamic–pituitary–adrenal (HPA) axis, which is one of the body's two major regulatory systems for responding to stressors and maintaining internal homeostatic integrity. Individual differences in reactivity may cumulatively lead to major individual differences in neuroendocrine aging as well as age-related risks for disease. Certain psychosocial factors can influence patterns of endocrine reactivity. Perceptions of control and the so-called Type A behavior pattern may influence increased reactivity with age. Gender differences in neuroendocrine reactivity are also posited because of the known postmenopausal increase in cortisol secretion in women not treated with estrogen replacement therapy (cf. Finch and Seeman 1999).

3. Psychological Theories of Aging

As for other life stages, there do not seem to be many overarching theories of psychological aging, but emphasis in theoretical development is largely confined to a few substantive domains. A recent exception to this observation is the theory of selection, optimization and compensation (SOC) advocated by P. Baltes (1997, Baltes and Baltes 1990). This theory suggests that there are psychological gains and losses at every

life stage, but that in old age the losses far exceed the gains. Baltes suggests that evolutionary development remains incomplete for the very last stage of life, during which a societal supports no longer suffice to compensate for the decline in physiological infrastructure and losses in behavioral functionality (cf. Baltes and Smith 1999).

3.1 Theories of Cognition

A distinction is generally made between cognitive abilities that are fluid or process abilities that are thought to be genetically overdetermined and which (albeit at different rates) tend to decline across the adult lifespan, and crystallized or acculturated abilities that are thought to be learned and be culture-specific, and which tend to be maintained into advanced old age. This distinction tends to break down in advanced old age as declining sensory capacities and reduction in processing speed also leads to a decline of crystallized abilities. Nevertheless, most theories of adult cognition have focused upon explaining the decline of fluid abilities, neglecting to theorize why is it that crystallized performance often remains at high levels into late life.

Most theoretical perspectives on cognitive aging can be classified into whether the proposed primary causal influences are distal or proximal in nature. Distal theories attribute cognitive aging to influences that occurred at earlier periods in life but that contribute to concurrent levels of performance. Other distal explanations focus on social–cultural changes that might affect cognitive performance. These explanations assume cumulative cohort effects that lead to the obsolescence of the elderly. Distal theories are useful, particularly in specifying why the observed age differences have emerged, since it is generally agreed that mere passage of time can not account for these differences.

Proximal theories of aging deal with those concurrent influences that are thought to determine age-related differences in cognitive performance. These theories do not specify how the age differences originated. Major variations of these theories include strategy-based age differences, quantitative differences in the efficiency of information processing stages implicating deficits in specific stages, or the altered operation of one or more of the basic cognitive processes (cf. Salthouse 1999).

3.2 Theories of Everyday Competence

Theories of everyday competence seek to explain how an individual can function effectively on the tasks and within the situations posed by everyday experience. Such theories must incorporate underlying processes, such as the mechanics (or cognitive primitives) and pragmatics of cognitive functioning, as well as the physical and social contexts that constrain the individual's ability to function effectively. Because basic cognitive processes are typically operationalized to represent unitary trait characteristics, it is unlikely that any single process will suffice to explain individual differences in competence in any particular situation, Hence, everyday competence might be described as the phenotypic expression of combinations of basic cognitive processes that permit adaptive behavior in specific everyday situations.

Three broad theoretical approaches to the study of competence have recently been advocated. The first perspective views everyday competence as a manifestation of latent constructs that can be related to models of basic cognition (see also *Cognitive Aging*). The second approach conceptualizes everyday competence as involving domain-specific knowledge bases. In the third approach, the theoretical focus is upon the fit, or congruence, between the individual's cognitive competence and the environmental demands faced by the individual.

An important distinction must further be made of the distinction between psychological and legal competence. While the former is an important scientific construct, the latter refers to matters of jurisprudence that are involved in the imposition of guardianship or conservatorship designed to protect frail individuals as well as to limit their independent decision-making ability. Although legal theorizing incorporates aspects of virtually all psychological theories of competence, it does focus in addition the definition of cognitive functioning and competence as congruence of person and environment, upon the assignment of status or disabling condition and a concern with functional or behavioral impairment (cf. Schaie and Willis 1999).

3.3 Social–Psychological Theories

Social psychologists coming from a psychological background are concerned primarily with the behavior of individuals as a function of microsocial variables. Relying upon experimental or quasi-experimental designs, they seek to understand social phenomena using person-centered paradigms whose core is the structural and functional property of individual persons. Social–psychological approaches to aging have contributed to the understanding of numerous normal and pernicious age-related phenomena. There has been an increased interest in theoretical formulations that explain how social–psychological processes exert normative influences on life course changes. Included among theories that have received recent attention are control theories contrasting primary and secondary controls, coping theories that distinguish between accommodative and assimilative coping, and theories about age differences in attributive styles. There are also theories that blend psychological and sociological

approaches, such as the convoy theory and the support–efficacy theory.

Of particular recent interest has been the model of learned dependency (Baltes 1996). In this theory, the dependency of old age is not considered to be an automatic corollary of aging and decline, but rather is attributed in large part to be a consequence of social conditions. This theory contradicts Seligman's (1975) model of learned helplessness, which postulates dependency to be the outcome of noncontingencies and which sees dependency only as a loss. Instead it is argued that dependency in old people occurs as a result of different social contingencies, which include the reinforcement for dependency and neglect or punishment in response to pursuit of independence.

Also of currently prominent interest is socio–emotional selectivity theory. This theory seeks to provide an explanation of the well-established reduction in social interactions observed in old age. This theory is a psychological alternative to two previously influential but conflicting sociological explanations of this phenomenon. Activity theory considered inactivity to be a societally induced problem stemming from social norms, while the alternative disengagement theory suggested that impending death stimulated a mutual psychological withdrawal between the older person and society. By contrast, socio–emotional selectivity theory holds that the reduction in older persons' social networks and social participation should be seen as a motivated redistribution of resources by the elderly person. Thus older persons do not simply react to social contexts but proactively manage their social worlds (cf. Baltes and Carstensen 1999).

4. Sociological Theories of Aging

4.1 Anthropological Theories

Interest in old age came relatively late for anthropologists with an examination of ethnographic data in the *Human Relations Area Files* in 1945 that considered the role of the aged in 71 primitive societies. Early theoretical formulations propose a quasi-evolutionary theory that links the marginalization of older people to modernization. Current anthropological theorizing is informed by investigations of the contexts in which older adults are living that range from age-integrated communities to those in the inner city and in urban settings, as well as by the study of special populations that include various ethnic group and older people with disabilities. Common theoretical themes currently addressed include the complexity of the older population leading to differential experiences of aging in different cultural context, the diversity of aging within cultures, the role of context specificity, and the understanding of change over the life course across different cultural settings. Prevailing issues in anthropological theorizing on aging seem to focus first on how maturational differences are incorporated into a given social order, and second, the clarification of the variability as to how differences in maturity are modeled by human cultures in transforming maturation into ideas about age and aging.

Anthropological theories consider generational systems as fruitful ways of thinking about the life course. They argue that every human society has generational principles that organize social lives. Generations have little to do with chronological time, but rather designate position in a web of relationship; hence kinship systems are emphasized. Although age–class systems have explanatory power in primitive societies, they are not helpful as life course models in complex societies because of their variability. If anything, age–class systems are more likely to explain social structuring in males than in females. More useful for the understanding of complex societies seem to be models of staged life courses. Such models suggest that the life course in complex societies is based on combinations of generational and chronological age, and further is understood as staged or divisible into a variable number of age grades.

Anthropologists also distinguish between theories about age from those about aging or the aged. Theories about age explain cultural and social phenomena. That is, how is age used in the regulation of social life and the negotiation of daily living. Theories about aging are theories about living, the changes experienced during the life course, and the interdependencies throughout life among the different generations. Finally, theories about the age focus on late life, describing old age not only as a medical and economic problem but also as a social problem in terms of social support and care giving (cf. Fry 1999).

4.2 Life Course Theories

Life course theories represent a genuinely sociological approach to what, at the level of surface description, is a rather individual phenomenon as represented by the aging and life course patterning of human individuals. Much of this theorizing occurred subsequent to the recognition that individual aging occurred concurrently with the occurrence of social change, providing impetus to efforts trying to separate aging from cohort effects. Life course theories generally represent a set of three principles. First, the forms of aging and life course structures depend on the nature of the society in which individuals participate. Second, while social interaction is seen as having the greatest formative influence in the early part of life, such interaction retains crucial importance throughout the life course. Third, that social forces exert regular influences on individuals of all ages at any given point in time. However, such thinking also introduces three signifi-

cant intellectual problems. These are the tendency to equate the significance of social forces with social change, neglecting intracohort variability, and a problematic affirmation of choice as a determinant of the life course.

Life course phenomena can be treated at least at three levels of analysis. First, at the individual level, the structure of discrete human lives can be examined from birth to death. Second, one can examine the collective patterning of individual lives in a population. Third, it is possible to examine the societal representation of the life course in terms of the socially shared knowledge and demarkation of life events and roles. For each of these levels it is in turn possible to specify personological aspect that are thought to be part of the organism as well as the enduring contextual factors that were internalized at earlier life stages. But another crosscutting level involves the social–cultural and interactional forces that shape the life course (cf. Dannefer and Uhlenberg 1999).

4.3 Social Theories of Aging

Social theories of aging have often been devised to establish theoretical conflict and contrast. Two dimensions of contrast that have been used involve the cross-classification of normative versus interpretive theories and macro versus micro theories. But there are also intermediate theoretical perspectives that bridge these two approaches or that link different approaches. Modernization and aging theory would be an example of a normative macrotheory. Self and identity theories represent interpretive microtheories. Disengagement theory represents a normative linking theory, and the life course perspective discussed above represents a theory that is both linking and bridging (cf. Marshall 1999).

Recent generalizations that cut across most social theories seem to focus on three changes in the construction of the social phenomenon of aging. These changes suggest that life course transitions are decreasingly tied to age with a movement from age segregation to age integration. Second, that many life transitions are less disjunctive, more continuous, and not necessarily irreversible processes. Third, specific pathways in education, family, work, health, and leisure are considered to be interdependent within and across lives. Life trajectories in these domains are thought to develop simultaneously and reciprocally, rather than representing independent phenomena (O'Rand and Campbell 1999).

A prominent example of a social theory of aging is presented by the aging and society paradigm (Riley et al. 1999). The distinguishing features of this paradigm are the emphasis on both people and structures as well as the systemic relationship between them. This paradigm includes life course but it also includes the guiding principles of social structures as having greater meaning than merely providing a context for people's lives. This theory represents a cumulative paradigm. In its first phase, concerned with lives and structures, it began with the notion that in every society age organizes people's lives and social structures into strata from the youngest to the oldest, and raised questions on how age strata of people and age oriented structures arise and become interrelated. A second phase concerned with the dynamisms of age stratification defined changing lives and changing structures as interdependent but distinct sets of processes. The dynamism of changing lives began with the recognition of cohort differences and noted that because society changes, members of different cohorts will age in different ways. A second dynamism involves changing structures that redefine age criteria for successive cohorts.

In a third phase the paradigm specified the nature and implication of two connecting concepts, that of the interdependence and asynchrony of these two dynamisms, that attempt to explain imbalances in life courses as well as social homeostasis. A fourth phase deals with future transformation and impending changes of the age concepts. It introduces the notion of age integration as an extreme type of age structure as well as proposing mechanisms for cohort norm formation.

Agnosia

Agnosia is a fascinating condition in which, as a consequence of acquired brain damage, patients lose the ability to recognize familiar stimuli, despite normal perception of those stimuli. For example, when encountering the faces of familiar persons such as family members or close friends, a patient with agnosia is unable to identify those persons, or even to recognize that they are familiar. A patient may look at pictures of entities such as animals or tools, and have no idea what the stimuli are. Or a patient may hear well-known sounds, such as a fire siren or a ringing phone, and not be able to identify the sounds or understand their meaning (despite being able to hear the sounds normally). Agnosia is a rare condition, and its clinical presentation borders on the bizarre; nonetheless, careful scientific study of agnosia has provided many important insights into the brain mechanisms important for learning, memory and knowledge retrieval.

