New York is tropical. This question is often seen (e.g., Fodor 1981) as having two parts: (i) what is it to have a belief? (ii) what is it to have a belief that expresses a particular proposition? The most widely accepted answer to the first question is that a belief is a functional state, i.e., it has a certain causal role. One approach to answering the second question is that a belief expresses the proposition that p in virtue of involving a *representation* whose content is that of the intentional state. So to believe that New York is tropical is to be in a functional state (believing) that involves a representation that has the intentional content *that New York is tropical*. This provides a nice explanation of why beliefs are truth evaluable, are about things, can be involved in inferences, etc. It is because these are features of the representations that they contain. The view that the mind contains representations is usually called 'the representational theory of mind' or RTM. It should be cautioned that RTM is restricted to *explicit* beliefs. Implicit beliefs (e.g., your belief you had prior to reading this sentence that no giraffe is bigger than the empire state building) are dispositions to form explicit beliefs under suitable circumstances. This account of propositional attitudes is the beginning of an account of how mental states can have intentional content. It has its dissenters. Some philosophers (Dennett 1981) suggest that there may be no internal representations with the same content as that clause we use in attributing a belief, but it is still appropriate to attribute the belief because of the person's behavioral (including linguistic behavior) dispositions that themselves may involve states that represent at the subpersonal level.

(e) What is the nature of mental representations? Cognitive science is up to its neck (and beyond) in representations. Some representations are involved in propositional attitudes, others in relatively high-level unconscious cognitive systems like the language faculty, and others lower level systems that may implement the higher level systems. There are various views about the nature of these representations. One widely held view (Fodor 1975) is that most mental representations, at least those involved in propositional attitudes, belong to an internal language of thought, 'mentalese.' Mentalese contains basic expressions—predicates, names, connectives, etc. and rules of combination. The rules allow for the construction of a potential infinity of complex expressions from a finite basic vocabulary. There are important differences between a natural language like English and mentalese. The most important difference (as will be further discussed in item (g)) is that mentalese syntax is logical form. Whereas English can be used for communication, mentalese is used for thinking. Understanding a natural language can be accounted for in terms of processes that 'translate' natural language into mentalese. But understanding mentalese cannot be understood in the same way on the pain of regress. Rather mentalese is not literally 'understood' but rather is the language in which thinking and other mental processes take place. Whereas natural languages must be learned, many proponents of mentalese think that in some sense it is innate.

(f) What is thinking? Perception and rational thinking involve mental states that are semantically related. For example, a person sees Macguire swing at a ball and the ball go over the centerfield fence. He thinks that it is a home run number 62 and then that Macguire has broken Maris' home run record. On the representational theory of mind the process running from the visual perception to the thought that the home run record has been broken consists of many representations, e.g., a visual representation of shapes and colors, a perception that the ball is going over the fence, etc. These are not arbitrarily related but are related to each other by virtue of their *semantic* features. These semantic features involve relations to things external to the mind, e.g., to Macguire, the property of being a home run, and so on. How does the mind 'know' to go from a representation, which refers one thing to a representation that refers to a related thing if it has access only to the representations and not to their references? A closely related question is how can the mind engage in reasoning, which leads it from some true representations (say about light striking the retinas) to other true representations (say about the scene in front of the eyes). The computational theory of mind suggests answers to this question. It says that mental processes like thinking and perceiving are *computations* on mental representations. A computer is a device which is able to follow a program for manipulating representations on the basis of their syntax. So any relation which can be reduced to or encoded in syntactical relations can, in principle, be computed. Logical relations, e.g. logical implication, can be reduced to syntactical relations of sentences whose syntactic forms are logical forms (as is the case for Mentalese) computation can then account for logical inference. By encoding semantic features in syntax the computer can manipulate representations in ways that respect their semantics. Researchers in computer science have shown how many tasks that apparently require intelligence can be educed to computations.

According to the computational theory of mind (CTM), the mind is a computer and mental processes consist of computations on Mentalese representations. In this way the mind is able to manipulate representations that are semantically related. Of course there is a big difference between a computer and a mind. The computer is programmed by a human programmer who supplies interpretations for the symbols it manipulates. If the CTM is correct the mind that programs what the mind implements is a product of the structure of the brain and that, presumably, is at least partly dependent on evolution. The interpretation of the symbols that the mind manipulates is not provided by a programmer. Exactly what determines the semantic

features of mental representations is discussed in item (i).

Not every cognitive scientist is impressed by CTM as an account of mental processes. Some go along with the idea that mental processes involve a kind of computation but conceive of computation very differently from the TM account. They suggest that the mind has a connectionist *architecture*. I discuss this view in the next section. The most famous philosophical objection to CTM is due to John Searle (1980). Suppose that understanding a language, e.g. Chinese, involves following a program. Searle argues that this cannot be correct since it is possible for a person who knows no Chinese but is able to follow program instructions just like a computer implements the program. The program is written so that questions in Chinese are input and answers in Chinese are output. Searle observes that although the man implements the program he clearly has no clue as to the meanings of the Chinese symbols. There have been many replies to this objection. Perhaps the most convincing from proponents of CTM is that implementing a program is necessary but not sufficient for language understanding. The language must also be translated into the person's Mentalese. Of course this still leaves open the question of what it is for a symbol of Mentalese to represent, which will be discussed in item (i).

A different worry about CTM is whether it can account for certain kinds of reasoning, specifically inductive inference. Inductive reasoning involves considering various hypotheses and coming up with the one that is best supported by the evidence. We employ it in producing explanations, identifying causes, and so forth. For example, Sherlock Holmes solved a case when he realized that the fact that no dog barked was evidence that the murderer was known to the dogs. The worry, which is sometimes called 'the frame problem' (Pylyshyn 1987), is that no computational program can realistically perform this kind of task. In inductive reasoning almost any bit of information may be relevant. We seem to have the ability to survey a great deal of what we know and come up with what is evidentially relevant. But a program that operated by having to survey a vast number of representations evaluating them for relevance would seem to be completely impractical. There are too many computations to be performed. One response to this is to think that CTM may provide good accounts of the information processing that occurs in mental modules but that it is not very good at accounting for the mental capacities of a general reasoner. Thus those who like CTM are attracted to the view that the mind is massively modular.

(g) Classical or connectionist architecture? In the classical account of computation discussed in item (f), the architecture of the mind is that of a classical computer (or system of such computers) and mental processes are operations on linguistic-like representations by virtue of their syntactic forms. There is an alternative account of cognitive structure and computation that has been developed called 'connectionist architecture.' Roughly, a connectionist system consists of a network of *nodes* joined together in a pattern of connections. Each node can be activated (or activated to a certain degree) and can receive signals and send signals to certain connected nodes. Whether or not a signal travels via a connection from node A to node N depends on the weight of the connection. Some nodes are activated by external stimuli (input nodes) and others send signals outside the network. At any time the state of the network is determined by the weights of the connections and the activation of the nodes. Signals that activate the input nodes are propagated throughout the system to the output nodes. Thus connectionist systems can be thought of as computing certain outputs given certain inputs. Further, the connectionist network can be 'trained' by altering the connection weights depending on whether or not a given output is 'appropriate' for a given input. Connectionist networks have been constructed that do a number of tasks e.g. recognize letters of the alphabet, 'read' text, recognize faces, and so forth by such training.

Connectionist cognitive architecture is apparently quite different from a classical computer. There is no 'executive' that is following a program. Computations are not performed on sentences but on the totality of connections among nodes. Although the state of a connectionist system can be thought of as a representation—say as representing that the cat is on the mat—unlike sentences of mentalese it needn't contain any parts that correspond to 'the cat,' 'is on,' and 'the mat.' Proponents of connectionism think that it provides a model of mental states and processes that is more plausible than classical accounts. One reason is that some find it difficult to believe in mentalese. Another is that it seems natural for connectionist systems to implement vague concepts since a connectionist system can be trained to respond in a graded manner. The holism of connectionist representation is also appealing to some and there are suggestions that its holistic features may help with the frame problem mentioned in item (f). Finally, connectionist networks are reminiscent of assemblies of neurons and so strike some as biologically realistic. Proponents of classicism point out that connectionism is more than reminiscent of behaviorism. Like behaviorism it is an *associacionist* psychology that construes mental processes in terms of establishing and modifying associations. Although it is in a sense holistic it is far from clear how that will help accounting for inductive inference. In fact critics of connectionism set up a dilemma (Fodor and Pylyshyn 1988, Fodor and McLaughlin 1990): either the connectionist architecture implements a classical architecture, in which case it is not really an alternative to classicism, or it fails to account for essential features of thought. These features are *productivity* and *syst-*

ematicity. Productivity involves the fact that once a thinker has basic concepts she is able to produce a potential infinity of novel thoughts involving those concepts. Systematicity is the feature that any thinker who can think a thought can think related thoughts that apparently have the same components. For example, if one can think Jack loves Jill then one can also think Jill loves Jack. These features are easily accounted for by classicism since the thoughts correspond to syntactically structured representations. But a connectionist system can be capable of being in a state that represents that Jack loves Jill without being capable of being in a state that represent Jill loves Jack since it need not have parts that correspond to *Jack*, *loves*, *Jill*. If the connectionist system does have such parts then it is merely implementing a classical system.

(h) What are concepts? The *concept* plays an important role in the cognitive sciences. Thoughts (beliefs, memories, desires, etc.) are composed of concepts and so what mental processes a thinker can engage in depends on what concepts she possesses. Developmental psychology is interested in how people acquire concepts and whether some concepts are innate. There are various views about the nature of concepts. Advocates of RTM think of concept tokens as representations but there is a wide diversity of views on what makes a particular representation a particular concept, say the concept *horse*. One view is that a concept is something like a definition. For example, the concept *horse* may be the definition *is a large land mammal that has been domesticated for riding*. To possess the concept *horse* is to know the definition. This view has come under much deserved criticism. One problem is that not all concepts can have definitions without circularity. More serious even is that most words (and the concepts they are associated with) do not seem to have definitions at all. There are horses that are not large and large animals that have been domesticated for riding (e.g., elephants) that are not horses. Another view is that concepts are prototypes. A prototype consists of a core exemplar—a representation of something that is a paradigm example of the concept—and then a similarity metric that determines how close something is to the paradigm. For example, the concept *bird* consists of the representation *robin* and a metric that makes eagles pretty good birds and penguins pretty bad ones. But while there is evidence that thinkers do judge instances of a concept as better or worse examples, the account faces some of the same difficulties faced by the definition account. A somewhat more general approach considers the inferences that a thinker is disposed to make concerning thoughts containing a concept as individuating the concept. Such 'conceptual role' theories of concepts face a dilemma. Either all of the inferences involving the concept are individuative of it (holism) or only some are (molecularism). If the first then, as our beliefs change so do our concepts and it is unlikely that two people ever share the same concept. If the second then the question arises of what makes some inferences concept constituting. There are arguments in the philosophical literature (Quine 1960, Fodor and LePore 1992) that there is no principled distinction between the two but also some proposals (Peacocke 1992) for how to make the distinction. Finally, there is the view that concepts are expressions in mentalese that are individuated by their syntax and by their reference (Fodor 1998). This view allows for thinkers with very different beliefs to share the same concept. But it also allows for the bizarre possibility of someone possessing the concept horse while believing that horses are edible fruits.

Cognitive theories that posit innate knowledge are also committed to the innateness of the concepts that constitute the knowledge. Some cognitive scientists go much further and claim that many of our concepts are innate. One reason for this is the difficulty in accounting for how concepts can be learned. As Fodor (1980) observed, they cannot be learned by testing various hypotheses about them since the formulation of the hypotheses already requires possessing the concept. At one time Fodor thought that this line of argument showed that even the concept *carburetor* is innate. Fodor has since moderated his view but there is no consensus concerning how concepts are acquired.

(i) How does the mind represent the world? What makes a component of a mental state a representation is that it possesses semantic properties, e.g., it refers, has truth-value, and so on. But what exactly determines that a given representation possesses a certain semantic property. The Cartesian tradition generally thought that intentionality is a distinct and basic feature of mental substance. But most philosophers of cognitive science who think that there are mental representations think that whatever determines semantic features has to be within the realm of natural science. On the view that was once widely held in philosophy that concepts are images the answer to this question is that resemblance makes for representation. But even cognitive scientists who posit mental images do not think that these literally resemble their references. The two views that are currently most widely advocated are *informational semantics* and *teleological semantics* or some combination of the two Millikan 1984, Fodor 1987, 1990, Loewer 1998). Simplified informational semantics says that the fact that a certain state carries certain information under certain circumstances or is reliably caused by certain properties under certain circumstances determines its semantic properties. *Teleological semantics* says that semantic properties of a representation are determined by its biological function. A simplified combined view is that the function of carrying certain information under certain circumstances determines representations of semantic properties. For example, it is not implausible that there is a certain system of a frog's brain with the function of being in a particular state R

if and only if a fly is nearby when the circumstances are normal (e.g., in a pond, good light, etc.). If the circumstances are normal then an occurrence of R in the frog's brain carries the information (to other parts of the frog's brain) that a fly is present. This kind of account fits very nicely with the view that the mind is a kind of information processor. But whether it can be developed so as to provide a plausible account of the semantics of the mental representations involved in human thought is a big and very open question.

Cognitive Styles and Learning Styles

1. Style Differences in Cognition and Learning

The chorus line of a popular song once claimed that … *it's not what you do but the way that you do it*. This idea—making the *how* as important as the *what*—is intriguing. Furthermore, as the song insists, the character of an individual is invariably woven into how a task is completed. This can be seen in any number of human endeavors, for example, sport, art, handwriting, thinking, learning, even conversation.

In any performance then, a sense of person, as well as context, combines to produce a typical pattern, hallmark, leit-motif, signature, or style. The very same idea underlies the suggestion that individuals possess a personal way of thinking (cognitive style) or learning (learning style). The following discussion will introduce the construct of style differences in cognition and learning and consider its significance for lifelong learning in both the world of education and workplace.

2. *The Style Construct in Psychology*

The term *construct* refers to a psychological idea or notion. Examples of constructs are intelligence, personality, or self-concept. A *style construct* appears in a number of academic disciplines—in psychology it has been used in a number of different areas such as personality, cognition, communication, motivation, perception, learning, and behavior.

The theory of style, unfortunately, has been characterized by a tendency for researchers to (a) work in isolation; (b) develop their own instruments for the assessment of style; and (c) the creation of independent style labels with little reference to the field. A widespread use of the term 'style' has led to a number of different definitions and terminology. Consequently, those interested in validity or verifiability, and an accepted nomenclature for a theory of style, have faced considerable difficulty. The idea of style in educational psychology, nonetheless, is recognized as a key construct of individual differences in human performance.

3. *Cognitive Styles*

While Allport (1937), in work which developed the idea of 'lifestyles,' was probably the first researcher to deliberately use the 'style' construct in association with cognition, the following key areas of psychology contributed to an emerging field of cognitive style.

3.1 *Perception*

Experimental work—reflecting an emphasis on the 'regularities' of information-processing which were derived from the German gestalt school of perceptual psychology—led to an early development of the 'style construct' of field dependence–independence (Witkin et al. 1971).

Individuals were found to rely upon the surrounding 'field' or 'context' to a greater or lesser extent, when reorienting an object relative to the vertical. This was subsequently found to correlate with competence in disembedding shapes from a field and experimental participants were found to either rely heavily on the field for orientation or shape discrimination (field-dependent) or little or not at all (field-independent).

3.2 *Cognitive Controls and Cognitive Processes*

A second significant influence in the development of cognitive style was the study of cognitive processes related to individual adaptation to the environment, exemplified by the work of Gardner and co-workers at the Messinger Clinic in the USA. This work was shaped, originally, by psychoanalytic theories of ego psychology—which was typified by studies focusing upon variables in ego adaptation to the environment.

This led to the identification of several cognitive processes including perceptual attitudes, cognitive attitudes, and cognitive controls. Further work related to this area led to several stylistic labels and models, supporting the general notion of a cognitive style (see Messick 1976).

3.3 *Mental Imagery*

A third key influence in the development of cognitive style reflected work looking at mental representation. Early in the scientific study of psychology, attention was given to the notion that some people have a predominantly verbal way of representing information in thought, while others are more visual or imaginal. Paivio (1971) further developed this notion with a dual coding measurement of mental imagery. Riding and Taylor (1976) identified, as fundamental to the construct of cognitive style, the verbal-imagery dimension of cognitive style.

3.4 *Personality Constructs*

A fourth and separate influence on the field of cognitive style involved researchers utilizing personality-based constructs to develop a model of learning style (Myers 1978). The most influential model was the Myers–Briggs Type Indicator, developed from Jung's typology of personality constructs and 'psychoanalytic ego psychology' (Jung 1923). It offered an alternative model of cognitive style in contrast to those flowing from cognitive psychology.

4. *The Further Development of Cognitive Styles*

A contemporary resurgence of interest in style differences over the last three decades has resulted in three distinct developments, all involving the generation of new models of cognitive style or learning styles.

The first development involved researchers independently constructing new models of individual difference in various aspects of cognitive functioning. This approach tended to conceptualize styles as the discovery of new psychological phenomena, for example, styles of thinking, intuition, creativity, decision-making, and motivation.

Examples of some of this work generating additional labels of cognitive style include a model of perceptual style (Gregorc 1982); the Adaptor–Innovator cognitive style of decision-making (Kirton 1994); and the Assimilator–Explorer cognitive style of creativity (Kaufmann 1989). Another more elaborate model of mental self-government presented by Sternberg (1996, 1997) represented a theory of style derived from notions of government. According to this theory, people can be understood in terms of mental government, that is, processes of function, form, level, scope, and learning, which impact upon thinking and learning.

The second development reflected work aimed at a synthesis of theory and a consensus in the understanding of cognitive style. This approach was characterized by a focus upon the construct validity of cognitive style and its application. The work of Curry (1987) and Rayner and Riding (1997), for example, both attempted to synthesize or integrate existing theory of cognitive and learning styles.

The work of Riding over 20 years involved a reclassification of cognitive style models (see Riding and Rayner 1998). The structure of cognitive style was defined as two-dimensional, comprising the Wholist–Analytic style dimension, relating principally to cognitive organization and the Verbal–Imagery style dimension, relating principally to mental representation.

An individual's cognitive style was defined as a person's tendency to process information wholistically or analytically, that is, either as a whole piece or piecemeal, while at the same time mentally representing information using imagery or language. While each dimension was thought to be independent, they were conceptualized as continua and it was not suggested that an individual could only use one or the other way of thinking.

The further development of a computer-based assessment for cognitive style analysis (CSA) by Riding reflected a deliberate attempt to integrate both the Wholist–Analytic and Verbal–Imagery dimensions of cognitive style (see Riding 1991). An extensive number of empirical studies over a number of years were conducted using the CSA at the University of Birmingham and provided evidence to support this model of cognitive style (see Riding and Rayner 1998).

5. *Learning Styles*

A third more widespread development in contemporary work on style differences in cognition and learning led to the generation of yet more labels, which were described as models of learning styles. This learning-centered tradition of 'style' is arguably distinguished by four major features:

(a) the intention of developing new concepts of learning to reduce reliance upon tests of intelligence or ability;

(b) a focus on the learning process and achievement;

(c) a primary interest in the effect of individual differences upon pedagogy;

(d) a parallel construction of new assessment instruments and models of learning style.

The primary concern for educationists working within this learning-centered tradition lay with the process of learning and its context. It focused on individual differences in the process of learning rather than within the individual learner. Models of learning styles in this tradition included the following four groups.

5.1 *Models Focusing on the Learning Process—Based on Experiential Learning*

These derived from a theory of experiential learning, and the most influential example was the work of Kolb (1976), who described learning style as the individual's preferred method for assimilating information, in an active learning cycle. Kolb constructed a two-dimensional model comprising perception (concrete/abstract thinking) and processing (active/reflective information processing) as fundamental aspects of an experiential learning cycle.

5.2 *Models Focusing on the Learning Process—Based on Orientation to Study*

These derived from a theory of information processing and learning processes, and the most influential example was developed by Entwistle called the 'Approaches to Study Inventory.' Entwistle (1981) found that approaches to study often reflected either a surface or deep engagement with the study task. This was later extended to include four key orientations to study: meaning, reproducing, achieving, and holistic. The model was further refined as an integrated conception of the learning process, which described a series of actions linked to specific learning strategies identified in his original model.

5.3 *Models Focusing on Instructional-preference*

These set out to measure a range of environmental or instructional factors affecting an individual's learning behavior. A leading example of this type was the Learning Styles Inventory (LSI) developed by Dunn et al. (1989). The learning style elements identified in the LSI were: *environmental stimulus* (light, temperature); *emotional stimulus* (persistence, motivation); *sociological stimulus* (peers, adults); *physical stimulus* (perceptual strengths, time of day—morning vs. afternoon); and *psychological stimulus* (global/analytic, impulsive/reflective).

5.4 Models Focusing on Cognitive Skills, and Learning Strategy Development

The fourth group of learning style labels focused on an individual's developing cognitive ability and repertoire of cognitive skills or ability to learn, together with related behavioral characteristics, which were understood to comprise an individual's learning profile. Learning style was typically perceived as a multimodal construct and understood to describe a range of intellectual functioning relating to the learning activity.

An example of this type of model was the Learning Styles Profile developed by the North American Association of Secondary School Principals (Keefe 1988). This style construct described 24 key elements in learning style, grouped into three categories: cognitive skills—relating to aspects of information processing; perceptual responses—encompassing perceptual responses to data; study and instructional preference—referring to motivational and environmental elements affecting learning preferences.

6. Cognitive Style or Learning Styles

The models in the learning-centered tradition shared several limitations. First, they reflected a construct that by definition was not stable—it was grounded in process and therefore susceptible to rapid change. Second, they did not describe a developmental rationale for the concept of learning style nor easily correspond to other models of assessment, thereby suggesting a problem for conceptual validity. Third, they attracted peer criticism for lacking psychometric rigor and a systematically developed theory supported by empirical evidence (see Grigerenko and Sternberg 1995).

The learning-centered tradition, however, reflected a continuing need for a theory of individual differences which could be applied to the learning context. It also reinforced previous work in the area of cognitive style and pointed to the potential for profiling the personal learning style of an individual (see Rayner 2000).

7. Implications of Style for Lifelong Learning

At the 1997 Seventh International Conference on Thinking, Howard Gardner argued that in the not too distant future people will look back to the end of this millennium, and laugh at the 'uniform school.' They will be greatly amused, he suggested, by the idea that educationists actually believed they could teach the same things to all children at the same time and in the same way. To believe that the *uniform school* can provide efficient or effective education, he concluded, was to endorse educational failure!

The extent to which an awareness of learning style or the self as a learner is currently considered and managed within the educational context raises key questions for the design of instruction and pedagogy, including a consideration of:

(a) assessment-based learning;
(b) differentiation in the curriculum;
(c) learning method routines;
(d) professional development.

Each of these approaches, if adopted with an eye to considering the benefit of a pedagogy which is style-friendly, encourages interactive learning, builds upon the principles of individual difference, and adopts the idea of developing a learning expertise within the learner, will provide a foundation for lifelong learning (see Rayner 2000).

Implicit in all of this work, and equally relevant to the classroom as to the workplace, is the notion of the *matching hypothesis*. The full value and significance to the professional of cognitive and learning styles rest ultimately with the belief that if it is possible to make a better match between person and environment, then performance will improve and achievement will be enhanced. Moreover, formal education might be made more effective by matching style to materials, to presentation, mode and structure, through nurturing strategy development to maximize style effectiveness.

The delivery of a curriculum, albeit for schooling or workplace training, will improve with an increasing depth of differentiation and a match between individual differences with targeted learning or activity. Such an approach will build upon personal strengths, sow seeds of success, and reap the benefits of learning enhancement.

The final word in offering an overview of style differences in thinking, learning, and behavior is left to Sternberg (1996, p. 363). He succinctly stated that in the world of learning and education, '*styles matter*'! This view mirrors that of many workers in the field who remain interested in knowing more about those individual differences which affect human performance.

Cognitive Theory: ACT

ACT is a theory of human cognition that posits particular ways of representing knowledge and the mechanisms by which such knowledge is acquired and used (Anderson 1983, 1993, Anderson and Lebiere 1998). The theory is implemented as a computer simulation system that generates the theory's predictions, thereby facilitating quantitative comparisons with experimental data.

1. *What's in a Name?*

The etymology of the acronym ACT is the subject of some debate. The original definition, Adaptive Control of Thought, has not been consistently used, and several books written about the theory suggest alternative candidates, e.g., *The Adaptive Character of Thought* (Anderson 1990) and *The Atomic Components of Thought* (Anderson and Lebiere 1998). However, these publications postdate ACT's modest beginnings by more than a decade, making the simpler moniker A Cognitive Theory seem the most parsimonious answer.

2. *Architectures and Models*

Among computational systems designed to model cognition, there is a critical distinction between a cognitive *architecture* and a cognitive *model* built within an architecture. A cognitive architecture defines a specific way of representing knowledge and a fixed set of mechanisms for processing knowledge. A cognitive model, on the other hand, specifies the knowledge that is required to perform a particular task. Any one architecture supports a wide variety of models, all of which use the same mechanisms to capture behavior in different tasks, just as the brain presumably employs a common set of mechanisms across a variety of tasks.

The ACT theory is a cognitive architecture. It provides mechanisms for the retrieval and learning of facts (declarative knowledge) and the selection, application, and learning of skills (procedural knowledge). All cognitive models built within ACT share these mechanisms; what differs across ACT models is the task-specific knowledge (i.e., the facts and skills themselves) input to the system. ACT models have successfully fit behavioral data across a wide variety of tasks, including arithmetic, navigation, categorization, and game playing (see Table 1). The success of these ACT models across such varied domains provides support not only for the models themselves but for the explanatory power of the ACT architecture.

This article focuses on the current version of the ACT theory, called ACT-R (Anderson and Lebiere 1998). Nevertheless, a historical sketch of the theory's evolution and how it relates to contemporary research are presented as well as a brief discussion of future research issues.

3. *Basic Features of the Theory*

The four main tenets of the ACT theory are as follows:

(a) the ability to perform a complex task can be decomposed into separate pieces of knowledge;

(b) these pieces of knowledge are learned through experience, i.e., using a piece of knowledge is akin to practice;

(c) at any given time, the current focus of attention (also called the goal) influences what knowledge is used; and

(d) there are two types of knowledge, *declarative* (for facts) and *procedural* (for skills), that have distinct representations and learning mechanisms.

Table 1
A list of tasks and phenomena modeled with the ACT theory

1	Visual search including menu search
2	Subitizing
3	Dual tasking including Psychological Refractory Period (PRP)
4	Similarity judgments
5	Category learning
6	List learning experiments
7	Paired-associate learning
8	The fan effect
9	Individual differences in working memory
10	Cognitive arithmetic
11	Implicit learning (e.g., sequence learning)
12	Probability matching experiments
13	Hierarchical problem solving tasks
14	Strategy selection
15	Analogical problem solving
16	Dynamic problem solving tasks including military command and control
17	Learning of mathematical skills including interacting with Intelligent Tutoring Systems (ITSs)
18	Development of expertise
19	Scientific experimentation
20	Game playing
21	Metaphor comprehension
22	Learning of syntactic cues
23	Syntactic complexity effects and ambiguity effects
24	Dyad communication

Declarative knowledge is represented as nodes in an associative network. The more activated a given node, the more easily the corresponding fact can be accessed. Each node has an associated base-level activation B that increases each time the fact corresponding to that node is accessed (learning) and decays with time (forgetting) according to the equation

$$B = \ln\left(\sum_j (t - t_j)^{-d}\right) \tag{1}$$

where t is the current time, t_j is the time of the jth use of the node, and d is a global decay rate. The quantity B offers a summary description of a node's past history of use and hence a reasonable estimate of its likelihood to be needed in the future.

Each link between two nodes in the network has a continuous-valued quantity S that measures the strength of association between those two nodes. The current focus of attention works by selecting a subset of nodes in the network to be attended. Each attended node gets a share of a limited amount of attentional activation W. (Because attentional activation is limited, the more nodes in the focus, the less attentional activation for each.) This activation then propagates from each attended node to related nodes in the network in proportion to the corresponding link strengths. This attentional activation produces context effects because only those nodes related to the current focus of attention receive extra activation.

The *total* activation at node i is the sum of its base-level activation B_i and the attentional activation it receives from nodes in the focus of attention:

$$A_i = B_i + \sum_j W_j S_{ji} \tag{2}$$

where the sum is over attended nodes j. Retrieval of facts is determined by the total activation of the corresponding nodes. Specifically, the node that is retrieved is the one whose total activation plus some added noise is highest, given that this sum is above a global threshold. This added noise represents stochasticity in the system. The time it takes to recall this node decreases exponentially as a function of its (noisy) activation which, combined with Eqn. (1), produces a power-law speedup with practice (see *Learning Curve, The*).

Procedural knowledge is represented by a set of condition–action pairs called production rules (e.g., IF the goal is to add two numbers a and b, and the fact that c is the sum of a and b can be recalled, THEN say c is the answer). Each production has several associated quantities that reflect how useful it has been in past applications. These quantities are learned by experience and used to compute an estimate of the expected gain from applying each rule. For example, the cost associated with a particular production rule is the weighted average of the rule's past costs of application (measured in units of time) and a prior estimate of cost. When several rules are candidates at the same time, the one whose expected gain plus some added noise is highest gets selected. In this way, production rules that have been more useful (i.e., more successful and less costly) in the past are more likely to be selected. In addition, each piece of procedural knowledge is strengthened with each application, and that strength decays with time. A production rule's speed of application increases exponentially with strength.

The ACT theory also posits more complicated mechanisms by which production rules and declarative nodes are initially created. In both cases, the goal plays an important role in the form that new knowledge takes. These separate mechanisms highlight ACT's distinction between acquiring new pieces of knowledge and refining the continuous quantities associated with each piece of knowledge. Moreover, these two modes of knowledge representation—symbolic (nodes, production rules) and sub-symbolic (activations, costs, strengths)—make ACT a *hybrid* system. This

distinguishes it from wholly symbolic (e.g., Soar) and wholly sub-symbolic (e.g., connectionist) systems.

4. Historical Development

ACT has been under development since the 1970s. It began as a theory of semantic memory and now encompasses learning, memory, problem solving, attention, perception, and action. The following provides a brief sketch of its development and places each version of the theory in its historical context. Until the 1970s, mathematical models were the typical formalism used to describe and predict cognitive psychological phenomena. A disadvantage of mathematical models, however, is that they are limited in the complexity of processes they can describe. Thus, to provide a mechanistic account of complex cognitive processes, computational models began to be developed. The first well-defined version of the ACT theory, called ACTE (Anderson 1976), was one such model. It introduced the distinction between declarative (i.e., factual) and procedural (i.e., skill-based) memory and the notion of declarative activation.

By the 1980s, however, some researchers were questioning whether the development of computational models (and the theories they implemented) was sufficiently constrained to produce reasonable models of the 'true' underlying representations and processes (e.g., Anderson 1978, Newell 1973). One approach that reduces this problem involves developing models within a cognitive architecture, where a fixed set of representations and mechansims are used to test a variety of models. That is, models are constrained to work within the strictures of the architecture. The next version of the ACT theory, ACT* (Anderson 1983) was a cognitive architecture, like others developed around this time (see also *Cognitive Theory: SOAR*; Newell 1990). ACT* extended its predecessor by specifying an activation calculus for declarative knowledge and a new mechanism for acquiring procedural knowledge.

Besides using ACT* to model a variety of task domains—from language processing to paired-associate learning—this version of the theory was applied to the practical problem of improving computer-aided instruction. So-called 'intelligent' tutoring systems were built based on ACT* cognitive models of algebra problem solving, geometry theorem proving, and computer programming (e.g., Anderson et al. 1989, 1990). Because these models could solve the required problems in each domain, they enabled the corresponding tutoring systems to follow students' problem-solving, give feedback when students made a mistake, and offer hints when students were confused. Moreover, because these systems tracked the steps students were taking and hence the knowledge they were using, specific predictions of the theory could be generated and tested in this scaled-up, real-world learning context.

The latest incarnation of the ACT theory, ACT-R (Anderson 1993, Anderson and Lebiere 1998), was developed in the 1990s, inspired by a rational analysis of cognition (Anderson 1990). Among other things, ACT-R includes a refined activation calculus and a more plausible mechanism for acquiring procedural knowledge. These changes were designed to reflect the way human cognition adapts to the structure of the environment. In addition, ACT-R has been put to the toughest challenges in testing its fidelity to empirical data: ACT-R models have been able to fit fine-grained, multivariate data simultaneously across several experiments (e.g., Anderson and Matessa 1997), and they have captured patterns of performance in individual subjects across tasks (e.g., Lovett et al. 2000).

In sum, the ACT theory has evolved into its current form by virtue of the guiding force of several kinds of constraints. Throughout ACT's development, experimental data have been used to test the veridicality of the theory. In some cases, this empirical constraint has invoked a reevaluation of some aspect of the theory (e.g., single-trial learning of production rules). More generally, even when the theory's predictions have been met, refinements were made so that more detailed, fine-grained datasets could be modeled. Besides these empirical constraints on the theory there are theoretical constraints imposed top-down from the architectural status of ACT's claims. That is, an ACT model may need to be designed in a certain way so that the knowledge it specifies is sufficient to perform the given task when ACT mechanisms are applied. Finally, based on the rational analysis of cognition (Anderson 1990), constraints have been imposed on the theory so that it includes the kind of processing that is necessary and sufficient to meet the demands of the environment.

5. Future Issues

The ACT theory is still under active development. An extension has been added (called ACT-R/PM, Byrne and Anderson 1998) that incorporates perception and motor modules (e.g., eyes, ears, and hands). This extension enables the system to model interaction with the environment. In addition, ACT models have been developed for a variety of new domains, including complex, dynamic tasks such as air-traffic control. In some cases, the data sets being modeled even include eye-movement protocols. Yet another area of development involves exploring the relationship between the algorithmic level of description of the ACT-R computer simulation system (cf. Marr 1982) and a corresponding neural level implementation.

Cognitive Theory: SOAR

SOAR is a computational theory of human cognition that takes the form of a general cognitive architecture (Laird et al. 1987, Newell 1990, Rosenbloom et al. 1992). SOAR (not an acronym) is a major exemplar of the architectural approach to cognition, which attempts the unification of a range of cognitive phenomena with a single set of mechanisms, and addresses a number of significant methodological and theoretical issues common to all computational cognitive theories (Anderson and Lebiere 1998, Newell 1990, Pylyshyn 1984). SOAR is also characterized by a set of specific theoretical commitments shaped primarily by attempting to satisfy the functional requirements for supporting human-level intelligence, manifest in soar's parallel existence as a state-of-the art artificial intelligence system (Laird et al. 1987). This focus on functionality, and its attendant theoretical commitments, is what makes soar both distinctive and controversial in cognitive psychology. SOAR represents the last major work of Allen Newell, one of the founders of modern cognitive science and artificial intelligence, and a pioneer in the development of architectures as a class of cognitive theory.

1. *Multiple Constraints on Mind and Computational Theories of Cognition*

Newell (1980a, 1990) described the human mind as a solution to a set of functional constraints (e.g., exhibit adaptive (goal-oriented) behavior, use language, operate with a body of many degrees of freedom) and a set of constraints on construction (a neural system, grown by embryological processes, arising through evolution). The structure of SOAR is shaped primarily by three of the functional constraints: (a) exhibiting flexible, goal-driven behavior, (b) learning continuously from experience, and (c) exhibiting real-time cognition (elementary cognitive behavior must be evident within about a second).

The emergence of computational models of cognition in information processing psychology (and artificial intelligence) represented a significant theoretical advance by providing the first proposals for physical systems that could, in principle, satisfy the functional constraints of exhibiting intelligence (Newell et al. 1958, Newell and Simon 1972). However, they raised a set of difficult methodological and theoretical issues that cognitive science still grapples with today. Among these issues are: (a) the problem of irrelevant specification (in a complex computer program, which of the myriad aspects of the program carry theoretical content, and which are irrelevant implementation details) (Reitman 1965); (b) the problem of too many degrees of freedom (an unconstrained computer program can be modified to fit any data pattern); and (c) the problem of identifiability (any sufficiently general proposal for processing schemes or representations can mimic the input/output characteristics of any other general processing or representation scheme (Anderson 1978, Pylyshyn 1973).

2. *SOAR as a Confluence of Five Major Technical Ideas in Cognitive Science*

SOAR can be seen as a confluence of five major technical ideas in cognitive science, which, taken together, are intended to address the three functional constraints summarized above, as well as the fundamental methodological issues concerning computational models.

2.1 *Physical Symbol Systems*

SOAR is a physical symbol system. The physical symbol system hypothesis asserts that physical symbol systems

are the only class of systems that can in principle satisfy the constraint of supporting intelligent, flexible behavior. Physical symbol systems are a reformulation of Turing universal computation (Church 1936, Turing 1936) that identifies symbol processing as a key feature of intelligent computation. The requirement is that the system be capable of manipulating and composing symbols and symbol structures—physical patterns with associated processes that give the patterns the power to denote either external entities or other internal symbol structures (Newell 1980a, 1990, Simon 1996). The key to the universality of Turing machines and physical symbol systems is their programmability: content can be added to the systems (in the form of programs) to change their behavior, yielding indefinitely many response functions.

2.2 Cognitive Architectures

SOAR is a cognitive architecture. A cognitive architecture is a theory about the fixed computational structure of cognition (Anderson and Lebiere 1998, Newell 1990, Pylyshyn 1984). Computational systems that are programmable must have some kind of fixed structure that processes the variable content: a set of primitive processes, memories, and control structures. The theoretical status of this underlying structure has not always been clear in cognitive models. For example, when a cognitive model is programmed in Lisp, the theorist intends to make some theoretical claims about the program (e.g., that the steps of the program corresponds in some way to the cognitive steps of the human performing the task), but probably intends to make no theoretical claims about Lisp as the architecture that executes the program (e.g., the fact that unused memory structure are reclaimed via a garbage collection process is theoretically irrelevant).

A cognitive architecture explicitly specifies a fixed set of processes, memories, and control structures that are capable of encoding content and executing programs. Cognitive models for specific tasks can be developed in such architectures by programming them. The theoretical status of various parts of a programmed implementation is now considerably clarified: what counts is the structure of the architecture (not its particular implementation), and the cognitive model's program, which makes a set of specific commitments about the form and content of knowledge used in a specific task. Thus, implemented cognitive architectures go a long way toward solving the irrelevant specification problem.

Cognitive architectures, especially those with temporal mappings and integrated learning mechanisms, can also address the degrees of freedom problem and identifiability problem in four ways. First, to the extent that architectures have a constrained temporal mapping, the space of possible programs that yield both the required functionality and temporal profile is considerably reduced. Second, to the extent that architectures have learning components that can acquire new knowledge (e.g., about a specific task), the form of that knowledge is no longer freely under control of the theorist. Third, to the extent that architectures are programmable (and are also constrained by a temporal mapping or learning mechanism), they permit a single set of processing assumptions to be applied to a diverse range of tasks, constraining that theory by a broader range of data. Fourth, to the extent that cognitive architectures are comprehensive and include some perceptual and motor components, they can be used to provide closed-loop models of complete tasks, so that no explanatory power need be ascribed to anything external to the model.

2.3 Production Systems

All long-term memory in SOAR is held in the form of productions (Anderson 1993, Newell 1973). Each production is a condition-action pair. The conditions form access paths and the actions form the memory contents. Productions continuously match against a declarative working memory that contains the momentary task context, and matching productions put their contents (actions) back into the working memory. Productions are the lowest level of elementary memory access available in SOAR, and Newell's (1990) temporal mapping onto human cognition places them approximately at the 10 ms level. This mapping provides strong constraints on the shape of cognitive models built in SOAR that must operate in real time.

SOAR's productions form a recognition memory. Such recognition memories have a number of features that make them attractive as models of human memory: they are associational in nature (access is via the contents of working memory); they are fine-grained and independent (which makes them a good match for continuous, incremental learning mechanisms); they are dynamic (a production system by itself defines a computationally complete system that can yield behavior; other processes are not needed to access or execute the memory structures); and they are cognitively impenetrable (their contents and structure may not be arbitrarily searched over, examined, or modified, but only accessed via automatic association). All of these properties place them in sharp contrast to memories in digital computers, which are static structures (not processes), freely addressable by location.

3. Search in Problem Spaces Supported by a Two-level Automatic/Deliberate Control Structure

SOAR achieves all cognition by search in problem spaces, and architecturally supports this by a flexible,

two-level recognize–decide–act control structure. Problem spaces are based in part on the idea that search in combinatoric spaces is the fundamental process for attainment of difficult tasks. The nature of such search is seen most easily in tasks like chess that have a well-defined set of operators and states. A search space consists of a set of (generated) representational states and operators that transition between states.

Problem spaces as realized in SOAR extend the standard notion of search in an important direction: problems spaces are taken to be the fundamental way that humans accomplish all cognitive tasks, including routine (i.e., well-practiced) tasks. SOAR is, therefore, one realization of the problem-space hypothesis (Newell 1980b), which asserts that all deliberate cognitive activity occurs in problem spaces. The key to this move lies in the role of knowledge in problem spaces: problem spaces freely admit of any amount of knowledge for guiding search, executing operators, or formulating the space initially in response to a task. Because SOAR provides a set of mechanisms (described next) that support this kind of knowledge use, behavior in SOAR spans the well-known continuum between knowledge-intensive processing (little search) and knowledge-lean processing (much search) (Newell 1990).

Supporting knowledge-driven search places strong functional demands on the architecture's control structure: at any step in the problem-solving process—selecting the next operator, generating the next state, etc.—any relevant knowledge must be brought to bear. There are two parts to the solution to this problem: the mechanisms for appropriate indexing of the knowledge, and the mechanisms for retrieving and applying the relevant knowledge during search. The indexing concerns learning, discussed below.

For retrieving and applying the knowledge during search, SOAR relies on a two-level control structure that separates the automatic access of knowledge via the productions from the deliberate level of problem solving. Each cognitive step is accomplished by a recognize–decide–act cycle. In the recognize phase, all productions that match the current state fire, producing new content in the working memory. Part of this retrieved content is about what the system should do next—the possible operators to try in the current state, the relative desirability of these operators (e.g., operator A is better than operator B), and so on. Next, in the decide phase, a fixed (domain independent) decision procedure sorts out these preferences in working memory to determine if they converge on a consistent decision. In the event that this processing clearly determines the next step, the decision procedure places in working memory an assertion about what that step should be. In the act phase, that step is taken (by additional production rule firings): the move to the next state in internal problem space search, or the release of motor intentions in external interaction. If it is not clear what to do next (e.g., several operators have been proposed, but no knowledge is evoked to prefer one option to another, or there are conflicts in the retrieved knowledge), an *impasse* has arisen, and the decision procedure records in working memory the type of the *impasse*, and sets a subgoal of resolving that *impasse*. In this way, SOAR's problem solving gives rise automatically to a cascade of subgoals whenever the knowledge delivered by the recognition memory is insufficient for the current task.

The critical feature of this control structure is its run-time, least-commitment nature: each local decision in the problem space is made at execution time by assembling whatever relevant bits of knowledge can be retrieved (by automatic match) at that moment. Decisions are not fixed in advance, and there are no architectural barriers to the kinds of knowledge that can be brought to bear on the decisions.

3.1 Continuous, Impasse-driven Learning

SOAR continuously acquires new knowledge in its long-term memory through an experience-based learning mechanism called chunking (Laird et al. 1987, Rosenbloom and Newell 1983). This mechanism generates new productions in the long-term memory by preserving the results of problem solving that occurred in response to impasses. The conditions of the new production consist of aspects of the working memory state just before the impasse, and the actions of the production consist of the new knowledge that resolved the *impasse* (e.g., an assertion that one of the proposed operators is to be preferred to the other in the current situation). Upon encountering a similar situation in the future, the production will automatically match and retrieve the knowledge that permits SOAR to avoid the *impasse*. Thus, chunking is a mechanism that converts problem solving into recognition memory, continuously moving SOAR from knowledge-lean to knowledge-rich processing.