1. Types of Knowledge and Levels of Knowledge Retrieval

Before discussing agnosia, it is important to explain some crucial differences in the types of knowledge that are processed by the brain, and how different task demands influence the mechanisms the brain uses to retrieve knowledge. To begin with, there is a dimension of specificity: knowledge can be retrieved at different levels of specificity, ranging from very specific to very general. Consider the following example: Knowledge about a unique horse ('Little Buck,' a sorrel roping horse) is specific and unique, and is classified at the subordinate level; less specific knowledge about horses (four-legged animals that gallop, used by cowboys; of which Little Buck is an example) is classified at the basic object level; and even less specific knowledge about living things (things that have life, of which horses and Little Buck are examples) is classified at the superordinate level.

Pragmatically, the level at which knowledge is retrieved depends on the demands of the situation, and those demands are different for different categories of entities. In everyday life, for example, it is mandatory that familiar persons be recognized at the unique level—e.g., that's 'President Clinton,' or that's 'my father Ned.' It is not sufficient, under most conditions, to recognize such entities only at more nonspecific levels—e.g., that's a 'world leader,' or that's 'an older man.' For other types of entities, recognition at the basic object level is sufficient for most purposes—e.g., that's a 'screwdriver,' or that's a 'stapler'; here, there is no need to recognize individual, unique screwdrivers and staplers in order for practical interactions with the entity to be productive.

One other critical distinction is between recognition, on the one hand, and naming, on the other. The two capacities are often confused. It is true that recognition of an entity, under normal circumstances, is frequently indicated by naming (e.g., 'stapler'; 'Little Buck'; 'siren'). However, there is a basic difference between knowing and retrieving the meaning of a concept (its functions, features, characteristics, relationships to other concepts), and knowing and retrieving the name of that concept (what it is called); moreover, this difference is honored by the brain. For example, brain damage in the left inferotemporal region can render a patient incapable of naming a wide variety of stimuli, while leaving unaffected the patient's ability to recognize those stimuli (H. Damasio et al. 1996). For the

examples of 'Little Buck' and 'siren' cited above, the patient may produce the descriptions of 'that's my sorrel roping horse that I bought two years ago and now lives on my dad's ranch,' and 'that's a loud sound that means there's an emergency; you should pull your car over to the side of the road.' Both responses indicate unequivocal recognition of the specific entities, even if their names are never produced. In short, it is important to maintain a distinction between recognition, which can be indicated by responses signifying that the patient understands the meaning of a particular stimulus, and naming, which may not, and need not, accompany accurate recognition (Caramazza and Shelton 1998, Gainotti et al. 1995, Pulvermuller 1999).

2. *The Term 'Agnosia'*

The term 'agnosia' signifies 'lack of knowledge,' and denotes an impairment of recognition. Traditionally, two types of agnosia have been described (Lissauer 1890). One, termed associative agnosia, refers to a failure of recognition that results from defective retrieval of knowledge pertinent to a given stimulus. Here, the problem is centered on memory: the patient is unable to recognize a stimulus (i.e., to know its meaning) despite being able to perceive the stimulus normally (e.g., to see shape, color, texture; to hear frequency, pitch, timbre; and so forth). The other type of agnosia is termed apperceptive, and refers to a disturbance of the integration of otherwise normally perceived components of a stimulus. Here, the problem is centered more on perception: the patient fails to recognize a stimulus because the patient cannot integrate the perceptual elements of the stimulus, even though those individual elements are perceived normally. It is important to emphasize that the nuclear feature in designating a condition as 'agnosia' is that there is a recognition defect that cannot be attributed simply or entirely to faulty perception.

The terms associative and apperceptive agnosia have remained useful, even if the two conditions do have some overlap. It is usually possible to classify a patient with a recognition impairment as having primarily a disturbance of memory (associative agnosia), or primarily a disturbance of perception (apperceptive agnosia). Not only does this classification have important implications for the management of such patients (e.g., what rehabilitation should be applied), but it also maps on to different sites of neural dysfunction. For example, in the visual modality, associative agnosia is strongly associated with bilateral damage to higher-order association cortices in the ventral and mesial occipitotemporal regions, whereas apperceptive agnosia is associated with unilateral or bilateral damage to 'earlier,' more primary visual cortices. This being said, though, the fact remains that separating associative and apperceptive agnosia can be difficult, which underscores the fact that the processes of perception and memory are not discrete. Rather, they operate on a physiological and psychological continuum, and it is simply not possible to demarcate a specific point at which perceptual processes end and memory processes begin (Damasio et al. 1990, Tranel and Damasio 1996).

In principle, agnosia can occur in any sensory modality, relative to any type of entity or event. In practice, however, some types of agnosia are considerably more frequent. Visual agnosia, especially agnosia for faces (prosopagnosia), is the most commonly encountered form of recognition disturbance. The condition of auditory agnosia is rarer, followed by the even less frequent tactile agnosia.

3. *Visual Agnosia*

3.1 *Definition*

Visual agnosia is defined as a disorder of recognition confined to the visual realm, in which a patient cannot arrive at the meaning of some or all categories of previously known nonverbal visual stimuli, despite normal or near-normal visual perception and intact alertness, attention, intelligence, and language. Typically, patients have impairments both for stimuli that they learned prior to the onset of brain injury (known as 'retrograde' memory), and for stimuli that they would normally have learned after their brain damage (known as 'anterograde' memory).

3.2 *Subtypes*

3.2.1 Prosopagnosia. The study of face processing has remained a popular topic in neuropsychology for many decades, dating back to the pioneering work of Bodamer, Hecaen, Meadows, and others (for historical reviews, see Benton 1990, De Renzi 1997). Faces are an intriguing class of stimuli (Damasio et al. 1982, Young and Bruce 1991). They are numerous and visually similar, and yet we learn to recognize individually as many as thousands of distinct faces during our lifetime; and not only can we learn many individual faces, but we can recognize them from obscure angles (e.g., from the side), attended with various artifacts (e.g., glasses, hockey helmet), after aging has radically altered the physiognomy, and under many other highly demanding conditions. Also, faces convey important and unique social and emotional information, providing clues about the emotional state of a person, or about potential courses of social behavior (e.g., approach or avoidance) (see Darwin 1872/1955, Adolphs et al. 1998). And there are a number of remarkable cross-cultural and cross-species consistencies in face processing (cf.

Ekman 1973, Fridlund 1994), which underscore the crucial and fundamental importance of this class of stimuli.

The inability to recognize familiar faces is known as prosopagnosia (face agnosia), and it is the most frequent and well established of the visual agnosias (Damasio et al. 1990, Farah 1990). The face recognition defect in prosopagnosia typically covers both the retrograde and anterograde compartments; respectively, patients can no longer recognize the faces of previously known individuals, and are unable to learn new ones. They are unable to recognize the faces of family members, close friends, and, in the most prototypical instances, even their own face in a mirror. Upon seeing those faces, the patients experience no sense of familiarity, no inkling that those faces are known to them, i.e., they fail to conjure up consciously any pertinent information that would constitute recognition. The impairment is modality-specific, however, being entirely confined to vision. For example, when a prosopagnosic patient hears the voices of persons whose faces were unrecognized, the patient will instantly be able to identify those persons accurately.

As noted above with regard to agnosia in general, prosopagnosia must be distinguished from disorders of naming, i.e., it is not an inability to name faces of persons who are otherwise recognized as familiar. There are numerous examples of face naming failure, from both brain-injured populations and from the realm of normal everyday experience, but in such instances, the unnamed face is invariably detected as familiar, and the precise identity of the possessor of the face is usually apprehended accurately. Consider, for example, the following common type of naming failure: you encounter someone whom you recently met, and cannot remember that person's name: you can remember when and where you met the person, who introduced you, and what the person does for a living—in short, you recognize the person normally. In prosopagnosia, the defect sets in at the level of recognition.

The recognition impairment in prosopagnosia occurs at the most subordinate level, i.e., at the level of specific identification of unique faces. Prosopagnosics are fully capable of recognizing faces as faces, i.e., performance is normal at more superordinate, nonspecific levels. Also, most prosopagnosics can recognize facial emotional expressions (e.g., happy, angry), and can make accurate determinations of gender and age based on face information (Humphreys et al. 1993, Tranel et al. 1988). These dissociations highlight several intriguing separations in the neural systems dedicated to processing different types of conceptual knowledge, such as knowledge about the meaning of stimuli, knowledge about emotion, and so on. In fact, these neural systems can be damaged in reverse fashion: for example, bilateral damage to the amygdala produces an impairment in recognizing facial emotional expressions, but spares the ability to recognize facial identity (Adolphs et al., 1995).

Although the problem with faces is usually the most striking, it turns out that the recognition defect in prosopagnosia is often not confined to faces. Careful assessment often reveals that the patient cannot recognize other visual entities at the normal level of specificity. The key determinants of whether other categories of stimuli are affected are (a) whether those stimuli are relatively numerous and visually similar, and (b) whether the demands of the situation call for specific identification. Whenever these conditions exist, prosopagnosics will tend to manifest deficits. For example, patients may not be able to identify a unique car, or a unique house, or a unique horse, even if they are able to recognize such entities at the basic object level, e.g., cars as cars, houses as houses, horses as horses. Similar to the problem with faces, they are unable to recognize the specific identity of a particular car, or house. These impairments underscore the notion that the core defect in prosopagnosia is the inability to disambiguate individual visual stimuli. In fact, cases have been reported in which the most troubling problem for the patient was in classes of visual stimuli other than human faces! For example, there was a farmer who lost his ability to recognize individual dairy (e.g., Holstein) cows, and a birdwatcher who became unable to tell apart various subtypes of birds (Assal et al. 1984, Bornstein et al. 1969).

Patients with face agnosia can usually recognize identity from movement. For example, upon seeing a distinctive gait of a familiar person, the patient can identify that person accurately, despite not knowing that person's face. This means not only that their perception of movement is intact, but also that they can evoke appropriate memories from the perception of unique patterns of movement. Conversely, patients with lesions in superior occipitoparietal regions (whose recognition of identity from form is normal, and hence do not have impaired face recognition) have defective motion perception and recognition. These findings underscore the separable functions of the 'dorsal' and 'ventral' visual systems, the dorsal one being specialized for spatial placement, movement, and other 'where' capacities; and the ventral one being specialized for form detection, shape recognition, and other 'what' capacities (Ungerleider and Mishkin 1982). In prosopagnosia, the dysfunction is in the 'what' system.

One of the most intriguing findings to emerge in this area of research is that despite an inability to recognize familiar faces consciously, prosopagnosic patients often have accurate nonconscious (or covert) discrimination of those faces. This phenomenon has been studied using a psychophysiological index (the skin conductance response [SCR]) to measure nonconscious discrimination (Tranel and Damasio 1985). SCRs were recorded while prosopagnosic patients

viewed a series of face stimuli. The stimulus sets included faces that were well known to the patients, mixed in random order with faces the patients had never seen before. While viewing the faces, the patients produced significantly larger SCRs to familiar faces, compared to unfamiliar ones. This occurred in several experiments, using different types of familiar faces: in one, the familiar faces were family members and friends, in another, the familiar faces were famous individuals (movie stars, politicians), and in yet another, the familiar faces were persons to whom the patients had had considerable exposure after the onset of their condition, but not before. In sum, the patients showed nonconscious discrimination of facial stimuli they could not otherwise recognize, and for which even a remote sense of familiarity was lacking. These findings suggest that some part of the physiological process of face recognition remains intact in the patients, although the results of this process are unavailable to consciousness. The fact that the patients were able to show this type of discrimination for faces to which they had been exposed only after the onset of their condition is particularly intriguing, as it suggests that the neural operations responsible for the formation and maintenance of new 'face records' can proceed independently from conscious influence.

3.2.2 Category-specific visual agnosia. Agnosia can develop for categories of stimuli other than faces, at levels above the subordinate, for example, at basic object level. For instance, patients may lose the ability to recognize animals or tools. This is generally referred to as visual object agnosia. The condition rarely affects all types of stimuli with equal magnitude (Farah and McClelland 1991, Forde and Humphreys 1999, Tranel et al. 1997, Warrington and Shallice 1984). In one common profile of visual object agnosia, there is a major defect in categories of living things, especially animals, with relative or even complete sparing of categories of artifactual entities (e.g., tools and utensils). Less commonly, the profile is reversed, in that the patient cannot recognize tools/utensils but performs normally for animals (Tranel et al. 1997, Warrington and McCarthy 1994). It has been shown that lesions in the right mesial occipital/ventral temporal region, and in the left mesial occipital region, are associated with defective recognition of animals; whereas lesions in the left occipital-temporal-parietal junction are associated with defective recognition of tools/utensils (Tranel et al. 1997).