Chunking in SOAR has two important functional properties. First, it begins to provide a solution to the knowledge-indexing problem raised earlier. The system assembles its own indices out of the contents of working memory in a way that is directly aimed at making the knowledge retrievable when it is relevant to the immediate demands of the task at hand. Second, learning permeates all aspects of cognition in SOAR. Chunking applies to all kinds of impasses, so any problem space function is open to learning improvements: problem-space formulation, operator generation, operator selection, and so on.

4. Major Architectural Implications and Specific Domains of Application

SOAR can be used as a theory in multiple ways (Newell 1990). Qualitative predictions can be drawn from SOAR

as a verbal theory, without actually running detailed computer simulations. These qualitative predictions can be both domain-general (cutting across all varieties of cognitive behavior) and domain-specific. The theory can be also be applied to specific domains by developing detailed computational models of a task; this involves programming SOAR by adding domain-specific production rules to its long-term memory, and generating behavioral traces.

4.1 Domain-independent Predictions

A principal prediction of a theory of human cognition is that humans are intelligent; the only way to clearly make that prediction is to demonstrate it operationally. SOAR makes this prediction only to the extent that the system has been demonstrated to exhibit intelligent behavior. As a state of the art AI system that has been applied to difficult tasks (ranging from algorithm design to scheduling problems), SOAR makes the prediction to a greater degree than other psychological theories.

SOAR makes a number of general predictions related to long-term memory and skill (Newell 1990). These include the prediction that procedural skill transfer is essentially by identical elements, and will usually be highly specific (Singley and Anderson 1989, Thorndike 1903); the bias of *Einstellung* will occur—the preservation of learned skill when it is no longer useful (Luchins 1942); the encoding specificity principle (Tulving 1983) holds; and recall will generally take place by a generate-and-recognize process (Kintsch 1970). The best known of SOAR's general predictions is the power law of practice, which relates the time to do a task to the number of times the task has been performed (Newell and Rosenbloom 1981, Snoddy 1926).

4.2 Domain-specific Predictions

SOAR models have been constructed across a range of task domains, and the behavior of the models has been compared with human data on those tasks. One area that has received considerable attention is human-computer interaction (HCI). Some of the successes in this area, such as a detailed model of transcription typing (John 1988), are a result of SOAR inheriting the results of the GOMS theory (Goal, Operators, Methods, and Selection rules), a theory developed in HCI to predict the time it takes expert users to do routine tasks (Card et al. 1983). (GOMS can be seen at one level as a specialization of SOAR, missing features such as learning and impassing.) Other SOAR HCI models depend crucially on SOAR's real-time interruptability (a function of the two-level control structure) and SOAR's learning mechanism. SOAR models have been developed of real-time interaction and learning in video games (John et al. 1994), novice-to-expert transitions in computer menu navigation (Howes and Young 1997), and a programmer's interaction with a text editor (Altmann and John 1999), among others.

SOAR models have also been developed of problem solving (Newell 1990), sentence processing (Lewis 2000), concept acquisition (Miller and Laird 1996), and interaction with educational microworlds (Miller et al. 1999). In all SOAR models (as with any cognitive model), the explanatory power is shared to varying degrees by both the content posited by the theorist for the particular task and the architectural mechanisms. For example, in the sentence processing model, SOAR's control structure and learning mechanism, coupled with the real-time constraint, lead directly to a theory of ambiguity resolution that yields a novel explanation of apparent modularity effects and their malleability (Lewis 1996a, Newell 1990), but the architecture provides little apparent constraint on the choice of grammatical theory, which also plays a role in the empirical predictions (Lewis 1996b). Similarly, the general theory of episodic indexing of attention events embodied in the text editor model depends critically on SOAR's continuous chunking mechanism (Altmann and John 1999), while the specific behavioral traces are a function, in part, of task strategies that could be accommodated by alternative architectures.

5. Critiques of SOAR, and Future Directions

Critiques of SOAR fall into three major classes: critiques of specific models built within SOAR, critiques of the architecture itself, and critiques of the general methodological approach of building comprehensive architectural theories. For example, specific empirical critiques have been made of SOAR models of the Sternberg memory search task (Lewandowsky 1992) and immediate reaction tasks (Cooper and Shallice 1995). The theoretical challenge is understanding the extent to which the empirical problems can be resolved within the existing architecture, or whether they point back to problems in the architecture itself (Newell 1992b). (The fact that the latter is a real possibility demonstrates that the architectural approach has made some headway on the identifiability and degrees of freedom problems.)

At the architectural level, nearly every major assumption of SOAR has been challenged in the literature (see the multiple book review in BBS for a range of assessments; Newell 1992a). Many of these architectural-level criticisms have been aimed at the *uniformity* assumptions in SOAR (all tasks as problem spaces, all long-term memory as productions, all

learning as chunking), which appear at first to run strikingly against the prevailing mode of theorizing in both cognitive psychology and cognitive neuroscience, which emphasizes functional specialization and distinctions over computational generality. The evaluation of SOAR in light of these concerns is not always transparent, however. For example, the analysis of SOAR's implications for modularity (particularly in language processing) revealed that SOAR is not only consonant with, but even predicts, many of Fodor's diagnostics of modular systems (Lewis 1996a, Newell 1990).

Finally, the general approach to cognitive theory that SOAR embraces has come under sharp criticism (most notably by Cooper and Shallice 1995) for not living up to the promise of addressing the methodological concerns identified above, and for not yielding theories with deep empirical coverage that clearly gain their explanatory power from general architectural mechanisms. To the extent that these critiques depend on practice with the SOAR theory specifically, their implications for the broader approach are insecure. Other architectural theories (e.g., ACT (Anderson and Lebiere 1998) and EPIC (Meyer et al. 1995)) exist in the field, and each has adopted somewhat different ways of dealing with these methodological issues that may or may not make them suspect to the same criticisms.

The evolution of SOAR as a theory, and its broader role in cognitive science, is likely to proceed along two fronts. First, SOAR will remain an important source of ideas for developing theories of complex cognition, even for those theorists who do not embrace the architecture whole cloth, or reject the architectural methodology. A harbinger of this can be seen in cognitive neuroscience: as researchers begin to tackle the problem of understanding the nature of 'executive' processes and their realization in the brain, models like SOAR can provide concrete proposals for a set of functionally sufficient mechanisms for the control of deliberate cognition; (see the recent volume on working memory and executive control for evidence of such interaction by Miyake and Shah 1999). Second, SOAR will continue to evolve as a unified set of mechanisms itself, informed in part by the continued application of SOAR to difficult AI problems, and in part by the continued construction and empirical evaluation of detailed models of cognitive tasks that focus on unique aspects of the architecture.

Cognitive Therapy

1. Definition

Cognitive therapy is one of a large number of psychotherapy approaches that was developed in the latter part of the twentieth century. It is associated principally with its originator, Dr. Aaron Beck. The treatment model falls within a broader class of treatments, which are referred to as the cognitive-behavioral therapies (Dobson, 2001). The cognitive-behavioral therapies share certain theoretical underpinnings, notably: (a) that cognitive events affect behavior (the mediational hypothesis); (b) that cognitive events can be assessed and systematically modified (the accessibility hypothesis); and (c) that cognitive change can be employed to cause therapeutic changes in behavior or adaptive functioning. In this regard, cognitive therapy is similar to other schools of cognitive-behavioral psychotherapy, such as rational-emotive psychotherapy.

Cognitive therapy distinguishes itself from other cognitive-behavioral therapies by the particular organization of its theoretical constructs. The model proposes that the manner in which an individual views, appraises, or perceives events around himself/herself is what dictates their subsequent emotional responses and behavioral choices. Although the content of situation-specific appraisals will vary as a function of the person's activities, the model also posits that these appraisals may be accurate or distorted, positive or negative. For example, an individual reacts to what another individual said in an interpersonal interaction, as well as to what he or she thinks about those statements.

The extent to which the individual sees situations accurately, or conversely may be distorting, is in part a function of the individual's core beliefs (also referred to as underlying assumptions, or schemas). These core beliefs are hypothesized to be intrapsychic phenomena that emerge over the person's lifetime, based on their experiences. Once established, these beliefs not only increase the likelihood of certain cognitive reactions to life events, but also then influence proactively the way in which an individual chooses to spend their time, career, partner choices, etc., which also tend to reinforce these beliefs. Thus, over time cognitive beliefs become the basic factor in what may become an increasingly negative and closed feedback loop (see Fig. 1).

Cognitive therapy is a systematic treatment, which is founded on the cognitive model of distress. The principal emphases in therapy are assisting the patient to identify, evaluate, and modify the potentially faulty information processing they engage in, as well as the underlying beliefs or schemas that drive that information processing. This process typically begins with an assessment of adaptive functioning and behavioral patterns that might either enhance or interfere with the process of treatment. In the case of depression, the patient may be encouraged to increase their activities to alleviate negative mood, and to ensure that the patient is at least engaged in their life sufficiently to generate negative information processing that can then be the focus of treatment. In the case of marital distress, negative interactional patterns (e.g., fighting, spousal abuse) will be assessed and modified before interventions aimed at relationship beliefs will be attempted.

Figure 1
The cognitive therapy model of emotional distress

Once the patient is able to engage in a review of their negative thinking, a number of methods can be employed to assess this thinking. Strategies include counts of particular thoughts, questioning in the therapy session, thoughts about imagined situations, or the use of a written thought record (J. Beck 1995). Dependent on the pattern of dysfunctional thinking that is identified, various therapeutic techniques can be employed to change these patterns. For example, if a patient recurrently believes they 'cannot' be assertive with certain people, the therapist and patient can collaborate to set up circumstances in which they can test this idea empirically. In doing so, adaptive thinking and various behavioral competencies can be enhanced.

At a certain stage of treatment, it is typically the case that a patient's situation-specific automatic thoughts are accurate and adaptive, and that they are functioning more adaptively than when they first arrived for treatment. At this stage of treatment, the focus will move to the more general beliefs that prompted the patient's problems in the first instance. This work includes a search for the common themes underlying specific thoughts. These themes can take the form of beliefs about how 'the world' operates, or schemas that have developed about the self. Techniques that can be used include inductive questioning, a review of the negative thinking patterns seen by the therapist and patient, examination of historical patterns of thought and behavior, and a review of life events related to the problem. Once identified, dysfunctional beliefs can be challenged systematically through behavioral experiments, bibliotherapy, open discussion with key people in the patient's life, and other 'assumptive techniques' (J. Beck 1995).

In summary, cognitive therapy is a systematic and progressive form of treatment that typically includes assessment and modification of adaptive functioning, situation-specific automatic thinking, and more engrained, long-term beliefs and self-schemas. The cognitive content of various forms of disorders is increasingly understood, and it includes themes of danger in anxiety (Beck and Emery 1985), loss in depression (Beck et al. 1979, Clark et al. 1999), and transgression in anger (Beck 1999). Further, the cognitive processes associated with various disorders (e.g., magnification of perceived danger in anxiety) are also increasingly understood.

2. *Intellectual Context*

Beck's original interest was in understanding and treating depression. He began his departure from his original psychoanalytic training through a series of studies of the dreams and daytime thoughts of depressed patients, in which he discovered that the content of these thoughts had stereotypical content. Further, he hypothesized that these depressed patients engaged in negative distortions of their world in order to obtain these thoughts. Based on these observations, he developed a treatment in which the negative cognitions were systematically tested, in order to undermine cognitive distortions and the negative thinking seen in depression (Beck et al. 1979).

The early formulation of cognitive therapy was put to its first empirical test in an outcome study in the late 1970s. Based on a developed treatment manual, cognitive therapy was contrasted with antidepressant medication. This study revealed that cognitive therapy had equal outcome to medication in the short term and superior outcome at follow-up. As a consequence of the original success of cognitive therapy, a number of outcome studies were conducted in the area of depression in subsequent years.

The first meta-analysis of these studies (Dobson 1989) used a standard outcome measure, the Beck Depression Inventory, and compared cognitive therapy to other forms of treatment. This analysis revealed that cognitive therapy patients ended treatment 0.5 standard deviations less depressed than patients receiving other treatments. Further, compared to wait list or placebo conditions, the effect size for cognitive therapy indicated that it was over 2 standard deviations superior to no treatment. Although the results

of the above meta-analysis were criticized due to questions about the selection process for including studies, the conclusion that cognitive therapy is at least equal to pharmacotherapy has not been challenged seriously. Further, a more recent meta-analysis (Gloaguen et al. 1998) has confirmed the results found earlier by Dobson (1989).

More specifically, Gloaguen et al. (1998) found similar effect sizes to the earlier analysis, although the overall magnitude of these effects was somewhat attenuated. Notably, in an examination of long-term effects, it was also reported that relapse rates from cognitive therapy were approximately one-half of those observed for drug therapy for depression. Most recently, DeRubeis et al. (1999) conducted a 'mega-analysis' of treatment for depression, in which they collapsed the data from four outcome studies and analyzed the effects of cognitive therapy for depression, relative to drug therapy. They concluded that these two forms of therapy were equally effective, even for severely depressed patients. As such, it is an established fact that cognitive therapy is an effective treatment for clinical depression.

Notwithstanding the demonstrated efficacy of cognitive therapy for depression, a number of questions continue to require theoretical and empirical attention. The model underlying cognitive therapy states that cognitive distortions and situation-specific negative thoughts emerge from an interaction between core beliefs (also referred to as cognitive schemas, or underlying assumptions) and the life events that impinge on these beliefs. Once the core beliefs are activated and negative cognitions are produced, the emotional and behavioral consequences of these thoughts naturally flow (see Fig. 1). This mediational model, while intuitive and having lead to a successful treatment technology, has yet to be validated through research. In fact, based on a comprehensive examination of the research that has tested the various assumptions of cognitive therapy (Clark et al. 1999), the conclusion is that cognitive mediation remains to be proven.

Another challenge for the cognitive therapy of depression model comes from a component analysis of this treatment. Jacobson et al. (1996) conducted a randomized clinical trial in which depressed patients received either only the behavioral interventions associated with cognitive therapy, behavioral interventions and those aimed at situation-specific distortions, or the complete cognitive therapy program. Contrary to predictions, all three treatment conditions had equal outcomes, both in the short term and at up to two years follow-up. This study suggests that the cognitive interventions that are the hallmark features of the treatment may not, in fact, contribute to outcome more than the behavioral components of the treatment. If replicated, these results suggest that the active ingredients of cognitive therapy should be reconceptualized.

Further issues exist with regard to cognitive therapy of depression. These include the role of patient characteristics that potentially effect treatment outcome, the role of life stress in depression, the recent focus on schema-focused cognitive therapy (Clark et al. 1999), the risk of relapse relative to other treatments, and assessment issues relative to the adherence and competence of therapists in providing cognitive therapy.

3. *Changes in Focus or Emphasis Over Time*

Branching out from the early work on depression (Beck et al. 1979), Beck and his colleagues extended the cognitive model to other clinical conditions. Beck and Emery published a treatment manual for anxiety disorders in 1985, which was followed by works dedicated to marital disorder (Beck 1988), personality disorders (Beck et al. 1990), substance use and abuse (Beck et al. 1993), and—most recently—anger and aggression (Beck 1999). Other works on cognitive therapy have appeared for bipolar disorder, as well as numerous chapters in various sources (see J. Beck 1995 for a review).

Throughout the development of cognitive therapy, some features have remained constant. First, while the *content* of cognition related to various forms of disorders necessarily varies, there has been a consistent emphasis on the *process* of thinking in cognitive therapy that permits many of the treatment techniques to be applied across disorders. For example, a common intervention in cognitive therapy is assessing the reality basis, or veridicality, of certain perceptions. This intervention can be used successfully in many forms of anxiety disorders, depression, marital distress, and anger-related problems.

A second consistent emphasis in cognitive therapy has been a focus on treatment efficacy. From the outset of the development of cognitive therapy, Beck and colleagues have maintained that efficacy studies are required to establish the clinical utility of cognitive therapy. No doubt it is in part due to this emphasis that many of the psychological treatments now being recognized as empirically supported are variants of cognitive therapy.

4. *Methodological Issues or Problems*

Two primary sets of methodological issues have constrained the development of cognitive therapy. The first of these is related to the methodological issues inherent in clinical research. The randomized clinical trial methodology, which has become the standard in the development of psychotherapy, makes a number of requirements on investigators. These include the need for a well-defined independent variable, which in the context of psychotherapy means a treatment

manual. Unfortunately, a consequence of this requirement is that fully developed treatment manuals are often developed before the research that is needed to substantiate them has been conducted. A second requirement of clinical trials is that the subject group be clearly specified. In psychotherapy research, this requirement has often been translated into using diagnostically related groups, ideally with few or no complicating co-morbid conditions. The relative homogeneity of research participants, while providing a good test of the intervention, unfortunately leads to what may be relatively poor generalizability of research findings. The requisite training for research trials has also been controversial. A fourth area of controversy surrounds the measurement and evaluation of outcome. Typically, the outcomes of a given treatment can be assessed in a number of ways (diagnostically, at the symptom level, or using specialized assessment tools), and the analysis of the outcomes can also be handled in several ways. As a consequence of these various strategies to conduct clinical trials, the scientific status of various treatments can be challenged. Given that most psychological treatments are developed in universities with publicly funded grants, and further given the necessarily limited set of questions that any one treatment study can address, it is not surprising that considerable efficacy and effectiveness research in the area of cognitive therapy is needed.

The second major methodological issue for cognitive therapy is the measurement of mechanisms of change. The cognitive model of distress makes a series of assumptions about the nature of cognitive processes involved in the development and treatment of various disorders (see Fig. 1). The measurement of cognition has been a difficult task, however—particularly as some of the constructs in the model are hypothetically latent until activated (Ingram et al. 1998). Even in the area of depression, where the greatest concentration of work has taken place to assess these constructs, some of the hypothesized mechanisms of change have yet to be established (Clark et al. 1999, Ingram et al. 1998). Research from the level of both theory and therapy are required to further evaluate the relationship between cognitive change and other parameters of clinical change in cognitive therapy.

5. *Probable Future Directions of Theory And Research*

Despite the success of cognitive therapy, and its phenomenal growth over the past two decades, there is no doubt that considerable development remains (Dobson and Khatri 2000). Some of the directions for this work that have been identified in the literature include:

(a) A need for continued emphasis on efficacy research, particularly as cognitive therapy is applied to new and innovative areas.

(b) A need for effectiveness research that assesses such issues as the utility of cognitive therapy relative to other treatments, the clinical acceptability of treatment to patients, and other issues that affect how practical the treatment is to apply in varied clinical contexts.

(c) Continued work on the measurement of cognition (Ingram et al. 1998) and the mechanisms of change in cognitive therapy is clearly warranted. Cognitive therapy is a complex, multi-component treatment, the mechanisms of which are only beginning to be studied. The results of this research will contribute both to the theory and application of the treatment.

(d) Theoretical therapy development and efficacy work are needed to address the issue of whether cognitive therapy is an exhaustive theory that can integrate other models (Dobson and Khatri, 2000), or whether it might be integrated optimally into other treatment models.

(e) There is a need for research that assesses the success and failure of cognitive therapy for patients of diverse backgrounds. This 'aptitude by treatment' research will help the theory of cognitive therapy to develop, as well as to ensure the most appropriate treatment is provided to different patient populations.

(f) Predicated on the assumption that cognitive therapy continues to enjoy strong clinical outcomes and popularity in the treatment community, further research is needed to understand the optimal method to disseminate this treatment approach. Tied to this development are issues related to how to best measure therapist adherence and competence in cognitive therapy.

Coh

Cohort Analysis

A cohort is a set of individuals entering a system at the same time. Individuals in a cohort are presumed to have similarities due to shared experiences that differentiate them from other cohorts. Cohort analysis seeks to explain an outcome through exploitation of differences between cohorts, as well as differences across two other temporal dimensions: 'age' (time since system entry) and 'period' (times when an outcome is measured). This article exposits difficulties inherent to cohort analysis, indicates promising directions, and provides context.

1. Cohorts

Cohorts as analytic entities appear in the social sciences, the life sciences, epidemiology, and elsewhere. A cohort can be a set of people, automobiles, trees, whales, buildings; the possibilities are endless. System entry can refer to birth—a person is born, or to any dated event—a machine is assembled on a particular date. A set of individuals who begin serving a prison term at the same point in time might also define a cohort for certain purposes, in which case 'birth' refers to initiation into a particular role system and 'age' becomes duration (time since system entry). The breadth of the time interval that defines membership in a particular cohort depends on analytic considerations and the nature of the phenomenon under study.

The main difficulties inherent to cohort analysis can be illustrated with data from the NORC General Social Survey, a national sample survey conducted annually or biennially in the United States. Respondents in this repeated cross-sectional survey are queried about their emotional wellbeing. Each cell in Table 1 shows the percentages, organized by age and survey year, of those who identified themselves as being 'very happy.' Each row shows how happiness levels change across survey year (period) for people within a given age group. Each column reveals age variation in any survey year. The diagonals permit tracking of a single birth cohort over time. Those aged 20–29 in 1973 were born between 1943 and 1953, as were those aged 30–39 in 1983, and those aged 40–49 in 1993. Ten-year age categories lead here to cohorts operationalized as individuals born in contiguous 10-year intervals.

Nominal attempts to extract information from Table 1 would summarize percent 'very happy' by rows, columns, and diagonals. The most immediately visible pattern is the association between age and happiness. In all three periods the percentages of respondents who identify themselves as 'very happy' are smaller for those under age 40. This reading of the table ignores the possibility that observed variation is due to birth cohort, with younger cohorts less likely to report being happy. Although visual inspection of the diagonals does not suggest a consistent association between decade of birth and eventual happiness, the absence of an observable relationship does not confirm that no such relationship exists. A potential association between birth cohort and adult happiness may have been obscured by the effects of age and period. Finally, there appears to be little systematic variation between years in percent 'very happy.' In this instance, however, a potential association between period and

Table 1
Percent 'very happy' by age and period

Age	Period

Note: Numbers in parentheses are base *N*s for the percentages

current happiness may have been obscured by age and cohort. A further, linked difficulty is that the data structure is imbalanced. Although periods are represented over all ages, and ages are represented over all periods, the observed age spans of cohorts necessarily differ.

This imbalance cannot be extirpated from analyses that take into account age, period, and cohort simultaneously. Comparable points hold for other data structures supporting the analysis of multiple cohorts.

Table 1 shows that data structures that allow for measurements on multiple cohorts necessarily measure age and period. Furthermore, knowledge of placement on any two of age, period, and cohort determines placement on the third. This dependency can be expressed as:

$$\text{Cohort} = \text{Period} - \text{Age}$$

which raises the questions of whether and how all three of age, period, and cohort can be included in cohort models. The linear dependency between age, period, and cohort, also known as the cohort analysis identification problem (see *Statistical Identification and Estimability*), is the point of departure for all modern discussions of techniques of cohort analysis. The identification problem is present irrespective of data structure.

2. Data Structures

Three commonly seen data structures engender cohort analysis (for a fuller discussion of data structures, see Fienberg and Mason 1985). Excluded from this discussion, however, would be the *single cross section*. Reducing Table 1 to a single column indicates the data structure of a single cross section. With this design, differences on an outcome variable by age can be interpreted either as age or cohort differences. The data structure provides no basis for choosing because there is but a single period. Interpretation of age differences on an outcome as being attributable to factors thought to vary with age or duration requires the assumption that there are no cohort or period differences, or that they are known. Parallel assumptions are necessary for interpreting the age differences as attributable to cohort. Thus, the single cross section does not permit cohort analysis.

Some cross-sectional surveys elicit retrospective data on birth, marital, or other kinds of histories. Figure 1(a) structures this design, a *single cross section with retrospective data*, as an upper-triangular age by period array with cohorts defined by diagonals.

The retrospective data structure provides information on ages, cohorts and periods, and introduces longitudinal information on individuals (see *Longitudinal Data*). When the longitudinal data in this design are used without regard to age, period, and cohort, the analyst is implicitly, and possibly inadvertently, assuming that at least one of age, period, and cohort is not essential. The same point holds for *panel study* data structures (Fig. 1(b)). A panel study begins with a single cross section, and is followed by one or more panels on the same individuals (units of analysis). This design is intended for the creation of longitudinal data. Figure 1(b) structures the panel study as a lower-triangular age by period array with cohorts on the diagonal. It is triangular because, in the simplest case, panel designs do not replenish the data structure with the addition of new cohorts after the initial cross section. A panel study could also be designed to include new cohorts at successive waves of data collection; the age, period, cohort dependency would remain.

In the *replicated cross-section* design or time series of cross sections (see *Longitudinal Data*; *Event History Analysis in Continous Time*) illustrated by Table 1,

Figure 1
Retrospective and prospective data structures that engender age, period, and cohort

typically the same individuals are not tracked from one period to the next. However, each cross section can have a retrospective component, and thus this design can be longitudinal. Like the other multiple cohort designs, this structure permits cohort analysis, although the class of models it supports is less rich when retrospective information is unavailable.

3. Cohort Models

Cohort models may be fixed or random effect (see *Hierarchical Models: Random and Fixed Effects*); terms for age, period, and cohort may enter the model as discrete or continuous; one or more of the age, period, and cohort dimensions may be included in the model via an explicit, substantive measure of that dimension; interactions are possible. These are the most prominent possibilities in the literature on cohort analysis.

3.1 Fixed Effect: Discrete Age, Period, and Cohort

Assume an $I \times J$ age by period array (Table 1 is a 6×3 illustration), with age groups and period intervals of identical widths. The $K = I+J-1$ diagonals of the array correspond to cohorts. The basic fixed-effect model treats a parameter (θ_{ijk}) associated with a response variable as a linear function of discrete age, period, and cohort. Using dummy coding for age, period, and cohort, let:

$$\theta_{ijk} = \beta_0 + \sum_{i=2}^{I} \beta_i A_i + \sum_{j=2}^{J} \gamma_j P_j + \sum_{k=2}^{K} \delta_k C_k \qquad (1)$$

where the A_i, P_j, and C_k ($k = i-j+J$) are dummies for ages, periods, and cohorts, respectively. This is a fixed-effect model because inference is conditional on the ages, periods, and cohorts represented by a particular dataset. Although Eqn. (1) manifests usual normalization restrictions (omission of one dummy from each classification), this is insufficient to break the linear dependency between age, period, and cohort. Omission of all terms in one of the age, period, or cohort classifications eliminates the dependency. This is a satisfactory strategy if prior theory and information suggest that age, or period, or cohort is superfluous. On the other hand, if all three dimensions are deemed indispensable to the analysis, the dependency must be eliminated by one or more further restrictions on coefficients if the fixed-effect, discrete model is to be employed. Problems with this approach include collinearity among terms on the right hand side of Eqn. (1) remaining after additional coefficient restrictions have been introduced, and coefficient bias. Moreover, restrictions that might appear to be innocuously different, such as equating the coefficients of different subsets of adjacent categories, can lead to quite different sets of age, period, and cohort effects, with the various models all fitting the data equally well, or nearly so. One response to the problems of estimating Eqn. (1) is to massively overidentify one or more dimensions. For example, a priori knowledge may suggest that period can be represented by several, rather than many, categories. The data *cannot*, however, be relied on to contain the information on which to base overidentifying restrictions (Fienberg and Mason 1985, Glenn 1989, Heckman and Robb 1985, Kupper et al. 1983, Mason and Smith 1985, Wilmoth 1990).

3.2 Fixed Effect: Continuous Time

Let age (A), period (P), and cohort (C) be measured in continuous time, with $C = P-A$. Then the continuous time equivalent to Eqn. (1) is:

$$\theta_{APC} = f_A(A) + f_P(P) + f_C(C) \qquad (2)$$

where $f_A(A)$ is an $(I-1)$th-order polynomial in A, $f_P(P)$ is a $(J-1)$th-order polynomial in P, and $f_C(C)$ is a $(K-1)$th-order polynomial in C. Because of the $C = P-A$ linear dependency, the coefficients of the linear terms for A, P, and C are not estimable. As in the discrete case, at least one linear restriction must still be imposed and in any event the discrete variable approach is generally preferable.

3.3 Random Effect, Discrete Age, Period, Cohort

It is possible to view the modeling of age, period, and cohort effects from a Bayesian, hierarchical perspective (Nakamura 1986; see *Bayesian Statistics*; *Hierarchical Models: Random and Fixed Effects*). In this approach, it is convenient to characterize age, period, and cohort effects through first differences, as in

$$\theta_{ijk} = \beta_0^* + \sum_{i=2}^{I} \beta_i^* A_i^* + \sum_{j=2}^{J} \gamma_j^* P_j^* + \sum_{k=2}^{K} \delta_k^* C_k^* \qquad (3)$$

where $A_i^* = A_i - A_{i-1}$, $P_j^* = P_j - P_{j-1}$, and $C_k^* = C_k - C_{k-1}$. The approach assumes that the β_i^*, γ_j^*, and δ_k^* are separately distributed, and that they are random or exchangeable (Nakamura 1986, Sasaki and Suzuki 1987, 1989, Glenn 1989, Miller and Nakamura 1996). The exchangeability assumption requires that within the age dimension, within the period dimension, and within the cohort dimension, all permutations of the first-difference coefficients must be equally acceptable. This assumption makes possible the determination of age, period, and cohort effects without resorting to restrictions on coefficients. To the extent that the assumption fails, and it can when there are shocks

(e.g., war, famine, plague, a stock market crash) in the process being modeled, the random effects approach is not a panacea.

3.4 Substantive Measurement of Age, Period, or Cohort

When one or more of the age, period, and cohort dimensions, whether represented as discrete or continuous, is replaced by a variable chosen to measure the underlying process thought to be captured by age, or period, or cohort, the linear dependency is almost always broken. Attention is then appropriately focused on the theoretical and substantive merits of the specification. Models that include age, period, and cohort should be thought of as starting points, given their inferiority relative to models that are able to test ideas of how and why a cohort, or period, or age mechanism affects an outcome. Concretely, suppose the cohort dimension is held to reflect the impact of measured variable X, then Eqn. (1) might change to:

$$\theta_{ijk} = \beta_0 + \sum_{i=2}^{I} \beta_i A_i + \sum_{j=2}^{J} \gamma_j P_j + \delta X \tag{4}$$

where X is either constant over ages within a cohort, or varies by age within a cohort. Relative cohort size is an example of a variable that could be defined at the birth of each cohort, or allowed to vary as cohorts 'age' through the life cycle. Measured variables can also be employed in extensions and revisions of Eqns. (2)–(3). For example, in Eqn. (2) the polynomial in C can be omitted upon inclusion of some function of X (X itself; a polynomial in X; interactions between X and age or period).

In the extension of the random-effects approach that includes measured variables, cohort analysis becomes a specific case of random effects multilevel analysis (see *Statistical Analysis: Multilevel Methods*). This development can be expected in the course of the continued deployment of Bayesian statistical solutions, because the use of measured variables can enhance the validity of the exchangeability assumption. In the random-effects approach, substantive variables can be written into the model in the following way, for one or all of age, period, and cohort:

$$\begin{aligned} \beta_i^* &= \lambda_{0A} + \lambda_{1A} X_A + \tau_{iA} \\ \gamma_j^* &= \lambda_{0P} + \lambda_{1P} X_P + \tau_{jP} \\ \delta_k^* &= \lambda_{0C} + \lambda_{1C} X_C + \tau_{kC} \end{aligned} \tag{5}$$

where, for example, X_C is a measured variable for cohort, and for simplicity only one measured variable per dimension has been included, and only as a linear term. In this extension it is the τ_{iA}, τ_{jP}, and τ_{kC} that are assumed to be exchangeable within the age, period, and cohort dimensions, and this is likely to be more defensible—because substantively plausible underlying, measured variables should covary with the phenomena that produce shocks. Moreover, the exchangeability assumption becomes comparable to the assumption of a random-error term in a fixed effects approach with measured variables.

4. Interactions

The need for interactions often arises, either for substantive reasons (Converse 1976), or for technical, adjustment purposes (Mason and Smith 1985). It is possible to include interactions in both fixed- and random-effect models, regardless of the presence of measured variables. Fienberg and Mason (1985) elaborate readily implemented strategies for doing so in the fixed-effect framework, using either discrete or continuous age, period, and cohort. Not all interactions are estimable, and hence they cannot be added into the model at will.

5. Conclusions

Panel studies, cross-sectional studies with retrospective information, and replicated cross sections (including age by period arrays created from process-generated data) engender the analysis of a response variable as a function of age, period, and cohort as well as other factors. Such analyses must contend with the linear dependency between age, period, and cohort membership. The use of one or more measured variables held to underlie at least one of age, period, or cohort can break the linear dependency. So too can application of credible prior information, whether expressed as constraints on coefficients in fixed-effect models, or as exchangeability assumptions in random-effects or hierarchical models. Measured variables can, of course, be incorporated into both fixed-effect and random-effect models. This strategy is to be preferred, since it makes it possible to test ideas about substantive processes in the most direct way. Models that include age, period, and cohort can also include interactions between these dimensions, though not all such terms have estimable coefficients. Models that do not explicitly consider all three of age, period, and cohort, and yet are based on data structures that permit their inclusion, rest on the implicit assumption that age, or period, or cohort is irrelevant. This assumption should and can be assessed.

6. Further Reading

Fienberg and Mason (1985) discuss the formalization of the identification problem; identifiability of nonlinear components; identifiability of certain inter-

actions beyond those implicit in the simultaneous inclusion of age, period, and cohort; polynomial models; and other topics. Kupper et al. (1983) and Kupper et al. (1985) explore in depth several issues raised by the identification problem for the fixed effect discrete case, and take the stance (Kupper et al. 1985) that age-period-cohort models are no more informative than exploratory graphical displays. Ploch and Hastings (1994) illustrate the use of smoothed perspective plots. Robertson and Boyle (1998b) provide an overview of different strategies for graphical display of age-period-cohort data.

In Nakamura's (1986) Bayesian formulation, identifying linear restrictions are replaced by the assumption of exchangeability of first differences in age, period, and cohort effects (although Nakamura chooses to emphasize the closely related assumption of 'smoothness'). Hodges' (1998, Sect. 2) development of hierarchical models as linear models contributes to an understanding of how Nakamura's specification overcomes the singularity of the fixed effects model matrix. Berzuini and Clayton's (1994) Bayesian formulation, which is focused on second differences of effects, does not solve the identification problem. The social sciences literature in which Nakamura's specification is used or discussed (Sasaki and Suzuki 1987, 1989, Glenn 1989, Miller and Nakamura 1996) fails to make clear that it is not the Bayesian approach *per se* that provides an alternative to linear restrictions on coefficients, but rather Nakamura's particular formulation. Nakamura's (1986) computational approach has been supplanted by the use of Markov Chain Monte Carlo methods (The BUGS Project 2000; see *Monte Carlo Methods and Bayesian Computation: Overview*; *Markov Chain Monte Carlo Methods*).

Robertson and Boyle (1998a), and Robertson et al. (1999) review the largely disciplinary-specific epidemiological literature on the methodology of cohort analysis, which has focused primarily on additive models, and conclude that only the nonlinear components of age, period, and cohort can be used reliably. Holford et al. (1994) employ substantive reasoning about cell malformation in carcinogenesis, develop specifications in which age is inherently nonlinear (e.g., logarithmic) and thus eliminate the identification problem through choice of functional form. Mason and Smith's (1985) extended study of tuberculosis mortality combines substantive reasoning based on prior information and expectations, uses one body of data to guide modeling of another, includes an interaction term, employs a substantive, measured variable, and concludes that potential interactions require at least as much attention as the identification problem itself.

Hobcraft et al. (1985) focus on theoretical reasons for the use of age, period, and cohort in different areas within demography. Ní Brolcháin (1992) takes aim at the relevance of the cohort dimension for understanding temporal variation in human fertility. Discussions of this kind can help cohort analysts become more substantively grounded. Research using measured variables in place of accounting categories (e.g., cohort size instead of a cohort classification) is not, however, in need of such assistance (Easterlin 1980, Ahlburg and Shapiro 1984, Welch 1979). Blossfeld (1986) provides a persuasive example of the use of massive overidentification within a single dimension.

Cold War, The

The term is widely accepted in historical writings. It refers to the epoch between 1947–8 and 1989–90. The nature of the Cold War, its causes and effects, and the reasons for its long duration are, however, controversial. Its meaning would exclude Asia because of the outbreak of wars there; the wars in Korea, Vietnam, and Afghanistan made a difference to how the United States (US) and the Soviet Union (USSR), the two superpowers, waged their global contest in Europe. The situation in Europe resembled neither peace nor war; *East–West Conflict: Confrontation and Détente* expresses the ambiguity, but this label is less eye-catching.

1. *The Concept and its Salience*

The persistent central features of the *Cold War* are the global contest between the US and the USSR, the dependence of the allies on the security guarantee of their respective superpower, and bipolarity. The latter was reinforced in the core area, the arms race, due to the widening gap between the extensive and highly diversified weapons systems of the superpowers and the arsenals of Britain, France, and the Peoples' Republic of China (PRCh), the other three established nuclear powers. This explains that American and Russian writings hold to *Cold War* as a concept fitting the entire epoch. It allows for distinguishing between moments of imminent war—Cuba, October 1962, and Yom Kippur war, October 1973—times of high tensions and war outside Europe—Korea, 1950–53; Vietnam, 1964–75; Afghanistan, 1979–88—long intervals of *détente*, and even moments of concerted crisis management (June 1967 Near East war) or collaboration (during the Laos crisis and Vietnam war in the 1960s and ending wars in Africa in the late 1980s).

This version pays less attention to the fact that throughout the four decades not all parties to the Cold War were involved on the same issue-at-stake and at the same time. France joined Britain (UK) and the US in 1948 in founding the West German state as the Western allies' response to Stalin's anchoring of Poland, Bulgaria, Romania, Hungary, and Czechoslovakia firmly into the Soviet security-zone, and maintained staunch opposition to proposals for a neutralized, but nationally rearmed united Germany (Hitchcock 1998). Since the mid-1960s, France became the spokesman for a Europe less dependent on the US and discussing terms of settlement with 'Russia.' The Federal Republic of Germany (FRG) converted *Cold War* into *cold peace* with the ratification of *Ost- und Deutschlandverträge* (1970–3). Both governments cooperated in defending *détente* in and for Europe; by implication, this aspiration for a European peace-zone rejected the American concept of the indivisibility of the global contest between East and West. The PRCh, the only principal ally the USSR ever had (1950–58/9), made its peace with the US in 1972 on Pejing's term of 'One China.' While the PRCh had provoked the US during the 1950s to continuous nuclear sabre-rattling, it turned its antihegemonic posture throughout the 1970s and 1980s against the USSR.

1.1 *The Components of the Term*

The definition refers to four aspects of the conflict: (a) the ideological antagonism between the Western concept of freedom of choice for the people of the domestic

regime and external alignments of their state and the Soviet-imposed monopoly of the 'workers' and land-labor party and subjugation to the community of socialist states; (b) the geostrategic struggle for bases of power-projection; (c) the domestic political contest, but almost exclusively within Western countries, about commitments to the military alliance or equidistance to both of the superpowers; (d) the dispute about where to draw the line between permissible and noncompatible elements in the policy mix of market-oriented and government-controlled economies. Of these four components, the last became least important for refueling the confrontation; the convergence of the mixed economies rather promoted the idea that *Osthandel*, credit facilities, and technology transfer might enhance not only 'liberalization' in the East European economies, but also generate transformation of the political system.

1.2 The Ideological Antagonism

The ideological antagonism was the first impulse for *confrontation*, but it was also subject to changing threat perceptions and shifts of emphasis in the balance between *confrontation* and *détente* in the overall relationship. The wider notion of *East–West Conflict* posits the Cold War as a distinctive period into the ideological struggle, originated in 1917–18, between the Wilsonian Impulse and Lenin's urge for peoples' democracy as the basis for securing peace (Link 1980). From this perspective, Stalin and Truman likewise took the lead in splitting the world along 'alternative ways of life.' Western leaders argued that the West had to learn its lessons from the vain hope to appease an expansionist regime. 'No more Munichs' informed the confrontation stance of *containment* as the West's answer to the external threat. The concomitant stance at the home-front is based on the thesis that authoritarian regimes abuse state-power against large parts of their own population; therefore Communists must not be given a chance to occupy crucial positions of government such as Interior, Public Transport, or Justice.

Conversely, Communist ideology maintained that *capitalism* on the one hand inspires the state to prosecute the working-class and thus breeds *fascism*, and on the other hand is inherently expansionist and therefore knows no boundary to its domination. The belief, however, that capitalist nations are bound to fight for defeating rivals, made Stalin expect that Britain would resist the US' aspiration to become heir to the British Empire. The *new feature* of the post-World War II international system is that the US and the UK were competitive partners in founding the International Organizations destined to develop and monitor rules of conduct for international trade, currency exchange, and development aid (Gardner 1969). The UK and France, but also Italy, expected the up-to-then reluctant US government to come to the rescue and infuse capital into the European economics as the only strategy which could render support to the parties willing to exclude Communists from governments (Lundestad 1986). The formation of Western-oriented governing coalitions ensured that the European allies, as well as Japan, cooperated with the US in the evolution of the International Economy, to which the USSR and the PRCh were not negotiating parties after the outbreak of the Cold War. Most allies did not comply, however, with the American demand to restrict 'trading with the communist enemy,' except in conspicious moments of Soviet war activities.

The ideological component became a wasted asset after its overexploitation during the first phase (1947–53). Khrushchev's condemnation of Stalin's death toll in February 1956 and the NATO allies' perception that the Kremlin was unlikely to launch a general war on European territory (1956/7) put a break on the momentum of ideology as a driving force in the East–West conflict. But it was on the Kremlin to end the system conflict. In 1987 Gorbachev rescinded the Breshnev doctrine and made it known that hardliners in Eastern European governments should not reckon with Moscow calling on the Red Army to back up unpopular communist regimes (Adomeit 1998).

1.3 The Long Duration of the Cold War

For explaining the longevity of the Cold War, the account therefore has to focus on the other two factors: the structures which emerged with the consolidation and reaffirmation of the divisions of Europe and of Germany, and the pecularities of the military–geostrategic balance between the two sides.

1.3.1 The divisions of Europe and Germany. The key feature is the hinge between the two *divisions*. The stark contrast between Stalin's refusal to consider concessions on Poland, Bulgaria, and Romania in exchange for American economic assistance and his demand to have a say on questions concerning primarily intra-West relations, e.g., the status of the Ruhr area or of Norway, provoked the US and the UK to tie their zones firmly to Western institutions (Deighton 1990). The implementation of this basic strategy was, however, complicated by clashes of interest between the US, France, and Britain. These tensions prevented them from advancing as far as the USSR had with incorporating its German state, the GDR, into the Soviet Empire. Hence they could not, as wanted, negotiate from a position of strength, but expected to be asked to give away on what 'the West' did not yet have, whereas the USSR would persist in its refusal to put its reign over Eastern Europe on the agenda. The stalemate was compounded, when the reimposition of the Ulbricht regime in 1953 revealed that the Kremlin considered the GDR as its west-side lever for control over Poland and Czechoslovakia.

The structural impediment to a negotiated settlement disappeared when Moscow tacitly bowed to Germany's entry into NATO (1955) and when the 'West' acknowledged the fact that the USSR was strong enough to prevail in Eastern Europe (1956). German *Ostpolitik* put the final stamp to the 'normativity of the facts.' On this platform, the so-called Helsinki process, the Conference on Security and Cooperation in Europe (CSCE), lingered on throughout the 1973–89 period. Neither side was ready to proceed towards peace-making.

The Cold War might have ended earlier if Gorbachev's predecessors had responded to the US view that Germany's double-bind into a US-centered NATO and European integrated structures would prevent Germany from positing a threat to the security of the USSR (Schmidt 1993–5). Instead, Moscow's attempts to push the divisiveness of nuclear diplomacy within NATO rather than wait for the outcome of such conflicts provoked the 'Atlanticists' to close ranks and reiterate the standard thesis that the West could prevent the USSR from winning the Cold War if its members resisted the temptation to court Moscow and make separate deals with the USSR. The Soviet leadership's 'stupidity' is said to have saved the US or NATO to get rearmament projects—such as NSC-68 or the 1979 dual-track decision—through.