4. Concluding Comment

Despite their relative rarity, agnosias have proved to be important 'experiments of nature,' and they have assisted with the investigation of the neural basis of human perception, learning, and memory. Careful study of agnosic patients over many decades, facilitated by the advent of modern neuroimaging techniques (computed tomography, magnetic resonance) and by the development of sophisticated experimental neuropsychological procedures, has yielded important new insights into the manner in which the human brain acquires, maintains, and uses various of knowledge.

Agonistic Behavior

1. Overview

Aggression and violence are serious social problems, as illustrated by acts ranging from school violence to wars. From an evolutionary viewpoint, on the other hand, aggression is often described as adaptive. From a humanitarian point of view it is difficult to imagine war among humans as being adaptive. The challenge to science is to resolve these contrasting views of aggression. Although research on aggression has been extensive, it has not led to significant progress in understanding and preventing aggressive acts. It was this lack of progress which led to the introduction of the concept of agonistic behavior in the mid-twentieth century. The definition of agonistic behavior was more inclusive of behaviors often not included under the umbrella of aggression. This provided a broader context for understanding aggression in relation to other behaviors.

The purpose of this article is to review the current status of aggression research as it relates to agonistic behaviors. The focus will be primarily on classifying and predicting human aggression. Lower animal research will be reviewed briefly in cases where the results add to the understanding of human aggression. (The term 'agonistic' has been used more frequently in research with lower animals than in human research.)

1.1 Definitions and Measurements

Although there are no universally accepted definitions of human aggression, it has generally been defined as behavior which results in physical or psychological harm to another person and/or in the destruction of property. It usually includes overt physical acts (e.g., fighting or breaking objects) or verbal abuse. Lower animals also engage in overt physical fighting. The counterpart of verbal abuse among lower animals is 'aggressive displays' in which animals vocalize and/or assume threatening postures (Kalin 1999). There are data suggesting that among lower animals size is often related to achieving dominance, and lower animals will often make themselves look larger when threatened; for example, fish will make themselves appear larger by extending their fins (Clemente and Lindsley 1967).

Agonistic behavior was defined as adaptive acts which arise out of conflicts between two members of the same species (Scott 1966, 1973). As noted, agonistic behaviors were more inclusive and provided a broader context within which to classify the more traditional concepts of aggression. In addition to overt aggressive acts or threats, agonistic behaviors included passive acts of submission, flight, and playful behaviors which involve physical contact. For example, human participation in sports or playful jostling would not generally be included as a form of aggression but would be included under the agonistic umbrella.

Since the introduction of the term 'agonistic,' the differences between agonistic and aggressive behaviors have blurred and the two labels are often used interchangeably in the literature. Its introduction did not result in more productive leads for understanding or preventing human aggression. Among humans it appears that developing techniques for killing have outstripped our knowledge of how to prevent killing. The substitution of a new term for aggression has not changed this trend. The major challenge in aggression research is to develop a model which can serve to synthesize data across a wide range of scientific disciplines (Barratt et al. 1997).

Techniques range from qualitative observations of behavior in naturalistic settings to more quantitative measures of aggressive behaviors in laboratory settings. Discipline-specific language has often produced confusion when comparing the results from cross-disciplinary research. Thus, as noted the major challenge to science is to view aggression from a more neutral context: a discipline-neutral model.

The focus here will be on classifying and measuring

both aggression and risk factors for aggression under four headings: (a) behavior, (b) biology, (c) cognitive or mental processes, and (d) environment or the setting in which psychosocial development takes place and aggression is expressed. No attempt will be made here to organize these four classes of descriptors and measurements into a model, but it should be noted that attempts to do so have been documented in the literature.

2. *Classifying and Measuring Human Aggression*

Aggression is behavior. Therefore, what is to be predicted in human aggression research are aggressive acts. These acts become the criterion measures for which risk factors or predictor measures are sought. One of the more difficult tasks in aggression research is defining these acts so they can be measured and related quantitatively to potential predictors. Unless the acts are quantitatively measured, the efficacy of various interventions for controlling aggressive acts cannot be reliably determined.

The properties of human aggressive acts which can be quantified are: (a) frequency with which the acts occur; (b) intensity of the act or degree of physical or psychological harm inflicted; (c) the target of the act; (d) the stimuli within the environmental setting which trigger the act; (e) the expressive form of the act (e.g., overt physical acts vs. verbal assaults); (f) the type of act in terms of intent. These properties of aggressive acts are often used singly or in combination as outcome or criterion measures of aggression.

There are three types of aggressive acts related to intent: (a) impulsive or reactive aggression or acting without thinking; (b) premeditated, planned or proactive aggression; (c) medically related aggression or aggressive acts which are committed secondary to a medical disorder, such as a closed head injury or psychiatric disorder. Classifying aggressive acts based on intent or effect is important because different interventions are effective with each type. If aggressive acts are a sign or symptom of a medical disorder, controlling the disorder should result in control of the aggression.

Impulsive aggression has been shown to be related in part to low levels of a neurotransmitter, serotonin, which helps selected neurons in the brain communicate with one another. Giving a medication which increases levels of serotonin has been shown to control impulsive aggression. Selected medications used to control seizures (anticonvulsants) have also been shown to control impulsive aggression.

In contrast, premeditated aggression cannot be controlled by medication but instead responds to cognitive/behavioral therapy which is based on social learning theory. This makes sense because premeditated or proactive aggression is learned in social situations. Premeditated human aggression is often compared with subhuman aggression which is related to protecting a territory for either food or reproductive purposes. These behaviors have in part a genetic basis which generally is learned in a social context.

2.1 *Human Agonistic Behaviors*

Not all agonistic behaviors among humans relate to social or clinical problems. For example, human sports activities are competitive and often result in physical harm to participants. Yet these events are condoned by society. The social value of these events is often explained in terms of the evolution of agonistic behaviors among lower animals that have become part of human biological drives. It is generally agreed that most common agonistic behaviors among lower animals relate to achieving dominance, which in turn is related to protecting a territory for purposes of food or reproduction as described above. Lower animals also engage in 'play-like' behaviors to learn to express and experience dominance in a tolerant environment. These behaviors are apparently not intended to do harm. If one observes a litter of pups as they mature, this type of 'play' behavior is obvious. At the human level, play and sports provide not only adaptive and socially acceptable outlets for aggressive impulses, but also an opportunity for non-participants to identify with a 'group,' hopefully as a 'winner.' This provides a sense of belonging.

2.2 *Techniques for Measuring Human Aggression*

As noted, one of the more difficult tasks in aggression research is quantifying the aggressive acts, especially at the human level. Opportunities to observe human aggression directly in natural settings are not common and are restricted primarily to institutions such as prisons or schools. The most common ways of measuring human aggressive acts are by structured interviews or self-report measures of aggressive acts. As emphasized earlier, aggression is behavior and should not be confused with anger or hostility, which are often precursors of aggressive acts. Self-report measures of aggression can be reliable in some instances but subjects may confuse their feelings of anger and hostility with aggression. Thus, in human-level research, reporters (e.g., spouse) who can observe an individual's behavior are also often used to document the aggressive acts of subjects. In hospital settings where aggressive patients are housed, rating scales of aggressive acts have been developed for use in quantifying patients' aggressive acts on the wards.

3. *Risk Factors for Human Aggression*

Risk factors or predictor measures of human aggression will be discussed briefly under the four headings listed in Sect. 1.1 above. Examples will be

presented in each category since lack of space precludes an indepth discussion.

3.1 Biological Predictors of Aggression

3.1.1 Neurotransmitters and hormones. The biological processes of the brain are controlled and maintained in large part by biochemicals called neurotransmitters and/or hormones. One of the most commonly quoted findings in psychopharmacology is that the serotonergic system of the brain is related to impulsive aggression, as noted above. Low levels of the neurotransmitter serotonin have been shown to be related in both lower animal and human studies to impulsive aggression, but not to other forms of aggression. Serotonin is involved primarily with brain systems which regulate behavioral inhibition (Ferris and Devil 1994). Other neurotransmitters (e.g., norepinephrine) have been shown to relate to creating the drive or impulse to be aggressive. As with most scientific findings, the results often become less clear as research progresses and it has been suggested that serotonin is not an exclusive or possibly even the best neurochemical marker for impulsive aggression. It is probable that in the long run a profile of neurochemical markers will be related to impulsive aggression rather than one or two neurotransmitters.

Hormones have also been related to aggression. For example, testosterone levels among males have been shown to be related to aggressive behaviors (Archer 1991).

3.1.2 Genetics. Although there is evidence of heritable aggressive behaviors in lower animals, especially mice and rats, there is no creditable evidence at this time for a genetic predisposition for aggression among humans. This is especially true for molecular genetic markers. There has been suggestive evidence in behavioral genetic studies for the inheritance of aggression, but these findings have been difficult to replicate.

3.1.3 Neuroanatomy. A number of brain areas have been related to aggression in lower animals but the relevance of these findings for understanding human aggression is limited because of differences in brain function and structure. One of the main problems in relating brain structures to aggression among humans is the hierarchical nature of the brain's structure, involving neurons which carry information across different parts of the brain. Implying that one area of the brain is responsible for aggressive acts ignores the interdependence of brain structures. Even parts of the same brain nucleus (e.g., the amygdala) can affect aggression differently because of their relationship with different brain systems. Neuroanatomical explanations of human aggression are limited but imaging techniques (e.g., PET scans) offer promise for the future.

3.2 Cognitive Precursors of Aggression

Research has shown that verbal skills including reading are related to impulsive aggression. It has been proposed that the reason for this relationship is that humans often covertly verbalize control of their behaviors. Among persons with verbal skill deficits this control would be diminished, hence they would more likely be aggressive if an impulse to aggress was present.

Another important cognitive process relates to conscious *feelings* of anger and hostility which are precursors of aggression. Measures of these two traits are often mistakenly used as measures of aggression. These traits are best classified as biological states which can be verbalized and cognitively experienced. One 'feels angry' but one acts aggressively.

3.3 Environmental Precursors of Aggression

It has been demonstrated among lower animals that different rearing environments can lead to changes in biological functions which are purportedly related to aggression (Kramer and Clarke 1996). For example, not having a mother in a rearing environment at critical developmental periods can lead to decreased levels of serotonin, which as noted above has been suggested as a major biological precursor of impulsive aggression. Among humans aggression is often related to living conditions (Wilson 1975). For example, persons in lower socioeconomic neighborhoods are more likely to be involved in fights than persons in higher socioeconomic neighborhoods. Again, these are complex interactions and caution is warranted in generalizing the results as 'causes' of aggression.

3.4 Behavioral Precursors and Laboratory Models of Aggression

As is generally true for most behaviors, one of the best predictors of aggression is a past history of aggressive acts. This is true for both impulsive and premeditated aggression.

Another way of studying human aggressive behavior is to generate it in laboratory situations. An example is a computer-simulated betting procedure. Individuals sit in front of a TV screen and attempt to accumulate money by pressing a button under different conditions. They think that they are competing with someone in another room for the money but they are not. Persons with tendencies toward impulsive aggression will display aggression in this well-controlled laboratory setting. This procedure can be used

to test the efficacy of 'anti-aggression' medications or for studying the effects of alcohol and other drugs on aggressive behavior.

4. Postscript

This article has focused primarily on one example of agonistic behaviors, namely aggression. The need for quantitative measures to study aggression was emphasized, as well as the problems related to predicting aggressive behaviors. It is important to realize that there are different types of aggression with different sets of precursors or risk factors for each. The greatest hindrance to advancing aggression research at this time is the lack of a discipline-neutral model which can be used to synthesize discipline-specific data in the search for precursors of aggression.

E. S. Barratt

Agricultural Change Theory

Agricultural change refers not just to the difference between the first plantings 10,000 years ago and today's computerized, industrialized, genetically engineered production systems; agricultural change occurs on a daily basis, as farmers in every country of the world make decisions about what, where, and how to cultivate. The importance of the topic goes well beyond how much food is produced, how much money is made, and how the environment is affected: agriculture is intimately linked to many institutions in every society, and to population. This article examines the most influential theories of agricultural change in general, with particular emphasis on the role of population growth.