1.3.2 The peculiarities of the military–geostrategic balance. The key feature is the fundamental asymmetry between the nature of America's and Russia's predominance in their respective sphere. This asymmetry is reinforced by the imbalance of military forces between NATO-Europe and the USSR's forward deployed forces (Kugler 1993).

The advantage of the US in its global contest with the USSR was that all other principal powers, including Germany and Japan, were allied to the US. This helped in the build-up of the international economy, but not necessarily in defense. Consequently, US diplomacy was absorbed as much in intra-West crisis management as in the context of East–West relations. The allies wanted to be assured that there were no long-term security risks involved for them in America's option for sponsoring the resurgence of the enemies and occupiers of World War II as strongholds of the West. Having imposed limits on Germany's and Japan's military status, the US could not reckon with a defense contribution for some years to come; both were prohibited to engage in 'out-of-area' defense activities (Schmidt and Doran 1996).

By contrast, the USSR gained a formidable ally in the PRCh, who was keen to test the credibility of the American commitment to South Korea and Taiwan. Although the USSR copied the West's community building by setting up COMECON (1949) and the Warsaw Treaty Organisation 1955, the Kremlin relied for exerting influence *de facto* on the penetration of the bloc partners' central agencies: the State Party, Secret Service, and top military echelon. The USSR also made sure through logistic measures that the Soviet military could operate from its allies' territory independently, and if need be without the consent of the incumbent governments (Wolfe 1970).

The military imbalance between NATO-Europe and the USSR existed throughout 1947 until the mid-1980s. The US found no takers—except the FRG from 1961 onwards—for its concept of balanced collective forces in the sense that the US were the sole provider of strategic forces, that is, weaponry projected to hitting targets located in the USSR, whereas the allies would recruit the ground forces and tactical air forces required for the defense of the region against infiltration or surprise attacks. Britain and France preferred to duplicate the US strategic role, albeit on a much minor scale, and took the relaxation of tensions in Europe and their entanglement in the legacies of their imperial rule as the rationale for reducing their force assignments to NATO.

2. *The Intersection of Economic and Strategic Decisions: The European Structure*

The failure of the 'Big Four' to cooperate on a German Peace Treaty is identified as a crucial turning point towards the Cold War (Leffler 1992). Stalin did not want to give the impression that the US, thanks to the atomic bomb and its economic wealth, could impose its will on the USSR; he therefore pressed his claims on Iran, Turkey, during the Peace Conferences with Germany's war-time allies and in the Allied Control Council. This in turn was taken in Washington as a signal that hope of Russian cooperation must be abandoned. Truman and Byrnes had been reluctant to confront the USSR when the Cold War started over the fate of Eastern European nations (1944–7). Now, in view of the havoc the 1946–7 crisis wreaked on the economies of Britain and France, the US government conceived that Western Europe could not save itself (Hogan 1992).

From there on, the 'West' displayed a dynamic of its own. The first act was that the economic recovery of Europe was said to require the inclusion of (West) Germany; the price for getting France to change its German policy was the assurance that the US and the UK would back up the French quest for security against a resurgent Germany. The second act followed: Britain and France pleaded with Washington that the Marshall Plan initiative would not suffice to attain stability without an American security guarantee. Against the background of the Berlin blockade, Truman in October 1948 ordered that the US provide the major counterbalance to the 'ever-present threat of the Soviet military power.' In September 1948, the Brussels Treaty Organization (BTO) had already resolved that the defense of Western Europe should be

as far to the east (of West Germany) as possible. Because this was beyond the means available to the BTO and not yet compatible with the military strategy of American and British defense planning, it was only a question of developments in the Cold War that the third issue be placed on the agenda: German rearmament. The logic behind the build-up of conventional forces sounded compelling: why do the old allies expect the US to provide ground and air forces and the Supreme Allied Commander to NATO's integrated forces with a view to realize the concept of forward defense when they deny the indispensibility of a sensible German defense contribution, on whose territory the French in particular wanted to stop the enemy's offensive? At that time, however, all the US military could offer was an air offensive to deter the USSR; they did not yet want to rely on 'the bomb' (Ross), and the USSR had acquired by then (Fall 1949) an atomic capability.

The outbreak of the Korean War generated the fear of a similar war-by-proxy in divided Germany. The US did not only reverse its stance on what countries were of absolute importance to US security by now declaring Korea the test case of what became the domino syndrome, that no US ally should fall prey to a Communist invader, but also designated the National Security Paper NSC-68 as the platform for a massive conventional rearmament of the US, adequate force deployment abroad and military aid to upgrade the defense capabilities of its European and Asian allies (May 1993).

The issue of German rearmament was divisive, but the US compromised with France on the understanding that German forces be integrated into a European Defense Community (EDC), whereas the EDC would delegate strategic planning and fixing force requirements to NATO. The project became the victim of French domestic politics; the US and the UK had to comply with the French request that no German soldier be officially recruited until France had ratified the EDC and German Contractual Agreements. The demise of the EDC meant that Washington had to forego the hope that US force deployment would be a temporary stop-gap until the European allies, and especially the FRG, were able to do more towards meeting NATO's minimum force requirements.

The parallel staged fourth act (1952–4) produced the *definitive structure of the Cold War in Europe*: the NATO, to which the FRG was finally admitted, had made itself dependent on the credibility of the US (and UK) strategic deterrent. This provoked the issue how the USSR would react to the logic that NATO's new member would have to be equipped with the same weaponry as the allied forces into which the German divisions were to be incorporated. Chancellor Adenauer made it clear that the FRG did not want to provoke Moscow unnecessarily by dislocating medium-range ballistic missiles on German soil, whose later replacements might be able to hit targets in Russia, but he and his successors insisted on having at least a crucial German vote in all decisions on the use of nonstrategic weapons in NATO's custody in case deterrence to all types of war failed (Heuser 1998, Trachtenberg 1999).

This final act of incorporating the two German states into alliances dominated by the nuclear-strategic superpowers had a far-reaching effect: plastering the 'front-line' states with short-range atomic weapons was the best insurance premium that the Germans would not launch war from their soil (Ullman 1991). As long as the US and USSR stationed troops there and resolved to maintain control over the warheads, the danger of accidental war could be excluded. The parallel to the military factor written into the strategic landscape is the interest of the Western nuclear powers in confirming the *status quo* and discuss on that territorial basis the questions of putting ceilings on rearmament. Separately, the two German states relaunched their rivalry and demanded (1955–73) allies and Third World countries alike to subscribe to the *Alleinvertretungsanspruch* of the Western democratic or peoples' democratic German republic.

3. *The History of the Concept, Major Developments, and Empirical Results*

The invention of the term is accredited to Walter Lippmann who took issue with G. F. Kennan's 'X'-article 'Sources of Soviet Conduct.' Kennan's long telegram of February 22, 1946 molded the agenda of America's containment policy. His arguments were selectively used by top officials in Washington to assert that the 'Soviets' will develop all means and methods ranging from threat of military aggression via propaganda warfare to clandestine activities to a degree without precedent in history. Therefore, the US had to strengthen its executive branch, introduce a national security policy, establish a professional intelligence agency, and develop an unassailable military–industrial base (Leffler 1992, Paterson 1979).

The opposite Communist view emphasizes three aspects: the economic aggressiveness of the long-standing hegemonic US project to attain a 'one-world market' and abuse of the open-door doctrine for penetrating other nations' economy; the manipulation of anti-communism as a club to suppress claims for social justice and equality of rights within the American and other Western capitalist systems; and America's acquisition of bases bordering on the USSR for purposes of encirclement and monitoring inside the USSR. *In geostrategic terms the US became a direct neighbor of the USSR*, whereas the USSR required long-distance bombers (it introduced such jets by 1955) and Inter-Continental Ballistic Missiles (ICBM) to show the US its vulnerability. The strong engagement of the US in the post-1990 contests about Caucasian and Middle East oil and gas concessions

and pipeline routes indicates that the US–USSR rivalry did not end with the Cold War.

The 'Revisionists' (LaFeber 1991, Paterson 1979) disclaim that Stalin pursued an offensive strategy aiming at extending Soviet rule; they discern rather the US' responsibility for causing the Cold War. The postrevisionist approach accounts for the Soviet aspect of the fundamental change in the Cold War since about 1954–5, and explains the US interest in *détente*, i.e., the coinciding interest in *Long Peace* (Gaddis 1987). Moscow settled the Austrian question, tolerated the FRG's entry into NATO, and opted for reconciliation with Tito, the only East European leader who had got away with breaking ranks with Stalin. The cumulation point was the declaration of the doctrine of *peaceful co-existence*. The Western allies' match was tacit satisfaction with consolidating the *status quo* after they had absorbed the FRG. Stability in Europe turned the UK's, US's, and France's attention to the Third World. In reaction to Communist China's revolutionary foreign policy, the Soviet leadership in 1960 declared wars of liberation from colonial rule legitimate and thus distinguished peaceful co-existence in the developed world from just wars in the 'southern' part of the globe. In this sense, the East–West conflict was exported to the Third World.

The US resolved on noninterference in the internal affairs of the Soviet bloc and relaxation of tensions. The US was somewhat dependent on Russia's resistance to become the air and nuclear strategic arm of Pejing's violent anti-American activities in the Far East. The emerging picture is that the US, in parallel with the Berlin and Cuba crises (1958–62), wanted to concert the superpowers' activities in China's '*hinterland*' (former 'Indochina') in the sense that both exert pressure on the parties to a conflict amenable to their respective influence and through such agreement attain the neutralization of the conflict area, including the instalment of all-party or power-sharing coalition governments, however unstable (Nelson 1995).

3.1 European Perspectives on the Cold War

A different strand in the history of the concept is the perception of the impact of the other Western powers, especially Britain and France, on how the struggle was waged (Greenwood 2000, Bozo 1991). The contribution is twofold: (a) the *Cold War* is viewed as a new stage in great power rivalry. These studies stress the Europeans' interest in devoting resources to restoring or preserving their assets and commitments overseas (Kent 1993, Bossuat 1992). (b) The second contribution takes a different direction: it challenges the assumption that Western Europe by 1947–8 was in such a critical state that the leading nations had to 'invite' the US to reconstruct and protect Western Europe. Examining the economic potential of the European nations and how their governments used the financial means provided under the Marshall Plan, Milward (1984) presents the thesis of the rescue of the nation-state. His complex argument also draws on the observation that at that time the West did not reckon with an immediate Soviet threat. The implication is that an unwarranted haste was imposed on a process which in any case depended on what the European countries did to and for another, formally, US assistance was tied to the Uniting of (Western) Europe and to parallel bilateral agreements between the US and the recipient country.

3.2 Competitive Cooperation Between the Superpowers

By the end of the 1960s, researchers discerned the convergence of five developments which demonstrated the continuing relevance of the 'competitive cooperation' between the superpowers for the changing structures of the *Cold War*: (a) Soviet policy shifted towards accepting the US's and Canada's presence in Germany; (b) German *Ostpolitik* presumed the engagement of the US in NATO; (c) de Gaulle realized in the context of the Prague 1968 crisis that Breshnev's Russia was no party to his vision that dissolving Cold War structures in the West, i.e., France's disengagement from NATO's military organization, might induce 'Russia' to allow for more evolution of national communist and then independent states in Eastern Europe; (d) the US embroilment in the Vietnam war caused a change in the intellectual climate; the abuse of the USSR being the cause of every evil became obsolete; instead the US became the villain in the piece; (e) new developments in arms technology—e.g., high-precision weaponry as a substitute for atomic weapons; MIRV-technique; antiballistic missiles—were beyond Britain's and France's capability to follow on; this reinforced NATO Europe's self-elected dependency on the US with respect to security and defense (Hanrieder 1989).

Renewed US pressures on its allies to extend their conventional military capabilities and share the burdens for the 'Defense of the West' more evenly, the re-escalation of the strategic arms race between the superpowers under the aegis of limitation treaties, and the evidence presented by German *Ostpolitik* that negotiations with Russia generate tolerable results, combined to raise the basic questions: what are the costs of the ongoing *Cold War*? on what terms could the conflict be ended and converted into politico-economic competition? (Garthoff 1985).

3.3 From the Second Cold War to the End of the Cold War

The USSR, after getting Germany's pledge to observe the invulnerability of the territorial *status quo* in Europe, revived the global contest with the US, which

was immersed in domestic turbulences *and* disputes with all its allies about oil and the dollar. The Kremlin demonstrated its self-confidence by expanding Soviet naval forces and establishing bases, however short-lived, stretching from Vietnam via Mozambique, Somalia, and Angola to Central America. In contrast to the 1950–3 period, the US catchword 'arch of crises' did not resonate well with its allies. The latter wanted to develop *détente*, notwithstanding the fear, expressed by German Chancellor Helmut Schmidt in 1977, that the Soviets' new equipment (Backfire bombers; SS-20) made NATO Europe hostage to the Kremlin's whip of the will. This raised the question whether the USSR was about to win the Cold War or whether the Kremlin was overstretching the country's resources and would thus expose the USSR sooner rather than later to the need for radical changes in her system. The wishful thinking that the USSR would fall victim to its inability of continuous adaptation worked out after three decades of aspiring military strategic and political parity with the US. Some authors argue that Reagan's defence build-up deliberately forced the Soviet leadership to acknowledge the failure of its domestic system and hence the USSR's inability to persist in the contest and sustain bipolarity. (Adomeit 1998, Gaddis 1987, Wells' article in Hogan 1992). The way the global contest ended invited Americans to believe that they had won the Cold War.

4. *Methodological Problems*

The immersion of the concept *Cold War* in the perpetual clash of interests between East and West and within each 'bloc' subjects the interpretator on the one hand to the political climate of his own times, and may thus reload or de-emphasize the contentions of the past; on the other hand, access to newly available records reveals new insights into previous phases of the Cold War and thus demands rethinking the past but in a different way. Getting the balance right between these two operations is difficult when knowledge about one party to the conflict is the result of generations of research, whereas the more recent presentations of findings from Soviet, GRD, Czech, or Polish sources are both less systematic or structured and more exposed to be taken instantly as evidence for one interpretation e.g., of Stalin or Krushchev or another. The task to study the records comprehensively, but also be prepared to modify one's assessments in response to newly available empirical evidence is prone to collide with the other obligation, namely to explain what were the basic causes of a conflict and which causes—meaning in politics: sins of commission and omission—are accountable for what developments.

A second main problem is the exact phase-by-phase and overall intersection between the interpretation of the collaboration leading to the evolution of 'Western' structures in the economic sphere and the assessment of the concomitant events in the politico-strategic (military) sphere, where the USSR appeared to be the winner, but then ended the Cold War on western terms.

5. *Future Direction of Research*

'East' and 'West' waged the struggle by all means and methods except 'hot' war in the area stretching from Vancouver to Wladivostok. Hence, research must attend to different subject areas and to the expertise developed in the many scholarly communities. Some areas of research, e.g., diplomatic or intellectual history and biography, are more established than others. The impact of *intelligence* on policy-makers is a relatively new area of systematic research. International cooperation projects have done much to promote *nuclear history* and *strategic studies*, but the history of the military alliances and of national defense organizations and policies depend still on the authorities' grant of access as well as clearance and permission for publishing inspected material. The studied ambiguity of the political leaderships and the top military echelon about the worth of strategic nuclear weapons in case deterrence should fail and about the use of short-range atomic weapons deserves further study in order to know the implications of nuclear weaponry on the conduct of Cold War diplomacy and governmental guidance to their military.

Future research should be more systematic in the sense of *extending* the conceptualization beyond the national and bilateral focus to the regional context and *intensifying* the approach by addressing the fundamental questions about the changing nature of the struggle, its costs, the persistence or recreation of patterns of conflict, and above all the question whether the Cold War structure affected all other bilateral or intraregional conflicts or whether re-emerging older conflicts pervaded the East–West conflict, so that the parties to such conflicts used the *Cold War* for the purpose of engaging wealthy allies on their side.

G. Schmidt

Coleman, James Samuel (1926–95)

James S. Coleman was born on May 12, 1926 in Bedford, Indiana. He died on March 25, 1995 in Chicago, Illinois. Coleman was among the most important American sociologists of his generation. By importantly influencing both intellectual and policy debate, Coleman was unique among sociologists. By making important contributions to a large range of areas of scholarly concern, including mathematical sociology, sociology of education, and social theory, Coleman was unique among social scientists.

1. Life

James Samuel Coleman was born into a family of teachers, with roots in the landed gentry of the South on his father's side, and in various places in the Mid-West on his mother's side. His grandfather, Samuel, was a minister. The family moved frequently in Coleman's youth between places in Ohio, Arkansas, and Kentucky to settle, finally, in Louisville, Kentucky, where Coleman graduated from Manual High School in 1941. The origin is important for his basic sociological interests and positions. The marginality from moving around between southern and northern American cultures and the diversity of his origins instilled a strong curiosity about social relations. The teacher occupations of both parents created a strong interest in schools and education. Samuel, the minister grandfather, and the mother were important for Coleman's preoccupation with moral issues that profoundly influenced his work.

Coleman's choice of sociology as a vocation came quite late. He graduated from Purdue University in 1949, with a degree in Chemical Engineering, and his first job was as a chemist with Eastman Kodak. He had almost no undergraduate education in any social science. Nonetheless, in 1951 he began graduate study in sociology at Columbia University. Coleman's dual attraction to science and moral engagement made sociology an impeccable choice, or so it would seem in 1951. He had found industry frustrating and a likely eventual career in management unappealing. He wanted to devote his life to discovery and concluded it could only be about people, their relationships, and their social organization.

Columbia's sociology department gave Coleman four intense years and three important teachers: Paul

Lazarsfeld, Robert Merton, and Seymour Martin Lipset. Coleman is usually regarded as Paul Lazarsfeld's student. This is not quite correct. Lazarsfeld was not his dissertation advisor; it was Lipset. Lazarsfeld was not the teacher who had the most profound intellectual influence on Coleman; it was Merton. Lazarsfeld did involve and use Coleman for the development of mathematical and statistical tools for social analysis, and these activities created the point of departure for some of Coleman's most important later work. However, there is an important difference between Coleman's *Introduction to Mathematical Sociology* (1964) and Lazarsfeld's branch of mathematical thinking in the social sciences. Coleman's main objective with the use of mathematics was the development of theoretical insights and conceptual development. Lazarsfeld's major contributions were to the codification of research procedures, that is, methodology. Coleman has made important contributions to methods, but his most remarkable quality as a sociologist was his ability to develop sociological ideas and sustain them with empirical evidence. This is much closer to Merton's style of theorizing about empirical matters, though Merton often relied on evidence produced by others.

Coleman obtained his first faculty position in 1956 as an Assistant Professor at the University of Chicago. In 1959 he moved to Johns Hopkins University to create his own sociology department. He developed a small organization with an intellectual intensity and excitement that was truly remarkable. It was perhaps unsustainable and, for a variety of reasons, Coleman went back to the University of Chicago in 1973, now as a University Professor, and stayed there until his death in 1995.

2. *Scholarship*

The body of scholarly work is large. It includes 30 books and monographs and more than 300 articles and chapters in books. These contributions have profoundly influenced and, in several cases, defined the agenda for important subfields of sociology: sociological theory, sociology of education, sociology of the family, mass-communication, social stratification, political sociology, mathematical sociology, and sociological methods. The contributions include three major pieces of policy-oriented research on schools and educational opportunities that are the major examples of 'sociology making a difference' in the 1960s, 1970s, and 1980s. The scholarly work covers a phenomenal range of approaches to social research. There is work about social systems (Coleman 1961) and about individual behavior (Coleman 1990b). There is basic research as well as applied. There is quantitative (Coleman et al. 1966, Coleman 1987) as well as qualitative analysis (Coleman 1961). There are contributions to economics (Coleman 1966), political theory (Coleman 1982), moral philosophy (Coleman 1974), statistics and probability theory (Coleman 1981), and education (Coleman 1990a).

It is difficult to characterize James Coleman's contributions to the discipline because there are so many components. It includes two major and two very different paradigms of what sociology is about. One is a Durkheimian paradigm: it sees the task as studying how social structure creates and constrains individual action and causal social processes. The other paradigm takes departure in individual purposeful action for developing properties of social systems and structures. The former project governs most of Coleman's empirical work on educational processes and social processes in educational institutions. The latter project, the development of a sociological, rational action theory, moves, so to speak, in the opposite direction. It is theory aimed at understanding social systems themselves, their development, and properties, beginning with a theory of individual action. It occupied most of Coleman's attention in the last years of his life.

Almost all of Coleman's empirical research was about growing up, about schools, and learning and educational opportunity. His first study of schools was a study of adolescent subcultures based on surveys of students in ten high schools in northern Illinois. The report on this research was published in 1961 as *The Adolescent Society* (1961). In the preface, Coleman notes two reasons for undertaking this study. One was his wish to study how schools might be more effective; he states that the study had its origin in 'a deep concern I have had, since my own high school days, with high schools and with…ways to make an adolescent experience with learning more profitable…' (1961, p. viii). The second concern was an interest in different types of social systems and the value systems they reflect. These two interests, in creating effective schools and other social organizations and in the values and cultures of social systems, would guide Coleman's research throughout his life.

The wish to study the effects of high schools on learning did not receive much attention in *The Adolescent Society*, possibly because the empirical evidence Coleman obtained about these effects, and their relationship to status systems, is quite difficult to interpret. *The Adolescent Society* is primarily a study of adolescent subcultures. The policy prescriptions Coleman drew from his analysis were about how to change these subcultures to encourage learning and academic achievement. This would be done by changing the structure of competition so that students would see academic achievement as a collective good, like sports.

The interest in the effects of schools and school social organizations on learning became the main preoccupation of Coleman's educational research for almost four decades. The link between the two concerns was always clear, and the interest in the social systems created in schools re-emerges as the

dominant concern again in his latest research. All of his educational research sees the effectiveness of schools related to the social systems created in schools and in the family and community that form the context for the school social systems. Coleman was very much a sociologist of schools.

Coleman performed three major studies of schools and educational processes after *The Adolescent Society*. The first so-called 'Coleman Report' (for a while referred to by many as the Coleman–Campbell report) was a report on the massive *Equality of Educational Opportunity* survey (Coleman et al. 1966). It is probably the largest social science survey research ever undertaken with some 600,000 students surveyed. The Report's main finding was that the instructional facilities and resources, including per pupil expenditures, have small and comparatively insignificant effects on academic achievement relative to the influence of family background. This result created considerable controversy, a controversy that continues today. A very large number of studies have focused on the issue since then. The best of this research has replicated the main conclusion: there is very little relationship between the amount of expenditure on schools and achievement outcomes, net of the family backgrounds of students. Next to family background, the family background of a student's peers, as measured for example by the racial composition of schools, seems most relevant, especially for minorities. This conclusion had an important consequence for American schools as it was used to justify racial desegregation in public schools. The second Coleman Report focused on this effect on policy: the use of busing to integrate schools and reap some of the benefits of desegregation on the academic achievement of minorities. The Report concluded that the policy had been ineffective. This conclusion was widely interpreted as denying the benefits of desegregation documented in the First Report and was strongly attacked by many, including many of Coleman's fellow sociologists. The interpretation was not correct. Coleman did not doubt the relevance of social systems created by student body composition for schools' educational climates. He doubted the long-term benefits of busing as a remedy for segregation because it encouraged white flight from desegregated public schools.

The allegation that Coleman had reversed his position would be repeated with the publications from the third major piece of educational research published in the early 1980s. In a series of publications, for example *Public and Private High Schools* (Coleman and Hoffer 1987), Coleman and co-authors concluded that Roman Catholic parochial schools produced more learning and superior educational outcomes than public schools because of superior social resources, or social capital created by the involvement of parents with schools and their personnel. These conclusions resulted in another set of published controversies, now about the existence of school effects—the very effects that were said to have been denied by Coleman in the first Report. Now, the tables had been reversed. The critiques now denied the existence of school effects, in particular the apparent superiority of Catholic schools.

Coleman strongly believed in the use of mathematics as a language for the development of social theory. His *Introduction to Mathematical Sociology* (1964) remains unsurpassed as a text on how to use mathematics, in particular stochastic process models, to mirror social processes of diffusion and influence in groups. It is an enormously rich collection of tools for the analysis of social processes. Coleman remained committed to the use of mathematics for the development of theory. Over time, he changed the type of theory focused upon, from modeling the mechanism of social processes in his early work, to modeling the outcomes of purposive action in his later work. Throughout, Coleman's contributions provide perhaps the most important demonstration of the power of mathematics as a tool for social theory in contemporary sociology.

Already in the 1960s, Coleman published several articles on a model for collective decisions where actors trade control over events and resources to maximize their interests. This work came about as a result of Coleman's interest in developing games for learning and for social theory, where players engage in transactions designed to mirror important learning tasks or to simulate basic rules of social systems. One of these games was called the legislative game, and was designed to simulate the transactions going on in a legislative body with vote trading. Coleman formalized this game in a simple model that provided equilibrium outcomes providing measures of the power of actors and the value of events. These ideas became the basis for what became his major preoccupation in the 1970s and 1980s: creating a rational action basis for social theory where the emergence of macro social structures are clearly linked to micro foundations.

The outstanding result of many years of effort became *Foundations of Social Theory* (1990). It is a major book in ambition, achievement, and size. It provides theory and theoretical tools for the analysis of existing society and the creation of better societies. The book moves from the analysis of elementary action and social relations of trust and authority to the development of norms and more complex authority systems or corporate actors, such as large corporations, and then on to the analysis of the major institutions of modern society. A major concern for Coleman was the distribution of power in society and the problem of holding corporate actors responsible for their actions. *Foundations of Social Theory* is an unfamiliar contribution to a discipline where theory often seems to be an exegeses about the theory created by those who are safely dead, or abstract conceptual development with little if any empirical reference. This

major book aims to shape the discipline by providing a theory and a mathematical structure that may have extraordinary potential for research. The realization of this potential depends not only on the quality of the ideas, but also on the discipline's ability to retool. Some concepts from the book have become prominent in sociology, for example Coleman's ideas about the micro–macro link and about social capital. However, this is only a part of this enormously rich contribution. Coleman knew that an extraordinary educational effort was needed, and he devoted much of his attention to this effort in his last years, for example, by founding and editing the journal *Rationality and Society*.

Coleman's theoretical work created a landmark in social theory. His concern for developing a mathematical language for the analysis of empirical processes created a rich set of tools that eventually may change the way sociologists work. His empirical work often includes imaginative interpretation and brilliant insights. Though his emphasis increasingly was on the project that resulted in *Foundations of Social Theory*, Coleman repeatedly returned to empirical research on causal processes with individual actions and lives as the outcome. The synthesis was accomplished in some of Coleman's latest empirical work, on schools, family, and community.

3. *Impact*

There was no lack of recognition of Coleman's scholarly contributions by the bodies that confer the highest prestige upon scientists. Coleman was elected to the American Academy of Arts and Sciences in 1966, the National Academy of Education in 1966, the American Philosophical Society in 1970, the National Academy of Sciences in 1972, and the Royal Swedish Academy of Sciences in 1984. He was a Fellow at the Center for Advanced Study in the Behavioral Sciences, a Guggenheim Fellow, and Fellow at the Wissenschaftskolleg zu Berlin. He received numerous honorary degrees from universities in the USA and Europe.

Despite all the recognition, American sociology had, and still has, considerable ambivalence toward Coleman. His international reputation, particularly in Germany, the Netherlands, and Scandinavia, and his reputation outside of sociology seemed often more solid than his reputation in American sociology. He became President of the American Sociological Association (ASA) from 1991 to 1992, but he never held another elected office in the ASA. His election to the Presidency in 1990 was the result of a write-in campaign and not of a nomination by the Association. Indeed, the leadership of the ASA, including the ASA President, tried to censor him in the mid-1970s for producing subversive sociology, because his work on the impact of busing on white flight threatened traditional liberal beliefs. It was an ignominious act that almost succeeded.

The ambivalence of the profession toward Coleman had two main sources. One was Coleman's unwillingness to specialize in one of the usual three main roles for sociologists: as theorist, methodologist, or researcher. This contradicts the implicit theory most of us have that one cannot be outstanding in all three roles. Coleman was outstanding in all three, but specialists in theory, methods, or research had difficulties recognizing his achievements. The second, and probably major, source of ambivalence was Coleman's use of research to draw policy inferences. Coleman stated what his research meant for policy and was not hesitant to do so when it contradicted conventional wisdom. He loved controversy. Each of the three Coleman Reports stated a conclusion that infuriated many: that school resources have little impact on academic achievement compared to the family resources of a child; that busing to achieve racial integration speeds up the process of white flight from our central cities; that schools organized as many private Roman Catholic schools produce more learning and less inequality in learning than schools organized like the typical public school. In every instance, an army of researchers tried to find fault with the evidence for these conclusions and largely failed. They concentrated on specific statistical issues. This was a mistake when confronting Jim Coleman. He anticipated criticisms by demonstrating the main finding in several ways. Moreover, his powerful intuitions about the mechanisms that create observed outcomes produced coherent arguments that Coleman effectively integrated with empirical analysis, while the opposition failed to formulate an alternative argument that could be sustained with evidence.

Sociology is profoundly influenced by James Coleman. So are many individual lives and careers. None of his students and followers moved with him through all the projects, but remain in one or the other of his many areas of interests. Those who had the privilege to know him were always profoundly touched by his excitement of translating into empirical analysis theoretical ideas about how social structure affects individuals. Coleman's enormous mental (and physical) energy never ceased to amaze. This energy and creativity were sustained by his certitude about the importance of the project of making sociology a better tool for a better society.

Appraisals of Coleman's scholarly and policy contributions may be found in Sørensen and Spilerman (1993) and Clark (1996). The latter volume, published after Coleman's death, includes a complete bibliography and several autobiographical fragments.

Collective Behavior, Sociology of

1. Introduction

The sociology of collective behavior begins simultaneously with the inception of modern sociology. Gustave Le Bon published *The Crowd in 1895*, two years before Emile Durkheim's *Suicide*, and two years after Durkheim's *The Division of Labor in Society*. Le Bon's descriptions and analyses of crowd behavior in the wake of the French Revolution and Paris Commune stimulated further study of crowds and, more generally, collective behavior.

Collective behavior is noninstitutionalized, unconventional group activity such as panics, crazes, mass delusions, incited crowds, riots, and reform or revolutionary movements. A sociological approach to collective behavior focuses on social conditions such as political structures and shared beliefs as these conditions influence patterns of collective behavior.

Le Bon approached the study of crowds skeptically. He argued that individuals can lose their self-identity in crowds and can commit acts they would not do alone, including physical aggression. He felt the anonymity of crowds permitted passions to surface which could be translated into violent behavior. These ideas were parallel to the distinction made by Gabriel Tarde between a public that rationally considers political issues and a crowd which acts hastily without rational consideration of the matters at hand. Yet Le Bon also felt that crowds were progressive in that they challenged existing social arrangements and often led to social change that would not have occurred without them (Wood and Jackson 1982).

Even pre-dating Le Bon in 1856 was Alexis de Tocqueville who, in *The Old Regime and the French Revolution*, argued that the French Revolution resulted from social changes occurring over several centuries, culminating in the Revolution of 1789, aided by—using a current term—the widespread sense of relative deprivation among the bourgeoisie (French middle class) and sans-culottes (French masses). He posed a paradox, and then resolved it, by indicating that the country less constrained by classical feudalism, France, was where the Revolution occurred instead of the more constrained England or Germany, for example. This occurred because France, by gradually dismantling feudalism, had improved the political and economic circumstances of the bourgeoisie and the *sans-culottes* over the centuries, but these people still felt deprived because it was clear the Old Regime would permit only so much advancement for them. This sense of deprivation relative to what they felt was their just station in life—that their expectations were significantly different from their experience–motivated participation in this monumental movement that toppled the Old Regime and became the exemplar for many subsequent revolutions.

2. Smelser's Theory of Collective Behavior

The modern, post-World War II, sociology of collective behavior is initiated by Neil J. Smelser's *Theory of Collective Behavior* (Smelser 1963). This book introduced a thoroughly sociological approach to the investigation of collective behavior. Smelser's theory contrasted with the previously dominant social psychological approach pioneered by scholars such as Robert Park and E. W. Burgess, Herbert Blumer, and Ralph Turner and Lewis Killian, who focused on topics such as crowd interaction, types of collective behavior, and emergent norms in undefined social situations.

Smelser, by stressing such variables as structural conduciveness and structural strain, along with the other variables in his theory—growth and spread of generalized beliefs, precipitating factors, mobilization of participants for action, and weakening of social control—highlighted the importance of sociological conditions as determinants of collective behavior.

In focusing on these six sociological factors, he moved the field of collective behavior away from

social psychological theories stressing single variables such as anonymity of crowds, economic deprivation, alienation, and strong leadership (Wood and Jackson 1982).

Smelser showed that these single variables had a place in understanding the development of collective behavior, but that they had to be seen in combination with other relevant variables in order to increase the likelihood of collective behavior actually occurring. Indeed, Smelser argued that the six variables in his system constituted necessary, or required, conditions for the occurrence of collective behavior; and when combined at the same time and place, the six variables constituted a sufficient, or fully predictive, condition for the occurrence of some type of collective behavior. Thus, when the six conditions occurred simultaneously, Smelser predicted that a craze, panic, riot, reform, or revolutionary movement would occur.

Smelser furthermore argued that different aspects of the six conditions, and their particular combinations, could help predict which of the five types of collective behavior mentioned above would be the one to occur (e.g., a reform or revolutionary movement). If, for example, there was considerable economic strain in society, the spread of radical political beliefs, precipitating factors such as the arrest of dissidents, attempts by movement leaders to mobilize politically large numbers of people, and the weakening effectiveness of agents of social control such as the police and army, Smelser's theory would then ask, in what kind of society did all this occur? If the society was democratic, Smelser argues that this kind of society would be structurally conducive to the development of a reform, or norm-oriented, movement such as the Civil Rights Movement in the USA. If instead the society was authoritarian, Smelser argues that this kind of society would be structurally conducive to the development of a revolutionary, or value-oriented, movement such as the Russian Revolution.

Smelser's theory attracted considerable attention from the start, and it generated a large empirical literature within a decade of its publication, much of which supported the theory (Marx and Wood 1975).

3. *Subsequent Approaches*

3.1 *Resource Mobilization*

Smelser's theory also attracted critics, some of whom developed their own approaches that form the basis of current collective behavior analysis. These other approaches will now be examined for their contributions to the sociology of collective behavior, many of which owe at least indirect inspiration from *Theory of Collective Behavior*, as is indicated by several themes such as conditions of conduciveness and strain in the seminal collection of articles covering the last decade of social movement research organized by McAdam and Snow (1997). As Klandermans (1997, p. 201) states, 'One need not concur with Smelser … to appreciate the usefulness of these categories and assess maybe with some surprise how akin they are to other more recent conceptualizations.'

The first well-known approach signaling not only a critique of, but also an attempted alternative to, *Theory of Collective Behavior*, was resource mobilization theory pioneered by Mayer Zald and John McCarthy. While retaining an interest in the origin of collective behavior and social movements—a key question for Smelser—the resource mobilization approach began to shift the basic question addressed. Resource mobilization, and other subsequent approaches, became particularly interested in social movement success or failure, and the conditions—such as availability of resources like money and media attention—that are associated with movement success or failure.

3.2 *Political Process Model*

Doug McAdam pioneered another important approach to understanding the success—as well as development—of social movements by focusing on the political process involved in such movement development and success. In his first book on the topic, *Political Process and the Development of Black Insurgency* 1930–1970, McAdam (1982) outlined, and documented the importance of, four conditions that he showed to be associated with the rise of militant black politics and black political achievements in the USA in this crucial 40-year period. These four conditions were as follows: (a) 'the degree of organizational "readiness" within the minority community'; (b) 'the level of "insurgent consciousness" within the movement's mass base'; (c) the 'structure of political opportunities'; and (d) the 'level of social control' (McAdam 1982, pp. 40, 53). Using historical examples to show variations in these four conditions, McAdam does a masterful job of explaining the ensuing black political movements of mid-twentieth century America.

In focusing on the four conditions, McAdam has both drawn upon, and extended, the scope of Smelser's six conditions of social movement development. There is overlap between McAdam's variables and Smelser's with, for example, organizational readiness being an aspect of mobilization of participants for action, and insurgent consciousness being an aspect of generalized beliefs. Yet McAdam also extends Smelser's model by using the four conditions to help explain the successes of black protest in the USA as well as understand its initial development in this historical period. Finally, McAdam, his associates, and others have further extended and applied the political process model to yet other instances of social movement activity (McAdam and Snow 1997).

3.3 Political Opportunity Model

One of the conditions in McAdam's model is 'the structure of political opportunities,' a concept elaborately developed by Sidney Tarrow. In a series of books and monographs, Tarrow (1991, 1998) has utilized the political opportunity model to understand the circumstances whereby contentious social movements can achieve success. Using a wide variety of case studies, often ranging from the social movements of the 1960s to the movements, conflicts, and changes in Eastern Europe in the 1990s, Tarrow shows how a variety of political structures have influenced the success, or lack of success, of these social movements.

Drawing on the seminal work of Michael Lipsky and others, Tarrow (1991, p. 32) defines political opportunity structure as 'political situations in which states become vulnerable to collective action and in which ordinary people amass the resources to overcome their disorganization and learn where and how to use their resources.' This definition clearly incorporates an important element of resource mobilization theory, namely the significance for movement success of masses of people obtaining and utilizing resources such as money, media attention, and organizational connections. But it also puts these resources in the special political context of governments being particularly susceptible to mass political pressure.

Regarding several scholars' use of political opportunity theory, such as J. Craig Jenkins and Charles Perrow, Tarrow (1991, pp. 34–6) points to five variables often used by these scholars to identify conditions associated with governments being especially susceptible to the influence of social movements: (a) the degree of openness or closure of the polity, with open polities more favorable to social movements; (b) the stability or instability of political alignments, with less stable alignments more favorable to social movements; (c) the presence or absence of allies or support groups, with more allies and support groups favorable to social movements; (d) divisions or lack of divisions within the elite, with elite divisions favoring social movements; and (e) tolerance or intolerance of protest by the elite, with tolerance of protest favoring social movements. These and other elements of political opportunity theory are woven throughout various complex analyses by Tarrow and others to show how shifting political circumstances significantly affect the fortunes of social movements, often resulting in cycles of protest for the movements.

3.4 Recruitment: Social Network Analysis

One of the more informative later approaches to social movements is social network analysis that helps explain why people with similar ideologies are differentially recruited—that is, why some of them join social movements and others do not. As discussed, Smelser (1963) was the first modern collective behavior analyst to note that single variables such as ideology, by themselves, did not have considerable explanatory power. Snow, Zurcher, and Ekland-Olson (in McAdam and Snow 1997) demonstrated that those who belong to social networks are considerably more likely to act upon their ideology by joining a social movement than those without network affiliations. This goes a long way toward explaining why empirical studies since the 1970s have shown low to moderate, as compared to strong, relations between ideological commitment and movement participation (Wood and Jackson 1982). That is, the relationship between ideology and movement participation is influenced by the extent of social network involvement, so that taking network involvement into account strengthens the relationship between ideology and movement participation.

In fact, this latter social network finding was preceded, and influenced by, the earlier finding that membership in secondary organizations—such as business, trade union, church, or even recreational associations—facilitated recruitment to social movements (Marx and Wood 1975, Wood and Jackson 1982). In contrast, mass society theory, as elaborated by William Kornhauser, had previously argued that the absence of such memberships facilitated recruitment. Other discussions of social network analysis have included topics such as the types of networks needed to facilitate recruitment, the role of conflicting group memberships in recruitment, and the size of networks for recruitment (McAdam and Snow 1997). Thus, with its organizational focus, social network analysis provides valuable insights into issues ranging from how political ideology gets translated into social movement participation to the influence of organizational size on movement recruitment.

3.5 The New Social Psychology

Bert Klandermans and his associates have developed a new social psychological approach to social movements, aptly summarized in his book, *The Social Psychology of Protest* (Klandermans 1997). This new social psychology analyzes recruitment to social movements, as did an earlier social psychological approach, but also includes such topics as framing of social movements, identity politics, new social movements, the transformation of discontent into movement participation, and the relation of social psychology to social movement organizations and interorganizational analysis. Whereas an earlier social psychology of social movements emphasized the influence of single variables such as relative deprivation or ideology on movement participation (Wood and Jackson 1982), or focused on emergent norms influencing such participation (Turner and Killian 1972), the new social psychology sees potentially sympathetic individuals responding to a variety of

social and cultural influences that may, or may not, lead to actual movement participation. Among these influences are the social networks and organizations discussed previously, which are seen to promote participation. The new approach also discusses circumstances, such as a deepening political consciousness, favoring—or inhibiting—sustained participation, as discussed by Molly Andrews in *Lifetimes of Commitment*.

Among the influences more recently discussed is the manner in which a movement is framed, which is its presentation to the public—especially by the media—an approach significantly inspired by Ralph Turner's important article, 'The public perception of protest' (Turner 1969). Is a movement for female reproductive rights portrayed as a movement to enhance the social, economic, and political rights of women, or is it presented as a movement to deprive unborn children the right to live? Is a movement for better hours, wages, and working conditions portrayed as a just cause for exploited working people, or is it an excuse for 'union bosses' to expand their power? The new social psychology goes into detail explaining how movements and their oppositions attempt to frame the movements in ways to encourage or discourage actual participation by those with initial interest in the movements.

One of the more controversial emphases discussed by the new social psychology—and which has its own literature by scholars such as Alberto Melucci—focuses on the role of personal identity in understanding the development of recent movements and why certain people are drawn to these movements. In an informative book entitled *Ideology and the New Social Movements*, Alan Scott (1990) indicates why social movements such as the student movement of the 1960s, the modern women's movement, and ethnic movements such as the black movement in the USA should be called new social movements. He argues that these movements are new because, first, they are not the traditional labor movement that arose from conflicts and contradictions between groups of labor and capital involved in the means of economic production, and second, because they are instead based on—and arise from—issues of personal identity such as one's gender, status as a student, and racial or ethnic background. This type of position draws loosely on Orrin Klapp's imaginative, though less empirically oriented book, *Collective Search for Identity*.

Whereas Scott argues that these considerations of identity are paramount in forming the new social movements—and figure in any success of the movements—others such as Todd Gitlin (1995) have argued that excessive involvement with personal identity issues such as these can detract from more general or universal themes such as the fight for decent conditions of work, fair allocation of income in a society, and improvement of lifestyles for all instead of just for particularistic group interests. Still other arguments have focused on the fact that a key basis for organizing women and ethnic minorities, especially, has been the need to improve their status economically, occupationally, educationally, legally, and in terms of lifestyles and life opportunities. Responding to higher education budget cuts in the 1990s, students from varying backgrounds rallied together, along with faculty from varying backgrounds, to fight these cuts and preserve educational and career opportunities (Wood 1998). Thus, identity politics may well be fairly important in organizing given modern social movements, but the continuing issues of economics, education, legal rights, lifestyles, and life opportunities remain as important to the new movements as to the labor movement.

3.6 Historical–Comparative Analyses of Revolutions

There is a body of highly scholarly, detailed historical and comparative analyses of revolutions. Barrington Moore, George Rudé, E. P. Thompson, Charles Tilly, Theda Skocpol, Eric Hobsbawm, and Jack Goldstone are among the major contributors to the understanding of such classical social and political upheavals as the French Revolution, Russian Revolution, English Revolution, and Chinese Revolution. These authors combine analyses of conditions common to several revolutions, such as the weakening of state authority, with analyses of conditions unique to some upheavals but not others, such as differing cultural ideology.

Skocpol (1979), for example, analyzes social revolutions that entail not only political change at the top of society, but also large-scale social–economic change throughout the society. She argues that weakening of the state and military, peasant rebellions, and alienated marginal elites combined to bring about social revolutions in France, Russia, and China. Goldstone (1991) also looks at similar conditions of revolutions, as well as demographic conditions, but adds in an ideological dimension of why social revolutions were more likely to occur in the West with its Judeo-Christian ideology that emphasized large-scale transformations of society. Thus, for Goldstone, social revolutions instead of palace coups or military conquests, for example, were seen as the secular application of Western ideology as compared with non-Western ideologies such as Hinduism or Buddhism that were associated with different political results. This body of literature is complex, but highly informative for deeper understandings of the processes whereby revolutions develop.