1. Overview

Scholarship on agricultural change has been anchored by two small books with enormous impacts, both focused on the relationship between farming and population. In 1798, British clergyman Thomas Malthus argued for an intrinsic imbalance between rates of population increase and food production, concluding that it was the fate of human numbers to be checked by 'misery and vice'—generally in the form of starvation and war. Although intended mainly as an essay on poverty, population, and Enlightenment doctrines, *An Essay on the Principle of Population* (Malthus 1798) infused popular and scientific thought with a particular model of agricultural change, in which a generally inelastic agricultural sector characteristically operated at the highest level allowed by available technology.

In 1965, Danish agricultural economist Ester Boserup claimed to upend this model of agriculture by arguing that, particularly in 'primitive' agricultural systems, farmers tended to produce well below the maximum because this allowed greater efficiency (output:input ratio). She maintained that production was intensified and additional technology adopted mainly when forced by population.

Each model is quite simple—dangerously oversimplified, many would now argue—but they provide invaluable starting points from which to address the complexities of agricultural change.

2. Malthus

Malthus's famous maxim from *Population* was that 'the power of population is indefinitely greater than the power in the earth to produce subsistence for man…Population, when unchecked, increases in a geometrical ratio. Subsistence increases only in an arithmetical ratio.' Subsequent empirical research has made this position appear dubious. He used sketchy accounts of population booms in New World colonies to show that unchecked populations double every 25 years, but such growth rates have been shown to be highly exceptional. His view of agricultural production

as relatively inelastic, with output increasable chiefly by bringing more land into tillage, has also fared poorly in subsequent comparative agricultural research.

Equally problematic has been the correlation of Malthus's 'positive checks' of starvation and warfare with populations outpacing their food supply. As Sen (1981) shows, famines result from political failures more than from inability of agriculture to keep up with population. For instance, history's greatest famine, which claimed 30–70 million Chinese peasants during Mao's Great Leap Forward in 1958–60 (Ashton et al. 1984, Becker 1996), was no Malthusian disaster, although in 1798 Malthus had opined that Chinese numbers 'must be repressed by occasional famines.' In fact, population had grown substantially since then, and has grown more since recovering from the Great Leap Forward; Chinese peasants have shown a historic capability of feeding themselves at such densities, principally through the ingenuity of highly intensive wet rice cultivation (Bray 1986). (The 1958–60 famine resulted from policies that disrupted locally-developed intensive practices as well the social institutions needed to sustain those practices (Becker 1996, Netting 1993)).

The Malthusian perspective nevertheless has proved remarkably durable in its effects on common perceptions and theories of agricultural change. Its survival is probably less related to empirical analysis than to the ways theories of agricultural change affect, and are affected by, their political context. For instance, Malthus wrote during the early stages of the Industrial Revolution in England, a time marked by a rapidly growing urban underclass and debates about obligation to feed them. Subsuming food shortages under inexorable laws of population and agricultural change was obviously appealing to prosperous segments of society, and Malthus was rewarded with a chair in political economy at the University of Haileybury. When the Irish Potato Famine hit in the late 1840s, it was widely interpreteted as a Malthusian disaster, despite Ireland's relatively low population density and the fact that food exports continued (in fact, increased) throughout the crisis (Ross 1998). The British director of relief efforts, a former student of Malthus at Haileybury, characterized the famine as 'a direct stroke of an all-wise and all-merciful Providence' (Ross 1998, p. 46).

Most recently, the perpetuation of the Malthusian perspective on agricultural change can be seen in debates on the merits of genetically modified (GM) crops. Parties in government, industry, and biological science with vested interests in GM products routinely cite famine and malnourishment in developing countries as a justification for the technology. The notion of an inelastic agriculture incapable of feeding the populace is entrenched enough that few question this claim, despite lack of evidence pointing to inadequacy of current crop plants or even the likelihood of GM plants offering higher levels of production.

3. *Boserup*

Boserup's *The Conditions of Agricultural Growth* (1965) brought an important new perspective on agricultural change. Since Malthus's time, there had been much comparative agricultural research, especially on peasant (i.e., not entirely market-oriented) systems, which Boserup used in developing a 'dynamic analysis embracing all types of primitive agriculture' (1965, p. 13). Rather than technological change determining population (via food supply), in this model population determined technological change (via the optimization of energetics). This countered Malthus's assumption that agricultural systems tended to produce at the maximal level allowed by available technology. Instead, land was shown often to be used intermittently, with heavy reliance on fire to clear fields and fallowing to restore fertility in the widespread practice of 'slash and burn' farming (Boserup 1965, p. 12). Therefore, comparisons of agricultural productivity had to be in terms of output per unit of land per unit of time—what some call 'production concentration.'

Boserup held that extensive agriculture with low overall production concentration is commonly practiced when rural population density is low enough to allow it, because it tends to be favorable in total workload and efficiency (output:input). Rising population density requires production concentration to rise and fallow times to shorten. Contending with less fertile plots, covered with grass or bushes rather than forest, mandates expanded efforts at fertilizing, field preparation, weed control, and irrigation. These changes often induce agricultural innovation but increase marginal labor cost to the farmer as well: the higher the rural population density, the more hours the farmer must work for the same amount of produce. In other words: as the benefits of fire and fallowing are sacrificed, workloads tend to rise while efficiency drops. It is because of this decreased labor efficiency that farmers rarely intensify agriculture without strong inducements, the most common inducement being population growth. Changing agricultural methods to raise production concentration at the cost of more work at lower efficiency is what Boserup describes as agricultural intensification (Fig. 1).

The model of peasant agriculture being driven by optimization of energetics, with population serving as the prime engine of change, brought a sea change in agricultural change theory. Boserup's name has become synonymous with this perspective, and indeed it was in *The Conditions of Agricultural Growth* that it was crystallized, but others have contributed significantly to this perspective. Most notable was the Russian economist Chayanov (1925), who analyzed peasant farming in terms of energy optimization, with change driven mainly by the demographic makeup of households.

Figure 1
Schematic view of relationships between production concentration and efficiency (output:input) of agricultural methods

Agricultural change theory has now been carried far beyond the simple outlines presented in 1965. Boserup initially stressed that intensification's costs came in the field as fallows were shortened, but she (1981, p. 5) and others have also identified other modes of intensification. Capital-based intensification is characteristic of industrialized societies. The amount of human labor required to produce food generally decreases, whereas the total direct and indirect energy costs can climb to exceedingly high levels. In infrastructure-based intensification, the landscape is rebuilt to enhance, or remove constraints on, production. Land improvements used well beyond the present cropping cycle—such as terraces, ridged fields, dikes, and irrigation ditches—are termed 'landesque capital' (Blaikie and Brookfield 1987). Since landesque capital depends on long-term control (although not necessarily formal ownership and alienability), Boserup posited a general association between intensification and private land tenure, which has been supported in subsequent research (Netting 1993).

At a very general level, the Boserup model of agricultural change has been found to fit fairly well: farmers with abundant land do tend to rely heavily on methods that are land-expensive and labor-cheap; farmers under more crowded conditions do tend to adopt labor-expensive (or capital-expensive) methods; and the decline in marginal utility on inputs does offer a causal mechanism for the change. The model has an impressive record of empirical support from both cross-cultural and longitudinal studies, and it has been indispensable in explaining cross-cultural agricultural variability (Netting 1993, Turner et al. 1977, Turner et al. 1993, Wiggins 1995).

4. *Post-Boserup Research*

The Boserup model has been widely influential, but its broad-brush success comes at the cost of neglecting many important aspects of agricultural change, and researchers from various fields have fault it. Major factors shaping agricultural change beyond Boserup's simple model may be grouped into the categories of ecological, social, and political-economic.

4.1 *Ecological Variation*

Boserup depicts intensification as a universal process cross-cutting environment, but her model relies heavily on agroecological features of fire and fallow that are hardly universal. Thresholds of intensification vary with local environment (Brookfield 1972, p. 44), and the relationship between production concentration and efficiency may be quite variable among environments (Turner et al. 1977, Turner and Brush 1987).

Figure 1 schematically depicts different concentration/efficiency trajectories. The large arrow represents the global pattern emerging from the many cases where productive concentration can be raised, but only at the expense of lowered efficiency. This is the broad pattern confirmed by the empirical studies cited above: Boserupian intensification, defined as the process of raising production concentration by accepting higher labor demands and lower efficiency. In general, this trajectory fits when the labor costs of intensification are both necessary and sufficient to raise production concentration: necessary in that higher production requires proportionately more work, and sufficient in that the proportionate increase in work succeeds in raising output. Where lowered efficiency is not necessary for higher production concentration, the slope would be flatter, as indicated by non-Boserupian trajectory A. The other non-Boserupian pattern occurs where productive concentration cannot be raised, or where the cost of raising it is intolerable: trajectory B. Such a trajectory requires nonagricultural responses to rising population pressure (Stone and Downum 1999).

Although the issue is by no means settled, paddy rice production appears to exemplify trajectory A in many cases. Although it requires high labor inputs (e.g., Clark and Haswell 1967), the pattern of declining yields may be overridden by the distinctive ecology of the paddy in which fertility tends to increase rather than decrease (Bray 1986). Trajectory B is exemplified by arid areas where increasing inputs into reduced land areas cannot overcome the moisture limitations on crops, and would only serve to increase risk (Stone and Downum 1999).

4.2 *Social Factors*

Social context affects both the demands for agricultural products and the relative efficiency of different production methods. Food requirements may be affected not only by calorific needs but by what

Brookfield (1972, p. 38) calls social production, meaning 'goods produced for the use of others in prestation, ceremony and ritual, and hence having a primarily social purpose.' Among New Guinea groups, Brookfield observed production levels that were 'wildly uneconomic' in terms of energetics, but which earned a very real social dividend.

But agriculture is not only practiced partly for social ends; it is practiced by social means, which can have marked effects on how agricultural methods respond to changes in population. Nonindustrialized agriculture is run largely through social institutions for mobilizing resources. Therefore, efficiency of production strategies can vary culturally, and even a purely 'calorific' analysis must consider social institutions that affect costs and benefits.

A comparison of Kofyar and Tiv farmers in central Nigeria provides an example. Expanding out of a crowded homeland on the Jos Plateau, Kofyar farmers began to colonize a frontier near Assaikio in the 1950s. By the early 1960s, there were Kofyar living in frontier communities with population densities below 10/km^2 and agriculture was mostly extensive. By the mid-1980s population density had risen to 100/km^2 and there had been considerable agricultural intensification, with a mean yearly labor input of over 1,500 hours per person (Stone 1996). Intensification was aided by the social institutions that facilitated intensive farming in the homeland, including social mechanisms for mobilizing labor with beer, food, cash, specific reciprocity, or generalized reciprocity. The Kofyar found the main alternative to intensification—migration—expensive and risky, and tended to avoid it.

Nearby were Tiv farmers whose agricultural trajectory followed a different course. Tiv began migrating northward in the 1930s from a homeland known for settlement mobility (Bohannan 1954), and settlement was also highly mobile in the Assaikio area. Their population densities grew more slowly than the Kofyar's, and they showed a clear aversion to the intensification of agriculture. Where the Kofyar had relied on pre-existing institutions for mobilizing labor to facilitate intensification, the Tiv relied on a set of interlocking institutions to facilitate movement (Stone 1997). As long as they could maintain a relatively low population density, they could keep in place an agricultural regime that was extensive enough to allow substantial amount of free time. Much of this time went towards travel and development of social networks that lowered the costs and risks of moving.

4.3 The Role of Political Economy

Agricultural change is shaped by external economic systems, and most farmers have to contend with economic factors that affect the cost of inputs and value of output beyond local energetics. Market incentives can induce farmers to intensify in the absence of land shortage (e.g., Turner and Brush 1987). Eder's (1991, p. 246) observation that farmers 'make their production decisions in terms of pesos per hour, not kilograms per hour' is apt, although it is not so much a cash/energy dichotomy but a gradient. Few small farmers today grow crops exclusively for subsistence or sale; most do both, and they often favor crops that can be used for food or sale. Market involvement does not totally negate the Boserup model (Netting 1993), but it clearly introduces variables that can override effects of local population and energetics.