3.7 Analyses of Other Forms of Collective Behavior: Riots, Panics, Crazes, and Mass Delusions

The sociology of collective behavior has been interested in longer-term, more organized social move-

ments, as well as shorter-term, less organized, and less political forms of noninstitutionalized group behavior. A. C. Kerckhoff and K. W. Back's interesting study of mass delusion, *June Bug*, analyzed perceptions in an American city that its inhabitants were being bitten each summer by a June Bug. The two researchers were in this city, determined that no such insect existed, and then utilized Smelser's (1963) theory of collective behavior to understand the development of this unusual craze.

In the late twentieth century, various cults have been the focus of collective behavior analysis, with discussions including Jim Jones' People's Temple cult that committed mass suicide, the Heavens Gate cult that acted similarly while anticipating transportation to another planet, and the San Diego-based cult focusing on a goddess, with a public access television show, who also promised her followers transportation to an extraterrestrial land (Tumminia and Kirkpatrick 1995). These studies have focused on the circumstances—social and personal—that would lead people to join such cults, as well as circumstances that keep them involved, especially in terms of members' susceptibility to suggestions and new influences due to their isolation from familiar surroundings and social networks.

Riots are a type of crowd behavior studied since Le Bon's *The Crowd*. For many years riots—that is, violent crowd activities—were seen as irrational, spontaneous, and unorganized group activities. This picture has changed over the years, with riots now more often seen as outcomes of oppression and deprivation, having some rational connection to anticipated outcomes, and having at least some organization (McPhail 1989). Indeed, Gary Marx felt compelled to add a correction to the increasingly ideological characterization of riots by discussing 'issueless riots,' such as crowd violence after athletic victories. Nonetheless riots, along with social movements, are typically seen as responses to difficulties that groups experience that are at least understandable, or even as rationally calculated responses to these difficulties (Tarrow 1991, 1998).

4. Conclusion

The sociology of collective behavior is one of the most dynamic and innovative fields of study in sociology. Indeed, Alain Touraine has stated that the study of social movements is sociology. Collective behavior has always had the ability to inspire and appall. Those sympathetic to the French Revolution remain in awe of the social class changes brought about by it, whereas those in opposition remain dismayed by the violence connected with it. Even a harsh critic of collective behavior like Le Bon felt that progress would not occur without the crowds he nonetheless disliked. As such, collective behavior will continue inspiring and appalling large numbers of people since it persists in dealing with the most electrifying of human dramas.

Collective Beliefs: Sociological Explanation

The sociological tradition considers the explanation of collective beliefs as an essential task. In his famous *Elementary forms of religious life* (1912, 1995), Durkheim presents this explanatory project as the center of gravity of the sociological discipline. Although of decisive importance, this project remains confronted with certain difficulties. First, the extreme diversity of the collective beliefs. The members of modern and traditional collectivities develop many and varied forms of thought: ideological, religious, magic, scientific, etc. Impressed by this diversity, sociologists have sometimes multiplied the explanatory categories and by doing so have forgotten that the vocation of any explanatory theory is to establish the simplicity behind the apparent complexity.

Another difficulty is the permanent and undoubtedly irreducible *tension* on which the sociological explanation of collective beliefs rests. The sociologist must maintain a sufficient proximity to the observed beliefs as to be able to identify their specific qualities, while remaining sufficiently distant to preserve the autonomy of the sociological interrogation. The history of the various ideological drifts of the sociological analysis shows that this balance is not always easily accessible.

A short detour by sociological tradition will initially remind us of the diversity of the sociological explanations of the collective beliefs. On a second occasion, we will identify some of the general criteria used by sociologists to evaluate the respective merits of these various explanations. Finally, we will be interested in the reasons why many contemporary sociologists consider the generalization of the principle of 'symmetry' as significant progress for the sociological explanation of collective beliefs.

1. *The Diversity of Sociological Explanations*

In a classical article intended to provide a general theoretical framework for the sociology of knowledge, R. K. Merton (1945) summarizes the nature of the sociological explanation in the following way: to establish the correlations between collective beliefs, conceived as dependent variables, and 'the other existential factors of society and culture' conceived as independent variables. If such a formula makes it possible to unify many sociological studies devoted to the explanation of collective beliefs, this unity remains however purely 'formal.' The diversity of the sociological explanatory modes must be considered on at least two levels: on the one hand the nature of these 'existential factors' mentioned by Merton, on the other the nature of the 'relation' which links these factors to the collective beliefs.

Some examples may be useful. Ideology constitutes a traditional object of the sociology of collective beliefs. These sociopolitical belief systems play a central role in the legitimization of the social order of modern societies. The sociological explanation of ideologies generally consists of replacing them in the singular interaction system in which they appear. There is not, however, a single way to conceive the nature of this system. The Marxist tradition, for example, identifies this system with a complex set of 'social interests.' This explanatory scheme initially suggested by Marx (1852) is primarily of a 'utilitarist' nature. If a social group believes in the value of such or such a politico-social organization, it is not because of its intrinsic value, but because this precise type of organization reinforces directly or indirectly its social domination, and consequently its material interests. The social utility of the ideological belief overrides its truth or falseness.

If this utilitarist approach of collective beliefs has been presented by K. Mannheim (1929, 1991) as a fundamental stage for the emergence of the sociology of knowledge, it is not the only possible one. The paretian study of religious beliefs, for example, rests on a very different conception of the existential factors mentioned by Merton. In his famous *Traité de sociologie générale*, Pareto (1916, 1968) analyzes the social diffusion of the religions as the consequence of social 'feelings.' He affirms the importance to clearly separate the respective influence of 'derivations'—ideas, theories, theologies, etc.—and 'residues'—deep-rooted feelings: 'the social value of the religions,' Pareto writes, 'depends very little on derivations, enormously on the residues. In several religions, there is a significant group of residues (…) which correspond to feelings of discipline, submission, hierarchy' (§1854). In a way, this explanatory scheme developed by Pareto is very different from the one proposed by Marx for the ideologies: if a social group massively adopts a religion, it is not because of its direct or indirect social 'utility' but because it somehow manages to satisfy the dominant 'passions' of this group. In another way, however, these two explanatory schemes are quite similar. Marx for the ideologies and Pareto for the religions both explicitly consider that the link between the dependent and independent variables has to be conceived as a 'causal' relation. The adoption of a belief by a social group appears in both cases as the mechanical consequence of 'forces'—interest or passions—which dominate the conscience of its members. These forces remain out of the control of the social actors.

This causal approach has sometimes been used to explain the existence of magic beliefs. Lévy-Bruhl (1922, 1960) sees the persistence of magic beliefs in traditional societies as the mechanical consequence of a specific mental structure: the 'primitive mentality.' This mentality, Lévy-Bruhl suggests, prevents the members of these communities from perceiving the

objective difference between verbal similarity and real similarity and, in a more general way, the difference between the relations between the words and the relations between the things. However, works of Durkheim and Weber show that this approach of magic beliefs is far from being the most fruitful. In their respective analyses of the magic beliefs, they both identify the 'existential' factor to the immediate environment of the social actors. They both also conceptualize the relation between this environment and the collective belief as 'rational' or more precisely as *subjectively rational*. 'The acts motivated by magic,' Weber writes (1922, 1979), 'are acts at least relatively rational (…): they follow the rules of the experience even if they are not necessarily acts according to the means and ends.' The same point is emphasized by Durkheim (1912, 1995), in particular, when he compares the rationality of traditional 'rites' and the rationality of modern 'techniques': 'the rites which [the primitive] use to ensure the fertility of the ground (…) are not, to him, more irrational than are, to us, the technical processes used by our agronomists (…). The powers linked to these rites do not appear particularly mysterious. For those who believe in them, those forces are not more unintelligible than are gravity or electricity to a contemporary physicist.' The explanatory strategy proposed by Weber and Durkheim thus exists mainly to identify the role of the collective belief in the adaptation process of the social actor to his immediate environment, and thus to reconstruct the 'meaning' of the belief for this actor.

The sociologists have also paid great attention to scientific beliefs. Sorokin (1937), for example, attempts to demonstrate 'that what a given society regards as true or false, scientific or unscientific (…) is fundamentally conditioned by the nature of the dominant culture.' He analyzes the relation between the social 'credibility' of scientific representations of reality and the evolution of cultural values. The Sorokinian 'existential' factor is different from the factors previously observed in Marx, Pareto, Weber, or Durkheim's works: it consists mainly of a 'cultural framework' evolving in a cyclic way. The 'relation' between dependent and independent variables remains however similar to the relation theorized by Durkheim and Weber. The social groups, Sorokin says, select their scientific beliefs according to a general principle of 'logical dependence' or 'logical consistency.' Merton (1938, 1970) shares with Sorokin the will to establish the social conditions of the scientific development. However, he emphasizes, the 'functional' nature of the relation which linked the natural sciences of the seventeenth century to their socio-historical contexts. Scientific knowledge, Merton observes, is obviously developed on the basis of cognitive constraints but this development also integrates, in variable proportions, the influence of social factors. The statistical analysis applied to technological inventions shows in particular that a great number of these inventions are intended to bring a solution to maritime transport, mining industry, or military technology problems. The production of the scientific beliefs may be partially interpreted as an attempt of the scientific community to satisfy an explicit or diffuse social demand.

2. *Three Elementary Conditions of Sociological Explanations*

As shown by these classical examples, sociologists refer in the course of their studies to multiple existential factors: interest (Marx), passion (Pareto), structure of interaction (Durkheim, Weber), cultural framework (Sorokin), socioeconomic development (Merton). They diverge moreover in their way of representing the nature of the relation between these factors and the studied collective beliefs. Three general approaches of this relation are regularly observable: causal (Marx, Pareto), functional (Merton), and rational (Durkheim, Weber, Sorokin). It also happens sometimes that sociologists try to evaluate the objective range of their own explanations. The question they then have to face can be summarized in the following way: which conditions do sociologist need to respect in order to produce a solid explanation of collective beliefs? Three elementary conditions deserve to be briefly underlined.

First condition: the sociological explanation of collective belief must be more than the translation of the phenomenon to explain a new idiom

The sociologists of beliefs generally start from the identification of an enigmatic phenomenon. Why does the industrial bourgeoisie of the nineteenth century believe in the virtues of parliamentary monarchy (Marx)? Why do Zunis Indians adopt a representation of the world in seven categories (Durkheim)? Why are corpuscular and ondulatory theories of light widely accepted during the nineteenth century (Sorokin)? etc. But it sometimes happens that their answers are only apparent. The methodological analysis of the theory of 'primitive mentality' shows thus that if the theory of Lévy-Bruhl does not convince anymore it is essentially because it does not explain anything. The key concepts of this theory, Boudon underlines (1990, 1994), 'only paraphrase the beliefs. They explain the confusion of the primitives between verbal associations and causal relations by the primitive's tendency to make this confusion, tendency whose reality is guaranteed by the fact that they do make it indeed.' A similar point is made by Merton (1945) concerning Sorokin's theory. 'It seems tautological,' Merton writes, 'to say, as Sorokin does, that in a sensualist society and culture, the sensualist system of the truth based on the testimony of the sensory organs must prevail. Because he had already defined the sensualist mentality as one

which conceives reality as being only what is perceived with the sensory organs.' More recently, S. Cole (1996) pointed out that the analysis of the production of scientific beliefs by certain constructivist sociologists of sciences is primarily of circular nature. These sociologists generally claim 'that it is impossible to separate the technical from the social; that all science is inherently social. This turns their entire argument into a tautology. If science is inherently social, this means that the technical aspects of scientific discoveries by necessity must be determined socially. This is indeed the question we are examining.'

Second condition: the sociological explanation of collective beliefs must avoid ambiguous and/or occult concepts

Sociologists use a great number of conceptual categories. Many proposals produced on the basis of the combination of these categories make clear and univocal sense, some however remain more ambiguous. For example, certain sociological explanations rest on an ambiguous concept of 'social,' or more precisely a confusion between the 'social' and 'historical' dimensions of a collective belief. To show, however, that a belief appears in a particular historical context is not the same as to demonstrate its social character. L. Laudan (1977) is right to observe that 'the fact that certain assertions are contextual, that one adhered to it only to a certain time and in a certain place establishes neither that they are necessarily of social origin, nor even that they are opened to the sociological analysis.' The sociological use of the concept of 'interest' constitutes another well-known example of ambiguity. This concept is sometimes used by sociologists of science in order to describe the origin of the prestige or credibility of scientific beliefs. In an underdetermined situation, contemporary sociologists of science say, the scientists choose between two concurrent theories the one which appears conform to their 'interests.' However, how do we have to conceive the exact nature of these interests? Are they material interests, symbolic interests, technical, or cognitive interests, etc.? As long as the concept of interest remains ambiguous, the sociologist cannot legitimately claim to explain the observed beliefs. In addition, following a Weberian principle, many sociologists closely associate the solidity of an explanation to the manner in which these explanations avoid using occult categories, i.e. invisible 'forces'—as the Paretian concept of 'residue' or the 'primitive mentality' of Lévy-Bruhl—which determines the behaviors of the social actors. The methodological principle is simple and easily acceptable: the sociologist seeking to account for the origin of a collective belief may refer to the existence of an occult cause only insofar as he cannot explain this belief more easily, in particular by identifying his meaning. The obvious difference between the explanations of magic beliefs proposed on the one hand by Lévy-Bruhl and on the other by Durkheim and Weber seems to be directly linked to the application of this general principle by the latter.

Third condition: the sociological explanation of collective belief must be compatible with observable facts

This third condition can be interpreted in various ways. The first and simplest one consists of assuming that explanatory theories of scientific beliefs are not different from other scientific theories. They must not only dispose of various internal qualities (absence of circularity, precision, etc.) but also be able to be confronted with precise facts, and further still to resist this empirical test. These facts might be elementary observations. The observation, for example, of the persistence of the magic beliefs in Western societies seems hardly compatible with the assumption of a causal link between the magic beliefs and a 'primitive mentality' (Lévy-Bruhl). In the same way the observation of the developments of new religious movements in large cities enters openly in contradiction with the hypothesis that the contemporary process of urbanization is essentially a vector of disintegration of collective belief (Borhek and Curtis 1975). These facts can also be more complex products of the interpretative reconstruction work done by the sociologist or anthropologist. When R. Horton (1993) argues for example against the tenants of symbolist theory of magic, he points out that this theory, for which magic beliefs are mainly the expression of a symbolic 'desire,' enters into flagrant contradiction with what the members of the traditional societies say about their own rituals: '(…) in denying the paramount importance of explanation, prediction and control as guiding aims of traditional African religious life, ''symbolists'' (…) are committing the cardinal interpretative sin of flouting the actor's point of view.' Another way to interpret this third condition consists of associating the solidity of an explanatory theory with its capacity to give an account of other beliefs than the one for which it was initially elaborated. Is it for example possible to apply the explanatory scheme imagined by Durkheim and Weber for magic beliefs to other types of beliefs, such as the ideological ones? The fact that this transposition is not only possible but brings an objective gain of intelligibility for the comprehension of the ideological phenomenon (Boudon 1986, 1989) demonstrates the real value of their general conception of the sociological explanation.

3. *The Symmetry Principle*

Sociologists frequently add to these three general conditions a final one: a condition known as the 'principle of symmetry.' This principle implies that the explanation of the collective beliefs should be equally applied to phenomena of various natures. This last condition is not reducible to the conditions previously mentioned (the third one in particular) insofar as, to identify the nature of this plurality, it introduces a

criterion of truth and falseness, rationality and irrationality. A sociological theory of collective beliefs is said to be symmetrical if it explains *in the same terms* true beliefs and false beliefs, rational beliefs and irrational beliefs. This principle, implicitly used by Sorokin (1937), is directly opposed to the 'a-rationality principle' according to which the sociological explanation of the collective beliefs cannot be indifferent to the content of these beliefs.

The interest of the principle of symmetry is double. From a methodological point of view, it requires the suspension of all evaluation related to the potential validity or invalidity of the analyzed collective belief. It thus represents a guarantee of neutrality. From the point of view of the empirical research, it makes it possible to follow in unified and thus simplified terms the manner in which the collective beliefs obtain a social recognition, or inversely an absence of social recognition.

The sociological use of this principle followed, however, two paths of unequal importance. The first, chosen by some sociologists of science, exists mainly to explain the scientific beliefs in terms of explanatory categories previously devoted to false beliefs. Linked to an exclusively causal approach of scientific belief production, this first use of the principle of symmetry has greatly contributed to the diffusion of a relativistic representation of science (Dubois 2001). There is, however, another way to apply this principle. It consists of following the major intuition of the theory proposed by Weber and Durkheim: to seek behind all collective beliefs, true or false, socially validated or socially marginal, the influence of 'reasons,' objective and/or subjective. Thus as R. Horton (1993) is reconstructing the limited rationality of certain African rituals, he defines the major nature of its explanatory project as follows: elaborating 'an explanatory framework which would deal "symmetrically" with the traditional and the modern, the prescientific and the scientific.'

Collective Identity and Expressive Forms

If key concepts or expressions can be identified that function to capture the animating spirit of different epochs, then certainly one candidate concept for the latter quarter of the twentieth century is the concept of collective identity. Indeed, it is a concept that came of age in the latter part of the past century, as reflected in the outpouring of scholarly work invoking the concept directly or referring to it indirectly through the linkage of various collectivities and their identity interests via such concepts as identity politics, identity projects, contested identities, insurgent identities, and identity movements. This article provides an analytic overview of scholarly work on the concept by considering, in order, its conceptualization, its various empirical manifestations, the analytic approaches informing its discussion and analysis, and several unresolved theoretical and empirical issues.

1. Conceptualization

The concept of collective identity, just as the base concept of identity, is rooted in the observation that interaction between two or more sets of actors mini-

mally requires that they be situated or placed as social objects. To do so is to announce or impute identities. Hence, interaction among individuals and groups, as social objects, is contingent on the reciprocal attribution and avowal of identities. This character of identity is highlighted in Stone's (1962) conceptualization of identity as the 'coincidence of placements and announcements.' This process holds for both individuals and collectivities, and it probably has always been a characteristic feature of human interaction, whether the interaction was among early preliterate humans or among those in the modern social world. To note this is not to ignore the sociological truism that the issue of identity becomes more problematic and unsettled as societies become more structurally differentiated, fragmented, and culturally pluralistic (Castells 1997, Giddens 1991). But historical variation in the extent to which matters of identity are problematic does not undermine the double-edged observation that the reciprocal imputation and avowal of identities is a necessary condition for social interaction and that identities are thus rooted in the requisite conditions for social interaction.

Delineating the interactional roots of identities does not explain what is distinctive about collective identity, as there are at least three conceptually distinct types of identity: personal, social, and collective. Although they often overlap, one cannot be inferred from the other. Hence the necessity of distinguishing among them.

Social identities are the identities attributed or imputed to others in an attempt to situate them in social space. They are grounded typically in established social roles, such as 'teacher' and 'mother,' or in broader and more inclusive social categories, such as gender categories or ethnic and national categories, and thus are often referred to as 'role identities' (Stryker 1980) and 'categorical identities' (Calhoun 1997). Whatever their specific sociocultural base, social identities are fundamental to social interaction in that they provide points of orientation to 'alter' or 'other' as a social object.

Personal identities are the attributes and meanings attributed to oneself by the actor; they are self-designations and self-attributions regarded as personally distinctive. They are especially likely to be asserted during the course of interaction when other-imputed social identities are regarded as contradictory, as when individuals are cast into social roles or categories that are insulting and demeaning (Snow and Anderson 1987). Thus, personal identities may derive from role incumbency or category-based memberships, but they are not necessarily comparable since the relative salience of social roles or category membership with respect to personal identity can be quite variable.

Just as social and personal identities are different yet typically overlapping and interacting constructs, such is the relationship between collective and social and personal identities. Although there is no consensual definition of collective identity, discussions of the concept invariably suggest that its essence resides in a shared sense of 'one-ness' or 'we-ness' anchored in real or imagined shared attributes and experiences among those who comprise the collectivity and in relation or contrast to one or more actual or imagined sets of 'others.' Embedded within the shared sense of 'we' is a corresponding sense of 'collective agency.'

This latter sense, which is the action component of collective identity, not only suggests the possibility of collective action in pursuit of common interests but even invites such action. Thus, it can be argued that collective identity is constituted by a shared and interactive sense of 'we-ness' and 'collective agency.' This double-edged sense can be culled from classic sociological constructs such as Durkheim's 'collective conscience' and Marx's 'class consciousness,' but is reflected even more clearly in most conceptual discussions of collective identity, although the agentic dimension is sometimes implied rather than directly articulated (e.g., Castells 1997, Cerulo 1997, Eisenstadt and Giesen 1995, Jasper and Polletta 2001, Jensen 1995, Levitas 1995, Melucci 1989, 1995).

A common theme running throughout a segment of the literature is the insistence that collective identity is, at its core, a process rather than a property of social actors. Such work acknowledges that collective identity is 'an interactive and shared definition' that is evocative of 'a sense of we,' but then highlights the process through which social actors recognize themselves as a collectivity, contending that this process is more vital to conceptualizing collective identity than any resultant product or property (e.g., Melucci 1989, pp. 34, 218, passim). Few scholars would take exception with the importance of the process through which collective identities develop, but it is both questionable and unnecessary to contend that the process is more fundamental than the product to understanding the character and functionality of collective identity. Not only is the product or 'shared we' generative of a sense of agency that can be a powerful impetus to collective action, but it functions, as well, as the orientational identity for other actors within the field of action. More concretely, it is the constructed social object to which the movement's protagonists, adversaries, and audience(s) respond (Hunt et al. 1994), and which, in turn, may have implications for the operation of its organizational carrier, affecting the availability and character of allies, resources, and even tactical possibilities (Jensen 1995). The initial projected collective identity may be short-lived and transient, subject to modification and even transformation during the course of ongoing collective (inter)action, but the set of properties that makes up the initial collective identity, as well as whatever subsequent ones emerge, constitute objects of orientation and interaction for other collectivities within the field of action.

If it is acknowledged that there is something of substance to collective identities, how are they distinguished from social and personal identities? Several factors appear to be at work. First, collective identities may or may not be embedded in existing social identities, since they are often emergent and evolving rather than firmly rooted in prior social categories. This is often the case with the collective identities that emerge in the course of dynamic social protest events (for illuminating examples, see Walder's research on the Beijing Red Guard Movement (2000), and Calhoun's account of the Chinese student movement of 1989).

Second, the collective, shared 'sense of we' is animating and mobilizing cognitively, emotionally, and sometimes even morally. The shared perceptions and feelings of a common cause, threat, or fate that constitute the shared 'sense of we' motivate people to act together in the name of, or for the sake of, the interests of the collectivity, thus generating the previously mentioned sense of collective agency. That potential inheres within social identities, but they typically function more like orientational markers as the routines of everyday life are negotiated. When they are activated or infused affectively and morally, it is arguable that they have been transformed into collective identities. Third, the emergence and operation of collective identities means that other social identities have subsided in relevance and salience for the time being. In other words, collective identities, when they are operative, generally have claims over—not so much normatively as cognitively and emotionally—other identities in terms of the object of orientation and character of corresponding action. Examples abound, as observed frequently in the case of many protest gatherings, gripping fads, joyous and celebratory sports crowds, and the concerted campaigns and actions associated with social movement activism. Fourth, while collective identities and personal identities are obviously different, they are still very much interconnected in the sense that collective identities are predicated, in part, on constituents' embracement of the relevant collective identity as a highly salient part of their personal identity and sense of self (Gamson 1991). Finally, while the attribution or avowal of all identities is interactionally contingent, collective identities tend to be more fluid, tentative, and transient than either categorically based social identities or even personal identities.

2. *Empirical Manifestations*

Empirical manifestations of collective identity can vary in a number of significant ways. One important axis of variation is the size of the collectivity and the corresponding scope of its claims. If the essence of collective identity resides in a sense of 'we-ness' associated with real or imagined attributes in contrast to some set of others, then it follows that collective identities can surface among almost any grouping or aggregation in a variety of contexts, ranging from relatively small cliques and gangs to sports fans and celebrity devotees, to laborers and occupational groupings, to neighborhoods and communities, to even broader categories such as sexual and gender categories, religions, ethnic groups, and nations.

The preponderance of empirical research on collective identity has focused on the last, more inclusive set of categories—sexuality and gender, religion, ethnicity, and nationality. Illustrative is Taylor and Whittier's (1992) research on lesbian identity and lesbian social movements; Nagel's (1996) work on the resurgence of collective identity among American Indians; Cornell and Hartmann's (1998) overview of the construction of ethnic and racial identities in the modern world; and Anderson's (1991) and Calhoun's work on nationalism, which the latter defines, in part, as one 'way of constructing collective identities' (1997, p. 29). An additional characteristic of research on collective identity is its association with the study of social movements, no doubt because such mobilizations tend to be both generative of and dependent on collective identities (e.g., Gamson 1991, Hunt et al. 1994, Jasper and Polletta 2001, Melucci 1989, Snow and McAdam 2000).

Although collective identities can congeal in various aggregations and contexts, they appear not to do so on a continuous basis historically. Instead, their emergence and vitality appear to be associated with conditions of sociocultural change or challenge, socioeconomic and political exclusion, and political breakdown and renewal, thus suggesting that they cluster historically in social space. The latter part of the twentieth century has generally been regarded as one such period of collective identity effervescence and clustering, with some scholars characterizing this period in terms of identity crises and collective searches for identity (e.g., Castells 1997, Gergen 1991, Giddens 1991, Klapp 1969).

In *The Power of Identity*, Castells captures both this characterization and the kinds of conditions thought to be associated with the various manifestations of collective identity during this period:

> Along with the technological revolution, the transformation of capitalism, and the demise of statism, we have experienced, in the last quarter of the century, the widespread surge of powerful expressions of collective identity that challenge globalization and cosmopolitanism on behalf of cultural singularity and people's control over their lives and environment (Castells 1997, p. 2).

3. *Analytic Approaches*

To note that expressions of collective identities cluster historically according to the conjunction of various social conditions does not specify the character or

content of the emergent collective identities. This issue has been addressed from the vantage point of three contrasting perspectives: primordialism, social structuralism, and social constructionism.

Both the primordialist and structuralist views can be construed as variants of an overarching essentialist perspective which posits that a collectivity's identity basically flows naturally from some underlying set of characteristics, often reduced to a single determinative attribute regarded as the collectivity's 'defining essence.' From the primordialist point of view, the defining characteristic is typically an ascriptive attribute, such as race, gender, or sexual orientation, or sometimes a deep, underlying psychological or personality disposition. From a structuralist perspective, the critical characteristic is typically a kind of master social category implying structural commonality, such as social class, ethnicity, or nationality; a set of relational ties or networks suggesting structural connectedness; or a mixture of both. Individuals who are similarly situated structurally, such that they are incumbents of similar roles, work in similar enterprises, are linked to the same social networks, or members of the same social class, religion, or ethnic group, are presumed to have a shared collective identity or at least be candidates for such.

The constructionist perspective, in general, rejects both the primodialist and structuralist variants of the essentialist argument, seeing the presumed link between identities and their ascriptive or structural moorings as being more indeterminate than postulated. Instead, attention is shifted to the construction and maintenance of collective identities. Collective identities are seen as invented, created, reconstituted, or cobbled together rather than being biologically preordained or structurally or culturally determined.

Assessment of the three perspectives in terms of their relative analytic utility for explaining the character and content of collective identities reveals considerable support for the constructionist thesis. This may be due in part to the currents of fashion, influenced by the winds of multiculturalism, postmodernism, and identity politics, but it is due, more importantly, to other factors. One is that the hypothesized link between identities and the primordial attributes or structural categories in which they are presumably anchored is too mechanistic. In its hard version, it is contradicted by the sociological observation that people are often members of the same categories or groups in different ways and with varying degrees of commitment and identification, thus suggesting that inferring correspondence between personal, social, and collective identities solely on the basis of primordial or structural categories is empirically suspect. Additionally, the claims of primordialist and structuralist arguments do not fare well when confronted with the observation that people generally have multiple identities (e.g., family, work, leisure, gender, ethnic, religious, political, and national) that are differentially invoked or avowed depending on their relative salience and their situational pervasiveness.

Salience refers to the relative importance of an identity in relation to other identities (Stryker 1980); pervasiveness or comprehensiveness refers to the situational relevance or reach of any particular identity and the corresponding degree to which it organizes social life, including collective action (Cornell and Hartmann 1998, Snow and McAdam 2000). Given the fact that increasing numbers of individuals live in a world in which they are the carriers of multiple and often conflicting identities, what determines any particular identity's relative salience and pervasiveness, and thus the influence of its claims, vis-à-vis others? Clearly such matters are not determined solely by an identity's primordial roots or structural footing. Finally, much of the empirical evidence is consistent with the constructionist argument. Two highly evocative examples include Trevor-Roper's (1983) account of the retrospective invention of the distinctive Highland culture and tradition so redolently associated with all of Scotland, and James' parallel conclusion, based on extensive archeological and archival research, regarding the origins of the modern Celts:

> …the idea of a race, nation or ethnic group called Celts in Ancient Britain and Ireland is indeed a modern invention. It is an eighteenth- and nineteenth-century reification of a people that never existed, a factoid…assembled from fragments of evidence drawn from a wide range of societies across space and time, This reification served the interests of a range of cultural expectations, aspirations, and political agendas—and still does (James 1999, p. 136).

Such conclusions should not be read as unequivocal refutations of the primordialist and structuralist arguments, since constructed identities are not fabricated whole cloth but typically knit together by drawing on threads of past and current cultural materials and traditions, structural arrangements, and even primordial attributes. These materials and attributes constitute the kinds of stuff from which collective identities—particularly ethnic, religious and national ones—are fashioned, and thereby function, in varying degrees, to constrain the construction process. Interpretative constraint also may be exercised by the institutional contexts and relations of power in which contestants are embedded (Castells 1997, Jensen 1995). Additionally, analyses of the relationship between collective identity and participation in social movements repeatedly point to the experience of collective action itself as a fertile seedbed for the generation of collective identities (Calhoun 1991, Fantasia 1988, Melucci 1989, Walder 2000). Thus, while collective identities are undeniably constructed, they rarely are constructed *carte blanche*; rather, they typically are forged not only with the

materials suggested by the primordialist and structuralist perspectives, but with and through the experience of collective action itself.

4. Theoretical and Empirical Issues

Relevant to a thoroughgoing understanding of collective identity, whatever its empirical locus, are several theoretical and empirical issues that require more careful consideration than often accorded.

4.1 Identity Work (the Expression of Collective Identities)

Fundamental to understanding collective identity, particularly from a constructionist standpoint, are the processes through which it is created, expressed, sustained, and modified. These processes have been conceptualized as variants of 'identity work,' which encompasses the range of activities people engage in, both individually and collectively, to signify and express who they are and what they stand for in relation or contrast to some set of others (Schwalbe and Mason-Schrock 1996, Snow and Anderson 1987, Snow and McAdam 2000). At its core is the generation, invocation, and maintenance of symbolic resources used to bound and distinguish the collectivity both internally and externally by accenting commonalities and differences (Eisenstadt and Giesen 1995, Schwalbe and Mason-Schrock 1996, Taylor and Whittier 1992). Symbolic resources include the interpretive frameworks (or frames), avowed and imputed names, and dramaturgical codes of expression and demeanor (e.g., particularistic styles of storytelling, dress, adornment, and music) that are generated and employed during the course of a collectivity's efforts to distinguish itself from one or more other collectivities. Concrete examples include the various forms of identity talk such as 'atrocity tales' and 'war stories' that group members repeatedly tell each other, prospective adherents, and the media (Hunt and Benford 1994); particular songs and styles of music that invite participation and that are politically and emotionally evocative, such as 'We Shall Overcome' (Eyerman and Jamison 1998); key words and slogans that function in a similar fashion, such as 'Liberte, Fraternite, and Egalite' and 'Workers of the World Unite'; and systems of gestures and signs, such as the raised clinched fist and the peace sign, that function similarly to the tradition of heraldry (Pastoureau 1997).

These and other symbolic resources function as boundary markers of collective differentiation, distinguishing insiders from outsiders, or protagonists from antagonists, in a fashion that heightens awareness of in-group commonalities and connections and out-group differences. Together they congeal into a kind of 'semiotic bricolage' (Schwalbe and Mason-Schrock 1996) that gives symbolic substance to the claimed distinctive 'we,' and it is largely through this *bricolage* that collective identity is expressed and known publicly. While the boundary making and maintenance functions of these symbolic resources, or *bricolage*, is widely acknowledged, what accounts for the differential resonance or carrying power of different symbolic markers is less well understood.

4.2 The Problem of Identity Correspondence

A not uncommon problem with analyses of collective identity is the tendency to reify the collective identity, and thus take for granted the link between the individuals that make up the collectivity and the shared, overarching identity. This gloss is particularly troublesome in light of the observation that people typically have multiple identities that vary in salience and pervasiveness. Thus, how is any particular collective identity reconciled with other identities adherents possess? How, in other words, do the shared cognitions and feelings indicative of a collective identity move center stage at the individual level? Such questions allude to what has been referred to as the problem of 'identity correspondence'—the alignment or linkage of personal and collective identities (Snow and McAdam 2000).

One general answer is that this alignment 'is accomplished by enlarging the personal identities of a constituency to include the relevant collective identities as part of their definition of self' (Gamson 1991, p. 41). But what are the processes through which prospective adherents come to embrace the relevant collective identity, such that personal and collective identity are correspondent or congruous? Two broad processes have been suggested: identity convergence and identity construction.

Identity convergence refers to the union of personal and collective identities when both are congruent, such that an extant collectivity provides a venue for an individual to act in accordance with her or his personal identity. The analytic problem is not one of identity construction or transformation, but one of linkage or bridging and the identification of the mechanisms that facilitate the convergence. A number of such mechanisms have been identified. One operates at the organizational level, entailing the occasional appropriation of existing solidary networks by movement organizations (Snow and McAdam 2000); the other mechanisms are variants of rational choice processes.

One is based on a 'tipping' or 'threshold' model, which posits that collective identities are assumed by individuals when the perceived actions of others reach a point that suggests that the payoffs for adopting, or at least acting in accordance with, the collective identity outweigh doing otherwise. Illustrative is the contention that such tipping points played a critical role in explaining language and identity shifts among

Russian-speaking immigrants 'beached' in four of the republics of the former Soviet Union (Laitin 1998). A related mechanism is the existence of intergenerational investments in personal identities that may have implications for the embracement of future collective identities (Laitin 1998). A third rational choice explanation holds that the collective identities associated with social movements—and, by implication, with other collectivities as well—can be regarded as 'selective incentives' for those who seek to express and affirm their personal identities (Friedman and McAdam 1992). The explanatory utility of these arguments, as well as the network appropriation thesis, is contingent on two underlying assumptions: that there is pre-established congruence among some number of personal identities and the proffered or available collective identities; and that collective identities are constituted by the aggregation or convergence of parallel personal identities. While the first assumption is empirically tenable, the second is questionable from the vantage point of many scholars of collective identity (e.g. Jasper and Polletta 2001, Melucci 1989, 1995).

In the absence of correspondence between personal identities and collective identities, some variety of identity work is necessary in order to facilitate their alignment. This alignment can vary significantly, ranging from the elevation of the salience of a particular identity to a fairly dramatic change in one's sense of self. Four identity construction processes have been identified that capture this variation: identity amplification, identity consolidation, identity extension, and identity transformation (Snow and McAdam 2000).

Identity amplification affects a change in an individual's identity salience hierarchy, such that an existing but lower-order identity becomes sufficiently salient to ensure engagement in collective action, as in the many cases in which in the identity of woman was elevated and expanded in conjunction with the Women's Movement; identity consolidation involves the adoption of an identity that is a blend of two prior but seemingly incompatible identities, as in the case of the union of environmentalists and labor activists and 'Jews for Jesus'; identity extension entails the expansion of the situational pervasiveness of an individual's personal identity so that its reach is congruent with the collectivity's, as when individuals come to see themselves as representatives for a specific cause that transcends other role obligations and identities; and identity transformation involves a dramatic change in identity, such that individuals now see themselves as remarkably different than before, as often occurs in the case of conversion to a new group or movement.

The mechanisms or processes underlying these various forms of identity construction include framing processes in which identities are announced or renounced, embraced or rejected, and modified or reframed in the course of various interactions with adherents, antagonists, and bystander audiences (Benford and Snow 2000, Hunt et al. 1994); engagement in collective action, as when direct observation or experience functions as a demonstration event that gives rise to a situationally specific collective identity or affirms collective claims and thus helps to render salient, and perhaps pervasive, what was previously a secondary or marginal personal or social identity (Melucci 1989, Calhoun 1991, Walder 2000); or some combination of both framing and actual engagement.

Given the variety of ways in which identity correspondence can be affected, the question arises as to whether the relevance of the convergence and construction processes varies by type of collectivity. In the case of social movements, for example, it has been hypothesized that movements that are culturally different, greedy in terms of the cognitive and behavioral demands, and/or politically radical are likely to rely more on identity construction than convergence processes (Snow and McAdam 2000). Whether this is the case is an empirical question, but it does caution against presuming that what accounts for identity correspondence and shifts in one context necessarily holds for another.

Just as there may be variation between types of collectivities and the processes of identity convergence and identity construction, so it is reasonable to ask whether these processes might vary in importance at different points in the life course of a social movement or ethnic or nationalist mobilization? Rather than assuming that a particular process, such as the tipping process or identity amplification, operates routinely with respect to the emergence of a collective identity, might not these processes be more relevant at particular junctures in the career of a movement's collective identity? Preliminary consideration of such questions suggests that network appropriation, rational choice, and constructionist explanations, rather than being mutually exclusive and antithetical, may interact and combine in interesting ways in explaining the emergence, institutionalization, and diffusion of collective identities across different contexts (Snow and McAdam 2000).

4.3 Dimensions, Layers, and Types of Collective Identity

Although there is an extensive literature on collective identity, with considerable discussion regarding its conceptualization and sources, this literature has been relatively mute regarding variation in its form. The concept is most often invoked as if it is an invariant, uniform collective phenomenon. This is not the case, however, as collective identities can be multidimensional and be multilayered within a specific locus, and they may also vary by type. The multidimensionality of collective identity is indicated by reference to its

cognitive, emotional, and moral dimensions (Jasper and Polletta 2001, Melucci 1989). The relative importance of each of these dimensions to the vitality and motivational force of a collective identity has not been elaborated, however. Presumably the presence of each of these dimensions yields a more robust and vital collective identity. Clearly a collective identity in which the boundaries between 'us' and 'them' are unambiguously drawn, in which there is strong feeling about those differences, and in which there is a sense of moral virtue associated with both the perceptions and feelings, should be a more potent collective identity than one in which either the emotional or moral dimensions are weakly developed.

Similarly, several analyses have noted that collective identity can be multilayered, such that there can be variation in its locus. Three such layers have been noted with respect to social movements (Gamson 1991, Stoecker 1995). They include, beginning with the broadest and potentially most inclusive layer: the social movement community or solidary group, which can be thought of as the constituent layer, as in the case of black Americans in relation to the civil rights movement; the social movement layer as in the case of the civil rights movement; and the organizational layer, as represented by the Southern Christian Leadership Conference (SCLC), the Congress for Racial Equality (CORE), and the Student Nonviolent Coordinating Committee (SNCC) in the context of the civil rights movement. In principle, each successive layer may be embedded in the larger more inclusive layer, giving rise to a generalized, cohesive collective identity at the community or national level. But clearly the existence of a collective identity at one level does not automatically generalize to or incorporate another level. Thus, collective identities can be built around the organizational carriers of a movement, as in the case of SCLC and SNCC, without necessarily representing the broader movement, which indicates the potential for identity conflicts at the collective level and the potential for schism and factionalization. Such observations suggest the need for more careful consideration of the often multilayered character of collective identities and of greater specification of the ways in which they can interact and combine, and with what consequences. Also, these observations call for caution in generalizing about the scope and functioning of collective identities, particularly with respect to broader social categories such as ethnicities and nationalities.

Finally, it is reasonable to wonder if collective identities vary by type. At the most general level, Hunt et al. (1994) distinguish among protagonist, antagonist, and audience or bystander identities, arguing that even though protagonist or oppositional identities have received most of the scholarly attention, each type or field of identity is fundamental to understanding the interactive dynamics underlying the emergence, character, and functioning of collective identities. Noting as well that collective identities arise and operate within an interactive context 'marked by power relationships,' Castells distinguishes among legitimizing, resistance, and project collective identities (1997, pp. 7–10). Legitimizing identities are associated with dominant institutions or the state, whereas both resistance and project identities represent two basic forms of the antagonist identity, the former generated by devalued and stigmatized collectivities, and thus constituting the seedbed for identity movements and politics, and the latter associated with movement beyond resistance to the construction not only of alternative identities but also a new system that valorizes rather than defiles the new identity. The important issue is not whether such typologies of collective identities are exhaustive, but the emphasis on their contextually embedded and interactional character and their different consequences.

Collective Memory, Anthropology of

Focused on shared, collective, or social memory practices, this article examines the linkages between memory and history with attention to the fields of power, in which the struggle for domination over remembrance and tradition, the manipulation of retrievable historical consciousness and collective forgetting, takes place.

1. *Definition of Concepts: Memory and History*

The term *history* is often used to describe representations of the past that appear in written or narrative form, a primary medium through which states, elites, or dominant descent groups confiscate linear time and proclaim official chronologies as master narratives. The writing of history is 'a colonization' of time 'by the discourse of power' (de Certeau 1988). The term *memory*, by contrast, is conventionally applied to those oral, visual, ritual, and bodily practices through which a community's collective remembrance of the past is produced or sustained (Connerton 1989). It includes the vast complex of unofficial, noninstitutionalized knowledge not yet sedimented into formal traditions and which represent the 'collective consciousness' of whole groups (Halbwachs 1980), forming a counterweight to the knowledge that is privatized and monopolized by certain elites for the defense of established interests. While memory may be a moving reservoir of history, furnishing the 'raw material' for representing the past, it is not the same as history (Le Goff 1992). Individual remembrance, collective memory, and narrative history interact in highly complicated ways, shaping each other as different versions of the past are constructed and reconstructed, modified, and invented.

2. *The Politics of Time: History and Anthropology*

The theories, models, and methods that were developed by anthropologists to study non-European worlds tended toward a 'rejection of historical research of any kind' (Evans-Pritchard 1962), at least within the limits of the discipline. Having as its central theme 'the unlettered and forgotten peoples,' the anthropological endeavor was inclined to disregard the existence of indigenous histories, which included, in particular, the trauma of the colonial encounter. But if

making history is a social practice that produces peoples, bodies, and places, as de Certeau (1988) suggests, then the very erasure of such a universe of time and being must be understood as a figuration of power. The effacement of historicity is a political operation.

Nineteenth-century anthropology was deeply implicated in the projects of Western modernity: the construction of nation-states and the creation of colonial systems with which Europeans came to dominate other worlds. During this process of global expansion, and the establishment of modern hegemonic polities, the past was increasingly mobilized as a symbolic discourse 'in the definition of, and the marking of, the boundaries of states and nations' (Cohn 1981, p. 228). Anthropologists of this period contributed to the colonial undertaking by a reliance on analytic tools that used Western notions of time as an index of unequal evolutionary development. The prerogative to know and control the past, by defining it as 'history' (an order of chronological or linear time), was an entitlement of civilization. The social worlds outside of Europe came to be marked as timeless: a closed symbolic universe inhabited by 'the people without history' (Wolf 1982). Displaced into the sphere of alterity, colonial subjects were incarcerated by the temporal logic of an expansive European world system.

The past as history became a way to construct schemes of classification which differentiated Europeans from others. Anthropologists began to delineate stages of human development via the comparative method: by identifying phenomena of a general type (taboo, totemism, polygamy), their goal was to map out a global history of social institutions. In this endeavor, however, analytic units were 'taken out of the flux of time' (Evans-Pritchard 1962, p. 175): social forms, stripped of their unique features and context-bound meanings, escaped temporality, appearing static and unchanging. The comparative method, in its attempt to achieve conceptual stability as a sociological proposition, was explicitly anti-historical in emphasis and thereby served to obscure the effects of Western contact and domination.