But of the factors neglected by the Boserup model, the most critical to many contemporary scholars is the variation in farmers' ability to intensify agriculture as they may wish (e.g., Bray 1986, p. 30). As Blaikie and Brookfield (1987, p. 30) put it, the Boserup model 'may be likened to a toothpaste tube—population growth applies pressure on the tube, and somehow, in an undefined way, squeezes out agricultural innovation at the other end.' Even within a single set of ecological, technological, and demographic conditions, population pressure may prompt very different patterns of agricultural change because of differences in farmers' ability to invest, withstand risk, and attract subsidy. While population pressure may stimulate technological change and creation of landesque capital, 'what appears at the other end of the tube is often not innovation but degradation' (Blaikie and Brookfield 1987, p. 30). For instance, Durham's analysis of environmental destruction in Latin America compares two separate feedback loops, both of which include population increase (Durham 1995, pp. 252–4).

The 'capital accumulation' loop leads to intensified commercial production and land concentration, while the 'impoverishment' loop leads to deforestation and ultimately reduced production; the loops feed each other.

The Boserup model is resolutely local in outlook: the cost and benefit of an agricultural operation such as plowing or tree felling is reckoned on the basis of effort required and crops produced. This holds constant the effects of external subsidy that is often available. Farmers may well achieve a higher marginal return on efforts to attract subsidy (e.g., fertilizer from a government program, irrigation ditches constructed by an NGO, or new seed stocks from a development project) than on plowing or tree felling. From the farmer's perspective, this allows new possibilities of raised production, as represented by the small arrow in Fig. 1. There may have been no absolute improvement in efficiency at all, merely a shifting of some costs to the outside by capturing subsidy. The ability to attract such subsidy is politically mediated, and it often varies sharply among segments of a farming population.

Agricultural Sciences and Technology

1. Introduction

The agricultural sciences and technology are usually seen to encompass the plant, animal and food sciences, soil science, agricultural engineering and entomology. In addition, in many research institutions related fields such as agricultural economics, rural sociology, human nutrition, forestry, fisheries, and home economics are included as well. The agricultural sciences have been studied by historians, economists, sociologists, and philosophers.

Most of the early work in Science and Technology Studies focused on physics, said to be the model for the sciences. Unlike the agricultural sciences, theoretical physics appeared disconnected from any clear social or economic interests. Indeed, one early study of the agricultural sciences described them as deviant in that they did not follow the norms found in physics (Storer 1980).

Prior to the 1970s studies of the agricultural sciences tended to be apologetic and uncritical. Then, critical historical, economic, sociological, and philosophical studies of the agricultural sciences began to emerge. These studies built on earlier work that was not within the purview of what is usually called STS. Moreover, despite attempts to incorporate perspectives from this field, it would be an exaggeration to say that studies of the agricultural sciences form an integrated body of knowledge. Indeed, fragmentation has been and remains the rule with respect to theoretical frameworks, research questions, and methods employed.

2. History

Recent historical studies have challenged the hagiographical approach of official histories, demonstrating how the organizational structure of agricultural science encouraged particular research strategies and products. Of particular import were studies of the role of the state-sponsored botanical and zoological gardens, and later the agricultural experiment stations, in the colonial project. In particular, historians began

to document the close relations between the rise of economic botany as a discipline and the creation of botanical gardens in the various European colonies in the seventeenth century (Brockway 1979, Drayton 2000). Such gardens served simultaneously to further the classification of botanical species and the colonial project by identifying plants of economic value that might serve to valorize the new colonies. Coffee, tea, cocoa, rubber, sugar, and other crops were developed as plantation crops and soon thrived in regions far from their locations of origin. In so doing, they provided revenue for colonial governments and profits for the emerging large colonial trading companies.

In the late nineteenth century, botanical gardens were superseded by agricultural experiment stations in most industrialized nations and their colonies. Until World War II, the agricultural experiment stations were *the* model and often the sole recipient of government support for non-military scientific research. The experiment stations focused on increasing yields of food crops in Europe and North America, thereby keeping industrial wages down through cheap food and avoiding feared Malthusian calamities. At the same time the experiment stations in the colonies focused their efforts on increasing yields of exports so as to provide a steady supply of raw materials to European industries. For example, the Gezira scheme in the Sudan combined science, commerce and irrigation so as to provide long staple cotton for the Lancashire mills (Barnett 1977).

In contrast to most plant and animal research, mechanical (e.g., farm equipment) and chemical technologies (e.g., fertilizers, pesticides) in agriculture were developed by private companies. Over the twentieth century, the agricultural sciences and technologies played an important role in increasing agricultural productivity per hectare and per hour of labor. However, some argue that this was only accomplished by displacing vast agrarian populations and increasing environmental degradation.

3. *Economics*

While economic studies as early as the 1930s celebrated the products of agricultural research and emphasized 'adjustment' to the new technologies by farmers, the newer literature has focused primarily on the social rates of return to agricultural research. Many such studies have been used to lobby for additional public support for research. Critics of this approach have argued that only the benefits are estimated while many of the costs are excluded as they are unmeasurable (e.g., acute pesticide poisoning, environmental damage, and research programs yielding few or no results) (Fuglie et al. 1996).

Of particular importance has been the development of the theory of 'induced innovation' as an explanation for the directions taken in agricultural research (Hayami and Ruttan 1985). Proponents of this framework argue that innovations are induced by the relative scarcity of land, labor, and capital. Thus, in Japan, where land is scarce, research has focused on increasing yields per unit of land. In contrast, in the US, where labor is scarce, research has focused on increasing yields per unit of labor. The theory further asserts that agricultural research is responsive to demands of farmers as voiced in the political sphere, since much agricultural research is publicly funded. However, critics have argued that this is only likely to be true in democratic regimes (Burmeister 1988).

Others have examined the allocation of research support across commodities, directing particular concern to what has come to be known as the problem of spillover. Since much public agricultural research has focused on the creation of products and practices that are not protectable by patents or copyrights, research completed in one nation or region can often be used with only minor adaptation in other locales. Economists have concluded that developing nations should not engage in research on commodities with high spillover, such as wheat; instead should rely on other nations and international agricultural research centers for such materials. They argue that such nations would be served better by investing in research on commodities not grown elsewhere. Others have argued successfully for the formation of international networks for research on particular commodities so as to spread the costs of research over several nations with similar agroecological conditions (Plucknett et al. 1990). Such networks have been used effectively to exchange information and materials as well as to foster collaboration. However, with the rise of stronger intellectual property rights in agriculture over the last several decades (including plant variety protection as well as utility patents for life forms), there is some evidence that spillovers may be on the decline.

Another area of interest to economists has been the division of labor between public and private financing of agricultural research. While some economists have argued that biological (as contrasted with chemical and mechanical) agricultural research is by definition a public good, others argue that stronger intellectual property rights make it possible for the private sector to shoulder most of the burden for such research. They have attempted to build the case that stronger intellectual property rights create incentives for private firms to invest in biological research (e.g., plant and animal biotechnologies, seed production), leaving only research in the social sciences and natural resource management to the public sector. Indeed, some nations (e.g., the UK) have privatized part or all of their agricultural research with varying degrees of success.

Finally, related to the division of labor is the issue of alternative public funding mechanisms. Traditionally, agricultural research has been funded institutionally,

based on annual lump-sum appropriations. However, there has been a shift toward more project-based competitive grant programs in which scientists compete to receive grants. Proponents of competitive grants argue that this approach ensures that the best research is conducted by the most competent scientists. In contrast, proponents of institutional funding argue that agriculture is fundamentally place based, necessitating that investigations be distributed across differing ecological zones. They also note that competitive grants tend to be funded over just a few years while much agricultural research requires a decade to complete.

4. *Sociology*

In sociology, adoption-diffusion theory was the dominant approach through the 1960s (Rogers 1995). Diffusion theorists accepted the products of agricultural research as wholly desirable. Hence, their work focused almost exclusively on the fate of innovations designed for farm use. They employed a communications model adopted from engineering in which messages were seen to be transmitted from sender to receiver, later adding the engineering term 'feedback' to describe receivers' responses to the messages sent to them. They argued that adoption could be best understood as based on the social psychological characteristics of adopters and non-adopters. Early adopters were found to be more cosmopolitan, better educated, less risk-averse, and more willing to invest in new technologies than late adopters, pejoratively labeled 'laggards.' This perspective fitted well with the commitments of agricultural scientists to transforming agriculture, making it more efficient and more modern. However, it ignored the characteristics of the innovations. Often they were large, costly, and required considerable skill to operate and maintain. Not surprisingly, those who rejected the innovations lacked the capital and education to use them effectively.

Later studies challenged the diffusion theorists. First, critics of the Green Revolution asked questions about the appropriateness of the research undertaken (Perkins 1997). They noted that, although inexpensive in themselves, Green Revolution varieties were often parts of packages of innovations that required considerable capital investment well beyond the means of the average farmer. While acknowledging that yields increased, they documented the considerable rural upheaval created by the Green Revolution: growing farm size, displacement of both small farmers and landless laborers to the urban slums, declining status of women, declining water tables due to increased irrigation, and contamination of ground water from agricultural chemicals.

Others asked how agricultural scientists choose their research problems (Busch and Lacy 1983). They noted that science and commerce were necessarily intimately intertwined in agriculture, in the choice of research problems, in the institutional relations between the public and private sectors, and in the value commitments of scientists (often from farm backgrounds) and wealthier farmers. They challenged the engineering model of communication, seeking to substitute for it one drawn from the hermeneutic-dialectic tradition. Drawing on philosophers such as Jürgen Habermas and Hans-Georg Gadamer, they asserted that communications between scientists and the users of the products of agricultural research had to be able to debate fundamental assumptions about what constitutes a desirable future for agriculture as well as specific technical details.

Sociologists have also studied agricultural commodity chains, i.e., the entire spectrum of activities from the production of seed through to final consumption (Friedland et al. 1978). Such studies have examined the complex interaction between scientists and engineers involved in the design of new seeds and equipment and various constituent groups. Unlike the diffusion and induced innovation theorists, proponents of this approach have engaged in detailed empirical analyses of new technologies, challenging the assumptions of the designers. For example, both the tomato harvester and the hard tomato needed to withstand mechanical harvesting were built on the initiative of scientists and engineers in the public sector rather than to meet any need articulated by growers. Together, these technologies transformed tomato production in many parts of the world by reducing the number of growers and farm workers while increasing farm size. Given the limited employment opportunities of those displaced, critics question whether this was an appropriate investment of public funds.

In recent years, sociologists have devoted considerable attention to the new agricultural biotechnologies (e.g., gene transfer, plant tissue culture), especially those involving transformations of plants (see *Biotechnology*). It is argued that these new technologies have begun to transform the creation of new plant varieties by (a) reducing the time necessary for breeding, (b) reducing the space necessary to test for the incorporation of new traits from large fields to small laboratories, and (c) making it possible in principle to incorporate any gene into any organism. However, analysts note that the vast sums of private capital invested in this sector stem as much from changes in property rights as from any advantages claimed for the new technologies. In particular, they point to the advent of plant variety protection (a form of intellectual property right), the extension of utility patents to include plants, and the imposition of Western notions of intellectual property on much of the rest of the world.

Before these institutional changes, most plant breeding was done by the public sector. Private breeding was not profitable as seeds are both means of

production and reproduction. Thus, farmers could save seed from the harvest to use the following year or even to sell to neighbors. Put differently, each farmer was potentially in competition with the seed companies (e.g., Kloppenburg 1988). In contrast, once the new intellectual property regimes began to be implemented, it became possible to prohibit the planting of purchased seed developed using the new biotechnologies. Suddenly, the once barely profitable seed industry became a potential source of profits. Agrochemical companies rapidly purchased all the seed companies capable of engaging in research in hopes of cashing in on the new opportunities. The result has been a shift of plant breeding research for major crops to the private sector and strong prohibitions on replanting saved seed.

Another line of work has examined particular agricultural scientific practices and institutions. These include approaches to irrigation and chemical pest control strategies (Dunlap 1981). Moreover, as environmental concerns have taken on greater significance for the general public, studies of agricultural science have begun to merge with environmental studies.

5. *Philosophy*

In recent years applied ethicists have begun to take an interest in the agricultural sciences, asking a variety of ethical questions about the nature of the research enterprise, its relation to larger environmental issues such as the conservation of biological diversity, and the distribution of the products generated by the agricultural sciences. Some have asked whether it is even possible to engage in applied science without considering the ethical issues raised by the research agenda. Two new interdisciplinary professional societies emerged out of that interest: The Agriculture, Food and Human Values Society and the European Society for Agricultural and Food Ethics.

In a major contribution to the field, Thompson asserts that agriculture is dominated by what he calls the 'productionist ethic', the belief that production is the sole metric for ethically evaluating agriculture (Thompson 1995). From this perspective, derived from the philosophical work of John Locke, land not in cultivation is wasted. Agricultural scientists, themselves often from farm backgrounds, have posited this as self evident. This was combined with a positivist belief in the value-free status of science and a naive utilitarianism that assumes that all new technologies adopted by farmers are ethically acceptable. From this vantage point, all distributive issues are to be resolved by making the pie bigger. Similarly, environmental problems are defined as arising from inadequate technologies. In contrast, Thompson proposes an ethic of sustainability in which agricultural production is embedded in environmental ethics. Even the quest for sustainable systems, he notes, will be filled with both ironies and tragedies.

Indeed, within the agricultural sciences, ethical concerns have a higher profile than they have had in the past. In most industrialized nations there has been greater recognition of the need for inclusion of ethics and public policy issues in agricultural scientific education and research (Thompson et al. 1994). Moreover, the challenges to the focus on production from within the agricultural sciences have increased receptivity to ethical and policy questions. For example, agronomy, once the province only of scientists concerned to enhance annual yield, has become more fragmented as those concerned with sustainable agriculture and molecular biology have entered the field. Thus, questions of the goals and practices of research, previously ignored, have moved closer to center stage.

Philosophers have also examined ethical aspects of the new agricultural biotechnologies. Among the many issues of relevance is that of informed consent. In brief, it is often argued that consumers have the right to know what is in their food and to make decisions about what to eat on the basis of that information. From this vantage point, those nations that do not label biotechnologically altered foods violate important ethical norms.

In addition, critics of biotechnology have raised questions about the ethics of the use of animals in laboratory experiments, the development of herbicide resistant crops, the use of bovine somatotropin to enhance milk production in dairy cows, the insertion of toxins from *Bacillus thuringiensis* to create insect resistance in maize and potatoes, and the establishment of intellectual property rights in plants and animals.

6. *Future Directions*

There is little evidence that the fragmentation that has plagued studies of the agricultural sciences in the past is coming to an end. Disciplinary boundaries between the relevant academic fields remain high. Moreover, there are rigid institutional boundaries that still separate academic agricultural sciences from other fields of research. In particular, agricultural research and education tend to be found in specialized institutions, partly because of the specialized activities in which they engage, and partly because of the high cost of animal herds and experimental fields. Furthermore, those who study the agricultural sciences often do so from within the confines of schools and colleges of agriculture. In some institutions, this puts restrictions on what topics are considered appropriate for research.

Agriculture, Economics of

Agriculture is distinguished from other sectors of the economy by virtue of its production processes (biological), its economic organization (on farms), and its products (food and fiber). The importance of these distinctions for economic analysis is not always evident, but they have been sufficient to make agricultural economics a separate sub-discipline of economics, with its own journals and professional organizations.

1. Agriculture's Primacy in Economic Development

In most of the world historically, and in much of the world today, the economics of agriculture is the economics of subsistence: the effort to wrest the food necessary for survival from productive but fickle resources. The essential economics concerns how individuals carry out such efforts, and how families, villages, or other social entities organize their members for doing so. Economic development begins when agriculture generates production in excess of local requirements. Until the mid-nineteenth century the majority of the labor force in most countries of Europe was employed in agriculture. By the end of the twentieth century this percentage had been reduced to less than five in the richest countries. Similar patterns have emerged since 1950 in much of Latin America and Southeast Asia. Nonetheless, the World Bank (1997) estimates that 72 percent of the world's poor live in rural areas, and the prospects for economic development in agriculture remain a matter of worldwide concern.

A long-debated issue is whether agriculture is best viewed as an engine of growth, with investment in the sector an important source of economic progress; or as an economically stagnant source of labor to be mobilized more productively elsewhere as the economy grows. 'Dual economy' models, in which agriculture is economically distinct from the nonagricultural sector, can accommodate both views, depending on how they treat mobility of labor and capital between the sectors, and the processes of technical change and investment in each. Such models can account for the observation of huge outmigration from agriculture together with wage and income levels in rural areas rising toward urban levels after falling behind in the early stages of industrialization. But they do not provide useful empirical guidance for fostering economic development in areas of the world where it still is most needed. For those purposes, attention to microeconomic and sectoral detail is necessary. For reviews of economists' work on micro-level and aggregate questions, respectively, see Strauss and Duncan (1995) and Timmer (2002).

One of the most striking, and still to some extent controversial finding about the economics of traditional agriculture is the wide extent to which farmers in the poorest circumstances in the least developed countries act consistently with basic microeconomic principles. They follow economic rationality in the sense of getting the most economic value possible with the resources at hand; but the innovation and investment that would generate economic growth are missing (Schultz 1964). What is needed is to break out of the poor but efficient equilibrium by means of 'investment in high income streams,' mainly physical capital and improved production methods embodying new knowledge, and investment in human capital that

would foster innovation in technology and the effective adoption of innovations by farmers. Events such as the 'green revolution' that boosted wheat yields in India in the 1960s showed promising trends that have been sustained in many areas, but agriculture remained moribund through the 1990s in many places, notably in Africa and the former Soviet Union. No more important task faces agricultural economics today than explaining and finding remedies for this stagnation.

2. Farms

Farms range from individuals working small plots of land with only primitive tools to huge commercial enterprises. Every operating farm embodies a solution to problems of product choice, production technique, mobilization of inputs, and marketing of output. Many of the choices to be made involve non-market, household activities. Consequently, the economic analysis of farm households has become a major area of empirical investigation, calling upon developments in population and labor economics as well as the theory of the firm. Using these tools, agricultural economists have attempted to understand alternatives that have arisen in the economic organization of agriculture: family farms, cooperatives, plantations, corporate farming, state farms (see for example Binswanger and Rosenzweig 1986).

2.1 Organization of Production

A basic decision is whether to specialize or to diversify production among a number of products. The trend is strongly toward specialization. For example, 4.2 million US farms (78 percent of all farms) had chickens in 1950, but by 1997 specialization had gone so far that only 100 thousand did (5 percent of all farms). Linked with specialization is the issue of economies of scale in farming. Throughout the developed economies there is a general tendency for farm size to increase over the last century. Data on farmers' costs indicate that a primary reason is economies of size. Yet there are many instances of very large farms failing. Collective farms in the former Soviet Union, employing thousands of workers on thousands of hectares, became paradigms of inefficiency. And in some developing country contexts there is evidence that small farms use their resources more efficiently than large ones. Optimal economic organization with respect to both specialization and scale depend on technical and institutional factors, most importantly the following.

2.2 Land Tenure

Land is a valuable asset and is necessary for farming. Yet farmers in many countries are poor. Institutional arrangements have evolved to enable farmers to cultivate and claim returns from land they do not own. The main ones are cash rental and sharecropping. Cash rental encounters several problems: the tenant may lack the means or access to credit for payment in advance, bears all the risks of crop failure or low prices, and has an incentive to use the land in ways that increase current output at the expense of future fertility of the land.

Under sharecropping, a common practice in both developing and industrial countries, the tenant pays after the harvest in the form of a fraction of the crop harvested. The share paid to the landlord varies widely, generally between one-fourth and one-half of the crop, depending on the quality of the land, the labor intensity of the crop, and the value of non-land inputs, if any, contributed by the landlord. In addition, the literature on optimal land contracting finds that shares depend on agency costs, production efficiency of tenants and landlords, and how risk averse each party is. Sharecropping divides production and price risk between landlord and tenant, and obviates the need for payment in advance. But it retains the principal-agent problem in lacking incentives to maintain future land quality, and adds a disincentive for tenant effort in that the tenant receives only part of the tenant's marginal product, and adds an incentive for the tenant to under-report output and/or price received so as to reduce the rent paid. Such problems can be dealt with through monitoring, but that is costly. For a comprehensive review of the issues, see Deininger and Feder (2001).

The problems and costs of land rental increase the attractiveness of owner-operated farms, even if they have to be smaller. However, in many countries the institutions for private land ownership are not fully developed, nor are credit markets that would enable people with few initial assets to become landowners. In developed economies, land rental functions as a mechanism through which farmers can mobilize the land resources needed to achieve the least-cost scale of production. In the case of the US in 1997, only 21 percent of cropland was on farms fully owned by their operators.

2.3 Agricultural Labor

About one-half the world's labor force works in agriculture, as either a farmer or a hired worker. (For data by country, see World Bank, *World Development Indicators*, 1998, Table 1.) Hired labor is common even on family farms. Hired farm laborers in both developing and industrial countries are among the least well paid and most economically precarious workers. Seasonal workers live under especially difficult conditions in that they often dwell in temporary quarters and are minorities or immigrants, sometimes with dubious legal status, which makes them ripe for exploitation. The plight of migrant workers in many

Table 1
Annual costs and benefits of protection of agriculture in the EU, US, and Japan

	EU	US	Japan
Consumer costs due to higher prices	35	6	7
Taxpayer costs of subsidies	12	10	0
Gains to producers	31	12	12

countries has led to legislative and regulatory attempts to limit their numbers and improve their condition, and adds to a general sense that policies should be undertaken to enable landless laborers to gain access to land of their own and become farmers themselves. Nonetheless, hired labor remains a substantial fraction of the farm labor force in both rich and poor countries.

2.4 Credit and Input Markets

As agriculture modernizes, an increased share of resources used are purchased seeds, fertilizers, chemicals, energy, and capital equipment. Farms that cannot invest become unable to compete effectively. If modern agriculture is to be undertaken by farmers other than those who already possess substantial assets, well functioning credit markets are essential. A major problem for agriculture in many countries is limited access to either purchased inputs or credit. Recent thought about credit markets has emphasized the problems that arise because of asymmetric information between lender and borrower leading to credit rationing or missing markets. If potentially productive loans do not get made, farmers and the rural economy are unable to grow to their potential. This reasoning has led many countries to provide subsidized credit to farmers, but the informational problems that cause market failure have not been overcome with government involvement. In addition the political provenance of these programs causes new problems.

2.5 Price Determination and Marketing

A recurrent complaint worldwide is farmers' lack of market power as compared to those who buy from and sell to them. Farmers typically have only a few alternative outlets for their products, and inputs they buy, but the extent of monopsony or monopoly power that results remains unclear. In many countries farmers have established marketing and purchasing cooperatives to increase their market power. In the United States, the first half of the twentieth century saw far-reaching governmental attempts to reduce the market power of meat packers, grain traders, railroads, food wholesalers and retailers, and banks through antitrust action and governmental regulatory agencies. The developed countries of the world are today replete with such efforts, and developing countries have followed suit as appeared technically and politically feasible. It is nonetheless unclear whether the economic problems of farmers have ever been principally attributable to their lack of market power, or that cooperatives or regulatory institutions have increased farm incomes appreciably.

Important recent developments in marketing involve contractual arrangements between farmers and processors that take some input provision and marketing decisions out of the hands of the farmer. Such changes have gone furthest in broiler chicken production in the United States, where the processor is an 'integrator' who supplies the baby chickens, feed, veterinary and other services, technical information, and perhaps credit. The farmer (or 'grower') receives a payment schedule, contracted for in advance, consisting of a fee per pound of chicken delivered that is adjusted for an efficiency indicator as compared to other growers (but not changes in the market for chicken) in return for the grower's effort in feeding and managing the flock and providing the properly equipped chicken house. Virtually all broilers in the country are now produced under some variant of this type of contract. Under these arrangements productivity indicators of output per unit input have grown far faster for broilers than for any other livestock product and the US price per pound (live basis) of chicken relative to beef has declined from a ratio of 1.7 in 1940 to 0.5 in 1995. Similar production arrangements are increasingly prevalent for other meat animals.

2.6 Risk Management

In subsistence agriculture, crops failing or livestock dying place the farmer at risk of starvation. In commercial agriculture, fixed costs of crops sown and interest on debt means that losing even a portion of the crop, or receiving low prices, can easily generate negative cash flow. Steps a farmer can take to manage such risk include savings, diversification of enterprises, emergency borrowing, and purchase of hazard insurance against output risk, or some form of forward pricing against price risk. It remains open to question however how risk averse farmers are. Basic evidence that risk aversion is important is farmers' willingness to pay for insurance and their interest in pricing their output in advance. Observations that give pause about the importance of risk aversion are the many farmers who do not buy even subsidized crop insurance and who do not attempt to lock in a price for their output, even when contractual means for doing so are available. Nonetheless, evidence from developing countries suggests risk aversion of a magnitude that could readily impair farmers' willingness to invest in new production methods even when innovation would pay in expected value (see Moschini and Hennessy 2001).