By the early twentieth century, anthropologists had decisively abandoned the comparative paradigm. But in spite of the shift to new methods of analysis, the discipline's aversion to historical research intensified. Scholars in Britain, Germany, and the United States asserted that the customs of native peoples were to be found not in colonial archives, missionary reports, or dubious travel accounts but *in the field*: reliable data about non-Western societies demanded first-hand observation. This was accomplished at first through brief expeditions, and later by long-term residence of the anthropologist in native communities. British scholars, in their interpretation of the ethnographic venture, reasserted the enlightenment program: anthropology was to become 'a natural science of society, based on a descriptive analysis of the structure and functioning of social forms' (Cohn 1981, p. 232). American scholars, by contrast, adopted a romantic idealist stance: anthropology emerged as a hermeneutic science, focused on the descriptive reconstruction and symbolic capture of entire cultural systems. Although the nation-bound projects of anthropology began to diverge, the ethnographic field method was adopted as a common research standard, thereby imparting and codifying the now conventional disciplinary gaze: the observers' eyes were trained to *see* society only at a particular point in time. Ethnography, in its obsession with reifying the authenticity of peoples, fabricated a closed temporal frame: a *present present* or a *past present*, as Evans-Pritchard (1962) termed it in a critical commentary on the discipline's 'breach with history,' illuminating the distortions which flow from the imposition of *a priori* temporal limits upon 'traditional societies.'

But it was precisely this aversion to history that led anthropologists to discover 'memory' as a valuable ethnographic tool. Evans-Pritchard (1962), for instance, suggested that the past was always 'incapsulated in a context of present thought': the past, *as memory*, was embedded in material, ritual, and narrative practices and therefore 'part of the social life which the anthropologist can directly observe' (pp. 177–8). The pursuit of collective memory was to constitute a major change in ethnographic practice: the 'life story' of local worlds—of bodies, magic, and markets—could be rendered intelligible through the oral archive. But in the colonizing imagination of Western anthropologists, the work of memory was consigned to the uneventful register of *structural*, *mythical*, and *sacred* time: an order of signs without history. Peoples' means of remembering traumatic events (famine, migration, conquest) 'were always seen to reinforce the system in place, never to transform it' (Comaroff and Comaroff 1992, p. 21). In a shift from historical past to ethnographic present, anthropologists erected 'counterfeit signposts' of a primitive world of enduring traditions—an analytic fiction. The anthropology of collective memory, in consequence, began as a kind of anti-history.

3. *The Shape of Memory: Modes of Historical Consciousness*

In their ethnographic explorations, anthropologists encountered indigenous memory forms that did not seem to fit the European idea of historical time: an objective, unmediated, linear account of past events. By a focus on myths, ritual, oratory, and body practices, they uncovered the narrative and performative possibilities of *a history of the present*: the social sense of time whereby people attempted 'to grasp the world as both a synchronic and a diachronic totality' (Lévi-Strauss 1966, p. 263). In the realms of memory,

past and present—although theoretically distinct—were conjoined to link, from generation to generation, the living with the dead.

Among Australian aborigines, for instance, *historical* or *commemorative rites* 'recreate the sacred and beneficial atmosphere of mythical times—the 'dream age'—mirroring its protagonists and their great deeds,' and transport 'the past into the present'; *rites of mourning* 'correspond to an inverse procedure: instead of charging living men with the personification of remote ancestors, these rites assure the conversion of men who are no longer living into ancestors,' thereby bringing 'the present into the past' (Lévi-Strauss 1966, pp. 236–7).

These images of time are different, perhaps, but not 'other.' In the rites performed, past and present are propelled into a social space—the body. The act of remembering takes corporeal form: memory is embodied (Connerton 1989). But this transposition of temporal worlds, which connects the living and dead to the ancestors via the mimetic power of embodiment, is not an abrogation of time. It is a generative reconstitution of society: a practice of empowerment, a political engagement with the matrix of life (Stoller 1995).

Other anthropological studies suggest that collective memory may be systematized on the basis of *relative temporalities*, that is, a flexible system of polymorphous reference points. Among certain peoples of the Ivory Coast, like the Guéré, 'the consciousness of a historical past has developed alongside a multiplicity of other times' (Le Goff 1992, pp. 8–9): *mythical*, *genealogical*, *lived*, and *projected time*. Such a register of memory forms belongs to the aftermath of the colonial project. Under the impact of prolonged social trauma, the disparate logics of time and memory chart the precarious matrices of life: a synchrony of struggle, violence, and perseverance.

4. *Memory-sites: The Localization of Remembrance*

The anthropological analysis of collective memory moves toward a renunciation of linear temporality in favor of multiple kinds of time as experienced at the levels where the individual takes root in the social: language, demography, economics, politics. Memory production is in this sense not dependent on a single individual's experience of the past. A remembrance, a social understanding of events that is represented as memory, can be constructed by sharing with others 'sets of images that have been passed down to them through the *media of memory*—through paintings, architecture, monuments, ritual, storytelling, poetry, music, photos, and film' (Watson 1994, p. 8). In every society, we can identify an array of memory-sites or places of commemorative record and practice where remembrance anchors the past: *topographical* places (archives, libraries, museums); *monumental* places (cemeteries, architectural edifices); *symbolic* places (commemorative rites, pilgrimages, emblems); *functional* places (manuals, autobiographies, associations); and places of *power* (states, elites, milieux) which 'constitute their historical archives in relation to the different uses they make of memory' (Le Goff 1992, pp. 95–6, Nora 1986). These memory-sites furnish a series of locations where knowledges of the past are conveyed and sustained by a circulation of signs that calls attention to its own logic of inclusion, exclusion, and selective incompleteness.

5. *Unsanctioned Archives: Memory and Countermemory*

The anthropology of collective remembrance is not only concerned with affirmation and heritage, but with processes of contestation, the aftermath of violence, and the emergence of countermemories (Stoller 1995). A *social history of remembering* must take account of 'the mechanisms that make unsanctioned remembrance possible' under repressive political regimes: in asking how people remember what is meant to be forgotten, 'matters of transmission'—the mechanics of shared memory and hidden histories—take center stage (Watson 1994). Here, interpersonal memories, commemorations, theater, drama, folklore, secret, and oppositional histories are 'the venues within which alternative remembrances'—unauthorized and unapproved memories of the past—can be located and analyzed (Watson 1994, p. 2). Collective memory practices are not only linked to sites of domination that attempt to legitimate a given social order, but also to unsanctioned sites of struggle, opposition, and transformation.

6. *The Traffic in Memory: Global Hegemonies and Local Struggle*

In all societies, there exist distinct moments when new representations of the past are forged, contested, and put to cultural and ideological use. Battles waged over ethnic origin or national identity may be linked to the constitution of radically new kinds of memory-archives (Hobsbawm and Ranger 1983). The creation of nations, ethnicities, and subjects inevitably alters the shape of the past. 'Memory' is therefore not a generic term of analysis, but itself an object appropriated, transformed, and politicized. Or, put differently, memory can be nationalized, medicalized, aestheticized, gendered, bought, and sold.

Historical consciousness shaped by nation-building, scientific ideology, and global capitalism plays a significant role in the formation of social identities. Detailing the politics of remembrance in postsocialist China, Schein (2000) shows how state-orchestrated

reforms, staged against the chaos of the Cultural Revolution and implemented during a period of increasing exchange and fascination with the West, produced a popular appetite for exotic others: commodified images of minority peoples, like the Miao, were fashioned by an acute nostalgia for 'ancient' traditions and those feminized cultural essences on which to recraft a distinctive Chinese nationness. The result was a boom in memory recuperation among China's urbanites and Miao elites, who simultaneously played to a Western valorization and high-spending tourist consumption of dwindling pasts. But such a newly forged cultural attachment to memory artifacts, the 'fossil bed' phantasms of folk heritage, also entails transformation. In other words, the work of symbolic restoration 'may conceal very new projects' (Le Goff 1992, p. 9). The recruitment of the past for revolutionary or political ends, as in the case of China, is entangled in a twofold venture: the forging of a distinctive ethnonational imaginary and the renegotiation or recalibration of *place* in the global order.

The pursuit, rescue, and celebration of collective memory is always socially motivated and has, thus, to be understood in positional terms. The global context—the theater of transnational consumer capitalism—is, according to Friedman (1994), particularly relevant in understanding how local memory forms are affected by the formative impact of world systemic processes. In the case of modern Greece, as Friedman shows, national selfhood was crafted by internalizing the ways in which European elites, in constructing their own 'civilized' origins, mythologized classical antiquity as the cradle of Western civilization. Greek nationalists found their past in the institutional memory of the West, thereby accelerating incorporation into an expanding European world system. Such acts of cosmological repositioning are symptomatic of a transglobal system that fuses socioeconomic transformation and collective memory to 'the reconfiguration of the map of the world's peoples' (Friedman 1994, p. 123).

Yet even in the global arena, there exist other possibilities of memory production. In the Hawaiian case, Friedman's instructive contrast, indigenous communities attempted to extricate themselves from Western dominance by projecting a value system, produced in the modern context, onto an aboriginal past. The result was a body of memories composed of mythic history, a work of folklore and folklorization 'rife with simulacra of tropical fantasies.' Social and economic marginalization, in the aftermath of World War II, gave rise to an intense period of Hawaiian cultural revival. Recuperation efforts, centered on the reconstitution of ethnic history by retrieving precolonial social forms, brought into play a *museology of memory* that was staged in opposition to the West: a precontact Hawaii stocked with all the items to be found in Western historical archives—libraries, museums, missionary records. The Hawaiian confiscation of these colonial memory-stores proceeded, as Friedman documents, by forging an indigenous past uncoupled from the larger world, a Western-imposed modernity, which had obliterated a population and absorbed its social history into the projects of global economic systems.

Anthropologists have firmly established the need to attend to these paradoxes of mobile cultural and symbolic forms—this *traffic in memory*—during periods of transnational crisis and restructuring (Appadurai 1996). In the context of global systems, where the practice of identity is brought on stage, the logic of time and the meaning of memory have been radically transposed. In the global arena, the production of historical consciousness becomes increasingly entangled with the commodity form: encoded by temporal longings and mythic value, it furnishes the common stock for a *memory market* saturated by cargo-type products of surplus and lack, bearing the deep imprint of the globally hegemonic mode in which people's ethnonational remembrances are manufactured, exchanged, and consumed (Taussig 1980). But memory consumption can also be a subordinate production, one that creatively and tactically resists the homogenizing tendency of centralized systems. This suggests, as Schein (2000) observes, an alternate sense for cultural production: 'the myriad ways in which people make use of received [memory] products presents a measure of possibility, not only for autonomy, but also for subversion of the dominant order' (p. 16). Put differently, the modalities of collective memory practice attest to the possibilities of *symbolic creativity*—even in the province of globalizing modernities.

Collective Memory, Psychology of

1. Introduction

Collective memory is a sociological concept, though shot through with psychological presumptions. Its most important theorist is Maurice Hawlbachs, a second-generation student of Emile Durkheim, who wrote *Les Cadres sociaux de la memoire* (*The Social Frameworks of Memory* 1992) and *La Memoire Collective* (*Collective Memory*) ([1950], 1992). Hawlbachs and those working in the collective memory tradition posit that not only do individuals remember, but collectivities as well. Just as there is great interest among psychologists, psychoanalysts, and neuroscientists to discover, describe, and specify the processes through which individuals remember—*how, what, when*, and *why* remembering occurs—so too do social scientists—sociologists, historians, anthropologists, political scientists—attend to the social processes through which collectivities—families, groups, nations—recover the past, conceptualize it through narrative structures, and memorialize it through memorials, museums, rites, and other commemorative forms.

Hawlbachs' essay was first published in English in 1980 with an introduction by Mary Douglas, herself a neo-Durkheimian. In her introduction, Douglas drew the link between Hawlbachs' concept and the research of the British psychologist, Sir Frederick Bartlett who, in *Remembering: A Study in Experimental and Social Psychology* (1932), contextualized memory by arguing that what is remembered of the past depends upon frameworks or schemas of understanding imposed upon it from the present. Since the publication of Hawlbachs' writings in English, the interest in collective memory has greatly accelerated the development of the themes defined by Hawlbachs, Bartlett and Douglas and their influence on disparate academic fields. In the last decades of the twentieth century, collective memory generated a large literature focusing on the relation between the past and the present, raising questions especially about how the present influences the reconstruction of the past and the ways in which historical events and circumstances impinge or intrude on the present. These issues have often been addressed through empirical studies of particular rites, festivals, commemorations, and memorials in different national and historical settings.

What follows is a discussion of the sources of convergence and divergence in the psychology of collective memory as expressed in the academic literature and as it impacts on these broader politics of memory. There is widespread agreement concerning both the reality of collective memory as well as its malleability, i.e., memory's susceptibility to revision, manipulation, etc. However, differences among scholars exist as well, focusing particularly on the question of the motives and interests that lie beneath the phenomenon and determine its form. A neo-Durkheimian framework will be characterized where the past is understood as a symbolic resource often employed to reduce tensions and strains presently confronting the collectivity; collective memory is understood as a complex social process—including instrumental and symbolic struggles by various members of the group over the definition of the past—to strengthen the ties that bind individual members together within the collectivity. Others adopt a neo-Freudian perspective where tensions and strains within a present day collectivity are largely understood as deriving from the unavoidable intrusion of a traumatic past. The past is the source, rather than a resource, of challenges confronting a present-day collectivity. Collective memory, here, is often seen as an impressive impediment to the establishment of a healthy, post-traumatic community.

2. Individual and Collective Memory: Convergence and Consensus

Students of collective memory, like researchers on individual memory studies, understand memory to be a constitutive feature of the present. In both, memory is distinguished from history; the former describes a process of reconstruction, occurring *ex post facto* and possibly bearing little relation to the historical past being remembered. Nonetheless, an understanding of oneself in relation to an 'as if it were true' past is believed to be an essential feature of individual life. Personal identity depends on locating oneself in a particular past in which the present is bounded and made meaningful through history. The person experiences him or herself in a continuous, com-

prehensible relation to a past; an orientation toward the present and the future is only coherent if in relation, in part, to an understood past. Collective memory similarly appreciates the temporal dimension of social life, where sociality depends on a past to support and give continuity and meaning to a present. No collectivity can function without a sense of its own traditions and its own continuity with the past (Shils 1983, Elias 1994). Where no such past exists—as in new collectivities, for example—traditions, as Eric Hobsbawm has argued, are 'invented.' 'The invention of tradition' (Hobsbawm 1983) is a social process in which memory is confabulated on behalf of a present requiring a history, for the purpose of creating a collective or national identity. But if collective memory emphasizes the diachronic relation between a present that requires a past, it also underscores the fundamentally social and synchronous character of memory formation. Collective memory concerns itself with dialogical, discursive processes occurring as a result of communication between various groups and institutions comprising the collectivity.

Just as the autobiographical memory of the individual is not identical to the history being recalled —always subject to reformulation, reconstitution, and distortion as a result of the temporal distance between remembering and what is remembered (Schachter 1995, Loftus and Ketcham 1994)—so, too, is collective (or historical) memory vulnerable to similar possibilities of confabulation, revision, and remodeling (Kammen 1995, Schudson 1995). Remembering, whether individually or collectively, always involves the representation after the fact of past events or experiences, never the return to the actual past. Freud himself described this parallel process between individual and collectivity when he wrote

> If we do not wish to go astray in our judgment of their historical reality, we must above all bear in mind that people's 'childhood memories' are only consolidated at a later period, usually at the age of puberty; and that this involves a complicated process of remodeling, analogous in every way to the process by which a nation constructs legends about its early history. (1913, p. 206n)

Particular memories, rather than being an enduringly stable feature of either individual or group life, are continually susceptible to instability and disruption. However, temporal distance is not the only explanation for the breach between history and memory. Interest and/or affect—present-day requirements of the individual or the collectivity—dictate the need for remembering. The imperatives of the present are decisive, it is believed, in the nature and character of remembering that occurs. As those present-day needs change, or are altered by circumstance, so too are memories altered. While there is probably not complete alteration, memory researchers are impressed by the capacity for substantial revision to occur.

3. *The Neo-Durkheimian Perspective: The Embeddedness of Collective Memory*

American sociology of collective memory has been dominated by a 'presentist' psychology, building upon, refining, and revising elements of Hawlbachs' insight concerning the present's contribution to the recovery of the past. Here, research has focused on the relation between memory as a mechanism of response and contemporary strains in the collectivity and other social practices similarly related to responding to tensions within the social fabric. The unifying idea behind this research rests on the importance of a common 'collective consciousness' to social solidarity and cohesion—as originally defined by Durkheim (1997)—and the important role that memory plays in constituting that consciousness. Memory, it is argued, is 'embedded' (Prager 1998) in 'mnemonic communities,' (Zerubavel 1996) meaning that it is constituted, elaborated, and altered in response to social processes and practices occurring in a collectivity at any given point in time. Armed with an uncontested understanding of the past, collective consciousness is strengthened because of a shared identity with the past; divergent memories, in contrast, express disunity and challenges to social solidarity.

3.1 *Rites and Sites of Remembrance*

Collective consciousness is heavily structured through historical referents and the practices of rituals, rites, and commemorations in part serve to strengthen a common sense of the collectivity through shared history. Shils and Young (1953, see also Cannadine 1983) writing about the British coronation ceremonies and Ozouf (1991) describing ritual forms of performative remembering of the French Revolution identify the social significance of these forms of political practices and, through careful readings of both the content and the form of commemoration, describe the symbolic process of historical recovery on behalf of present-day political and ideological needs and interests (Connerton 1989). While it has been noted by Bakhtin (1968) and others that commemorations, like other moments of liminality (Turner), have the potential to take on a life-of-their own (e.g., Davis (1977) by either anticipating the restructuring of the collective consciousness or promoting social division, collective memory research has largely concerned itself with the particular stabilizing effects of past events remembered (e.g., Olick 1999, Schwartz 1996, Wagner-Pacifici 1991, Zelizer 1992) and its contribution to the collective consciousness. Nora (1989) calls attention to *les lieux de memoire*, or sites of memory, highlighting the necessity in the modern world to locate special sites for memory to occur. Because of the discontinuity in modern societies between memory and history—in contrast to tra-

ditional societies where 'real environments of memory' exist—memory sites occupy sacred ground self-consciously constructed to mark the present's continued link with its past and to combat forgetting.

3.2 Frameworks of Remembering

Contemporary researchers have identified narrative, discursive, and other semantic features of collective memory to demonstrate the socially embedded, constructivist, and presentist quality of collective memory. In *Presenting the Past*, Prager (1998) describes how individual memory relies upon available cultural narratives to provide context and meaning to what otherwise would be relatively meaningless and random events in an individual's life (see also Schudson 1995). These narratives—for example, a tale of victimization or of physical or sexual abuse—speak to contemporary understandings of the ways in which the past informs or frames the present. Collective memory, too, relies on culturally provided narratives coding the past so as to make it meaningful and available to the present. The past can only be remembered discursively and rhetorically, as part of a dialogical process between social members or organizations collectively remembering (Middleton and Edwards 1990, Douglas 1986, Shotter 1990).

3.3 History as Constraint

'The past in the present versus the present in the past' (Schudson 1989) captures one important emendation to Hawlbach's presentism, arguing against a too strong unmooring of the present from the past. Seeking to explicate the ways in which history imposes certain constraints upon what can be remembered, researchers have sought to restrict an unbridled social constructivism seemingly encouraged by Hawlbachs and others. Collective memory, despite its role as a resource for legitimation, cannot completely override history. As Schudson argues, the past imposes itself on memory (a) through the strength of prior remembrances that cannot be contested, e.g., the institution of slavery in American history, but instead are part of an obdurate historical reality that cannot be ignored, and (b) because the process of historical reconstruction occurs through a 'politics of memory' in which various groups within the collectivity offer differing versions of the past, are debated and socially negotiated, and form 'the rhetorical structure of social organization' (see Schudson 1992). A third constraint that elevates history in relation to memory, according to Schudson, is the role of individual trauma, a topic that will be returned to shortly. In a similar vein, Schwartz (1996) argues against a radical presentism that fails to recognize the importance to the collectivity of continuity and coherence with the past. He suggests that the reinterpretation of the past *de novo* is inhibited by counteracting social imperatives to understand the present as continuous with and coherent to what has preceded it. Finally, Olick (1999) strikes a similar cautionary note by emphasizing the ways in which earlier commemorations of historical events themselves serve as constraining influences on current memory. He refers to the dialogue between current memorializations and prior ones as constituting 'genre memories,' in which the present is discursively steeped in these mediated pasts.

4. Neo-Freudianism: Trauma and the Embodiment of the Past in the Present

Neo-Durkheimian approaches to collective memory emphasize the continuity of the present to the past, underscoring the important role that remembering plays in the constitution of the present. A neo-Freudian perspective, in contrast, insists that collective memory is a social process in response to social ruptures, or discontinuities, that have occurred in the past that, because not fully assimilated in conscious experience, subsequently interfere with the smooth functioning of collective life. The title of Friedlander's autobiographical work, *When Memory Comes* (1991), an account of his discovery of his Jewish roots in pre-Holocaust Czechoslovakia, captures this idea that memory is an imperative, driven from the past, intruding upon and interfering with the present. Memory, as the title suggests, *will* come. Memory and Freud's 'return of the repressed' are complementary concepts: together they define the present as always susceptible to intrusions from the past. Collective memory expresses not merely social practices but rather processes driven by psychological law. Friedlander (1992) acknowledges the large debt that scholars of the Holocaust owe to Freud when they invoke his ideas to the remembering and understanding of this event. The study of the Holocaust, it should be noted, has emerged as the paradigmatic literature for those researchers studying the phenomenon of collective memory in various world settings and who approach it in relation to past social ruptures. The past, it is argued, persists as a kind of 'haunting' presence in the present, hovering but intangible.

The endurance of 'traumatic disruptions' occupy, for the neo-Freudians, comparable conceptual terrain to that of collective consciousness for the neo-Durkheimians. But in the latter, the past finds expression in the present: trauma dictates that the past survives *as if* it were the present. Caruth (1996) defines trauma as wounds inflicted on the individual too overwhelming to be fully absorbed and available to consciousness. The consequence is that trauma lives on unconsciously—latently—but ultimately finds a voice in the present. A traumatic moment becomes 'embodied' (Prager 1998) or engraved on the person

and, in time, intrudes upon later experiences in the present (Van Der Kolk and Van Der Hart 1996). Yet if this process describes the persistence of the past in individual experience, similar processes are also believed to shape collective experience, in which collective memory is characterized as the mediated process of remembering earlier collective or cultural trauma.

Moses and Monotheism (1939) serves as a foundational text, in which Freud describes how trauma transforms the present as repetition of a prior traumatic moment. He characterizes the Jewish murder of their leader, Moses, as a traumatic reliving of the earlier murder of the primal father and thus captures the way in which traumatic guilt, for a time buried, finds expression in an unconscious reenactment of the past in the present. As Caruth asserts about Freud's argument, traumatic history helps explain not the practices that help reinforce the collective consciousness, but the overwhelming traumatic history that shapes the culture. Collective memory articulates the relation of a particular present for a group to its traumatic history that helped constitute it; in *Moses and Monotheism*, Freud attempts to capture the historical origins of both a particular Jewish culture, and the Christian response to it. Building upon this theme but extending it, Asman (1997) asserts that an original traumatic assault on an early period of Egyptian monotheism, long before Moses, continued to serve as a 'stabilizer of memory,' repetitively creating a religious enemy, long after the 'real' memory no longer possessed any carriers. While this early brutal assault on the first monotheists did not survive in memory, its real impact nonetheless led to the Egyptian experience of the Jew as a symbol of danger and crystallized into Western anti-Semitism, which continues to this day to shape Western political culture. Here, trauma knows no closure—even after the events are long forgotten and the victims no longer survive, it shapes and molds subsequent history in the image of the traumatic past.

Profound social disruptions—like slavery and the Civil War, the Vietnam War, and political assassinations in the United States (Neal 1998), the dictatorships and the 'disappeared' in the Southern Cone of Latin America in the 1970s and 1980s (Hollander 1997), the European Holocaust, the rise and fall of communist regimes in Eastern Europe, ethnic conflicts in Central and Eastern Europe—have contributed to the prolific production of neo-Freudian scholarship on post-traumatic collective memory. Unlike neo-Durkheimian perspectives that tend to downplay the reality of historical experience and its impact upon the collectivity in favor of an appreciation of constructivism, a neo-Freudian approach takes seriously the materiality of terror and oppression and seeks to understand its enduring consequences after the fact on the collectivity. The lasting effects of the past on the present rely on the ideas of the persistence of unconscious guilt, transference, and projection. Despite the appeal, this perspective holds because it seriously confronts historical realities and its insistence that social institutions and individuals are irrevocably transformed as a result of these experiences, these concepts nonetheless seem inadequate analytic tools to provide a psychological justification for the survival of trauma long after its victims have disappeared. A more robust theory of the transmission of trauma across generations, or across eons, is necessary, if one is not to think that ultimately history, however traumatic, in time finds closure in spite of the enormity of the crime, the disruption, the terror.

5. *Conclusion*

Collective memory is of more than passing academic interest. Hannah Arendt (1951, p. 423) defines totalitarianism as a system that forbids grief and remembrance; it severs an individual's or a group's relation to a continuous past. This obliteration of the past, for Arendt, is synonymous with the death of moral man. Today, political elites throughout the world appreciate the constructed nature of a national memory and seek, through it, to shape their own political cultures. Similarly, there is often recognition of traumatic pasts that threaten to overshadow present experience and their need to proactively respond. As many nation-states in Eastern Europe, Southern Africa, and Latin America have attempted to recover or institutionalize democracy in the 1980s and 1990s, the challenge to incorporate the past into current politics—either by defining the polity in relation to the past or by insisting upon its transcendence—relies on both politics and psychology of collective memory. The Tribunal of Truth and Reconciliation, for example, in the Republic of South Africa, not only acknowledges collective memory as a political reality, but also endorses a psychology that recognizes the heuristic effects of remembering to overcome the legacy of apartheid and to promote national unity. Other nations, still cognizant of the importance of collective memory, rather than promoting reconciliation between past and present, have implemented a politics of 'forgetting,' taking the position that the present can serve to refashion the past. The psychology of collective memory has emerged as a central point of political and intellectual controversy in various democratic states, and the politics of memory a central feature of post-dictatorial states.

Collectivism: Cultural Concerns

Collectivism is a cultural pattern found especially in East Asia, Latin America, and Africa. It is usually contrasted with individualism found in the West, e.g., in Western and Northern Europe, the USA, Canada, Australia, and New Zealand. Any typology is an oversimplification. Societies are not purely individualist or collectivist, but some mixture of the two. The construct is widely used by those interested in studying cultural differences.

1. Characteristics

Among the most important characteristics of this cultural pattern are the following:

(a) Individuals define themselves as aspects of a collective, interdependent with some ingroup, such as the family, tribe, co-workers, nation, or religious, political, ideological, economic, or aesthetic group.

(b) They give priority to the goals of that collective rather than to their personal goals.

(c) Their behavior is determined more often by the norms, roles, and goals of their collective than by their personal attitudes, perceived rights, or likes and dislikes.

(d) They stay in relationships even when the costs of staying in these relationships exceed the advantages of remaining.

These are defining attributes of collectivism. There are as many kinds of collectivism as there are collectivist cultures. To distinguish among collectivist cultures, additional attributes are necessary (Triandis 1995).

2. *History*

The term was first used in political philosophy in the eighteenth century in contrast to the individualism advocated by John Locke and Adam Smith. An early exponent was Jean Jacques Rousseau, who in his *Social Contract* (1762) advocated submission to the 'general will,' which was conceived as the common core of societal opinion. Georg Fredrick Hegel and Karl Marx also proposed collectivist philosophic systems.

The term was introduced into psychology by Hofstede (1980), in a study of the values of IBM employees in some 80 countries. He found that by summing the responses to value items of individuals from each country, and using the country as the unit of analysis, it was possible to identify a cluster of responses that reflected collectivism and individualism. Triandis (1995, in press) summarized the literature which used that construct in social psychology, and Kagitcibasi (1997) provided a critical evaluation of the construct.

Historical analysis suggested that collectivism was the typical cultural pattern in traditional societies, and individualism began emerging in England as early as in the thirteenth century. Traces of individualism have also been found in ancient Greece.

3. *Distribution*

Within any society there are individuals who behave like persons in collectivist cultures. They are called *allocentrics*, and contrast with those who behave like persons in individualist cultures who are called *idiocentrics*. It is assumed that there are both allocentrics and idiocentrics in every society, but their distributions are different, with more allocentrics found in collectivist cultures. The distinction between collectivism and allocentrism is important because in some cases a phenomenon observed at the cultural level is quite different from the phenomenon at the individual level of analysis.

Collectivism is maximal in relatively homogeneous societies, such as theocracies and monasteries, while individualism is maximal in heterogeneous societies that are very affluent. Thus, there will be few idiocentrics in monasteries and few allocentrics among Hollywood stars.

All individuals have access to cognitive systems that include both allocentric and idiocentric cognitions but they sample them with different probabilities, depending on the situation. For example, if the ingroup is under attack most individuals become allocentric. In the company of other allocentrics the norms for allocentric behavior become salient and individuals are more likely to sample allocentric cognitions. Some situations provide very clear norms about appropriate behavior (e.g., in a house of worship), while other situations do not (e.g., at a party). Individuals will be more allocentric in the former than in the latter situations. When the ingroup can supervise an individual's behavior norms are more likely to be observed, and the individual will be more allocentric. When individuals are asked to think for two minutes about what they have in common with their family and friends they are likely to sample allocentric cognitions. Situations are more important than the personality of individuals as determinants of allocentric behaviors.

Collectivism can appear in all or none of the domains of social life. For example, it can be found in politics, religion, aesthetics, social life, economics, or philosophy, as was the case in China during the Mao period, or in none of these domains, as among Hollywood stars.

4. *Antecedents*

4.1 *Homogeneity of the Collective*

An important antecedent is the homogeneity of the collective. If members of the collective do not agree concerning what are the group's norms of behavior, it is left up to the individual to decide which normative system to follow.

4.2 *Interdependence Imposed by the Situation*

Collectivism is higher when members of the collective are interdependent, for example when they engage in activities that must be coordinated and when what one does affects the success of others, or where cooperation is essential for success. When the goal is to execute large projects such as irrigation canals, or defensive walls, collectivism is more likely. In societies where people are financially interdependent, collectivism is high.

4.3 *Population Density*

In dense social environments many rules develop that are designed to reduce conflict and ensure the smooth functioning of the group. People make sure that the

rules are observed. When group norms are more important than attitudes as determinants of social behavior, collectivism is high. Urban environments often include members of different groups, and individuals can decide for themselves whether to observe the norms of one or another group, thus they become idiocentric. On the other hand, an urban setting may have neighborhoods of culturally homogeneous individuals, which increases the collectivism of that group.

4.4 Social Stability

When the collective is stable, it is more likely to develop agreements about norms, and to make sure that the norms are observed. By contrast, individuals who have migrated from their societies or have experienced social mobility are more likely to be idiocentric. When social change is slow, the norms can be observed more reliably than when social change is rapid. There is evidence that the older members of all societies are more allocentric than the younger members.

4.5 Low Economic Status

The lower social classes tend to be more conforming to social norms than members of the upper classes. The poor have fewer choices in life, and tend to do what norms specify. When resources are limited, one often depends on group members for assistance, especially in emergencies. These factors increase collectivism. On the other hand, those in positions of leadership tend to be idiocentric.

4.6 One Large Ingroup Rather than Many Ingroups

Those who only have one ingroup can channel all their energy into that group. Also, they cannot afford to develop poor relationships with members of that group, so they are more likely to observe its norms. Those who have many ingroups have superficial relationships with most of them, and if they do not have good relationships with one of these ingroups they drop it and spend more of their energy with some other ingroup. Intense involvement in relatively large ingroups (extended family, religious, or national ingroup) is more common among collectivists than individualists. Intensive involvement in individualist cultures is usually limited to first-degree family members.

4.7 Low Exposure to Other Cultures

People who only know one culture are unlikely to have more than one set of norms for social behavior. They tend to be maximally ethnocentric, authoritarian, and submissive to ingroup authorities. Those who are more educated, traveled, and have lived in more than one cultural group develop idiocentric tendencies.

4.8 Salient Common Fate

Common fate with members of the ingroup (e.g., the ingroup is under attack) increases collectivism. Time pressure for decisions has similar consequences. When there is time pressure an ingroup authority must make quick decisions that do not allow time for discussion, and that places most members of the ingroup in a condition of common fate, as well as requiring conformity to these decisions.

4.9 Collective Mobility is Advantageous

If individual upward social mobility is not possible, then collective mobility may be used. Thus, individuals invest their energy in promoting the status of their ingroup.

4.10 Large Families

In large families it is not practical to allow each child to follow idiosyncratic schedules, or have much privacy. Many rules are enforced, and that creates collectivism.

4.11 Strict Religious Upbringing

Most religions use a large number of norms that are reliably observed. That increases collectivism.

4.12 Little Exposure to Modern Mass Media

US-made television is widely available throughout the world. Content analyses show that the themes used are highly individualistic (emphasis on pleasure, doing what the individual wishes to do even if that is inconsistent with the wishes of authorities). Countries where people have little exposure to the US-made mass media are more collectivist.

5. Consequences

5.1 Socialization

Children are socialized to be obedient, reliable, follow traditions, do their duties, sacrifice for the ingroup, and be conforming. An important value is self-control.

For example, in a Chinese preschool children are taken together to the bathroom only three or four times a day. This procedure is extolled by Chinese teachers as providing orderliness and training in self-control. American educators find it objectionable because it does not allow for individual differences or personal choice, which is an important value among individualists.

5.2 Low Well-being

While members of all cultures are satisfied with their life, members of collectivist cultures are less satisfied than members of individualist cultures. Well-being tends to be correlated with individualism (Diener et al. 1995). Even when controlling statistically for income, this relationship persists.

5.3 Consequences for Cognition, Emotion, and Motivation

Markus and Kitayama (1991) have reviewed an extensive literature that shows that members of collectivist cultures differ from members of individualist cultures in their cognition, emotion, and motivation.

5.4 Social Behavior

Collectivists are extremely concerned with saving their face, and even attempt to save the face of the persons with whom they are interacting. Preserving harmony within the ingroup and being pleasant in relationships with ingroup members are often important values. On the other hand, collectivists do not care much about their relationships with outgroups. They usually behave quite differently toward ingroup and outgroup members, showing sacrifice and extreme cooperation with ingroup members, and suspicion and hostility toward outgroup members.

5.5 Receive Much Social Support if they Conform

Allocentrics report that they receive more social support and a better quality of social support than idiocentrics. However, those who do not conform to ingroup norms are rejected, and may even be killed (Triandis 1995).

5.6 Have Poor Skills in Entering New Groups

Members of collectivist cultures do not have good skills for entering new groups because they are not socialized to do this. They are comfortable as members of their ingroups, thus they do not need to enter others. On the other hand they have more intimate relationships with those with whom they interact than idiocentrics who tend to have superficial relationships (e.g., cocktail parties).

5.7 Are Easy to Mobilize for Confrontations with Outgroups

When ingroups are in conflict it is easier to arouse members of collectivist cultures to fight for the ingroup than it is to do so with members of individualist cultures. Ethnic cleansing is more often found in collectivist than in individualist cultures.

5.8 Describe the Self by Using Roles, Groups

When asked to complete 20 statements that begin with 'I am ...,' members of collectivist cultures provide sentence completions that have more social content (I am a brother, I am a member of the communist party) than members of individualist cultures.

5.9 Attributions

Allocentrics make external attributions in explaining events, while idiocentrics show the opposite pattern. Thus, idiocentrics make the fundamental attribution error (seeing internal rather than external causes for the behavior of other people, while actors see external causes more often than internal causes) more frequently than allocentrics. Also, allocentrics attribute their successes to the help they have received from others and their failures to personal shortcomings (e.g., I did not try hard enough).

5.10 Have the Ideal of Fitting-in Rather than Shining

Allocentrics prefer to fit in and be like most others in their ingroup rather than shining and sticking out. Idiocentrics tend to be high in self-enhancement (report that they are better than most other people on most desirable attributes). Allocentrics tend to be modest when they compare themselves to others.

5.11 Show Little Social Loafing

Allocentrics show little evidence of social loafing (the tendency to produce less when they work in a group than when working alone if their output is not identifiable). They usually produce as much as possible when they work with ingroup members, but they show social loafing if their co-workers are outgroup members.

5.12 Within the Ingroup Distribute Resources Equally or According to Need

When interacting with ingroup members, members of collectivist cultures tend to distribute resources equally or according to need. When interacting with outgroup members, however, they use the equity principle (to each according to contribution).

5.13 Recreation Occurs in Groups

Members of collectivist cultures seek recreation in groups to a greater extent than members of individualist cultures (e.g., bowling rather than skiing).

5.14 Communication

Members of collectivist cultures rely on the context (distance between and position of bodies, eye contact, gestures, tone of voice) more than on the content of communications. For example, rather than saying 'no' they may serve incongruous foods, to put across their negative message without causing the other person to lose face. When they describe a person they are likely to use context, e.g., 'he is intelligent in the market place,' rather than decontextualized statements such as 'he is intelligent.' Silence is used more than in individualist cultures. Compliments are not used as frequently as in individualist cultures. The languages of collectivist cultures do not require the use of 'I.' Collectivists use more action verbs (e.g., he asked for help) rather than state verbs (e.g., he is helpful), which suggests that they use communications that make greater use of context, are more concrete, and place less emphasis on internal attributes of the person.

5.15 Conflict Resolution

Members of collectivist cultures avoid conflict with ingroup members, and in the case of disagreement prefer silence to argument. They prefer mediation to confrontation.

5.16 Conformity

Members of collectivist cultures show more conformity in experiments that measure conformity.

5.17 Emotions

Members of collectivist cultures get angry when something unpleasant happens to ingroup members more often than when something unpleasant happens to themselves. They do not express negative emotions as often as members of individualist cultures.

5.18 Apologize More for Transgressions of the Ingroup

Members of collectivist cultures apologize more when an ingroup member commits a crime than is common in individualist cultures.

6. Globalization and Collectivism

In the process of globalization, is collectivism to be avoided and individualism to be promoted? This issue is especially relevant as societies become more affluent, because they tend to acquire some of the attributes of the West, including individualism. The tribe is rejected, and the individual becomes the center of social change. People in cities, in small apartments that do not have room for extended families, drift toward individualism.

Is 'economic development' necessarily associated with more individualism and less collectivism? My view is that the problem is much more complex than just stated. First, one can be both modern (use computers and fax machines) and collectivist. Second, societies are complex, i.e., they have many aspects. Some aspects might change and become more Western, while most aspects may stay the way they were. In general superficial attributes, dress, public behavior, and economic life might change while fundamental values may not. In any case, for collectivist societies, one might ask: is it desirable to 'promote' individualism, or is it better to stay with collectivism? As is the case with most complex issues, the answer is 'it depends.'

A major problem can be the extremity of collectivism and individualism. Extreme collectivism is stifling. One becomes a tool manipulated by others, unable to reach personal goals. Extreme individualism is isolating, and leads to ego-centered narcissism. Furthermore, extremely individualistic societies are often extremely competitive, and that results in remarkably high levels of stress. Escapes from stress may include drug abuse.

It is possible to list both positive and negative factors associated with each cultural pattern. In the case of individualism we find affluence, self-determination, and self-actualization. These factors are associated with feeling good about oneself, and being satisfied with life and happy. Also, in individualist cultures there is an emphasis on individual rights, and people are expected to shape the direction of societal change to fit their personal needs. Participation in democratic processes is emphasized. Personal freedom is an important value. In democracies the state usually acts so as to satisfy personal values.

On the other hand, Naroll (1983) has assembled much empirical information suggesting that the weak interpersonal bonds that are associated with individualism result in higher rates of civil disturbance,

riots, murder, delinquency, theft and fraud, drug and alcohol abuse, suicide, brawling, wife beating, child battering, and mental illness. The competition found in individualist cultures often results in some segments of the society remaining economically behind and becoming especially susceptible to social pathologies.

By contrast, collectivism is associated with social controls, including extreme punishment for crimes, prompt punishment, and active gossip. Social control is also achieved through emotional closeness, social support, appeals to memorable myths, and a plausible ideology that supports the ingroup's norms. People feel embedded in the social system, so they are less likely to try to change it, to commit crimes or suicide, to steal from the ingroup, or use drugs that isolate them from it. One of the best predictors of drug abuse is the combination of high pressure for achievement with low social support, a combination often found in individualist cultures.

On the negative side, collectivism is often found in societies where groups assume that the individual is relatively unimportant and must do what is best for the group. This is especially significant when the group is the state. People are expected to be 'patriotic,' i.e. sacrifice themselves for the good of the state. However, very often what is good for the state is in fact only good for those in power, who frequently take advantage of the masses to further their personal goals. As we have seen, leaders in all cultures are idiocentric, and the history of the world offers too many examples where they order their followers to do what is good for the leader rather than what is good for the followers. Also, collectivism makes it easier to convince the ingroup to fight outgroups, and wars are more frequent between collectivist countries than between individualist cultures. In a world with nuclear weapons, there may be much to be said in favor of reduced collectivism.

Note also that while the social pathology associated with individualism is formidable, it does not affect most individuals in a society. Pathology by definition is found among a small minority in any society. Thus, the majority can enjoy the benefits of affluence without the negative consequences of individualism.

In short, an evaluation of the desirability of collectivism or individualism depends on what criteria we wish to maximize. If we wish to emphasize the creativity that individualism allows, which often results in more affluence, the freedom and self-actualization of individuals, democratic processes, and the independence of individuals from the social pressures of groups, we may wish to see globalization leading to more individualism. But if we wish to emphasize the values of the ingroup, we may resist the weakening of collectivism associated with affluence. These values include religious beliefs, the social support that one can get from the ingroup in moments of crisis, and the security, both material and emotional, that the ingroup can provide.

In addition to the above considerations, there are issues of individual differences. For those who are intelligent, educated, easily changed, adaptable, an individualistic society can offer a great deal. Creativity requires freedom to pursue different courses of action, and in a society where one is supposed to consult others, and act according to well-established customs, creativity is not likely to flourish. On the other hand, for those who value especially family life, harmony, security, and a life of little stress, a collectivist society may be optimal.

Colonialism, Anthropology of

The story of the relationship between colonialism and anthropology (or more specifically, of the anthropology of colonialism) is not the story of a neatly unfolding self-consciousness. It is, rather, the story of successive contexts of questions that have shaped the intellectual space in which the problem of colonialism for anthropology has been formulated and engaged.

Anthropological self-consciousness of colonialism, that is, of colonialism *as a distinctive problem for anthropological knowledge and anthropological practice*, begins roughly in the 1970s. In the early years of that decade two edited volumes appeared dealing with anthropology's relation to the social and political world of which it was a part. One came out of the tradition of US cultural anthropology, *Reinventing*

Anthropology edited by Hymes (1972); and the other out of the tradition of British social anthropology, *Anthropology and the Colonial Encounter* edited by Asad (1973). Both collections perceived the discipline to be in serious crisis; and both were radical in the sense that they were explicitly concerned to subject that crisis to a fundamental self-scrutiny.

Hymes's volume urged that the social and political conditions in which anthropology had emerged as a professional academic discipline in the US at the turn of the twentieth century had, by the late 1960s, significantly altered. First, there was the overwhelming fact that with political decolonization there was a fundamental change in the conditions in which fieldwork could be conceived and undertaken. At the same time, the relation between the US government and the Third World (as the colonized or recently decolonized part of humanity came to be called from the 1950s) had given rise to troubling moral-political questions about the state of the anthropological enterprise. In particular, US involvement in attempted counter-insurgency in Latin America, and the role of anthropologists as cultural experts in the war in Indochina, served to pose the question of the relationship between 'objectivity' of ethnographic data and political interest in a very acute way (see Stocking 1991). What place would anthropology have in raising fundamental questions about injustice and inequality in the world it inhabited, and what was its role in trying to transform that world? Was anthropology to be employed as an instrument of Western domination or as a means of liberation? Moreover, the publication of Malinowski's field diaries in 1967 and the revelation of his barely veiled racism further focussed attention on the ethics of the relation between ethnographer and informant.

In this context, the challenge *Reinventing Anthropology* sought to pose was whether the discipline would be able to transform—to *reinvent*—itself in a way that reflected the demands for political accountability, ethical concern, and critical social commitment on the part of anthropologists. Two strains in US anthropology inspired the volume's contributions: one—reflected especially in the articles by Hymes and Stanley Diamond—was the radical Boasian tradition in the work of people like Edward Sapir, Ruth Benedict, and Paul Radin, who thought of anthropology as a reflexive critique of civilization. The other strain—reflected in Eric Wolf's contribution—was a post World War II Marxism (much influenced by the cultural-evolutionary materialism of Julian Steward) which was concerned to highlight the plight of peasant societies caught in the juggernaut of capitalist imperialism.

The intellectual tradition of British social anthropology has of course a very different historical context than US cultural anthropology, one far more intimately interconnected with the subordination, management and rule of colonial subjects. Not surprisingly, then, the concerns of Asad's *Anthropology and the Colonial Encounter* were somewhat differently inflected than those of Hymes's volume. To be sure, they shared a concern that since World War II fundamental changes had occurred in the world inhabited by social anthropology. The emergence of new nations, especially in Africa where much British social anthropological fieldwork was carried out—Sudan (1956), Ghana (1957), Nigeria (1960)—made it increasingly difficult to avoid the pertinence of a more historical approach that brought the larger political and economic system of colonialism into view. And in consequence it was increasingly difficult not to be critical (as indeed Edmund Leach was in a limited way) of the ahistorical functionalism and empiricism that characterized British anthropological theorizing.

In the middle 1960s, New Left critics had in fact launched an attack on British social anthropology. And part of the project of Asad's volume was to respond to these and other radical claims, not simply to affirm or deny them, but to more adequately specify and formulate them. There was a sense that perhaps, while undeniable, the relation between colonialism and social anthropology was more complicated than was allowed by the polemical tone of accusation and disavowal. In her contribution, for example, Wendy James argued that the very existence of social anthropology in the colonial period constituted a source of *potential* radical criticism of the colonial order, and she sought to provide a more nuanced account of Malinowski's own active social reformism during the interwar years. Stephan Feuchtwang, in his contribution, discussed the relation between the social and institutional conditions of British anthropology and the knowledges it produced. In an allied way, Asad examined 'objectifications' of colonial power produced in two authoritative domains of systematic knowledge—the functionalist anthropology of Africa and Islamic orientalism. Asad was concerned to understand the connections between these different images of rule (one largely of 'consent,' the other largely of 'repression'), their ideological roots, and conceptual consequences.

In subsequent decades, the anthropological preoccupation with colonialism has tended to be largely (if not solely) a phenomenon of the US academy. At any rate, in the 1980s there was a gradual shift away from the concern with the *role* of the discipline in the colonial/imperial enterprise and the politics of its practitioners, toward a concern with colonial forms of knowledge about non-European worlds. The register in which the problem of colonialism for anthropology was conceived was now less a political than an epistemological one. Or rather, linking power and knowledge, colonialism was now conceived as a problem of (in the language of the day) the politics of representation. This shift has many interconnected sources. I shall only be able to touch on a few of the more salient ones.

At one level, of course, the shift is connected to the decline of anti-imperialism and anticolonialism as going *politico-ideological* concerns. On the one hand, beginning with the end of the Vietnam War and accelerating through the years of Ronald Reagan's US Presidency there is a marked decline in the First World intelligentsia's interest in revolutionary change in the Third World. On the other hand, in the Third World itself there is a decline (indeed a rapid unraveling) of the experiments with radical social transformation in many of the independent countries of South Asia, Africa, the Caribbean, and Latin America. At another level this shift was connected to a number of *intellectual* transformations in the understanding and practice of the human sciences. Very broadly speaking, these may be characterized in terms of a general drift away from the determinism (Leslie White, Julian Steward) and functionalism (Radcliffe-Brown) of postwar anthropology and toward a social/cultural constructionism. Principal among these transformations was the so-called 'turn to meaning' in social and cultural analysis. In many ways, of course, the work of Geertz (1973) embodied—indeed, helped to constitute—this constructionist moment. In his work, culture came to be understood as a web of semiotic processes or relations, and cultural analysis as a practice less of uncovering determinate causes, or of explaining functions, as of deciphering meanings. Two features of this anthropology are of special importance here: one is that its criticism of objectivism brought about a renewed sensitivity to 'the native's point of view' and 'local knowledges'; and the other is that the critique of positivist social science led to a greater openness to interdisciplinarity, to literature and history in particular (Geertz's famous 'blurring of genres').

This work, in turn, set the stage for the emergence in the 1980s of an interest in the *textuality* of ethnographic description and analysis, in the senses in which these are artifacts of language—hence, in their way, *literary*—and therefore open to an investigation of their rhetorical and poetic structures (Clifford and Marcus 1986). How is ethnographic authority constructed? What are the linguistic devices that enable anthropological representations to produce their distinctive 'realistic' effects? Some of this work sought explicitly to reconceive the task of a critical anthropology (Marcus and Fischer 1986).

This preoccupation with modes of representation in social and cultural analysis was, in part at least, the context for the rise of what would come to be called colonial studies. An interdisciplinary field (drawing largely on literary critics, anthropologists, and historians), colonial studies would help to institutionalize the renewed scholarly focus on colonialism. The central inspiring text here was Said's *Orientalism* (1978). Borrowing in some measure from the middle work of Foucault (1979), this book thematized the idea of colonialism as a *discursive* formation. Said set out to demonstrate the ways in which, in the (especially French and British) colonial discourse of orientalism, the Orient was invented. The Orient, therefore, was less a geo-political location than a figure in the cultural-political imagination of the West. *Orientalism* opened up a rich vein of research and a critical demand to interrogate the West's authoritative discourses on the non-West—anthropology chief among them—and to unmask the ways in which they produced and reproduced their hegemonic knowledges. Interestingly Said himself (1988) would later express doubts about the value and future of a discipline so deeply implicated in the making of such hegemonic knowledge.

One anthropological work that drew together some of these themes—though in a way less pessimistic about the possibility of a revised anthropological enterprise—was Fabian's *Time and the Other* (1983). The subtitle of the work was significant: *How Anthropology Makes its Object*. It focussed attention precisely on the 'constructedness' of anthropological discourse, specifically on the uses of Time in anthropology's constitution of its object (the savage, the primitive, the native, the Other). Fabian sought to show how the existential copresence of the Other in the dialogical interaction of ethnographic fieldwork gets transformed into a temporal distancing—what he called a denial of coevalness or cotemporality—in the theoretical construction of authoritative anthropological knowledge. This 'conjuring trick' served perpetually to consign the native to a temporal zone outside of the Time of anthropology, which is to say the privileged Time of the West. It is easy to see that the lessons of Fabian's book are wider than the issue of temporality alone. What it demonstrated was that unless anthropology subjects its own discourse to critical scrutiny, unless it pays attention to the conceptual assumptions that go into the *making* of its objects, it is liable to reproduce colonial knowledge. Other work would later seek to extend and develop this inquiry into the formation of anthropological objects (see Scott 1994).

Another set of anthropological concerns with colonialism in the 1980s was more closely connected to the antinomies of Marxism. The defeat of the communist project in Western Europe after 1920 had given rise to a strain of Marxism (soon to be called Western Marxism) focussed on what had hitherto been dismissed as superstructural issues. Marginalized until the rise of the New Left in the 1960s, this strain became more prominent in the 1970s, especially in the North Atlantic academy. Antonio Gramsci's theorization of hegemony, Louis Althusser's reconceptualization of ideology as representation, and Raymond Williams's displacement of the base/superstructure model for the analysis of literature (and cultural production more generally) offered less reductionistic critical languages in which to situate social and cultural life in relation to capitalism. An interest in rethinking the problem of the articulation of modes of production, and of

precapitalist (and precolonial) formations was one direction of Marxist work that had actually begun earlier. But in another direction, folded into the anthropological concern with local knowledges and finite histories, this cultural Marxism offered the prospect of an antiuniversalistic account of hitherto invisible idioms of resistance to dominant power (including, of course, globalizing capital), and of hitherto unacknowledged forms of (often informal) agency in the quotidian making of histories. In their very titles, James Scott's *Weapons of the Weak* (1985), and Jean Comaroff's *Body of Power, Spirit of Resistance* (1985), offer exemplification of this interest in the anthropology of anticolonial resistance.

Throughout the 1980s history was becoming a site of profound scholarly preoccupation. Indeed within the discipline of history itself there was already a growing interest in the intersection of modes of cultural and historical representation. Work in feminist history, in particular, helped to reformulate relations between power, difference, and representation. But perhaps the most significant contribution to the argument for more than a nodding relationship between anthropology and history—and this too on the terrain of colonialism—has been the pioneering work of Cohn (1987). Cohn's essays were only brought together in 1987, under the title, *An Anthropologist among the Historians and Other Essays*, but from the early 1960s he had been urging the theorization of the intersection of history and anthropology. In a number of wide-ranging essays on British India—from concerns with the formation of historical, legal, and statistical modes of colonial knowledge, to an interest in ritualized representations of political authority—Cohn demonstrated that historical analysis of colonial rule was indispensable for anthropological understanding. This work inspired a number of innovative studies in the historical anthropology of colonial India (among them Dirks 1987). Significantly too, India was the conceptual and intellectual-political site of another important contribution to the debate about history for an anthropology of colonialism—the Subaltern Studies Collective's re-interrogation of liberal and nationalist accounts of colonial rule in India and the anti-colonial struggle against it (Guha 1984). Transdisciplinary in perspective, the work of the Collective resonated with the anthropological discontent with universalism and Eurocentrism and its interest in the agency of non-dominant idioms, knowledges, and practices.

In the 1990s one can discern another shift in the questions driving the anthropology of colonialism. These new questions turn less on the textuality of colonial representation or the agency of resistance than on the problematization of the relationship between colonialism and modernity, and the implications of this relationship for understanding the postcolonial present (Asad 1991, 1992, Scott 1997). The profoundly epochal sense attending the *fin de siecle*, the sense of a crisis of modernity (and for some, an emerging *post*modernity), has made for a growing preoccupation with a re-examination of the formation of the modern world and its moral, epistemic and political modes of legitimization. Much of this re-historicizing work has sought to criticize the progressivist story of modernization.

There are several dimensions to this anthropological preoccupation with colonialism and modernity. One of the earliest has been the concern with the problem of nation and nationalism. There had of course been an older multidisciplinary interest in nations and nationalisms, namely, the 'new nations' projects of the early 1960s. These studies were primarily concerned with inquiring into the modernizing and democratizing challenges facing the newly independent nation-states. However, two books more than any others reopened and significantly reshaped the debate about the nation: Gellner's *Nations and Nationalism* (1983), and Anderson's *Imagined Communities* (1983). Each was focussed differently, but they were both inspired by the problem of the relation between nation/nationalism and *modernity*. If the 'new nations' work tended teleologically to take nationhood as a normal developmental threshold, what Gellner and Anderson foregrounded was the idea that nations were not natural entities nor nationalisms primordial sentiments or ideologies. Both, they argued, were profoundly historical, and that historical character, moreover, owed most to the making of the *modern* world.

Gellner and Anderson would both be criticized for their emphasis on the modernity of nations and nationalisms, but it was precisely this connection that those interested in colonialism were concerned to explore. Anticolonial nationalisms and the making of postcolonial sovereignties clearly had a very complex—and as yet, perhaps, unresolved—relation to the modernizing project of late colonialism. In this regard the decisive work was Chatterjee's seminal book, *Nationalism and the Colonial World*, originally published in 1986 but becoming influential in debates from the early 1990s. A noticeable feature of this work was its interdisciplinarity, and especially the place of anthropology (as the authoritative discourse on Europe's Others) within it. While indebted to Said's *Orientalism* for its opening deconstructive move, Chatterjee undertook a sustained examination of anthropological assumptions (e.g., about rationality) undergirding the distinction between Western and non-Western nationalisms.

Connected to this focus on rethinking the relations between modernity and nation, has been the renewed attention given to the problem of modern colonial power generally, and the colonial state in particular. Especially important here has been the later work of Foucault on governmentality (1991) that raised the question of the place of the state in a larger and much transformed understanding of power. Questioning a

deeply influential tradition of social and political analysis owing much to both Marx and Weber, Foucault's concept of governmentality sought to think (conceptually) about a field of power in which the state was not the central analytical domain; and (historically) about a concrete moment in European history when political power becomes more dispersed, less dependent upon the institutions of coercion. This concept opened up the possibility of reconceiving the questions through which the problem of colonial power was formulated. Where modernization narratives (liberal or Marxist) had plotted a story of the progressive rationalization of the state (the more or less of power; the counter-positioning of power and freedom), what now emerged was the possibility of a story of colonial power told in terms of the political rationalities by which it was organized. The point here was to urge an historicization in which the emergence of a colonial rationality of government (i.e., a form of colonial power directed at transforming conditions so as to produce effects on colonial conduct) could come more sharply into view. And the significance of this is that this rationality is central to the making of our postcolonial worlds (see Scott 1999).

There have been critics, of course, who are skeptical about this thematization of governmentality in the anthropology of colonialism. The more sympathetic of them argue that neither the old master-narrative of progress and modernization nor the new Foucauldian revisionism are adequate because neither appreciates the inherent *doubleness* of colonial rule. The essential paradox of the colonial state, it is argued, is that it was always caught between *two* principal imperatives—ruling subjects and making citizens—and, therefore, always moved simultaneously in two directions: coercion and civilization. The crucial hinge on which this doubleness hung was the colonial language of law and legality (Comaroff 1998). In a related direction some critics have been concerned that the whole relation between metropole and colony has been ill-conceived (Cooper and Stoler 1997). The worry here is the assumption among many students of empire of a Manichaeism that sees the problem of colonialism as a binary—colonizer/colonized—one. These critics argue that, to the contrary, the conception of an encounter between an empty colony simply remade by Europe and a Europe that remains ever unmarked by its empire is untenable. They urge a view that places metropole and colony in a single (if internally differentiated) analytical field, and focuses precisely on the multiple tensions—inclusions/exclusions, hierarchies, reversals, etc.—through which Europe and its empire were (unevenly and asymmetrically) co-constructed.

Since its emergence as a distinctive theme in anthropology in the 1970s, the problematization of colonialism has been thought of as part of an orientation towards the present at least as much as, if not more than, the past. In this sense there has always been about it an animating ethos of criticism—whether criticism of our worlds or criticism of our disciplines. The anthropological problem about the colonial past, in other words, has been connected to raising critical questions about the postcolonial present: it is part of the making of a distinctively *postcolonial* anthropology. However this connection and its implications have been more often assumed than systematically thought out. Consequently, anthropology has been less concerned than it might, not merely about the ways in which understandings of the colonial past are conditioned by contemporary 'scenes of inquiry,' but more importantly about the ways in which a self-consciousness about alterations in the latter ought *strategically* to alter the kinds of questions we pursue about the nature of the former. The point, then, is that for anthropological criticism to have purchase on the present it is not enough to insist that the purview of colonial studies be enlarged (to encompass Europe, for instance, or gender, or the state), it is necessary to specify the domain of contemporary questions that are being addressed in so doing. This is the only way to gauge the extent to which our critical exercises are meeting a contemporary demand as opposed to simply expanding an already established cognitive field.

This is the challenge. It is an important challenge because the crisis upon which the formerly colonized world entered in the 1980s and 1990s (unlike those of the 1960s and 1970s) is a crisis not merely of policy orientations or development options or even ideological alternatives. It is a crisis of the legitimacy of the modern/modernizing assumptions that have undergirded the very making of these colonial and postcolonial societies and polities (assumptions, for example, about the relation between culture and politics; between nation and sovereignty; between individual rights and historical traditions, and so on). Our *conjuncture*, in short, is shifting. And therefore, if it is to more adequately theorize the relation between the problem–space in which it produces knowledge and the questions through which it does so, the anthropology of colonialism has to attend more systematically to the changing contours and character of this postcolonial present and its crisis.

D. Scott

Colonialism: Political Aspects

Colonialism in the English language originally indicated a practice or idiom associated with British colonies (e.g., the phrase 'the place was going ahead' was described in 1887 as a 'colonialism') and was only recently applied to the relationships between metropolitan states and their colonial possessions. Its modern usage dates from the 1950s, although the relationships it embraces have a very long history indeed.

The word is derived from the Latin *colonia*, which was a synonym for the Greek ἀποικία, meaning a settlement of people from home, and it should, therefore, properly apply to the process of establishing and governing such settlements. It is now closely linked, and often interchangeable, with imperialism (e.g., see *Imperialism: Political Aspects*), but it is a particular form of the latter. The ideas that the term embraces have shifted in line with the shift in the idea of a colony.

1. The Classic Colony

The classical Greek colony was a new community, originating from an existing πόλις, and, apart from the Corinthian colonies, was independent, although tied to the mother country by sentimental and religious affinities. The high era of Greek colonization lasted from the middle of the eighth century BC until the early sixth century BC, by when Greeks had 'colonized' much of southern Italy, Sicily, and the Black Sea littoral. The motives were a mixture of land shortage and traded expansion (Boardman 1980).

Roman colonies generally had greater strategic purposes. They were settlements of Roman citizens, normally veterans, who garrisoned a new town in a hostile country and thus extended Rome's *imperium* or rule. Similar expansionist activities occurred in many other parts of the world, as with the Mogul and Ottoman Empires or the Vijayanagara Empire in southern India.

At the beginning of the sixteenth century, European powers extended their physical occupation of land to settle in the Americas, later in Australasia and parts of Africa. Colonialism involved settlement in areas noncontiguous to the motherland and should be carefully distinguished from conquest *per se* which involves physical incorporation into the parent state. Settlers left their homes for many reasons. Some fled religious and other forms of persecution; some were risk-takers, seeking opportunities to better themselves; some were sent abroad by families to resolve domestic difficulties or by the state to penal colonies.

Governing such distant possessions has always been problematic. Initially, the local, or native, populations were subdued forcibly or persuaded to sign agreements, and administrative authority passed to the new immigrants and their successors. Financial and military strength ensured metropolitan dominance at first. Over time, as the colonies grew in population and economic strength, their immigrant inhabitants sought a much greater degree of self-governance. Initially, the European powers opposed such aspirations and anticolonial wars took place that ultimately wrested much

of South America from Spanish and Portuguese control and part of North America from British control.

The American War of Independence, which gave birth to United States of America composed of 13 ex-colonies, persuaded British governments to treat more sympathetically the demands of their surviving colonies. Following Lord Durham's 1839 Report, the North America Act granted Canada considerable autonomy. In 1867, Canada became a Dominion, a term adopted by the major self-governing British colonies in 1907 and sought unsuccessfully by others, such as Southern Rhodesia. Genuine devolution of powers kept Australia and, after the Anglo-Boer War, South Africa within the British Empire. These countries still remained constitutionally subject to the British Parliament and it was not until the Statute of Westminster in 1930 that they acquired sovereignty.

The metropolitan states were largely successful in twentieth century in managing the transition of their possessions from an inferior 'colonial' status to an independent state attached emotionally to the motherland. The British failed in Ireland as did the French in Algeria. Australia, Canada, and New Zealand retained the monarch of the United Kingdom as their head of state, although vocal groups challenged this relationship in the latter part of the twentieth century. In South Africa, where the original Dutch immigrants (the Afrikaners) were dominant, this link was broken in 1961.

Colonies, in the sense of territories largely peopled, and certainly controlled, by descendants from the motherland, developed political cultures of their own, closely related to the specific circumstances that generated the initial settlements (Hartz 1964).

2. Modern Colonialism

Modern colonialism was not characterized by settlements but by external control. As a practice it dates, with a few exceptions (e.g., the Indian subcontinent), from the end of the nineteenth century, when the major European powers laid claim to, and attempted to rule over, enormous tracts of the globe—mostly in Africa and Asia—without establishing permanent settlements in them. In the twentieth century, Japan, Russia, and the USA joined the major European powers in such colonial activity. The term thus came to refer to a condition of unequal relations in which a strong 'colonial' state controls, and usually exploits, an alien and weaker people in the latter's 'homeland.' The senior administrators were nonresidents.

While the practice has a long pedigree, the word itself, with its pejorative overtones, only appeared in the aftermath of the World War II. President Harry S. Truman used the word 'imperialism' in 1949 to cover all forms of external control over indigenous inhabitants, but by 1955, when the first volume of his *Autobiography* was published, he used the term colonialism to describe such relations. At this time, colonialism was limited to the practices of the Western European powers, the expansionist policies of the Soviet Union and China still being subsumed under the umbrella of imperialism.

This was short-lived. The term 'colonial power,' referring to any state dominating another, was soon extended to the Soviet Union and the USA, and even in Pakistan, to India where Kashmir was concerned.

The 1919 *Treaty of Versailles* generated the League of Nations, which introduced a new type of colony, by granting to certain imperial powers (and Dominions like Australia and South Africa) mandates to rule over what had been the German and Italian empires. In theory, the recipient countries were obliged to ensure the paramountcy of 'native interests.' With the creation of the United Nations, mandated territories became trust territories and more attention was given, through its standing Trusteeship Council, to the responsibilities of the colonial powers. By the 1950s, 'native interests' (except in South West Africa where South Africa was the trustee) came to embrace the right to self-determination and independence.

The major colonial powers, Britain and France, organized their relations with their settler colonies, their modern colonies, and other states through different departments or offices (e.g., the Dominions Office or the India Office in Britain) to reflect their distinct relationships.

3. Colonialism in Practice

3.1 Administration

Ruling modern colonies presented difficult problems. Metropolitan states had neither had personnel nor the resources to administer them closely. Occasionally they relied upon chartered companies to act on their behalf. Some parts were intensively controlled; much was ignored altogether for many years; most were administered through the acquiescence of local leaders. This British principle of indirect rule, with roots in the Indian experience, was ideologically based (Lugard 1922) as well as pragmatically required. Other European powers emphasized direct rule. In fact, all powers practised both models as needs demanded.

The debate on the nature of colonial political rule continues. While the exercise of power was crude and excessive on occasions, recent scholarship has emphasized how local peoples sometimes took the initiative in crafting political strategies that limited colonial opportunities. After World War I, colonial administrators lacked the military support or the will to impose unwelcome policies on subjects accepted the paternalistic assumptions of trusteeship (Robinson 1965) but worked, in the British empire, towards economic and political development (Kirk-Greene

2000) and, in the French, towards assimilation. The idea that colonialism was unacceptable arose with the growth of democracy in the metropolitan states and the changing intellectual climate after World War II.

3.2 Anticolonialism

Throughout the modern colonial period some individuals and groups campaigned for independence, most notably in India, but the real pressure to end colonial rule came immediately after 1945. This reflected a number of seismic shifts in the context of international affairs. The arrival of internal democracy in the colonial states themselves challenged the undemocratic politics of the colonies; the battle against Nazism virtually destroyed the legitimacy of a racial hierarchy; both the Soviet Union and the USA, linked by the bipolar confrontation of the Cold War, yet representing quite different ideologies, shared an antipathy to overt colonial empires; the financial and military costs of retaining overseas possessions became politically prohibitive in the United Kingdom and the Netherlands.

Most colonies obtained a negotiated independence peacefully. Violence—both civil and military—was sometimes apparent, most especially in the Portuguese empire and where white settlers (classical colonists) were entrenched. The logic of colonialism worked itself out as the motives for occupation disappeared and the costs of continued rule escalated. The British colonies became independent seriatim. With their emphasis on retaining the initiative in the 'transfer of power,' officials sought the kind of educated professionals who were calling for independence (on India, see Mansergh and Moon 1970–83). In contrast, the French absorbed that elite into metropolitan organisations until the logic dictated a rapid and almost simultaneous decolonisation in 1961 (Mortimer 1969). Colonialism had effectively come to an end by the middle of the 1960s.

However, postmodernists such as Edward Said have argued that colonialism was neither a finite era nor a particular institutional structure of superordination and subordination. Both the departing colonialists and the triumphant nationalists failed to appreciate the enduring consequences of colonial rule. Cultures, economies, and institutions were so deeply embedded in the new states that their futures remained dependent upon the heritage of colonial overrule (Said 1978).

3.3 Neocolonialism

Political independence, however, was not matched by full local control. At the Bandung Conference of nonaligned states in April 1955, the Indonesian president, Ahmed Sukarno, claimed that colonialism 'has also its modern dress, in the form of economic control, intellectual control…by a small but alien community within a nation.' This perspective, similar to Said's, gave birth to the idea of 'neocolonialism' and fitted well with the growing strength of Marxist scholarship in the 1960s and 1970s.

The word itself probably first appeared in 1961 in the pages of the radical journals *The New Statesman* and *The New Left review*, but it was soon common usage in most European languages. Lord Home, when British Foreign Secretary, attempted at the United Nations in October 1961 to answer 'the charge of neocolonialism.' With the end of formal control over most of the empires, scholars and activists still perceived a decisive degree of control exercized by the metropolitan powers, essentially through economic, technological, and cultural dominance (Crozier 1964). Francophone scholars spoke of the Philippines as being '*entièrement néocolonisés par les Etats Unis*.'

Charges of neocolonialism were not limited to the great colonial powers but were extended to any state from the rich and developed world exerting influence over the policies of poor and less developed countries. Several forms have been identified. Political, economic, and cultural forces have been said so to constrain the choices available to such countries that they are determined by the interests of the stronger states. Further, it has been argued that the rapid decolonization was a calculated policy to move from overt colonial rule to indirect control through political superiority in the international community, economic dominance, and cultural influences. While the evidence for such a conscious policy is weak, the poorer excolonies were undoubtedly constrained by their political, economic, and cultural inheritances. Some states responded more robustly and effectively than others to their weaknesses.

3.4 Internal Colonialism

There has been a further recent refinement of the term. Whereas it had been used to describe a particular relationship between countries (originally metropolitan states and colonies, later sovereign states), it is sometimes used to describe broadly similar processes at work within a single state. Thus, particular groups, through their dominance of political and economic power, ensured that other groups are kept in long-term subservience. It has been used in the context of East Bengal in Pakistan and in South Africa, where the 'colonial' people were the white minority and the 'subject' people the black majority.

4. Conclusion

Colonialism is now normally used in a pejorative sense and is associated with crude exploitation. Few would deny the reality at times of oppression, economic exploitation and an unconcern for human and civil rights. The colonial powers' primary interests were

usually selfish and largely economic. But alongside was a genuine commitment to the principles of trusteeship and paternal development. Attempts to evaluate the costs and benefits of colonialism coincided with its formal ending (Perham 1962), but a growing revisionist literature, in part reflecting the reduced status of Marxist scholarship, is emphasizing the advantages for the modern state of the enlargement of scale, modern educational and economic practices, and the opportunities provided for some (but not all) by integration into the world economy. Nevertheless, it is equally important to acknowledge the relative short period of colonial rule. Davidson (1964) was right to observe: 'Looking back, one may see now that the colonial period was no more than a large episode in the onward movement of…life; in another sense, it was an unexampled means of revolutionary change.'

Colonization and Colonialism, History of

1. Introduction: Problems of Definition and the Semantic Field

'Colonization is [...] a phenomenon of colossal vagueness' (Osterhammel 1997, p. 4), because it covers large and rather different parts of the world and its history. Therefore, a convincing theory of colonization and colonialism in general or of European colonialism in particular does not exist and will probably never exist, because it is not feasible. But scholars have still to define the concepts they use, because an agreement upon their meaning makes communication possible. *Colonization* has to do with *migration*, because it describes the movement of people from one part of the world to another to establish a settlement, quite often an agrarian one. In this sense, the term has a neutral connotation. In contrast, *colonialism* has become a general invective against western policy, especially since the Bandung conference of recently decolonized Asian countries in 1955. In the nineteenth century, however, it was used more or less neutrally to characterize the condition of colonies and the (speech) habits of colonials (Fieldhouse 1981, p. 6).

We have no choice but to accept the change of meaning that *colonialism* has undergone, though we can try to neutralize political emotions. In this sense, colonialism can be defined as the control of one people by another, culturally different one, an unequal relationship which exploits differences of economic, political, and ideological development between the two (Reinhard 1996, p. 1). *People* instead of *nation* or *state* is used because basically no sophisticated political organization is necessary on either side. And the terms *difference* and *development* are used in a strictly descriptive sense and without any value judgement. They do not suggest that it is more desirable to have nuclear weapons instead of bow and arrow or that there exists a general and 'normal' path of human development with the West at the end. But differences of development are essential to distinguish colonial rule from *empire* in general. Roman rule over ancient Greece and Russian control of East Germany were imperial, not colonial.

Colonialism, as an unequal relationship between human groups, very often was the outcome of *imperialism*, defined as a political activity with the intention to establish colonialism. But if the meaning of *imperialism* is limited to expansive policy of the nineteenth and twentieth centuries, *colonial expansion* has to be used to designate earlier policies. After *decolonization*, colonialism as a form of political dependency has become a mere phenomenon of history. But economic and cultural domination by former colonial powers such as Britain and France on the one hand, and by the US and the US controlled world economy on the other, still exists. It has been labeled *neocolonialism*. In the 1960s and 1970s theories of structural *dependency* explained economic underdevelopment as a consequence of western economic domination and as self-reproducing without chance of escape because of western control of the world economy. Several success stories of former colonies have falsified these theories, but their lesson on informal control as an element of colonialism remains. *Semicolonies* such as China or the Ottoman Empire about 1900 were formally in-

dependent, but in reality under economic and therefore indirect political control of the West. Western colonies in the Americas, in South Africa, and Australia established a *secondary colonialism* in their parts of the world. Even in European countries unbalanced internal group relations as in the case of Britain's 'celtic fringe' were qualified as *internal colonialism* (Hind 1984).

2. *The History and Geography of Colonization and Colonialism*

The expansion of Europe between the fifteenth and twentieth centuries was one of the most momentous processes of history. World history in the sense of global history became possible only through that process, because no part of the world escaped the direct or indirect impact of Europe. In 1914 half of the land surface of the earth and one-third of its population were still under direct colonial rule. But this was only the last chapter of a long story, because colonization and colonialism are essential components of history in general, especially, if we do not omit continental expansion in Russia, the Americas, and elsewhere in favor of overseas colonialism. Colonization in the sense of expansion of settlement and agrarian land use could even be considered the quintessence of human history before industrialization. Chinese colonialism is perhaps the most remarkable case because of the relative continuity of Han-Chinese expansion starting from the lower Huang basin thousands of years ago and leading to the present penetration of Tibet, Mongolia, and Xinjiang. The ancient world of the Mediterranean was full of Phoenician, Greek, and Roman settlement colonies. Colonial phenomena of the European Middle Ages became predecessors and models of the later expansion of Europe. Spain and Portugal colonized the reconquered South of the Iberian peninsula and the Canaries, whereas England did the same in Wales and Ireland, Old World experiences to be used in the New World later. People from central and western Europe settled in the East, a process to be continued by Russia in Siberia until the Pacific Ocean was reached. The French who were excluded from the colonization of the East became protagonists of the crusades instead. The first European colonies established by the crusaders in the Middle East were a failure, but in that context Italians developed a system of maritime trade and factories combined with the colonial production of high value commodities such as sugar. Not by chance America was 'discovered' by a Genoese and 'baptized' after a Florentine.

Beginning in 1415 the Portuguese followed the coast of Africa until they found their way to India in 1498. To control the spice trade of the Indian Ocean they established a trade empire based on fortified ports, factories, and colonial rule over spice producers such as Ceylon and the Moluccas, extending from East Africa to China and Japan, with Goa in the center. During the European conflicts of the early seventeenth century, the Dutch East India Company, in contrast to Portuguese crown capitalism, a privileged private corporation of shareholders, conquered most of the Portuguese system, but established a new capital in Batavia on Java. Arriving at the same time, the French and English East India Companies created their bases on the coast of India, a comparative advantage when European demand changed in the seventeenth century and Indian textiles became the leading commodity. In the eighteenth century they were replaced by tea and coffee with the China trade as core business. But trade remained under strict control of the Chinese and Japanese empires and 'western barbarians' were only tolerated until the middle of the nineteenth century when China and Japan were 'opened' for free trade by western military aggression. On Java and in India, however, the Mataram and Mughal empires began to disintegrate in the eighteenth century. This led to the control of Java by the Dutch and the conquest of all India by the British until 1818–49. Most of it was the result of contingency, but besides the interest in profits the ambition of local military, the 'men on the spot,' was a constant factor.

Since 1492 Castilians competing with the Portuguese discovered and conquered their India in the West. Spaniards emigrated to live in the cities of a New World. But despite a tremendous loss of native population, mostly through infectious diseases imported by the conquerors, the labor force consisted mostly of Amerindians, especially when, after the discovery of silver mines in northern Mexico and highland Peru, America became the treasure house of the Spanish monarchy. A proto-bureaucratic system of colonial government was established instead of traditional feudal lordship desired by the conquerors. But Iberian America was to remain a racially stratified society. Metropolitan Spain did not profit much from American silver which, because of differential inflation rates and overambitious policy, flowed out of the country to feed the Asian trade of the Dutch and the English. Via Europe and directly via the Philippines much of the American silver ended up in India and China. A kind of world trade system originated, but probably with rather marginal economic impact on Europe and on Asia. Brazil became a Portuguese colony almost by chance, economically important only in the later sixteenth century when sugar cane was grown on its abundant fertile soils. Indian labor was scarce here but the Portuguese controlled the opposite coast and therefore were able to provide the sugar industry with African slaves. When the sugar cycle reached its end, gold and diamonds created a new boom in Brazil during the eighteenth century, but with similar negative consequences for Portugal as for Spain 200 years earlier.

In the seventeenth century the Dutch transferred the Brazilian plantation economy to the Caribbean where the English, French, and Dutch had conquered several islands from Spain. No Amerindian labor force was left there, but the Dutch had occupied some of the Portuguese strongholds on the West African coast with the British and the French to follow. Thus the West Indies could be provided with African slaves. The English were the leading slave traders of the eighteenth century when the sugar business reached its culmination point. Large parts of the Caribbean were converted into an agro-industrial complex with a completely artificial society of black slaves, white lords, and an increasing number of mulattos.

In the meantime, another type of artificial new world had originated in North America which in the long run became a white man's country, the first and most successful of several 'new Europes' created by about 60 million Europeans who emigrated between the sixteenth and the twentieth century. North American Indians were few in number and not able to defend the land white immigrants desired. Whereas French Canada with its small settler population could at least attempt their integration, British North America had no room for them. They were removed, marginalized, or wiped out. Around 1780, British North America had more than 2.6 million inhabitants, compared with about 8 million inhabitants of England and Wales.

In 1775–1823 Europe lost most of her American colonies. But Britain, which dominated the colonial scene for most of the nineteenth century, compensated for the loss with the conquest of India and with several new colonies, some of them acquired during the wars against France, like Canada from France and South Africa from the Netherlands, other new foundations in Australia and New Zealand which had been explored during the late eighteenth century. But they were accepted rather reluctantly, because in an age of British dominated free trade colonial rule was considered unnecessary and too expensive. Therefore, self-financed self-government of white settler-colonies was now welcome. Between 1840 and 1931 these British 'dominions' became quasi-independent.

This relaxed attitude was to change in the age of *imperialism* (see *Imperialism, History of*), when nervous competition of old and new powers under the ideological impact of nationalistic social Darwinism led to the division of Africa within a few decades. Most of what was left of Asia was also occupied or at least controlled economically. Besides Britain's notorious rival France and the old colonial powers Portugal and Spain new competitors entered the stage: Russia and the King of Belgium, Germany and Italy, the USA and Japan, the first non-western imperialist power, which a few decades earlier had been close to becoming a semicolony. After World War I (see *First World War, The*) the German colonial empire and the Ottoman Empire were divided among the victors. The formal qualification as mandates of the League of Nations did not make much difference. Neither was the League of Nations able to prevent the Japanese occupation of Manchuria in 1931–2 and the Italian conquest of Ethiopia in 1935. Ethiopia had defended herself successfully against Italian aggression in 1896, but as the last African country had to yield to colonialism—if only for a few years. Times were beginning to change.

Less spectacular than expansion overseas, and therefore often ignored by historians of colonialism, was the 'quiet' continental expansion of Russia and the USA, of Canada, Australia, and South Africa, of Brazil, Argentina, and Chile. This expansion was possible only at the expense of indigenous populations and through the exploitation of differences of development. This turned out a very effective variety of colonialism, because the result was most often a white man's country, another 'new Europe,' where the former population was marginalized or wiped out. Only in few cases such as South Africa, Russian Central Asia and Caucasia non-western groups were numerically and culturally strong enough for later successful decolonization.

3. *Typology of Colonization and Colonialism*

There was no master plan for colonial expansion. Quite often it happened as an unintentional consequence of some other action. Nevertheless, typical sequences of actions occurred again and again, for instance preventive occupation to keep out possible competitors. The Portuguese used this in sixteenth-century Brazil, as did most European powers in nineteenth-century Africa. Military intervention in Africa was sometimes not intended as permanent occupation, because it was much too expensive. But when African resistance made a retreat impossible without loss of national prestige, the temporary occupation became a permanent colony. If not a matter of prestige, colonial policy was always based on a kind of cost-benefit analysis. Colonies were expected to be profitable. At least they had to finance their own government. The famous British model of *indirect rule* did originate much less from political wisdom or respect for other civilizations than from the necessity to keep administration costs down. In reality national budgets only profited from colonial empires in exceptional cases, because infrastructural costs were considered the responsibility of the government, whereas colonial profits remained private.

The most common individual motives for participating in colonial activities were indeed the desire for extra profits and the improvement of social status. These were certainly not the only motives, but they were almost never absent. Of course, their character changed over time. The conquerors of British India were capital accumulating profit seekers, but like those of Spanish America still with the intention to invest in

social status and not in capitalist enterprise in the way of the nineteenth and twentieth centuries. The second most common motive, missionary zeal, also changed over time. Instead of spreading the gospel *and* European civilization, modern colonizers followed the urge of a civilizing mission to educate barbarians. In the age of imperialism, however, it became common conviction that inferior races could not be 'improved,' but were doomed to serve or to die. Thus colonial adventurers could feel entitled to pose without restraint as the master race.

From the fifteenth to the twentieth century colonies usually represented one of three basic types, sometimes as a mixture:

(a) *Trade and/or military bases* such as the stronghold system of the Portuguese trade empire or Britain's naval bases in the nineteenth century or the frontier forts of the US, Spanish ecclesiastical missions sometimes served a similar purpose.

(b) *Colonies of settlement*, probably the primitive type of colony, especially when combined with a kind of stronghold as in the case of the roman 'Colonia.' Larger settlement colonies could only be founded at the expense of indigenous people who were either removed (New England) or transformed into a dependent labor force for an 'improved' economy (Spanish America, Algeria) or replaced by workers of foreign origin (Africans in the Caribbean, East Indians in Guyana).

(c) *Colonies of exploitation* with only a small number of members of the ruling people present most of them only temporarily, to run business, administration, and defense. Parts of colonial Latin America resembled that type, but it became the dominating type during nineteenth and twentieth century colonialism with British India as the prototype and much of Africa to follow.

Colonies of exploitation could not be ruled without massive collaboration of indigenous people (Robinson 1972). Collaboration had already been a necessary precondition for the Spanish conquest. To consider such collaborators as traitors, though, is an anachronistic value judgement of modern nationalist historiography. People like the Tlazcaltecans quite rationally served their own interest regardless of a Mexican nation that did not yet exist. Recent research on the *colonial situation* from the perspective of people under colonial rule has corrected such simplifications. Non-European history no longer looks just like an inversion of the eurocentric pattern when the colonialist image of benevolent western heroes ruling inferior races for their own benefit is simply inverted in the anticolonial story of western rascals systematically abusing helpless non-western victims. To some extent, the image of the helpless native itself is a creation of latent racism. In reality, a broad range of options to cope quite successfully with colonial domination ranging between complete acceptance of western patterns of behavior and very subtle methods of boycott was available to indigenous people, to some extent even to African slaves (see *Slaves/Slavery, History of*). The traditional contrast between colonial lords as active initiators of colonial processes and colonial subjects who had no choice but to suffer passively or at best to react against the actions of their betters has been questioned. But to believe after decolonization that colonial rule was only a short episode without much impact on the colonies seems to be an anticolonialist oversimplification.

4. *Decolonization*

The term *decolonization* was created in 1932 (Albertini 1966, p. 28) but the process is much older. A first wave of decolonization, the independence movements of most American colonies 1775–1823, reduced European colonial empires drastically. But Britain at least knew how to compensate for these losses. On the other hand, some lessons of the first wave were learned and made the second wave, the gradual increase of self-government in Britain's white dominions 1840–1931, much more easy going. Between world wars, anticolonial movements emerged in several exploitation colonies, with British India in the lead. Japanese occupation of Asian colonies during World War II (see *Second World War, The*) fostered independence movements which were successful after the war in a third wave of decolonization in the 1940s and 1950s. At that time, Africa was apparently not yet ready for decolonization. Colonial powers once again tried instead to compensate for their losses in Asia by economic development of their possessions in Africa. However, under the growing political pressure of the superpowers, the UN, and world public opinion some African countries became independent in the 1950s, and most in what was the fourth wave of decolonization during the 1960s. A fifth wave began in the Portuguese colonies in 1974–5 and accelerated political change in South Africa. But the sixth wave of decolonization in the 1990s, this time internal, included not only the end of South Africa's white minority regime, but also quite unexpectedly the breakdown of Soviet rule in Central Asia and Caucasia and Israel's first arrangements with her Arabs.

Decolonization was a truly dialectical process, because colonial rule produced its own contradiction, that is politically frustrated new indigenous elites. Everywhere westernized groups and not the traditional authorities were in the lead of independence movements. But an independence movement or even an independence war was not enough. In most cases a triangular constellation of political factors was the essential precondition: besides an internal independence movement, favorable international conditions such as allies, anticolonial policies of the world powers and the UN, and the willingness of the colonial power to accept the unavoidable were also necessary.

5. The Consequences of Colonialism and the Postcolonial World

Colonial processes were certainly never a one-sided affair, but it is simply not true that they left no impact on former colonies. The postcolonial world is not the same as before, even in Europe. Several American plants, the potato in particular, became essential for Europe's population and economic growth. Colonial bullion and colonial profits contributed to the rise of Europe, if rather marginally and indirectly. They were certainly not the sufficient precondition of industrialization. Colonial problems influenced European power relations, but rarely dominated them. Europe assimilated new cultural elements from all over the world, but without changing her character. In the colonies, however, ecology, economy, politics, society, and culture often changed more thoroughly, sometimes even fundamentally.

Intentionally or unintentionally colonial rule has transformed ecological systems. After new plant foods had been introduced, American savannahs changed into corn fields suffering from soil erosion and new weeds. Domesticated animals formerly unknown in the Americas, in Australia, and New Zealand revolutionized working and eating habits, transportation systems and even the whole way of life of such groups as the Indians of the North American plains. Unknown infectious diseases killed millions who were replaced by a new population of immigrants and imported slaves.

The deliberate diffusion of European and especially American cultivated plants such as maize and manioc created a new agriculture and allowed an expansion of food production, a necessary precondition of modern population growth in the colonies. But colonial economies were first of all based on the systematic exploitation of mineral resources such as American silver, African diamonds, gold and other ore, and more recently of oil in the Middle East and other parts of the world. In addition, they specialized in the production of high value agrarian products such as sugar, coffee, and tea on large plantations. Mines and plantations more often than not ruthlessly exploited a colonial labor force of slaves, contract and forced laborers. Because, as a rule, colonies could not industrialize, their independent successor states remained dependent on the world market price of their raw materials, which only in the case of oil took a turn to their advantage.

The essential political heritage of colonialism is the modern state (see *State, History of*) with its legislative, administrative, judicial, military, and educational apparatuses. Every former colony has changed into a modern nation state, but strictly within the arbitrary and sometimes absurd colonial borderlines. Therefore, some are extremely poor and very few are powerful enough for an independent foreign policy. But in contrast to former periods of history weak states today have their existence guaranteed by the international community (Jackson 1990). Internally, only few of them can build upon the tradition of a historical community. Instead of a modern civil society their colonial heritage is ethnic fragmentation, to some extent artificially created by colonialism. Quite often they had no alternative to the language of the former colonial power as national language. Under these circumstances the modern state in general and western democracy in particular could not become a success and were replaced by the para-stateliness of self-organizing groups based on remarkable combinations of traditional and modern elements.