3. Production and Technology

The evolution of world agriculture over the long historical record is tied principally to changes in technology. Throughout the developed world a large and sustained record of growth in agricultural productivity has been achieved. In the US case, after 50 years of steady but unspectacular growth, agricultural productivity accelerated markedly after 1940 to a pace of about 2 percent annually, well above the rate of productivity growth in manufacturing. Moreover, that rate of growth has been maintained for 60 years, with little evidence of the productivity stagnation that plagued manufacturing in the 1970s and 1980s (Fig. 1).

Economists have devoted much effort to measurement and analysis of productivity changes and farmers' decisions about input use. Nerlove (1958) developed a method of estimating both short-run and long-run output response to product prices. Empirical work using many variations on his approach over the last four decades has estimated generally small short-run effects of price. But in many cases the long-run effects are substantial. Griliches (1957a) provided the first fully developed economic analyses of the adoption of technology in his study of hybrid corn in the United States. Technical change and supply response have been merged in studies of 'induced innovation.' The chief causal factors identified in both supply and productivity growth have been advances in knowledge, improved input quality, infrastructure development, improved skills of farmers, and government policies. But the relative importance of these factors, even for the most-studied countries, still remains in doubt. A comprehensive review is Sunding and Zilberman (2001).

US Farm Total Factor Productivity Index

4. Demand and Markets

The world's population tripled in the twentieth century from the two billion of 1900. Agricultural production grew sufficiently not only to feed an additional four billion people, but also to provide the average person with a substantially improved diet. And, the incidence of famine and starvation among the world's poor has been greatly reduced. This capability was not evident 200 years ago when Malthus formulated the proposition that the earth's limited production capacity, coupled with the propensity of population to grow whenever living standards rose above the subsistence level, meant the inevitability of increasing food scarcity (and worse) over the long term. One of the most notable facts about the twentieth century is the failure of Malthusian pessimism to materialize. Nonetheless, the plausibility of elements of this view—basically the fixity of natural resources in the face of increasing population—is sufficient that the Malthusian worry resonates to the present day. It is therefore important to establish the circumstances under which food scarcity has ceased to be a salient social problem as well as the situations in which scarcity and famine remain a major cause of distress, and to understand why supply and demand have conspired to work out predominantly in the counter-Malthusian direction.

The single best indicator of food scarcity is the real price of staple commodities: cereals and other basic foods. Despite price spikes in wartime and the 1970s, the trend is for ever cheaper commodities. This trend primarily reflects lower real costs of production, a consequence of the productivity trends illustrated in Fig. 1. While all acknowledge the uncertainty of any forecast, expert participants in a recent comprehensive assessment of world food prospects were in broad agreement that the trend of lower real prices of staple food commodities is most likely to continue in the twenty-first century (Islam 1995).

An important factor in food demand is Engel's Law: the share of income spent on food decreases as consumers' incomes rise. The general rise of real incomes over the last century, coupled with the growth in agricultural productivity have meant an inexorable decline in agriculture's economic importance, and have been a source of chronic downward pressure on the economic returns of farmers. In many developing countries, especially former colonies whose economies became attuned to exports of primary products, declining commodity prices have been a key part of a bigger story of economic disappointment. Economic problems of farmers in both developing and industrial countries have kept agriculture firmly on the policy agenda almost everywhere.

5. *Government and Agriculture*

Political responses to problems of agriculture have generated a wide variety of government action. Four areas of activity warrant discussion: regulation of commodity markets; rural development policy; food policy; and resource and environmental policies.

5.1 *Commodity Programs*

Government intervention in agricultural commodity markets has been pervasive throughout recorded history. The primordial form of this intervention is taxation. With urbanization, implicit taxation of agriculture has arisen in many countries in the form of regulations intended to keep food prices from rising in times of scarcity. A sharp divide exists between the developing world, in which agricultural output is generally taxed, and the industrial world, in which agriculture is generally subsidized. This pattern of taxation and subsidy has had the unfortunate consequence of encouraging overproduction in industrial countries and discouraging investment in agriculture in developing countries, many of which have a comparative advantage in agriculture. Contrary to what one might have expected, the share of world agricultural exports accounted for by industrial countries increased from 30 percent in 1961–3 to 48 percent in 1982–4, with a corresponding decrease in developing countries (World Bank 1986, p. 10).

Not only does the protection of agriculture in industrial countries harm agriculture in developing countries, in addition each industrial country's protection makes it more costly for other industrial countries to maintain protection. The Common Agricultural Policy (CAP), created with the establishment of the European Economic Community in 1958, is notorious in this respect. The main policy instruments of the CAP go back to Britain's Corn Laws of the ninetieth century tariffs that maintain protection against imports by rising when world prices fall ('variable levies') and export subsidies to dispose of domestic surplus production (see Ritson and Harvey 1997). In the first two decades of its existence the CAP moved its members from being net importers to net exporters of wheat, rice, beef, and poultry meat. Other grain-growing countries, which also desired to maintain support prices for their producers, introduced or accelerated export promotion and subsidy programs of their own, notably the US Export Enhancement Program of the 1980s. The subsidy competition exacerbated a worldwide decline in commodity prices in the 1980s, increasing the costs of US 'deficiency payments' that made up the difference between legislated 'target' prices and market prices for grains. This in turn triggered massive acreage-idling programs; in 1985–7 about a fourth of US grain-growing land was idled.

The World Bank (1986, p. 121) assessed the annual costs and benefits of agricultural protection in the largest OECD countries as shown in Table 1 (in billions of dollars).

Note that the costs to consumers and taxpayers together far outweigh the producer (more specifically, landowner) gains, with the sum for the EU, US, and Japan being a net welfare loss of US$25 billion.

Accurate measurement of these gains and losses is difficult, but virtually all analysts estimate substantial net losses in the industrial countries and to producers in developing countries during most of the post-World War II period, and accelerating losses in the 1980s. This situation provided the stimulus for agricultural policies, after lengthy and contentious negotiations in 1986–93, to be subjected to internationally agreed disciplines that began to be implemented in 1995 under the auspices of the World Trade Organization.

Individual countries have also initiated moves towards less market distorting intervention in the commodity markets in the 1990s. In the developing world, substantive steps in deregulating commodity markets were taken in many countries of Latin America and East Asia; and in Africa many countries reformed and/or abolished marketing boards and related interventions. Most radically of all, beginning in the late 1980s (and before the breakup of the Soviet sphere in 1989), a renunciation of state control of farm enterprises occurred in China and throughout Eastern Europe and the former USSR. But the reforms have as yet achieved nothing near complete liberalization in either developed, developing, or transition economies, with the exception of New Zealand.

5.2 *Rural Development Policy*

A broader agenda of governments in promoting economic growth in agriculture and rural areas has more widespread support. Economists have generally concluded that provision of certain public goods and infrastructure investment has been crucial in the economic development of agriculture, and that the absence or deficiency of such governmental support is an obstacle, perhaps an insuperable obstacle, to economic growth in agriculture in countries where it has not yet occurred. The World Bank has taken a strong role in urging market liberalization in developing countries and at the same time proposing a broad program of public investment in pursuit of rural development (World Bank 1997).

5.2.1 Legal Institutions. The most fundamental economic service the State can provide is a system of law governing property and contracts, and protection from lawbreakers. This requirement is not of course peculiar to agriculture, but must be mentioned because legal institutions in rural areas are no-

tably weak in many transition and poor economies, and especially regarding use and control of farmland and water resources. In industrial countries, too, these institutions have to evolve in response to changes in technical and social realities, most notably in the 1990s the establishment of property rights and contractual procedures that bear on innovations in biotechnology.

5.2.2 Agricultural Research, Extension, and Education. Even with well established institutions fostering private sector research and development, research and information dissemination are likely candidates for public funding, and have long been so funded in many countries. Griliches (1957b) pioneered methods of estimating the costs and benefits of publicly supported research. Since then hundreds of studies in both developing and industrial countries have replicated his finding of extraordinarily high rates of return to public investment in research and the dissemination of knowledge through extension activities (Evenson 2001).

Since the work of Schultz (1964, Chap. 12) investment in schooling has been seen as a cornerstone of what is needed to improve the economic well-being of farm people, and of increasing agricultural productivity. Solid empirical evidence of the effects of education on farming has been hard to come by, however. Even so, there is widespread support for improved education in rural areas, recently with particular attention to the education of women. Evidence is strong that schooling improves peoples' earning capacity, so it is a promising remedy for rural poverty even if it causes its recipients to leave agriculture.

5.2.3 Rural Infrastructure. Governments in industrial countries have made major investments in roads, railways, shipping channels, and ports to provide remote areas with cheaper access to markets. Lack of such infrastructure is a major impediment to agricultural development in many parts of the world today. But we have nothing like the studies of returns to research to provide evidence on the rate of return to such investments, and the anecdotal evidence is replete with failure as well as success stories. Even more controversy swirls around investments in water projects. Irrigation was important in facilitating fertilizer response to the new grain varieties that triggered the green revolution of the 1960s, and is essential for opening up arid areas for production. At the same time, dams and irrigation works have been heavily criticized in recent years. Many cases of low or negative returns to large investments have been cited, and the environmental costs of lost habitat for endangered species and reduced water quality have been emphasized. Recent work by agricultural economists has emphasized improving institutions for water pricing and assignment of use rights more than further investment in large projects.

5.3 Food Policy

A chief source of governmental discrimination against agriculture in developing countries is a desire to keep food prices low for urban consumers. In industrial countries, too, attempts have been made via price ceilings and export restrictions to keep a lid on food prices in periods when they have risen sharply, as occurred in the commodity boom of the 1970s. More important ongoing policies address the regulation of food quality and safety, food assistance for poor people at risk of undernutrition, and famine relief. Chemical residues on food and the use of genetically modified organisms (GMOs) in agriculture were especially contentious issues in the 1990s.

An important bifurcation of countries today is between those in which food security remains a pressing national issue and those in which assurance of an adequate diet is the problem of only a small minority of the population. International food aid has become a permanent policy in industrial countries, particularly famine relief. Mobilization of funds for such efforts can be difficult except in cases of well publicized disasters, but the more salient analytical issues have involved the nature of famines and the effectiveness of alternative approaches to remedy the suffering and death they cause. It has become apparent that in most famines the problem is not so much physical unavailability of food as a lack of income with which to acquire food. This may seem a distinction without a difference but the implications are profound for the most effective administration of aid. It has been argued, for example, that it can be counterproductive simply to ship food products to be disbursed by local governments. The undesired result is distribution that too often scants those who most need the goods, and at the same time a depression of commodity prices and hence of the incomes of local farmers who produce goods that compete on the same market as goods brought in but lack income for an overall adequate diet. Generally, international donors have to be careful not to take actions harmful to local coping mechanisms, which in many poor areas are well developed from long and bitter experience. See Barrett (2002) for a comprehensive review.

5.4 Resource and Environmental Policy

The relationships between agriculture and water quality, soil and other resource depletion, wildlife habitat, and chemical contamination have become front-burner policy issues in industrial countries, and are

beginning to get attention in developing countries. A difference from the regulation of industrial polluters is that agricultural pollution sources are typically small, scattered, and difficult to monitor. Certain agricultural pesticides have been banned in industrial countries, but reasonably good substitutes have so far been available. Non-intensive uses of erodible or otherwise environmentally sensitive lands, has been fostered in the US and Europe by paying farmers to undertake recommended practices.

Nonpolluting and resource saving practices for developing countries have been promoted by international agencies as conducive to 'sustainability' of their productive resources. However, countries have resisted some of these ideas, such as restraints on opening up new land or eschewing large new dams and irrigation projects. The debate is difficult because of a lack of documentation that the loss of forests and conversion of other lands to agricultural purposes at rates now occurring is a mistake that will come to be regretted. In Europe and North America, an issue that has become prominent in recent decades is the conversion of farmland out of agriculture and into residential and commercial use in suburban areas, not so much out of concern about lost food production but rather because of the loss of open space and other community amenities that farming provides. Land use regulation and agricultural subsidies of various kinds have been introduced, most extensively in Europe.