Everywhere colonialism has created new social groups living in western-style urban environments: workers and employers, school teachers and professionals, civil servants and professional soldiers. Women have found new roles and quite often emancipated themselves from traditional restrictions. All this is based on western science and technology, on western ideas and ideologies like rationalism and individualism, the rule of law and human rights, Christianity and socialism. Nevertheless, it is essential to understand that this state of things no longer implies cultural dependency, but rather the opposite: non-western people in the meantime have become owners of a cultural heritage of western origin. For example, the role of English as common language of the world stems from historic British and American dominance. Increasingly, though, the acceptance of 'new Englishes' all over the world indicates that the Anglo-Saxons have been expropriated of their language.

Color Classification and Symbolism

'Color classification' is an ambiguous concept. It may refer to 'classification *of* colors,' or 'classification *by* colors'. Most research on color classification has opted for the first approach, which is concerned with the variation of linguistic categorization of colors in different cultures. This kind of research has been undertaken by linguists, psychologists, and cognitive anthropologists. By contrast, the few anthropologists who have opted for the second approach have been concerned rather with symbolic anthropology, or have worked in a structuralist tradition of sociocultural anthropology. Research into color classification has a long history, dating back to the 1870s (Allen 1879, Gladstone 1877, Magnus 1877). However, it was not until Berlin and Kay published their seminal book on basic color terms (1969) that research in this field virtually exploded, especially within cognitive and linguistic anthropology. Over the last 25 years, a wealth of data on color categories has been meticulously collected in different parts of the world, mainly with the help of the 'Munsell color chips.' As a general rule, randomly chosen informants have been asked to define the colors on these chips, and to 'map' them. The findings have then been tested as 'hard data,' often using quantitative methods (e.g. MacLaury 1986, Kay et al. 1991). This 'hard-wire' approach to color classification research has been further strengthened by the general assumption that color perception is a matter of neurobiology, universality, and evolution.

Although the evolutionary paradigm had featured in research on color classification for almost 100 years, Berlin and Kay were the first scholars to present substantial evidence for a theory concerning the universality and evolution of basic color terms. In the original formulation of their theory, they defined a particular sequence of developmental 'stages' of basic color terms, and suggested that these stages would correspond to the stages of technological evolution. The few cultures in which only two basic color terms were used would represent Stage I on the evolutionary ladder, while the prevalence of three color terms would place a particular culture one step higher up (Stage II). Four basic color terms would imply Stage III, five terms Stage IV, and so on. Societies with the maximum number of color terms (11) would represent the highest level of technological evolution.

Although Berlin and Kay have modified the original formulation of their theory (Kay et al. 1991), the main features of the paradigm have been generally accepted by scholars in their own and related fields. Part of the reason for this is that Berlin and Kay backed up their theory with a wide range of cross-cultural linguistic data, which showed a remarkable regularity with respect to the sequence of basic color terms: if only two terms were found in a particular culture, they were invariably white and black. If three terms were recognized, these were always white, black, and red. The fourth basic color term to be introduced was either yellow or green, the fifth either green or yellow, the sixth blue, and so on. In spite of some revisions and later developments of the theory (see Hardin and Maffi 1997, MacLaury 1999), there is still a general consensus among anthropologists about the sequence of basic color terms—even though the hypothesis about a corresponding technological evolution has yet to be proved. It would, for example, be difficult to maintain the theory about technological evolution, given that many hunting/gathering societies recognize more basic color terms than agriculturalists. In Africa, even the most sophisticated Bantu-speaking agricul-

turalist and agropastoral societies have only three basic color terms, whereas their hunting and gathering neighbors may have five or more.

However, strictly cognitive and linguistic research on color classification has met with criticism on several other accounts. The main criticism has been leveled at the 'hard-wire' methods employed in this kind of work, and at the lack of 'emic' approaches to the issue of color classification. It has been argued that the 'meanings' of color terms cannot be evaluated adequately when the data have been collected under conditions reminiscent of a laboratory situation (Saunders 1999; cf. Tornay 1978), and that 'affective features of meaning' may contribute to Berlin and Kay's evolutionary sequence of color terms (Osgood et al. 1975, Taft 1997). The problem of 'meaning' is perhaps the most controversial issue associated with the concept of color classification. Though a few representatives of the 'hard-wire' approach have attempted to account for the 'meanings' of individual color terms (Kay and McDaniel 1978, MacLaury 1992), the focus has still been on the implications of the informants' task of 'mapping' color chips (Lucy 1997, p. 327). By way of contrast, Lucy directs attention to Conklin's pioneering work on color categories in the 1950s (Conklin 1955). Applying a structural approach, Conklin discovered that the four-color categories recognized by the Hanunóo corresponded to an underlying four-way classification of other visual stimuli as well.

Conklin's findings correspond to the ideas proposed by the Swiss-French school of semiology, as represented by Saussure and Derrida. According to them, the meanings of signs depend on their positions in a larger system of signs (Layton 1997). Meanings are thus anchored in the syntagmatic relations among signs, but if we also take into consideration the meanings which Barthes (1967) has referred to by the concept of 'the symbolic relation between the sign and the signified,' it may be possible to identify congruities of symbolic meanings when 'parallel' syntagmatic sequences of signs are compared. Such a 'parallel' structure of signifying, syntagmatic sequences of signs may be referred to as a paradigmatic structure of meaningful categories.

To identify such paradigmatic structures in cultural symbolism is the core of anthropological research on symbolic classification. This approach has characterized symbolic anthropology since the late 1960s. When colors have been included in this kind of symbolic analysis, the research has thus been concerned with classification *by* colors, rather than *of* colors. However, at the same time as this structurally oriented research developed, there was also a growing awareness among some anthropologists of the importance of contextualization in the study of symbolic meanings.

The pioneering research in the domain of symbolic classification by colors was carried out by Victor Turner, who in 1966 wrote an article on the symbolic meanings of white, black, and red among the matrilineal Ndembu of Zambia (Turner 1966). Not only did Turner attempt to trace the basic symbolic meanings of the three colors, he also analyzed their variable references in different ritual and social contexts, and thus became one of the first anthropologists to put contextual analysis of cultural symbols on the agenda.

Turner's article stirred up an enthusiastic interest in color classification, especially among anthropologists working in the structuralist tradition. No matter whether the anthropologists found two, three, or four colors to be key symbols in a particular culture, they usually attempted to identify a dualistic system of symbolic classification, of which the colors formed a part. Thus, for instance, most of the contributions to Needham's book on dual classification included references to colors as 'parallel' devices of classification, alongside the right/left division that was the main topic of the book. While the concept of 'paradigmatic structures of signs' was not mentioned, there was an insistence on the congruity between different levels of symbolic classification. In many articles referring to different areas of the world, colors were regarded as part of this dual classification.

Needham's book was cast in the kind of structuralist tradition that marked the 1970s, and which was inspired by Lévi-Strauss (1963). The basic assumption was that human beings everywhere tend to classify their world into binary oppositions. However, even if a dualistic approach could account for the choice of two opposing categories of classification in certain specific situations in any society, it cannot solve the enigma of triadic classification, which is typical of the ritual use of colors in many parts of the world.

In most African cultures south of the Sahara, triadic classification by colors appears to permeate the ritual practice of healers and diviners (Baumann 1935, Straube 1960, White 1961, Ngubane 1977, Jacobson-Widding 1979, Kirby 1999). This applies particularly to the Bantu-speaking societies, where only three basic color terms are recognized, namely white, black, and red. In a systematic investigation of the symbolic references of the three colors in the matrilineal belt of Central Africa, Jacobson-Widding (1979) found that the only situations in which all three colors were visually represented were in connection with certain rituals, when the ritual specialist manipulated the colors as symbols with particular, contextually dependent references. In profane contexts in which the official ideology of social and moral order was referred to as a matter of principle, on the other hand, white and black were the only colors demonstrated (cf. Jacobson-Widding 1991). In Central Africa, there is even a formal prohibition against showing the color red in such contexts, for instance in connection with lawsuits. This implies that white and black are contrasted as binary oppositions only in certain contexts, like those in which the dominant structure of order is

supposed to be manifested, and in which the rationality of a logic based on two opposite values is to be applied. In contrast, red is represented in situations where indeterminate values are dealt with, and where a simplistic two-value logic would fail to account for the truth.

The concrete references of the color red may vary according to the context. However, whatever tangible phenomenon it may refer to in any particular situation, most ritual experts in central and southern parts of Africa will employ this color when they wish to represent ambiguity. In particular, red is used to represent phenomena that seem to defy classification into any of the 'officially' recognized categories of determinate values that are represented by white and black. Such phenomena, or states of affairs, may consist of bewildering emotions, anomalies, or mysterious spirits. Or they may be 'twilight' situations like dusk and dawn, birth and death, or any state of 'betwixt and between'—such as the state of initiands in a bush camp, or the state of adolescent girls, whose bodies are painted red during a period of seclusion. In essence, the color red can be viewed as a symbol of the kind of ambiguity that may result from conceptual boundary crossings. That is, when a particular phenomenon, or state of affairs, is considered to blur the boundaries of the concepts on which a 'rational' order is based, it is depicted as 'red.' This implies that the color red is associated with irrational feelings, and with the unknown.

Considering the ways in which ritual experts in Africa tend to interpret and manipulate colors, we may regard the color triad as a device for philosophical categorizations. At the most general level of meanings, the color triad appears to classify different kinds of phenomena according to three basic values of truth and morality. Whereas the combination of white and black is supposed to represent clear-cut values as logical opposites (i.e. 'good' vs. 'bad,' 'true' vs. 'false,' 'us' vs. 'them,' 'sky' vs. 'earth,' and so on), red will be introduced when the logical boundary distinguishing A from B is impossible to define. The color red will thus represent a third, indeterminate value, which can be classed neither as A, nor as B (nor as non-A), but rather as C (cf. Leach 1975).

This implies that the two-value logic of the Aristotelian philosophy of knowledge is supplemented with a third term, which in the case of African ritual practice is regarded as an *a priori* neutral value, in relation to the determinate values of truth and morality. However, this 'three-value logic' is assumed to be valid only in ritual thought and praxis, and not in contexts where profane, 'rational' reasoning is supposed to be applied.

Since red is used to symbolize an unknown factor, which by definition is initially value-neutral, this color will be associated with unknown potentialities and acquire a dynamic quality. Accordingly, it is sometimes associated with powerful emotions, sometimes with 'magic' power—a magic power that many people may regard as dangerous, polluting, or taboo, whereas others may associate it with miracles and miraculous healing. It is this 'magic' power that is exploited by the ritual expert in Africa, whenever he or she manipulates the color red in any of the many possible combinations or oppositions with white or black. As a general rule, the ritual expert will begin any 'sacred,' ritual seance with a visual demonstration of all three colors, as if to show the cards he or she intends to play with.

If we understand the concept of 'magic power' in a broad sense, some of the African associations of the color red may also be discerned in sacred rituals outside Africa, even within the Christian church in Europe. When red is combined with white, it usually points to connotations of the 'sacred,' or the 'holy.' Correspondingly, we often find that the combination of white and black is resorted to in situations where the order of society, or its moral dogma, is supposed to be demonstrated—not only in Africa, but in Europe and other parts of the world as well. However, whether used to represent 'sacred' values in the church or 'profane' values in the courtroom, any combination of colors from the triadic set of symbols constituted by white, black, and red may have different concrete references in different situations, in both Europe and Africa. The 'meanings' of these colors as culturally instituted symbols are thus to be found on different levels of interpretation. Colors may be used as concrete signifiers with context-dependent meanings and, at the same time, as representations of more general values of 'truth' and 'power.'

Color Terms, Linguistics of

The words that different languages use to name colors have furnished a prime focus for research on the doctrine of *linguistic relativity*. This doctrine holds that (a) different languages categorize the world very differently and (b) the nonlinguistic thought and behavior of different peoples are deeply influenced by these differences in linguistic categorization. Words for colors have been considered an ideal area of lexicon for testing this doctrine because there exist scientific color order systems, which provide a precise metalanguage for describing color sensations independent of the words of any natural language. Such a metalanguage furnishes the means to characterize precisely the sameness or difference in meaning of color words in different languages.

1. *Restricting the Domain*

It is clear, however, that every language has immense—probably infinite—resources for denoting color sensations. First, every language so far studied can productively create complex expressions which describe the color of an object by indicating similarity to another kind of object which is known to saliently display the color. An example from English is 'like the color of a male mallard duck's neck feathers.' (Although most languages do not have a word that straightforwardly translates the English word 'color,' the speaker of such a language who wishes to characterize, say, a kind of fish as mallard green can usually say that, for example, the fish 'looks like' the neck feathers of a male mallard, relying on context and background knowledge to provide the interpreter with color as the relevant dimension of visual similarity. Although relativist critiques of color naming research have maintained that absence of a word meaning 'color' in a language indicates that its speakers see and/or conceive of colors very differently from, say, speakers of European languages, the experiences of workers who have actually studied color vocabularies in the field do not provide significant support for this claim. See, e.g., Conklin 1955, p. 340, Turton 1980, p. 322.) Second, many language have words like 'blond' or 'bay,' which denote a color only as restricted to a class of objects (hair and horses, respectively). Third, many languages have morphological and syntactic processes which create complex color terms out of simple color terms. English examples include 'blue-green,' 'yellowish,' 'pale reddish purple,' and so on. Finally, some languages, English included, have many linguistically simple terms which denote subtypes or 'shades' of colors denoted by other simple terms. For example, 'scarlet,' 'crimson,' 'vermillion,' 'puce,' 'magenta,' 'burgundy,' and 'maroon' are among the more commonly named shades of 'red.' The linguistics of color terms has become a focus of research and a source of controversy in part because of the practical need to arrive at a manageable set of 'color terms' in each language to enable comparative study.

2. *Color Terms and Linguistic Relativity*

Before taking up in greater detail the ways researchers have attempted to delimit the linguistic domain of color, it is useful to consider briefly the role color

naming has played in the long-running debate over linguistic relativity vs. semantic universals (q.v.). In the second half of the nineteenth century it had become common knowledge among scholars that the major color words of different languages were not always perfectly translatable into one another. To some, this represented *prima facie* evidence of biologically based, perceptual differences among different groups of human beings, in fact the last traces of Darwinian evolution observable among humans. For example, William Gladstone, Homeric scholar and Prime Minister of Britain, observing differences between the color words of classical Greek and the modern European languages, wrote, '… the organ of color and its impressions were but partially developed among the Greeks of the heroic age' (1858, pp. 457–99).

Although this view was widespread in the late nineteenth century, it was not unanimous. For example, in order to study the discrimination and naming of colors independently, the German ophthalmologist Hugo Magnus circulated a questionnaire to missionaries and traders with ten standardized color samples and instructions for using them in the 1870s. These instructions contained an explicit warning that failure of a language to distinguish lexically between two colors did not necessarily imply that speakers of that language did not distinguish the two colors perceptually. Magnus received completed questionnaires on twenty-five African, fifteen Asian, three Australian, and two European languages. He concluded in part, 'As regards the range of the color sense of the primitive peoples tested with our questionnaire, it appears in general to remain within the same bounds as the color sense of the civilized nations. At least, we could not establish a complete lack of the perception of the so-called main colors as a special racial characteristic of any one of the tribes investigated for us. We consider red, yellow, green, and blue as the main representatives of the colors of long and short wavelength; among the tribes we tested not a one lacks the knowledge of any of these four colors' (Magnus 1880, p. 6, as trans. in Berlin and Kay 1969, p. 141). Magnus did find widespread *lexical* neutralization of green and blue, that is, a single word covering both these colors, as have all subsequent comparative studies of color lexicons.

While nineteenth century and early twentieth century researchers saw differences among vocabularies in an evolutionary perspective (biological and/or cultural), in the second quarter of the twentieth century the tide began to turn against evolutionary explanations of human variation and toward cultural and linguistic relativity. This was especially true in America, in the tradition of the anthropologists and linguists F. Boas, E. Sapir, and B. L. Whorf, although there were precursors in the views of the German romantics, who had tended to associate the *geist* of a people strongly with its language. According to Whorf, 'The categories and types that we isolate from the world of phenomena we do not find there because they stare every observer in the face. On the contrary the world is presented in a kaleidoscopic flux of impressions which have to be organized in our minds. This means, largely, by the linguistic system in our minds' (1956, p. 212). Throughout the 1930s and 40s this view gained increasing prominence and in the 1950s and 60s achieved virtual hegemony in American anthropology and linguistics, with considerable influence in Britain and elsewhere outside of the US. (Chomskian universalism and nativism were to become influential only at the end of this period.)

The parade example chosen by the mid-century American relativists to make the twin points of semantic arbitrariness and linguistic determinism was the lexicon of color. The most influential introductory linguistics textbook of the period, for example, stated: 'There is a continuous gradation of color from one end of the spectrum to the other. Yet an American describing it will list the hues as red, orange, yellow, green, blue, purple, or something of the kind. There is nothing inherent either in the spectrum or the human perception of it which would compel its division in this way' (Gleason 1961, p. 4). This sweeping conclusion appears to have been based on two small-scale empirical studies of color terminology, whose results have subsequently been interpreted differently, one on the Hanunóo language (Philippines) (Conklin 1995) and the other a comparison of the color terminologies of languages (Ray 1953). Despite the paucity of evidence, the idea that different languages divide up the perceptual color space in mutually incomparable ways was widespread at the time, doubtless because it fits so well with the prevailing doctrine of radical cultural and linguistic relativity.

3. *Color Terms as Linguistic Objects*

Against this background a study appeared in 1969 which reached exactly contrary conclusions. After examining the color term systems of ninety-eight languages, Berlin and Kay (1969) [B&K] proposed that (a) the differences in color lexicons of the languages of the world could be explained as different combinations of a few landmark colors (which were probably human perceptual universals) and (b) the differences in color lexicons of the world's languages could be arranged in an evolutionary progression. In order to carry out this study, B&K found it necessary to limit the domain of inquiry to the 'basic color terms' of the languages being compared. (They examined twenty languages experimentally, using standard color stimuli, and interpreted another seventy-eight reports of color terminologies from the literature based on their formulation of the results of these twenty.) As a preliminary to this research, Berlin and Kay offered what they called a definition of 'basic color term' and much of the subsequent research on the linguistics of

color terms has had to do with attacking, defending, revising and evaluating this definition.

The B&K study was not without direct precursors. Lenneberg and Roberts (1956) [L&R] compared the color terms of Zuni monolinguals with those of Zuni-English bilinguals and English monolinguals. After isolating the words whose denotation was to be studied, L&R had each informant indicate on a representative array of 230 color samples the denotation of each color word as well as the color sample which best exemplified the reference of that word. B&K used essentially the same method and the same stimulus array as L&R (except for adding black, white, and shades of gray) with the exception that the color words whose denotation was to be studied were selected differently by L&R and by B&K. L&R proceeded by getting speakers to list as many color words as they could think of without color stimuli present, which produced a list of fifty-two terms. They also elicited lists of color words by asking for names for twenty-four selected color stimuli, producing a list of 105 terms. The color terms for which L&R show mappings are those most frequently elicited by the second method. L&R show mappings for seven color terms for Zuni monolinguals, corresponding closely to English pink, red, brown, yellow-orange, green, blue, and purple. (Recall they had no white, black, or gray stimuli.) They show mappings for eight color terms for Zuni bilinguals, adding a term for orange, '°olechin-anne' ('orange.like' < Eng. 'orange' + 'anne' 'like') and retracting the area of yellow accordingly. (They show ten mappings for English color terms (pink, red, orange, brown, yellow, green, light green, blue, light blue, purple). No terms like greenish, blue-green, or crimson were mapped, but light green and light blue were apparently ruled in by naming frequency considerations. (L&R's text is not explicit on this point.) Clearly in L&R, as in Conklin's, Ray's, and other early investigations of color word systems some tacit, if hazy, notion of major color term or principal color term is at work. It was this tacit notion that B&K tried to operationalize in their 'definition' of basic color term.

4. *B&K's Definition of Basic Color Term*

B&K offered what they unfortunately called a definition of basic color term [bct]. Their intent was not to postulate and define a new theoretical entity but to operationalize, insofar as possible, a tacit concept that was already in general use. The guiding intuition of the B&K 'definition' of basic color term was that each language has a small set of simplex lexemes (or word *senses*, as in the case of English 'green [color]' and 'orange [color]') of pure color meaning (i.e., unlike words such as 'blond'), which collectively name all the color sensations. The bcts are the members of that set. However, B&K stated the definition in terms of eight criteria, four primary and four subsidiary, the latter to be used in cases where application of the former is not sufficient to decide the bcts of a language. The four primary criteria for a bct were that it (a) be monolexemic (its meaning not predictable from the meanings of its parts, eliminating 'greenish,' etc.), (b) not be a hyponym (eliminating, e.g., 'crimson'), (c) be predictable of any kind of object (eliminating, e.g., 'blond') and (d) be 'psychologically salient' (eliminating e.g., 'puce' and 'like the neck feathers of a male mallard duck'). Two telling criticisms that have been leveled against the fourth criterion are (i) that it is not a linguistic criterion, while the other three are and (ii) that 'psychological salience' is neither a conceptually limpid nor a readily measurable notion. The four subsidiary criteria, designed for use in *ceteris paribus* situations, were that a questionable term (i) have a morphological distribution similar to that of the established bcts, (ii) not be the name of a kind of object (which would eliminate English 'orange' if subsidiary criteria were allowed to override primary criteria), (iii) not be a recent borrowing from another language, and (iv) not be morphologically complex. The B&K definition of bct has led both to practical problems in determining the bcts of a language and to conceptual and theoretical problems regarding the semantics of color in natural languages.

5. *Practical Problems with the B&K Definition of Bct*

The main practical problem in applying the B&K criteria to given languages is that since language change is always gradual there are many transitional cases. For example, there are many languages with bcts for black, white, red, yellow, and 'grue,' i.e., a single word covering green and blue. There are also many languages with bcts for black, white, red, yellow, green, and blue. When a language changes from the first type to the second type, it is not the case that everyone goes to bed Sunday night speaking the 'grue' language and gets up Monday morning speaking the 'green' vs. 'blue' language. Many kinds of in-between situations arise which make it difficult to say which words of the language naming part or all of the green/blue region of color space are bcts. Moreover, there is virtually always widespread inter-speaker variation in such cases, complicating further the task of deciding the bcts of 'the language' (See *Sociolinguistics*). Second, the four primary criteria of B&K do not always correlate and the definition gives no clue as to how the different criteria should be weighted in such cases. Also, as mentioned, cultural salience is not a straightforwardly observable characteristic. Workers who have taken the B&K 'definition' as a recipe rather than a heuristic have complained of problems in application in particular cases. Usually, however, these problem cases have involved a single

term or a single area of the color space, indicating that the area is one undergoing change.

A third practical issue has arisen in connection with the first B&K criterion of non-predictability of meaning of a bct from the meaning of its parts. It has been noted that in several Oceanic and Australian languages many of the presumably basic color terms are in fact reduplicated forms of roots that denote objects notoriously exhibiting the corresponding color. For example, in Yélîdnye (Rossel Island, Melanesia [Non-Austronesian]), the word for white *kpaaîkpaapî* represents reduplication of the nominal root *kpaapî* denoting a pure white cockatoo species. A similar situation holds for the black and red words, the only other plausible candidates for bcts in this language (Levinson 2000). The question arises whether *Yélîdnye*, and similar languages, can be said to have any bcts at all. The answer is yes. The criterion of non-predictability of meaning requires not only that from knowing the rest of the *Yélîdnye* language—including the word *kpaapî* and the pattern of reduplication which yields a salient attribute of the denotatum of a noun from reduplication of the noun stem—one could as a *listener* guess the meaning of *kpaapîkpaaî*, but also that as a *speaker* one would know an advance that *kpaapîkpaaî* was the way to express the idea of white. The latter of course would not be possible without memorizing this particular fact, because not all attributive words are formed by reduplication and even if they were the meaning 'white' might be based on some other object or substance.

6. Theoretical Issues Concerning the B&K Definition of Bct

It has been argued, principally by John Lucy (e.g., Lucy 1997), that a set of bcts isolated by B&K or associated researchers doesn't correspond to any linguistically legitimate system because there is no insistence in the B&K tradition of research that the set of bcts for a given language be definable by strictly formal, distributional criteria. This critique of the bct concept and practice is based on the questionable assumption that all morpho-syntactic categories correspond to semantic categories and vice versa (see Kay 1999). Moreover, careful empirical studies have shown that application either of the explicit B&K criteria or of the underlying intuition of a small set of linguistically simplex lexemes jointly exhaustive of the color domain can isolate sets of basic color terms which obviously form a coherent semantic system and whose members belong to several different form classes (see, for example, Maffi 1990 on Somali). It has also frequently been found that morphological category, including native vs. borrowed origin, can correlate with the evolutionary sequence posited by B&K ({black, white} > {red} > {yellow, green} > {blue} > {other}). The Somali case is again illustrative: the words for black, white, and red are intransitive verbs, the words for yellow and green are denominal adjectives and the word for blue (*buluug*), also a basic color term, is a noun. To say that something is blue, one has to say that it 'has' blue (Maffi 1990). Such neat correlations between morphology and evolutionary status are, however, sporadic.

Recently, the question has arisen whether all languages do in fact have a small set of lexemes whose denotations are restricted to color sensations and which jointly name all the color sensations. That is, does every language have a full set of basic color terms? This idea has been dubbed the Emergence Hypothesis (EH). (The question was first raised in unpublished work by Luisa Maffi. See also Lyons 1995, Lyons 1999, Kay 1999, Levinson 2000, Kay and Maffi 2000.) Research on this hypothesis has just begun but it appears that a small fraction of the world's languages may lack complete lexical partitions of the color domain (Levinson 1999, Kay and Maffi 2000). Preceding, and in some cases overlapping temporally, with the evolution of basic color term systems there may exist an evolution toward basic color term systems.

7. Nonbasic Color Terms and Noncolor Meanings of Color Terms

The vast majority of studies of color terms, especially since the early 1970s, have restricted themselves to the basic or major color terms, considering nonmajor terms only with a view to excluding them from further consideration. The L&R study described above typifies this practice. There have, however, been studies covering all the lexicalized color expressions of a language, a classic example being André's (1949) study of Latin color terms and a more recent example being Bricker's (1999) study of productive and semi-productive morphological process in the formation of secondary color words in two Mayan languages. Bricker also provides a thorough analysis of the non-color aspects of meaning of Mayan non-basic color terms, often involving texture and other aspects of surface appearance. Color words frequently also display metaphorical associations to moral, emotional, supernatural, and other kinds of non-physical entities and beliefs. Such associations have been widely reported in the ethnographic literature.

Color Vision

Color has long interested people from many different professions: artists, engineers, physicists, psychologists, and biologists, all with their own viewpoints and areas of primary interest. We consider here how the underlying neural organization of the eye and brain allows us to discriminate color and produces our various color percepts.

The light from every location in space varies in two physical dimensions: intensity (or the number of photons) and wavelength (or the energy levels of the photons). Color vision is the ability to discriminate changes in the spectral composition of a visual stimulus independently of its effective intensity, and vice versa. Because color vision apparently evolved independently several times, it is an ability that we share with many other species. However, we will restrict our discussion to the color vision of humans and other Old World primates.

1. Trichromatic Limitation

A visual scene may include millions of different local spectral distributions of light. A human observer with normal color vision, however, can visually match every one of these millions of different colored stimuli by appropriately combining and adjusting the intensities of just three different chromatic lights. The three variable-intensity lights that can be combined to match any color are known collectively as primaries. Despite what one may have been taught, there is no requirement that the primaries be red, blue, and yellow, or any other particular set, and they can be drawn from similar colors or from very different colors. The only restriction is that no two primaries can be combined to match the third. This trichromacy implies that at some processing stage, color information is limited by being transmitted through a three-channel pathway. It does not identify the point at which the three-channel bottleneck occurs. Many earlier theories assumed that trichromacy implies the existence of only three cone types, but recent evidence indicates that the limited number of different channels to the brain, not the number of receptors, limits our color vision to three dimensions. The trichromatic limitation to our color vision, the collapse of millions of physical dimensions into just three perceptual dimensions, should not be taken to mean that we are poor at discriminating colors. We make very fine discriminations within this three-dimensional space and can distinguish millions of different colors. However, the colors we see are not related to the physical spectral characteristics of objects in any simple fashion.

To gain any useful information from the retinal image is a much more difficult task than one might imagine; it requires multiple levels of neural computation involving billions of cells that occupy about a third of the whole cortex. An understanding of some aspects of this complex computational problem helps explain some otherwise-puzzling features of color vision.

2. Separating Objects from the Illuminant

One problem faced by the visual system is that most natural objects are visible not because they themselves emit light, but only indirectly because they reflect some proportion of whatever light falls on them. The light that reaches our eyes from a given object is, therefore, a product of the intensity and spectrum of the light source and the reflectance characteristics of the object's surface. Since we do not have any independent

information about the illuminant, it is not possible to determine the reflectance characteristics of any region, its color or its lightness, with certainty. The visual system can only guess at the solution. The main way it does so is by assuming that the illuminant is relatively constant whereas objects vary across space and time (with eye movements). It then estimates the intensity and spectral distribution of each region by comparing the activity evoked by the light from this region with the average neural activity (assumed to be primarily a function of the illuminant) over small neighboring retinal regions and across 100 msec or so of time. As a result, the perceived color of an object depends not only on the light coming from it but also on the light coming from nearby points in space, as well as the light to which the eye has been adapted recently. Among the consequences of this process are the well-known color and brightness contrast effects.

3. *Separating Intensity and Wavelength Information*

A second problem for the visual system is that a photoreceptor can only report how many photons it has absorbed, and the number of photons absorbed is determined both by the number of incident photons (the intensity of the light) and by their respective energy levels (the wavelength of the light). Thus, intensity and wavelength are completely confounded in the receptors. The information, for instance, that 100 photons were absorbed—the only thing that the receptor can report—does not allow one to determine either the intensity or the wavelength of the light in that region. To determine *either* the wavelength *or* the intensity requires neural comparisons of the outputs of neighboring receptors and of different cell types in the cortex.

4. *Conflict between Acuity and Color Vision*

A third difficulty results from the fact that the visual system, over at least part of the retina, needs to maintain as high spatial acuity as possible. To build a detailed spatial map requires treating each receptor within the high-acuity area as a separate, equivalent spatial unit. However, it requires a comparison of the outputs of at least two receptors that *differ* in their spectral sensitivities at each location to separate intensity and wavelength information. There is then an inherent conflict between the requirements for color and those for high spatial acuity.

We do not yet fully understand how the visual system handles these and other problems, but we do understand some of the processes that contribute to the solutions in the early stages of visual processing. We will describe briefly the sequence of steps, as we understand them to date, in the neural processing in the retina and visual cortex that lead to our ability to

Figure 1

These cells are spectrally-opponent, being excited by light of some wavelengths and inhibited (negative numbers) from the maintained rate by light of other wavelengths. **C**: A diagram of how the different spectrally-opponent geniculate cells may be combined in the striate cortex to produce the basic perceptual color systems

identify and characterize the color and lightness of objects.

5. Photopigments and Spectral Sensitivity

The initial stage in the visual response is the absorption of light by the photopigment molecules in the rod and cone receptors. Variations in the amount of light absorbed by the photopigments in a receptor trigger a complex series of reactions, leading ultimately to synaptic transmission of the information to the next neurons in the pathway to the brain. Each receptor type is differentially sensitive to light of different wavelengths. The basic shapes of the spectral sensitivity functions of the various cone photopigments are similar, but the spectral region to which they are most sensitive differs among the S, M, and L (for short-, medium-, and long-wavelength) cones (see Fig. 1A). The cone photopigments all have quite broad spectral sensitivity. The L and M pigments in particular absorb significantly at all visible wavelengths. The wavelength of the light is thus not given by which receptor is activated, since all are activated by lights of most visible wavelengths, but only by the relative activation of the three different receptor types.

The compromise made by the visual system between the requirements for spatial vision (all cones the same) and for color vision (cones differing in spectral sensitivity), can be seen in the fact that the spectral sensitivities of the L and M cones are very similar whereas the S cone curve is very different. Almost all our spatial vision is based on the L and M cones, with the S cones contributing just to color vision.

6. Color Vision Deficits

Almost all human observers appear to have the same S-cone photopigment, but some differ in their L and M cone pigments. About 7 percent of human males and perhaps 1 percent of females have so-called red-green color vision deficiencies. The most extreme of these color-defective individuals (very few are truly color-blind, although that term is often used) are missing either the L or the M cone pigment and therefore have only two cones types. They are thus dichromats, and can match any color using only two primaries. Protanopes are missing the L cone pigment, and deuteranopes the M cone pigment. With only the S cones and either the L or M cones, these dichromats can distinguish short from long wavelengths, but they confuse colors over the whole red-yellow-green portion of the spectrum, where the S cones are insensitive.

More common than dichromats are anomalous trichromats, in whom either the L or the M cone pigment is present but shifted in spectral sensitivity with respect to that in normal observers. They thus are trichromats, but they make different color matches than normals do. Finally, there are very rare individuals, tritanopes, who are missing the S cones and are, therefore, dichromats.

7. Genetic Basis of Color Vision Deficits

The prevalence of red–green color-vision defects and their higher incidence in males can be accounted for by the chromosomal location of the various photopigment genes. The S cone pigment gene is on chromosome 7, and tritanopia occurs equally frequently in both sexes. The M and the L cone photopigment genes, however, lie end-to-end on the X chromosome. Because they are very similar and are in adjacent positions on the same chromosome, the L and M photopigment genes are subject to interchanging parts. This results in a variety of L and M genes in the population. The extreme case is one in which the two genes end up being the same, thus specifying only an M or an L photopigment. Since males only inherit one copy of the X chromosome while females inherit two, a female would have to inherit anomalous genes from both parents to be color-defective. A male, on the other hand, only receives a single X chromosome, from his mother, and is correspondingly more likely to have anomalous or dichromatic color vision. An important corollary of this is that many females appear to have more than just two LM pigments, and thus more than three different cone photopigment types. Nonetheless, females with more than three cone types still have only a trichromatic color vision system. Presumably the two L cone types that such a woman might possess are treated as being identical by later neural processes and thus do not produce an additional chromatic dimension. This strongly suggests that the trichromatic limit to human color vision is the result of only three types of analyses in the retina, and of only three paths from there to the cortex, not, as was long supposed, because of the presence of only three cone types.

8. Receptor Function

The retina is part of the brain that just happens to lie some distance away, in the eye, and receptors are similar to neurons elsewhere in the nervous system. They respond to stimuli by either a depolarization or a hyperpolarization of their outer membranes, and they communicate by releasing synaptic chemicals in proportion to the amount of depolarization in the synaptic region. While ordinary neurons respond to external transmitter chemicals, however, photoreceptors respond to chemicals generated within the receptors themselves, triggered by the absorption of photons by their photopigments.

The photopigment molecules are in the outer segments of the photoreceptors. The receptor outer

segment membrane is maintained at an intermediate level of polarization by a balance between opposing sets of chemical interactions. The effect of increases and decreases in the amount of light absorbed by the photopigment molecules (due to a change in either the intensity or the wavelength of incident light) is to shift the polarization balance briefly in one direction or the other. This polarization change in the outer segment is conducted down the receptor to its synaptic region where it produces a change in the rate of synaptic chemical release. A decrement in light absorbed shifts the balance towards depolarization and leads to an increase in synaptic transmitter release to activate the next neurons in the chain to the brain; an increment in light absorption shifts the balance towards hyperpolarization and produces a decrease in transmitter release. As we move our eyes around in a scene, the amount of light absorbed by each receptor oscillates up and down, and the receptors quite faithfully transduce these oscillations into oscillating amounts of synaptic transmitter release. Since these variations in absorption could be due to either intensity differences or wavelength differences in the scene, however, it is left to the neural processing to sort out which is which and thus identify the color and brightness of each visual object.

9. *Retinal Connectivity*

There are three main types of retinal processing and three main paths from the eye to the cortex, which we will refer to as the $\boldsymbol{M}_c$, $\boldsymbol{P}_c$, and $\boldsymbol{K}_c$ paths. They are so called because they pass through the magno-, parvo-, and konio-cellular layers of the lateral geniculate nucleus, the relay station between the eye and the cortex. None of the cells in these three paths signals the amount of light in its region of the retina. Rather, each cell signals the differences between different distributions of light within its receptive field (RF), the region from which it receives its input. The cells do not signal the outputs of just one cone type, either, but rather they signal the sums and differences between the activity of different cone types.

The cells in the $\boldsymbol{M}_c$ path, in a spatially-opponent organization, signal changes in the amount of light absorbed by a small group of L and M cones relative to the amount absorbed by the L and M cones in a larger, overlapping area. Recall that the L and M cones absorb across the whole visible spectrum. Half the cells in this path fire if there is more light in the RF center than in the surround ($+\mathrm{LM}_c - \mathrm{LM}_s$); the other half fire if there is less light in the center than the surround ($-\mathrm{LM}_c + \mathrm{LM}_s$). With uniform illumination, center and surround responses will tend to cancel. This organization begins to emphasize information from objects and minimize that related to the illuminant, because if all the L and M cones in a region absorb more light, or if they all absorb less, it is probably due to a change in the illumination (as when the sun goes behind a cloud or emerges from one). The reflections from different parts of an object, on the other hand, will likely differentially activate one group of cones relative to their neighbors. Information about such intensity variations is what is captured and carried to the cortex by cells in the $\boldsymbol{M}_c$ pathway.

The cells in the $\boldsymbol{K}_c$ path, in a spectrally-opponent organization, signal changes in the amount of light stimulating one or more S cones relative to the amount stimulating the neighboring L and M cones ($+\mathrm{S}_c - \mathrm{LM}_s$). We shall refer to these as S-opponent cells, or $+\mathrm{S}_o$. Since the cone photopigments each have broad spectral sensitivity, one cannot identify the wavelength by which cone is activated. However, differences in the relative amount of activation of the different cone types is related to the spectral distribution of the light, and this information is captured by a spectrally-opponent organization. Short-wavelength light is absorbed relatively more by the S than by the L and M cones. It will therefore excite a cell in the $\boldsymbol{K}_c$ path. Long-wavelength light is absorbed more by the L and M cones than by the S cones, and will thus inhibit a $+\mathrm{S}_o$ cell in the $\boldsymbol{K}_c$ path.

Finally, cells in the $\boldsymbol{P}_c$ path (about 80 percent of the total) have both a spatially- and a spectrally-opponent organization. These cells, at least in the central retina, receive input from a single L or M cone in their RF center, and a small group of L and/or M cones in the surround. There are thus four varieties of these cells: $+\mathrm{L}_c - \mathrm{M}_s$ (or L_o), $-\mathrm{L}_o$, $+\mathrm{M}_o$, and $-\mathrm{M}_o$. The $+\mathrm{L}_o$ and $-\mathrm{M}_o$ cells have the same spectral response characteristics (both L−M), as do the $+\mathrm{M}_o$ and $-\mathrm{L}_o$ cells, (both +M−L), and are therefore combined in Fig. 1B. Since they encode the difference between the activity of L vs. M cones in spectrally-opponent organizations, they respond to color differences in the long-wavelength half of the spectrum. (It is the absence of these cells, because of a lack of either L or M cones, that makes a protanope or deuteranope unable to discriminate red from yellow from green.) However, these cells also signal changes in activation of a single L or M cone relative to that in the surrounding cones, in a spatially-opponent organization. A $+\mathrm{L}_o$ cell, for instance, fires to a large red patch, but also to a small light spot on a dark background. The $\boldsymbol{P}_c$ cells thus carry both color and intensity information. The neural processing in the retina begins but does not complete the process of separating color and intensity information.

10. *Cortical Processing*

The three main retino-cortical paths project separately to the striate cortex (also known as the first visual cortical area, V1), but within the cortex the paths are no longer discrete. Rather, V1 cells combine the outputs of the different cell types in various ways. Most of the early cortical processing involves building RFs to detect various spatial aspects of the pattern

(e.g., spatial frequency, orientation, motion, depth) within a local cortical region. With respect to color vision *per se*, the primary processing involves separating color and luminance information, and further separating changes due to the illuminant from those due to visual objects, by lateral interactions over large regions.

To separate luminance and color information, the outputs of $\boldsymbol{P}_c$ cells are combined in two different ways. When their outputs are summed in one way, the luminance components to their responses sum and the color components cancel. Summed in a different combination, the color components sum and the luminance components cancel. Consider a striate cortex cell that combines inputs from one or more $+L_o$ and $+M_o$ cells in a region. The cortical cell would respond to luminance variations but not to color variations, since the neurons providing its inputs both fire to luminance increments in the RF center and to decrements in the surround, but the color organizations of its inputs are opposite to each other (one being L-M and the other M-L). Combined with input from a $+S_o$ cell, this would produce a V1 cell that fires to white (light increments) and inhibits to black (light decrements) but does not respond to pure color variations. This is represented in the top row of Fig. 1C. However, a V1 cell receiving inputs from both $+L_o$ and $-M_o$ cells, or from both $+M_o$ and $-L_o$ cells (columns in Fig. 1C), would respond to color changes but not to luminance variations since their color responses would add, but their luminance RFs, which are opposite to each other, would cancel. This organization by itself would produce L-M color cells that would fire to so-called warm colors (red and yellow) and inhibit to cool colors (blue and green). M-L cells would fire to cool colors and inhibit to warm colors. As shown in Fig. 1C, the further addition of $+S_o$ or $-S_o$ cells can split these classes into separate red and yellow, and separate blue and green systems, respectively.

All of the primary visual information is passed through V1, but subsequent visual areas are partially specialized for the further analysis of various different functional aspects of vision. One later visual area (V4) is crucially involved with color perception. Individuals with localized V4 lesions can still discriminate objects on the basis of their color variations, but they report that the objects now appear to have no hue, as if viewed on a black-white television screen. There is also a report of one case with the reverse loss: a patient who could see colored but not black-white objects.

11. Color Appearance

The appearance of a color can be specified by values along just three perceptual dimensions known as hue, saturation and brightness. Hue refers to the characteristic described by such color names as red, yellow, green, and blue. Saturation refers to the extent to which the stimulus differs perceptually from a purely achromatic (i.e., white, gray, black) axis. The third dimension is brightness or lightness. That our perceptual space is three-dimensional reflects the basic trichromacy of vision.

A normal observer can describe the hue of any light (disregarding surface characteristics) by using one or more of only four color names (red, yellow, green, and blue). These so-called unique hues form two opponent pairs, red–green and blue–yellow. Red and green normally cannot be seen in the same place at the same time; if unique red and unique green lights are added in appropriate proportions, the colors cancel and one sees a neutral gray. Orange can be seen as a mixture of red and yellow, and purple as a mixture of red and blue, but there is no color seen as a red–green mixture (or as a blue–yellow mixture). This perceptual opponency is also reflected in color contrast. Red can induce the appearance of green into neighboring regions, and after staring at a red surface one sees a green after-image. The yellow–blue opponent pair produces similar effects. It was these perceptual characteristics of color that led Ewald Hering in the nineteenth century to propose that the various color systems were not independent but rather that color was processed in a spectrally opponent organization, an idea which has since been amply verified in the presence, discussed above, of spectrally-opponent cells in the path from receptors to the cortex.

Color Vision Theory

Color vision is the ability to distinguish and identify lights and objects on the basis of their spectral properties. This entry presents several key topics that underlie current theories of human color vision. These are trichromacy, color opponency, adaptation, and color constancy.

1. Introduction

Information about color is transformed as it flows from the stimulus through the initial stages of the human visual system. At each image location, the color stimulus is specified by the amount of power it contains at each wavelength. The classic color matching experiment shows that the normal human visual system is trichromatic: only three dimensions of spectral variation are coded by the visual system. The biological basis of normal trichromacy is that the retina contains three classes of cone photopigment. After the initial encoding of light by the cones, further processing occurs. Two aspects of this processing are particularly important. First, signals from three classes of cones are recombined to form a luminance and two color opponent channels. Second, there is adaptive signal regulation that keeps neural signals within their operating range and stabilizes the appearance of objects across changes of illumination.