5.5 Agricultural Politics

Why has agriculture been widely discriminated against in developing countries, and supported in developed countries? Evidence that the explanation is not country specific is that countries that have grown sufficiently rich to move from the developing to the developed category, largely in East Asia, have moved from taxing agriculture to subsidizing it. A large body of recent work has attempted to explain the strength and resilience of farmers' political clout in the richest countries, especially in Western Europe, Japan, and the North America. It is particularly notable in that this strength has been maintained even as the farm population has declined from one-fourth to one-half of the total population 50 years ago to 2 to 10 percent today. It is also instructive that some commodities are protected much more heavily than others within each country. Many reasonable hypotheses on these and related matters have been advanced, generally linked to interest group lobbying and democratic politics. Knowing more about agricultural politics is important because a governmental role is essential in many aspects of agricultural and rural development, yet governmental action in commodity support programs, trade restrictions, and other regulatory areas have imposed large social costs that are notably resistant to reform. The goal is governmental institutions that provide the services that contribute to sustainable development and that reform wasteful policies. The goal is far from being realized.

AIDS (Acquired Immune-deficiency Syndrome)

The AIDS epidemic of the 1980s shone a dark light on the assumptions of contemporary biomedicine. The world was confronted with a disease which it did not understand, could not treat, and which often attacked previously healthy young men. It had echoes of the great plagues of medieval times that decimated the cities of Europe and Asia. Theories abounded about its cause until it was discovered that a rare retrovirus instigated the destruction of human immune cells. Western medical science had recently been comfortable in the belief that infectious diseases were coming under scientific control and that the major health problems of the age lay in the understanding and treatment of chronic diseases.

What was particularly challenging about AIDS was that its impact on society extended beyond the usual concerns of biological medicine. Medical science was at the time appropriately basking in groundbreaking discoveries in the arenas of genetics and cellular and molecular biology. It was coming to better understand the mechanisms of disease and was devising innovative methods of diagnosis and treatment. What medicine did not do particularly well at the time was to attend the psychological, social, political, and ethical dimensions of illness. The onslaught of AIDS altered that, and forced the biomedical world to broaden its conception of illness and consider elements that went beyond the physical basis of pathology. The old authoritarian models of the doctor–patient relationship are gradually being replaced by a process where patients are empowered to gather more information about their condition, play a greater role in making treatment decisions, and become more self-directive in maintaining their health. All of this has taken place in an environment where new discoveries about virology, immunology, and treatment strategies are rapidly occurring.

The story of HIV infection and its culmination in the disease that is called AIDS starts in the USA in the early 1980s. Surprised physicians treating young gay men noted that they were falling ill and dying in increasing numbers. There was no clear diagonistic reason for this phenomenon, and a variety of guesses was ventured as to the cause. The number of reported incidents of this strange illness began to increase. Soon it was discovered that patients receiving transfusions for hemophilia and also intravenous drug users were being reported with this disease. Reports began coming in from Africa documenting that heterosexual men and women were likewise falling ill in alarming numbers. It became evident that the primary site of the pathology was the destruction of an important component of the immune system, the CD4 helper T cells which are responsible for mounting a critical defense against infectious agents. As a result of the loss of immune competency, an array of 'opportunistic' infections attacked the victim and instigated a wide array of illnesses which infiltrated many body organs, chiefly the lungs and central nervous system.

In the USA, the number of people contracting this disease rose over a span of two decades. By 1997 it was estimated that the prevalence of acquired immunodeficiency syndrome was approaching 900,000. AIDS became the leading cause of death among all Americans between 25 and 44 years of age. Approximately 40,000 new cases were reported yearly and the same number would die of complications of the disease. By the mid-1990s, the Centers for Disease Control estimated that the incidence of new cases had declined by six percent, but the prevalence of the disease had remained stable. (The number of new cases was approximately the same as the number of deaths by the late 1990s.) New treatments for this disease were rapidly emerging by the 1990s, but the high cost of treatment meant that many poor people and people of color did not receive the benefits of these medications.

1. The Etiology, Immunology, and Clinical Pathology of HIV/AIDS

There has been some confusion in the public mind about the use of the meaning of the concepts of HIV and AIDS. The term 'HIV' refers to a person's infection with the HIV (human immunodeficiency virus). This virus can be transported from one person to another through the exchange of certain body fluids (blood, semen, vaginal discharge). It enters certain immune cells in the body and *can* progressively destroy them over time. The presence of this virus can be detected by testing antibody titers which reveal the body's response to its presence. A person can be HIV+ and be asymptomatic for long periods of time, or show only mild flu-like symptoms after acquiring the virus. The human immunodeficiency virus belongs to a *retrovirus group* called *cytopathic lentiviruses*. This class of viruses insert their genetic material into a cell's genetic pool through a process called *reverse transcription*.

There are two types of HIV viruses which have been shown to cause AIDS in humans: HIV-1 and HIV-2.

These viruses share similar molecular structures and cause similar pathological disruptions. Currently, HIV-1 causes the majority of cases of AIDS throughout the world, while HIV-2 is found mostly in Africa. There are many different subtypes among the HIV-1 strain. These viruses can rapidly change their molecular structure within the body, making them difficult for the immune system to destroy. The mutability of these viruses also makes them difficult targets for preventive immunization strategies.

The term *AIDS* refers to a critical stage of the HIV infection when a large number of CD4 helper lymphocytes have been destroyed and the body is not able to mount an effective immune defense against secondary pathogens or the toxic effects of the HIV virus itself. The first symptomatic signs of immune breakdown may not occur for a number of years after the acquisition of the virus; latency might vary between four and ten years. The HIV virus can provoke diseases that involve the lymph nodes, lungs, brain, kidneys, and the abdominal cavity. There is no universal sequence of clinical symptoms, but the most frequent presentation can include enlarged lymph glands, pneumonia-like symptoms, decline in blood counts, fungal infections, as well as diarrhea, weight loss, bacterial infections, fatigue, and disorders of the central nervous system. The Centers for Disease Control in 1993 compiled a list of conditions which defined AIDS. This included such diseases as toxoplasmosis of the brain, tuberculosis, Kaposi's sarcoma, candidiasis infection of the esophagus, cervical cancer, and cytomegalic retinitis with loss of vision. Conditions on the list include opportunistic infections, or diseases that would otherwise not occur in the presence of a healthy immune system.

In order to best understand this devastating disease and its treatment, it is important to understand the relationship of the virus to the immune system. The HIV virus is known as a retrovirus, which means that it can alter the flow of genetic information within a cell. It uses the enzyme *reverse transcriptase* for utilizing viral RNA as a template for producing DNA. In most cells, DNA produces RNA as a genetic messenger. The sequence of infection after the entry of the virus through exchange of body fluids is the following: (a) the virus attaches to a host immune cell; (b) the virus sheds its molecular coat and begins the processes of reverse transcription; (c) viral DNA is integrated into the host cell, causing transcription and translation of the viral genetic code into viral protein, and inducing the host cell into producing more copies of the invading virus; (d) the newly formed viruses are released into the blood stream, with the death of the host cell and the re-invasion of new immune host cells.

The helper T cells have the CD4 surface receptor, which has a high affinity for the HIV surface protein gp120. However, the HIV virus can attach to other cells including macrophages and monocytes (other immune cells), as well as cells in the intestines, uterine cervix, and Langerhans cells of the skin. Researchers have found that chemicals called cytokines also play a significant role in facilitating viral invasion. Interestingly, there are certain mutant strains of cytokine genes that actually prevent the entry of the HIV virus into the target CD4 cell. The presence of these genes in certain people may explain why some individuals remain resistant to HIV infection despite exposure to virally loaded body fluids and why some people show slower rates of disease progression.

Not all infected cells immediately produce new viral copies which destroy the cell and infect many others. Some cells may remain dormant without producing new viral copies. There may be adjuvant factors that convert latent infected cells into ones that produce viral copies. It is speculated that coexisting infections with their additional antigen load may have a facilitating effect, as may certain drugs, possibly stress, fatigue, etc. Anything that reduces immune competency may become a cofactor. Many persons who are infected try to find ways to strengthen the immune system. These attempts may include meditation, exercise, herbs, dietary supplements, prayer, and support groups. Whether these have any long-lasting ameliorative effects is uncertain, but they may give the person a greater sense of self-maintenance and control over a devastating illness.

2. *Issues of Testing for HIV and Stages of the Infection*

When HIV infection was first recognized in the early 1980s, it was most prevalent among young men who had sex with other men and were living in large metropolitan cities. Prevention programs and the availability of tests for the infection have significantly decreased the rate of new AIDS cases among this population. Unfortunately, the rate of new AIDS cases reported in the USA has risen dramatically among women, African American men, and Latinos. Adolescents have shown a marked increase in AIDS during the decade of the 1990s. The major routes of infection with HIV have been shown to be through fluid-exchanging sexual behavior; use of HIV-contaminated needle exchange; from mother to infant during pregnancy, delivery, or breast feeding; and through HIV-contaminated blood products passed during transfusions. The development of accurate testing procedures for the infection became important both to assist in the diagnosis of the disease and to protect the nation's blood supply.

Various means of testing for the presence of the HIV virus or its effects have been developed since the discovery of the disease. The virus can be cultured directly from the blood, but the most efficient means of diagnosis has come from detecting antibodies to the virus. Such testing can determine whether the body

has come into contact with the virus and has mounted an immune defense. However, antibody testing can produce both false positive and negative results. Most tests take two weeks to receive results, but more rapid same-day tests are available. The usual procedure is for the patient (or blood sample) to be tested first using an enzyme-linked immunosorbent assay (ELISA), which is very reactive to HIV antibodies. False negative results are uncommon using this procedure. If the ELISA test is positive, it must be repeated. False positive results are more common using this approach. If a second ELISA test is also positive, a Western Blot procedure using an immunofluorescent assay is used as confirmation. It has a high level of specificity for detecting protein antigens of the HIV virus. New testing procedures have been developed which can also test saliva and urine, which bypasses the use of a blood draw.

Though there are reasonably accurate and fast methods of testing for the HIV virus, not all people who suspect that they have been exposed to the virus seek testing, and not all who do arrange for it early in the progress of the infection. There is a variety of reasons why this is so. Some people are simply not aware of the risks of infection and the procedures of arranging for testing. Others have been properly educated but, because of fear, denial, shame and concern about loss of privacy and public exposure, avoid learning if they have been infected.

Often when a person has received a reliable diagnosis of HIV infection, they experience a variety of negative psychological symptoms. They can become anxious, are often depressed, may feel guilt about their past behavior, and are worried about physical deterioration and eventual death. If they have observed friends experience the progress of the disease, they may have frightening images of what may happen to them. Suicidal thoughts are often present immediately after a diagnosis is made and the patient becomes exquisitely sensitive to any physical symptoms.

It is vital that such persons receive comprehensive, sensitive, and accurate medical and psychological counseling upon receiving news of a positive test. Many persons at this point in the illness feel isolated, shamed, and unable to talk about their fears and questions. Since the onset of the epidemic, many outstanding clinical and community programs providing vital information and emotional support have been established. Since significant advances in therapies have been developed, with a marked increase in survival rates, early detection and humane medical and psychological interventions is essential for all.

3. *The Clinical and Immunological Progression of the Illness*

The finding of a positive antibody test for HIV does not predict an inevitable disease course for all people. Some people exhibit only mild symptoms initially and then remain totally asymptomatic throughout their lifetime. Others demonstrate severe symptoms shortly after the virus is detected and others show no sign of illness for eight to ten years after being diagnosed as positive. HIV/AIDS is a disease of uncertain symptoms, long quiescent periods for many, and often a devastating end state.

There are many reasons to explain this variability. Some may have a genetic resistance to the virus, a robust (innate and adaptive) immune system and have been exposed to a less virulent strain of the virus. For others, diagnosis may occur long after they were exposed to the virus and their immune system may be severely compromised.

People told that they may develop AIDS face many uncertainties, complex medical and lifestyle decisions, and the need to adapt to changing medical conditions throughout their life. These decisions involve trusting communications with health care workers, friends and family, social support systems, and work associates. For some, the complexity of these decisions may prove overwhelming and they may make many poor health and lifestyle decisions. For others, the illness may reactivate old psychiatric problems or create new neuropsychological symptoms. Indeed, one of the most provocative complications of the disease is the emergence of cognitive disabilities for the patient.