2. Trichromacy

2.1 Color Matching

The physical property of light relevant for color vision is the spectral power distribution. A light's spectral power distribution specifies the amount of power it contains at each wavelength in the visible spectrum, often taken to lie roughly between 400 and 700 nm. In practice, spectral power distributions are measured at discrete sample wavelengths. Let the measured power values be denoted by $b_1, \ldots, b_{N_\lambda}$ where N_λ denotes the number of sample wavelengths. Then the vector

$$\mathbf{b} = \begin{bmatrix} b_1 \\ \vdots \\ b_{N_\lambda} \end{bmatrix} \tag{1}$$

provides a compact representation of the spectral power distribution. Use of a vector representation for spectral quantities facilitates a variety of colorimetric computations (e.g., Brainard 1995). Wavelength sample spacings between 1 and 10 nm are typical.

Trichromacy is demonstrated by the basic color matching experiment (Wandell 1995, Brainard 1995). In this experiment, an observer views a bipartite field. One side of the field contains a test light. This light is experimentally controlled and can have an arbitrary spectral power distribution. On the other side of the field is the matching light. This consists of the weighted mixture of three primary lights. Each primary has a fixed relative spectral power distribution, but its overall intensity in the mixture can be controlled by the observer. The observer's task is to adjust the primary intensities until the mixture has the same color appearance as the test light. The primaries used in the experiment are chosen to be independent, so that no weighted mixture of any two produces a match to the third.

Because the matching light is constrained to be a weighted mixture of three primaries, it will not generally be possible for the observer to make the test and matching lights physically identical. For many test lights, however, the observer can adjust the matching light so that it appears identical to the test light even though the two differ physically. For some test lights, no choice of primary intensities will afford a match. In these cases one or more of the primaries can be mixed with the test light and primary intensities found so that the primary/test mixture matches the mixture of the remaining primaries. A useful descriptive convention for the color matching experiment is to assign a negative intensity to any primary that must be mixed with the test to make a match. Given this convention, any test light can be matched by a mixture of three independent primaries.

The color matching experiment is an empirical system. Given a test light described by a vector $\mathbf{b}$, the experiment returns a vector

$$\mathbf{t} = \begin{bmatrix} t_1 \\ t_2 \\ t_3 \end{bmatrix} \tag{2}$$

whose entries are the individual primary intensities. When the primaries are scaled by these intensities and mixed, a match to the test light is created. The vector $\mathbf{t}$ specifies what are called the tristimulus coordinates of the light $\mathbf{b}$. A theory of color matching should let us predict $\mathbf{t}$ for any test light $\mathbf{b}$, given the spectral power distributions of the primary lights.

As an empirical generalization, the color matching system is a linear system (e.g., Wyszecki and Stiles 1982, Brainard 1995, Wandell 1995). That is, if we have two test lights $\mathbf{b}_1$ and $\mathbf{b}_2$ with tristimulus coordinates $\mathbf{t}_1$ and $\mathbf{t}_2$, then any weighted mixture $(a_1\mathbf{b}_1 + a_2\mathbf{b}_2)$ of the two test lights has tristimulus coordinates given by the corresponding mixture $(a_1\mathbf{t}_1 + a_2\mathbf{t}_2)$. In these vector expressions, multiplication of a vector (e.g., $\mathbf{b}_1$) by a scalar (e.g., a_1) consists of multiplying each entry of the vector by the scalar, while addition of two vectors (e.g., $a_1\mathbf{b}_1$ and $a_2\mathbf{b}_2$) consists of adding the corresponding entries of the two vectors.

The linearity of color matching makes it possible to predict the match that will be made to any test light on the basis of a relatively small number of measurements. Consider the set of monochromatic lights with unit power. If N_λ wavelength samples are used in the underlying representation, then there are N_λ such lights and we can denote their spectral representations by $\mathbf{c}_1, \mathbf{c}_2, \ldots, \mathbf{c}_{N_\lambda}$. Each of the $\mathbf{c}_i$ has a 1 as its ith entry

and zeros elsewhere. Note that any light $\mathbf{b}$ may be thought of as a weighted mixture of monochromatic lights, so that $\mathbf{b} = \sum_i b_i \mathbf{c}_i$ where b_i is the ith entry of $\mathbf{b}$. Let the vectors $\mathbf{t}_i$ specify the tristimulus coordinates of the monochromatic lights $\mathbf{c}_i$. The linearity of color matching then tells us that the tristimulus coordinates of any light $\mathbf{b}$ are given by $\mathbf{t} = \sum_i b_i \mathbf{t}_i$.

A set of tristimulus values $\mathbf{t}_i$ measured for monochromatic lights $\mathbf{c}_i$ is referred to as a set of color matching functions. Although these are often plotted as a function of wavelength, they do not represent the spectral power distributions of lights. The color matching functions may be specified by a single matrix

$$\mathbf{T} = \left[\mathbf{t}_1 \mathbf{t}_2 \mathbf{t}_3 \cdots \mathbf{t}_{N_\lambda} \right] \tag{3}$$

whose N_λ columns consist of the individual tristimulus coordinate vectors $\mathbf{t}_i$. This specification allows computation of tristimulus coordinates from spectral power distributions through simple matrix multiplication:

$$\mathbf{t} = \mathbf{T}\mathbf{b}. \tag{4}$$

Both tristimulus values and color matching functions are defined with respect to the primaries chosen for the underlying color matching experiment. The Commission Internationale de l'Eclairage (CIE) has standardized a system for color representation based on the ideas outlined above. The CIE system is widely used to specify color stimuli and many sources describe it in detail (e.g., Wyszecki and Stiles 1982, Brainard 1995, Kaiser and Boynton 1996).

The advantage of using tristimulus coordinates to describe color stimuli is that they provide a more compact and tractable description than a description in terms of wavelength. Tristimulus coordinates are compact precisely because they do not preserve physical differences that are invisible to the human visual system. The representational simplification afforded by tristimulus coordinates is extremely valuable for studying processing that occurs after the initial encoding of light. On the other hand, it is important to remember that the standard tristimulus representations (e.g., the CIE system) are based on matches made by a typical observer looking directly at a small stimulus at moderate to high light levels. These representations are not necessarily appropriate for applications involving some individual observers, nonhuman color vision, or color cameras (e.g., Wyszecki and Stiles 1982, Brainard 1995).

2.2 Biological Basis of Color Matching

The color matching experiment is agnostic about the biological mechanisms that underlie trichromacy. It is generally accepted, however, that trichromacy typically arises because color vision is mediated by three types of cone photoreceptor. Direct physiological measurements of individual primate cones support this hypothesis (see Wandell 1995, Rodieck 1998). First, the responses of individual cones depend only on the rate at which photopigment molecules are isomerized by the absorption of light quanta; once the intensity of two lights has been adjusted so that they produce the same isomerization rates, the cone response does not distinguish the two lights. This idea is referred to as the principle of univariance. Second, individual cones may be classified into one of three distinct types, each with a characteristic spectral sensitivity. The spectral sensitivity is proportional to the probability that light quanta of different wavelengths will isomerize a molecule of the cone's photopigment. The three types of cones are often referred to as the long- (L), middle- (M), and short- (S) wavelength-sensitive cones. If an observer has only three types of cones, each of which obeys the principle of univariance, two physically distinct lights that produce the same isomerization rates for all three classes of cones will be indistinguishable to the visual system. Quantitative comparison confirms that color matches set by a standard observer (defined as the average of matches set by many individual observers) are well predicted by the equations of isomerization rates in the L-, M-, and S-cones.

As described above, trichromacy occurs for most observers because their retinas contain cones with three classes of photopigments. Genetic considerations, however, indicate that some individuals have retinas containing four classes of cone photopigments (Sharpe et al. 1999). Either these individuals are tetrachromatic (mixture of four primaries required to match any light) or else their trichromacy is mediated by information lost after quantal absorption. In addition, some human observers are dichromatic (only two primaries must be mixed to make a match to any light.) Most cases of dichromacy occur because one photopigment is missing (Sharpe et al. 1999, Neitz and Neitz 2000).

An alternative to using tristimulus coordinates to represent the spectral properties of lights is to use cone coordinates. These are proportional to the isomerization rates of the three classes of cone photopigments. The three dimensional vector

$$\mathbf{q} = \begin{bmatrix} q_L \\ q_M \\ q_S \end{bmatrix} \tag{5}$$

specifies cone coordinates where q_L, q_M, and q_S denote the isomerization rates of the L-, M-, and S-cone photopigments respectively. It can be shown (e.g., Brainard 1995) that cone coordinates and tristimulus coordinates are related by a linear transformation, so that

$$\mathbf{q} = \mathbf{M}_{tq}\mathbf{t} \tag{6}$$

where $\mathbf{M}_{tq}$ is an appropriately chosen 3 by 3 matrix.

Computation of cone coordinates from light spectra requires estimates of the cone spectral sensitivities. For each cone class, these specify the isomerization rates produced by monochromatic lights of unit power. The sensitivities may be specified in matrix form as

$$\mathbf{S} = \begin{bmatrix} \mathbf{s}_L \\ \mathbf{s}_M \\ \mathbf{s}_S \end{bmatrix} \tag{7}$$

where each row of the matrix is a vector whose entries are the spectral sensitivities for one cone class at the sample wavelengths. Given $\mathbf{S}$, cone coordinates are computed from the spectral power distribution of a light as

$$\mathbf{q} = \mathbf{Sb} \tag{8}$$

Because Eqns. (4), (6), and (8) hold for any light spectrum $\mathbf{b}$, it follows that

$$\mathbf{S} = \mathbf{M}_{tq}\mathbf{T} \tag{9}$$

Current estimates of human cone spectral sensitivities are obtained from color matching data using Eqn. (9) together with a variety of considerations that put constraints on the matrix $\mathbf{M}_{tq}$ (Stockman and Sharpe 1999).

3. *Postabsorption Processing*

Color vision does not end with the absorption of light by cone photopigments. Rather, the signals that originate with the absorption of light are transformed as they propagate through neurons in the retina and cortex. Two ideas dominate models of this post-absorption processing. The first is color opponency: signals from different cone types are combined in an antagonistic fashion to produce the visual representation at a more central site. The second idea is adaptation: the relation between the cone coordinates of a light and its central visual representation is not fixed but depends instead on the context in which the light is viewed. Section 3.1 treats opponency, while Sect. 3.2 treats adaptation.

3.1 *Opponency*

Direct physiological measurements of the responses of neurons in the primate retina support the general idea of opponency (e.g., Dacey 2000). These measurements reveal, for example, that some retinal ganglion cells are excited by signals from L-cones and inhibited by signals from M-cones. One suggestion about why this occurs is that it is an effective way to code the cone signals for transmission down the optic nerve (see Wandell 1995).

A possible approach to understanding post-absorption processing is to keep the modeling close to the underlying anatomy and physiology and to characterize what happens to signals at each synapse in the neural chain between photoreceptors and some site in visual cortex. The difficulty is that it is not presently possible to cope with the complexity of actual neural processing. Thus many color theorists have attempted to step back from the details and develop more abstract descriptions of the effect of neural processing. Models of this sort are often called mechanistic models. These models generally specify a transformation between the quantal absorption rates $\mathbf{q}$ elicited by a stimulus and a corresponding visual representation $\mathbf{u}$ postulated to exist at some central site. The idea is to choose a transformation so that (a) the color appearance perceived at a location may be obtained directly from the central representation corresponding to that location and (b) the discriminability of two stimuli is predictable from the difference in their central representations.

Most mechanistic models assume that signals from the cones are combined additively to produce signals at three postreceptoral sites. Two of these sites carry opponent signals. These are often referred to as the red-green (RG) and blue-yellow (BY) signals. A third site carries a luminance (LUM) signal, which is not thought to be opponent. If we take

$$\mathbf{u} = \begin{bmatrix} u_{LUM} \\ u_{RG} \\ u_{BY} \end{bmatrix} \tag{10}$$

to be a three-dimensional vector with entries given by the LUM, RG, and BY signals, then the additive relation between cone coordinates $\mathbf{q}$ and the visual representation $\mathbf{u}$ may be expressed in matrix form:

$$\mathbf{u} = \mathbf{M}_o\mathbf{q} \tag{11}$$

Many (but not all) detailed models take LUM to be a weighted sum of L- and M-cone signals, RG to be a weighted difference between the L- and M-cone signals, and BY to be a weighted difference between the S-cone signal and a weighted sum of the L- and M-cone signals. In these models $\mathbf{M}_o$ would have the form

$$\mathbf{M}_o = \begin{bmatrix} m_{11} & m_{12} & 0 \\ m_{21} & -m_{22} & 0 \\ -m_{31} & -m_{32} & m_{33} \end{bmatrix} \tag{12}$$

where all of the m_{ij} are positive scalars representing how strongly one cone class contributes to the signal at one post-receptoral site.

Considerable effort has been devoted to establishing whether the linear form for the mapping between $\mathbf{q}$ and $\mathbf{u}$ is appropriate, and if so, what values should be

used for the m_{ij}. Several types of experimental evidence have been brought to bear on the question.

As an example, one line of research argues that four color perceptions, those of redness, greenness, blueness, and yellowness, have a special psychological status, in that any color experience may be intuitively described in terms of these four basic perceptions. Thus orange may be naturally described as reddish-yellow and aqua as greenish-blue. In addition, both introspection and color scaling experiments suggest that the percepts of redness and greenness are mutually exclusive so that both are not experienced simultaneously in response to the same stimulus, and similarly for blueness and yellowness (e.g., Hurvich and Jameson 1957, Abramov and Gordon 1994). Given these observations, it is natural to associate the RG signal with the amount of redness or greenness perceived in a light (redness if the signal is positive, greenness if it is negative, and neither red nor green if it is zero) and the BY signal with the amount of blueness or yellowness. Judgments of the four fundamental color perceptions, obtained either through direct scaling (e.g., Abramov and Gordon 1994) or through a hue cancellation procedure (e.g., Hurvich and Jameson 1957), are then used to deduce the appropriate values of the m_{ij} in the second and third rows of $\mathbf{M}_o$. When this framework is used, the entries for the first row of $\mathbf{M}_o$, corresponding to the LUM signal, are typically established through other means such as flicker photometry (e.g., Kaiser and Boynton 1996).

Other approaches to studying the opponent transformation include analyzing measurements of the detection and discrimination of stimuli (e.g., Wyszecki and Stiles 1982, Kaiser and Boynton 1996, Eskew, et al. 1999, Wandell 1999), and measurements of how the color appearance of lights is affected by the context in which they are viewed (e.g., Webster 1996). In part because of a lack of quantitative agreement in the conclusions drawn from different paradigms, there is currently not much consensus about the details of the transformation between $\mathbf{q}$ and $\mathbf{u}$. One of the major open issues in color theory remains how to extend the simple linear model described above so that it accounts for a wider range of results.

3.2 Adaptation

Figure 1 illustrates a case where the same light has a very different color appearance when seen in two different contexts. The figure shows two disk-annulus stimulus configurations. The central disk is the same in each configuration, but the appearance of the two disks is quite different. To explain this and other context effects, mechanistic models assume that at any given time and image location, the relation between the quantal absorption rates $\mathbf{q}$ and the visual representation $\mathbf{u}$ depends on the quantal absorption rates

Figure 1
A color context effect. The figure illustrates the color context effect known as simultaneous contrast. The two central disks are physically the same but appear different. The difference in appearance is caused by the fact that each disk is seen in the context of a different annular surround. This figure is best viewed in color. A color version is available in the on-line version of the Encyclopedia

at other locations and at preceding times. To help fix ideas, it is useful to restrict attention to the disk-annulus configuration. For this configuration, the visual representation of the disk may be written as

$$\mathbf{u}_d = f(\mathbf{q}_d; \mathbf{q}_a, \varphi) \tag{13}$$

where $\mathbf{u}_d$ is the visual response to the disk, $\mathbf{q}_d$ and $\mathbf{q}_a$ are the cone coordinates of the disk and annulus respectively, and φ represents other contextual variables such as the size of the disk and annulus and any temporal variation in the stimulus. Clearly, f( ) must incorporate the sort of transformation described by the matrix $\mathbf{M}_o$ in Sect. 3.1 above.

As was the case with the discussion of opponency above, there is not wide agreement about how best to model adaptation. A reasonable point of departure is a cone-specific affine model. In this model, the visual representation $\mathbf{u}$ of a light is related to its cone coordinates $\mathbf{q}$ through an equation of the form

$$\mathbf{u} = \mathbf{M}_o(\mathbf{D}_1\mathbf{q} - \mathbf{q}_1) \tag{14}$$

where $\mathbf{M}_o$ is as in Eqn. (12) and

$$\mathbf{D}_1 = \begin{bmatrix} g_{L1} & 0 & 0 \\ 0 & g_{M1} & 0 \\ 0 & 0 & g_{S1} \end{bmatrix}, \quad \mathbf{q}_1 = \begin{bmatrix} q_{L1} \\ q_{M1} \\ q_{S1} \end{bmatrix} \tag{15}$$

In this formulation, the g's on the diagonals of $\mathbf{D}_1$ characterize multiplicative adaptation that occurs at a cone-specific site in visual processing, before signals from separate cone classes are combined. The entries of the vector $\mathbf{q}_1$ characterize subtractive adaptation. Equation (14) is written in a form that implies that the subtractive adaptation also occurs at a cone-specific

site. The entries of $\mathbf{D}_1$ and $\mathbf{q}_1$ depend on the cone coordinates $\mathbf{q}_a$ of the annulus as well as on spatial and temporal variables characterized by φ. Note that the cone-specific affine model is a generalization of the idea that the visual representation consists of a contrast code.

Asymmetric matching may be used to test the adaptation model of Eqn. (14). In an asymmetric matching experiment, an observer adjusts a match stimulus seen in one context so that it appears to have the same color as a test stimulus seen in another context. More concretely, consider Fig. 1. In the context of this figure, an asymmetric matching experiment could be conducted where the observer was asked to adjust the central disk on the right so that it matched the appearance of the central test disk on the left. Suppose such data are collected for a series of N test disks with cone coordinates $\mathbf{q}_{ti}$. Denote the cone coordinates of the matches by $\mathbf{q}_{mi}$. Within the mechanistic framework, the corresponding visual representations $\mathbf{u}_{ti}$ and $\mathbf{u}_{mi}$ should be equal. If Eqn. (14) provides a good description of performance then

$$\begin{aligned}\mathbf{M}_o(\mathbf{D}_{m1}\mathbf{q}_{mi}-\mathbf{q}_{m1}) &= \mathbf{M}_o(\mathbf{D}_{t1}\mathbf{q}_{ti}-\mathbf{q}_{t1})\\ &\Leftrightarrow \mathbf{q}_{mi} = \mathbf{D}_{m1}^{-1}(\mathbf{D}_{t1}\mathbf{q}_{ti}-\mathbf{q}_{t1}+\mathbf{q}_{m1})\\ &\Leftrightarrow \mathbf{q}_{mi} = \mathbf{D}_{tm}\mathbf{q}_{ti}-\mathbf{q}_{tm}\end{aligned} \tag{16}$$

where $\mathbf{D}_{tm} = \mathbf{D}_{m1}^{-1}\mathbf{D}_{t1}$ and $\mathbf{q}_{tm} = \mathbf{D}_{m1}^{-1}(\mathbf{q}_{t1}-\mathbf{q}_{m1})$. This prediction may be checked by finding the diagonal matrix $\mathbf{D}_{tm}$ and vector $\mathbf{q}_{tm}$ that provide the best fit to the data and evaluating the quality of the fit. Tests of this sort indicate that the cone specific affine model accounts for much of the variance in asymmetric matching data, both for the disk annulus configuration (Wandell 1995, 1999) and for more complex stimuli (Brainard and Wandell 1992). Nonetheless, there are clear instances for which Eqn. (16) does not give a complete account of asymmetric matching (e.g., Delahunt and Brainard 2000) and other color appearance data (e.g., Webster 1996, Mausfeld 1998, D'Zmura and Singer 1999).

The cone-specific affine model may also be tested against psychophysical data on the detection and discrimination of colored lights. Here again the model provides a reasonable point of departure but fails in detail (e.g., Eskew et al. 1999).

To extend the cone specific affine model, various theorists have suggested the need for adaptation at a second site (after signals from separate cone classes have been combined) and for the inclusion of nonlinearities in the relation between $\mathbf{q}$ and $\mathbf{u}$ (see references cited in the previous two paragraphs). An additional open question concerns how the entries of $\mathbf{D}_1$ and $\mathbf{q}_1$ are determined by the viewing context (e.g., Brainard and Wandell 1992, Delahunt and Brainard 2000).

4. *Color Constancy*

The discussion so far has focussed on how the visual system represents and processes the spectrum of light that enters the eye. This is natural, since light is the proximal stimulus that initiates color vision. On the other hand, we use color primarily to name objects. The spectrum of the light reflected to the eye from an object depends both on an intrinsic property of the object, its surface reflectance function, and on extrinsic factors, including the spectral power distribution of the illuminant and how the object is oriented relative to the observer.

Given that the light reflected to the eye varies with the illuminant and viewing geometry, how is it that color is a useful psychological property of objects? The answer is that the visual system processes the retinal image to stabilize the color appearance of objects across changes extrinsic to the object (e.g., changes in the spectrum of the illuminant). This stabilization process is called color constancy.

Color constancy is closely linked to the phenomenon of adaptation described above (Maloney 1999). Indeed, quantitative models of color constancy generally incorporate the same idea that underlies mechanistic models of visual processing: at some central site there is a visual representation $\mathbf{u}$ that correlates with color appearance. To stabilize this representation against changes in illumination, it is supposed that the relation between the quantal absorption rates $\mathbf{q}$ elicited by the light reflected from an object and the visual representation $\mathbf{u}$ depends on the scene in which the object is viewed. In the case of color constancy, the emphasis has been on how the visual system processes the retinal image so that the transformation between $\mathbf{q}$ and $\mathbf{u}$ has the effect of compensating for the variation in the light reflected to the eye caused by changes of illumination and viewing geometry. Psychophysical data on the color appearance of objects viewed under different illuminants are often well-modeled by transformations consistent with Eqn. (14) (e.g., Brainard and Wandell 1992).

The central theoretical question of color constancy is how the visual system can start with image data and factor it into an accurate representation of the surfaces and illuminants in the scene. This question has received extensive treatment, at least for simple scenes. A brief introduction to this literature on computational color constancy follows.

4.1 *Computational Color Constancy*

Consider a scene consisting of diffusely illuminated flat, matte surfaces. For such scenes, the spectrum $\mathbf{b}$ reflected to the eye from each surface is given by the wavelength-by-wavelength product of the spectral power distribution of the illuminant $\mathbf{e}$ and the surface reflectance function $\mathbf{s}$. The surface reflectance function specifies, at each sample wavelength, the fraction of

incident light reflected to the eye. The information about **b** coded by the visual system is its cone coordinates, which may be computed as

$$\mathbf{q} = \mathbf{S}\mathbf{b} = \mathbf{S}\ \mathrm{diag}(\mathbf{e})\mathbf{s} \tag{17}$$

where the function **diag**( ) returns a square diagonal matrix with its argument placed along the diagonal. Clearly **e** and **s** are not uniquely determined from knowledge of **q**: without additional constraints the color constancy problem is underdetermined. Fortunately the spectra of naturally occurring illuminants and surfaces are not arbitrary. Although the physical processes that constrain these spectra are not well understood, analyses of measurements of both illuminants and surfaces shows that their spectra are well described by small-dimensional linear models (see Brainard 1995, Maloney 1999).

Consider surface reflectances. It is possible to define three fixed basis functions so that naturally occurring surface reflectances are reasonably well approximated by a linear combination of these basis functions. Thus for any surface, we have

$$\mathbf{s} \approx w_{s1}\mathbf{b}_{s1} + w_{s2}\mathbf{b}_{s2} + w_{s3}\mathbf{b}_{s3} \tag{18}$$

where $\mathbf{b}_{s1}$, $\mathbf{b}_{s2}$, and $\mathbf{b}_{s3}$ are the spectra of the basis functions and w_{s1}, w_{s2}, and w_{s3} are scalar weights that provide the best approximation of **s** within the linear model. Eqn. (18) may be rewritten as

$$\mathbf{s} \approx \mathbf{B}_s\mathbf{w}_s \tag{19}$$

where the three columns of matrix $\mathbf{B}_s$ contain the basis functions and the vector w_s contains the scalar weights.

When the surface reflectance functions lie within a three-dimensional linear model Eqn. (17) may inverted, once an estimate $\hat{\mathbf{e}}$ of the illuminant has been obtained (see below for discussion of illuminant estimation.) Start by rewriting Eqn. (17) as:

$$\mathbf{q} = [\mathbf{S}\ \mathrm{diag}(\hat{\mathbf{e}})\mathbf{B}_s]\ \mathbf{w}_s = \mathbf{L}_{\hat{\mathbf{e}}}\mathbf{w}_s \tag{20}$$

where $\mathbf{L}_{\hat{\mathbf{e}}}$ is a three-by-three matrix that depends on the illuminant estimate. This matrix may be inverted using standard methods to yield an estimate of $\mathbf{w}_s$:

$$\hat{\mathbf{w}}_s = \mathbf{L}_{\hat{e}}^{-1}\ \mathbf{q} \tag{21}$$

The estimate may then be used together with Eqn. (19) to estimate the surface reflectance function.

Many computational color constancy algorithms assume a linear model constraint for surface reflectance functions. This reduces the constancy problem to finding an estimate of the illuminant to plug into Eqn. (20). For illustrative purposes, an algorithm due to Buchsbaum (1980) is described here. In Buchsbaum's algorithm, two additional assumptions are added. The first is that a three-dimensional linear model also describes illuminant spectral power distributions, so that

$$\mathbf{e} \approx \mathbf{B}_e\mathbf{w}_e \tag{22}$$

The second is that the spatial average of the surface reflectance functions ($\bar{\mathbf{s}}$) is the same in all scenes and known. These additional constraints imply that

$$\bar{\mathbf{q}} = [\mathbf{S}\ \mathrm{diag}(\bar{\mathbf{s}})\mathbf{B}_e]\hat{\mathbf{w}}_e = \mathbf{L}_{\bar{s}}\hat{\mathbf{w}}_e \tag{23}$$

where $\bar{\mathbf{q}}$ is the spatial average of the quantal absorption rates and $\mathbf{L}_{\bar{s}}$ is a known three-by-three matrix. Inverting Eqn. 23 yields an estimate for the illuminant $\hat{\mathbf{e}} = \mathbf{B}_e\mathbf{w}_{\hat{e}}$. This estimate is then used to provide the matrix $\mathbf{L}_{\hat{e}}^{-1}$ to be used in Eqn. (21).

Buchsbaum's algorithm shows how the addition of appropriate assumptions allows solution of the computational color constancy problem. The difficulty with Buchsbaum's algorithm is that its assumptions are too restrictive. In particular, it seems unlikely that the spatial average of surface reflectances is constant across scenes, nor do real scenes consist of diffusely illuminated flat, matte surfaces. Subsequent work has focused on ways to provide reasonable estimates of the illuminant and surface reflectances under other sets of assumptions (e.g., Maloney 1999).

4.2 Computational Color Constancy and Human Performance

How does the computational work relate to human performance? This question has not yet been resolved, but it seems appropriate to close with a few observations. First, the estimated linear model weights of Eqn. (21) may be associated with the mechanism responses **u** discussed in Sect. 2. In both types of theory, these quantities represent the visual response computed from the quantal absorption rates, and both are meant to allow direct prediction of appearance. In the mechanistic approach, one considers a series of transformations whose form is derived from experiments with simple stimulus configurations. In the computational approach, the form of the transformation is derived from consideration of the problem color vision is trying to solve. In both cases, however, the emphasis is on finding the appropriate parametric form of the transformation and on understanding how the parameters are set as a function of the image data. The connection between the two approaches is discussed in more detail by Maloney (1999).

The value of the computational approach to understanding human vision depends on how accurately the transformations it posits may be used to predict the appearance of stimuli measured in psychophysical experiments. There have been only a few empirical comparisons of this sort to date. These comparisons do, however, indicate that the computational approach shows promise for advancing our understand-

ing of human color vision (Bloj, Kersten, and Hurlbert 1999, Brainard, Kraft, and Longre 2001).

Combinatorial Data Analysis

Combinatorial data analysis (CDA) refers to a class of methods for the study of relevant data sets in which the arrangement of a collection of objects is the absolutely central concept. Characteristically, CDA is involved with either: (a) the identification of arrangements that are optimal for a specific representation of a given data set, and where such an exploratory process is typically carried out according to some specific loss or merit function that guides a combinatorial search over a domain of possible structures constructed from the constraints imposed by the particular representation selected; or (b) a confirmatory determination as to whether a specific object arrangement given *a priori* reflects the observed data, and where such a confirmatory process is typically operationalized by comparing the empirically observed degree of correspondence between some given data set and the specific structure conjectured for it, to a reference distribution constructed from the collection of all possible structures of the same form that could have been conjectured.

The boundaries of what CDA might encompass are somewhat open but generally we would exclude methods based on the postulation of strong stochastic models and their specific unknown parametric structures as underlying a given data set. Although CDA might use or empirically construct various weighting functions, the weights so obtained are not to be interpreted as parameter estimates in some presumed stochastic model viewed in turn as responsible for generating the data. Manifest data are emphasized solely, and the traditional concern for an assumed relationship between the data and a restrictively parameterized stochastic model is avoided. For

monograph-length reviews for both exploratory and confirmatory CDA, along with extensive bibliographic sources, see Hubert (1987), Arabie and Hubert (1992, 1996), Hubert et al. (in press).

Within each of the two sections to follow on confirmatory and exploratory combinatorial data analysis, we present several representative areas of application, from among many that could have been given, and hope that by induction, a reasonable characterization can be constructed for both confirmatory CDA (CCDA) and exploratory CDA (ECDA). At the least, CCDA includes most (if not all) of classical nonparametric statistics as a special case, and all extensions or generalizations that rely on randomization (or permutation) arguments (see, for example, Edgington 1995, for a variety of elegant experimental design applications). Similarly, and with not much of a stretch, most of scaling and seriation (multidimensional and otherwise), clustering (partitioning, hierarchical, and in the construction of additive trees and other network models), or more general representational structures (e.g., approximation by sums of (anti-)Robinson matrices—see Hubert and Arabie 1994) can be encompassed within ECDA.

1. *Confirmatory Combinatorial Data Analysis (CCDA)*

CCDA seeks a comparison of some given structure to a reference distribution constructed from all possible similar structures (and with typically the hope for the rejection of the null conjecture of a random assignment based on the extreme size of some index such as $I_{\text{obs}}(U, V)$ and its resulting small p-value). To introduce a general notational structure that can be used to present several ECDA exemplars, we first assume our interest is in some object set $S = \{O_1, O_2, \ldots, O_n\}$ (for example, S may contain n subjects), and we denote by $U = \{u_1, u_2, \ldots, u_n\}$ and $V = \{v_1, v_2, \ldots, v_n\}$ the two sequences of information we have on the objects. Thus, for object O_i, u_i and v_i might denote single numerical values on two variables, or possibly two sets of nominal scale labels, or even vectors of numerical information over a set of attributes (among other entities that would need to be explicated for each particular application). By various means, an index $I_{\text{obs}}(U, V)$ is obtained between the two sequences (where 'obs' denotes 'observed' and is used as a subscript to denote the particular one-to-one matching of u_i and v_i for $1 \leqslant i \leqslant n$). The relative size of $I_{\text{obs}}(U, V)$ is evaluated against all possible $n!$ indices that could be formed by permutating the u_i against the fixed v_i (for all i) or conversely (an index formed by some such permutation will be denoted simply by $I(U, V)$, and without a subscript of 'obs'). If $I_{\text{obs}}(U, V)$ is sufficiently extreme with respect to this reference distribution (i.e., if we have a small probability or p-value of obtaining an index as or more extreme than $I_{\text{obs}}(U, V)$ under the random matching of the entries within U and V), one could declare a significant association between the information provided by U and V for the n objects in S.

Although complete enumeration and subsequent tabling may be the most direct means for constructing a reference distribution for $I(U, V)$ (and against which the specific value of $I_{\text{obs}} \equiv I_{\text{obs}}(U, V)$ can be compared), in practice and because n may be so enormous for even moderately-sized values of n, various approximations must be used. For example, a distribution based only on a random sample could be considered close to what would be generated from complete enumeration (and used to obtain what can be referred to as a Monte Carlo p-value—see Hope 1968); or closed form formulae may be available for the first few moments of the complete distribution (such as the mean and variance), and an approximation based on these may be possible (see Mielke 1979, Hubert 1987, for extensive discussions of such approximations in a variety of CCDA cases).

1.1 *The Linear Assignment (LA) Model*

The LA model assumes a particular form for I_{obs} based on a given $n \times n$ matrix $\mathbf{R} = \{r_{ij}\}$, where r_{ij} denotes some measure of proximity derived or computed from the observed data values, u_i and v_j, i.e., $I_{\text{obs}}(U, V) = \sum_{i=1}^{n} r_{ii}$. The mean and variance of $I \equiv I(U, V)$ are known under the random assignment conjecture:

$$E(I) = \frac{1}{n}\sum_{i,j} r_{ij}$$

$$\text{Var}(I) = \frac{1}{n(n-1)}\left[\frac{1}{n}\left(\sum_{i,j} r_{ij}\right)^2 - \sum_j\left(\sum_i r_{ij}\right)^2 - \sum_i\left(\sum_j r_{ij}\right)^2 + n\sum_{i,j} r_{ij}^2\right] \quad (1)$$

Thus, assuming the appropriateness of a normal approximation (see Hubert 1987, pp. 8–12), $(I_{\text{obs}} - E(I))/\sqrt{V(I)}$ might be compared to a standard normal random variable to obtain the p-value that I_{obs} would engender.

We consider three applications of the LA model:

(a) If U and V denote two numerical sequences (e.g., rank orders or interval scales) for the objects in S, and we define the proximity

$$r_{ij} = \frac{(u_i - \bar{u})(v_j - \bar{v})}{\sqrt{\frac{1}{n}\sum_i (u_i - \bar{u})^2}\sqrt{\frac{1}{n}\sum_i (v_i - \bar{v})^2}} \quad (2)$$

where $\bar{u}$ and $\bar{v}$ are the means within U and V respectively, then I_{obs} reduces to the usual Pearson product-moment correlation coefficient. Thus, $E(I) =$

0 and $\mathrm{Var}(I) = 1/(n-1)$ provide the usual randomization moments, and in turn, a permutation test for a Pearson correlation is obtained as a special case of the LA model.

(b) If, however, the sequences U and V contain the consecutive integers from 1 to K that are used as nominal scale labels, and

$$r_{ij} = \begin{cases} 1 & \text{if } u_i = v_j \\ 0 & \text{if } u_i \neq v_j \end{cases} \tag{3}$$

then I_{obs} is the number of agreements between U and V in labels over the n objects in S. Here,

$$E(I) = n \sum_{k=1}^{K} \left[\left(\frac{n_k^{(u)}}{n} \right) \left(\frac{n_k^{(v)}}{n} \right) \right] \tag{4}$$

is the expected number of agreements under random assignment, where $n_k^{(u)}$ and $n_k^{(v)}$ denote the number of labels having the value k within the U and V sequences, respectively. Using $E(I)$ and $\mathrm{Var}(I)$ from its general formula in Eqn. (1) to standardize I_{obs}, a (normal) approximate p-value for the observed number of agreements could be given directly. It is more typical, however, merely to standardize I_{obs} for descriptive purposes based on the general index form of

$$\frac{I_{\text{obs}} - E(I)}{\max(I) - E(I)} \tag{5}$$

to produce Cohen's κ statistic (which for $\max(I) = n$ is bounded above by 1.0 and has expected value 0.0 under random assignment).

(c) As a final example of using the LA model, suppose U is a numerical sequence (e.g., rank order or interval scale) for the objects in S, where $u_1, \ldots, u_{n_1}$ refer to one group (G_1) of n_1 observations and $u_{n_1+1}, \ldots, u_n$ denote a second (G_2) of $n_2 (= n - n_1)$ observations; $V = \{v_i\}$ for $v_i = 1/n_1$, $1 \leqslant i \leqslant n_1$, and $v_i = -1/n_2$, $n_1 + 1 \leqslant i \leqslant n$; and the proximity $r_{ij} = u_i v_j$. Then, $I_{\text{obs}}(U, V) = \bar{u}_{G_1} - \bar{u}_{G_2}$, where $\bar{u}_{G_1}$ and $\bar{u}_{G_2}$ are the means within G_1 and G_2, respectively. Under random assignment, the $n!/n_1!n_2!$ possible allocations of n_1 scores to G_1 (and n_2 to G_2) are equally-likely, and $E(I) = 0$ and $\mathrm{Var}(I) = (n/((n-1)n_1 n_2)) \sum_i (u_i - \bar{u})^2$, where $\bar{u}$ is the mean for the entries in U. Thus, as the usual approximation for the randomization test for two independent samples, based on the difference between the two group means, $I_{\text{obs}}/\sqrt{\mathrm{Var}(I)}$ could be compared to the standard normal distribution to generate the approximate p-value.

1.2 The Quadratic Assignment (QA) Model

The QA model again assumes a specific form for the index $I_{\text{obs}}(U, V)$ but is now based on two given $n \times n$ matrices, $\mathbf{R}^{(u)} = \{r_{ij}^{(u)}\}$ and $\mathbf{R}^{(v)} = \{r_{ij}^{(v)}\}$, where $r_{ij}^{(u)}$ (or $r_{ij}^{(v)}$, respectively) denotes a measure of proximity between u_i and u_j (or v_i and v_j). The index I_{obs} is defined as the raw cross-product, $\sum_{i,j} r_{ij}^{(u)} r_{ij}^{(v)}$, and as before, the first several moments are available under the null conjecture of random assignment. The first moment is simple, $E(I) = (1/(n(n-1))) \sum_{i,j} r_{ij}^{(u)} \sum_{i,j} r_{ij}^{(v)}$; the variance and higher-moments are more involved and will not be reproduced here (see Mantel 1967, for $\mathrm{Var}(I)$ and the first application using the general form of the QA model in the literature).

(a) As a first example of the QA model, suppose U denotes a numerical sequence for the objects in S and V consists of the integers from 1 to K as labels to indicate membership in one of K groups (with n_k denoting the cardinality of group k, $1 \leqslant k \leqslant K$). Letting

$$r_{ij}^{(u)} = (u_i - u_j)^2 \quad \text{for } 1 \leqslant i, j \leqslant n$$
$$r_{ij}^{(v)} = \begin{cases} 1/(2n_k) & \text{if } v_i = v_j = k \\ 0 & \text{otherwise} \end{cases} \tag{6}$$

I_{obs} is then the common within-group sum-of-squares as in one-way ANOVA, and defines one of the common test-statistics used to evaluate the one-way ANOVA conjecture under random assignment. So, evaluating the size of I_{obs} by all $n!$ permutations of the u_i against the v_i for all i, provides the usual randomization test in the one-way ANOVA framework.

(b) As one immediate extension of this one-way ANOVA framework to assess what is called spatial autocorrelation (SA) (see Upton and Fingleton 1985, for an extensive review of assessing SA using the CCDA randomization approach), suppose $\mathbf{R}^{(u)}$ is still defined as above from the numerical sequence in U, but $r_{ij}^{(v)}$ is a distance measure between geographical locations for objects O_i and O_j. Then I_{obs} is an index of the degree to which objects that are close in value in U are also similar in geographical location (in fact, I_{obs} is proportional to what is called Geary's index of SA—see Upton and Fingleton 1985).

(c) As a final example of the QA model, assume both U and V contain nominal scale numerical labels for the objects in S, with U containing the integers from 1 to $K^{(u)}$ (with $n_k^{(u)}$ denoting the cardinality of group k, $1 \leqslant k \leqslant K^{(u)}$), and V containing the integers from 1 to $K^{(v)}$ (with $n_k^{(v)}$ denoting the number in group k, $1 \leqslant k \leqslant K^{(v)}$). If

$$r_{ij}^{(u)} = \begin{cases} +1 & \text{if } u_i = u_j \\ -1 & \text{if } u_i \neq u_j \end{cases}$$
$$r_{ij}^{(v)} = \begin{cases} +1 & \text{if } v_i = v_j \\ -1 & \text{if } v_i \neq v_j \end{cases} \tag{7}$$

then I_{obs} is twice the difference between the number of agreements (A) and disagreements (D) in the classifi-

cation of all object pairs by the two separate partitions represented by U and V. Explicitly, an agreement for an object pair is where the labels for the pair are identical in U and identical in V, or different in U and different in V; a disagreement occurs when the labels are the same in U (or V) but different in V (or U). What has now become known as Rand's Adjusted Index (using the general form for a descriptive statistic already noted for Cohen's κ, as discussed in detail by Hubert and Arabie 1985) can be given as

$$\frac{I_{\text{obs}}(U, V) - E(I)}{\max(I) - E(I)} \tag{8}$$

where $I_{\text{obs}}(U, V) = 2(A - D)$, $\max(I) = n(n-1)$, and

$$E(I) = \frac{1}{n(n-1)} \left[2 \sum_{k=1}^{K^{(u)}} (n_k^{(u)})^2 - (n+1)n \right] \times \left[2 \sum_{k=1}^{K^{(v)}} (n_k^{(v)})^2 - (n+1)n \right] \tag{9}$$

2. *Exploratory Combinatorial Data Analysis (ECDA)*

In contrast to CCDA, ECDA generally tries to optimize such an index and in the process to identify a structure that best represents a given data set. As the exemplars that follow will show, the data analysis tasks arising in ECDA usually can be given some type of combinatorial characterization that involves the identification of object groupings, partitions, or sequences of various types.

2.1 *Sequencing/Seriation/Unidimensional Scaling*

One of the most common tasks encountered in ECDA is the ordering of a set of objects (such as S) along a continuum so that the available data are well depicted by the identified ordering. Commonly, the given data are in the form of an $n \times n$ proximity matrix, say $\mathbf{Q} = \{q_{ij}\}$, whose entries we presently assume are non-negative and symmetric ($q_{ij} = q_{ji} \geqslant 0$ for $1 \leqslant i, j \leqslant n$, and without loss of generality, $q_{ii} \equiv 0$ for $1 \leqslant i \leqslant n$), and keyed as dissimilarities so that larger values correspond to the more dissimilar pairs of objects. The canonical ECDA task in this case is to find some reordering of the rows and simultaneously the columns of $\mathbf{Q}$ so that ideally the (so-called anti-Robinson) gradient structure or pattern is apparent in the reordered matrix, which would generally be reflected by an increase of entries moving away from the main diagonal within any row or within any column. More formally, we might ask to identify a permutation $\rho^*(\cdot)$ of the first n integers (so $\rho^*(i) = j$ for $1 \leqslant i, j \leqslant n$) that when used to relabel the rows/columns of $\mathbf{Q}$ as $\mathbf{Q}_{\rho^*} \equiv \{q_{\rho^*(i)\rho^*(j)}\}$, the following order conditions generally hold within $\mathbf{Q}_{\rho^*}$ (see Hubert and Arabie 1994):

$$\begin{aligned} q_{\rho^*(i)\rho^*(j)} &\leqslant q_{\rho^*(i)\rho^*(j+1)} \quad \text{for } 1 \leqslant i < j \leqslant n-1 \\ q_{\rho^*(i)\rho^*(j)} &\leqslant q_{\rho^*(i)\rho^*(j-1)} \quad \text{for } 2 \leqslant j < i \leqslant n \end{aligned} \tag{10}$$

There are a number of ways to operationalize the search for such a $\rho^*(\cdot)$:

(a) one of the best-known optimization problems in the Operations Research literature, the QA task (that we also met briefly in an earlier confirmatory context), can be used indirectly to find a 'good' $\rho^*(\cdot)$. Explicitly, given two $n \times n$ matrices, we might seek that row and column permutation, $\rho^*(\cdot)$, to maximize the QA cross-product index, $\sum_{i,j} q_{\rho^*(i)\rho^*(j)}(|i-j|)$, between the reordered matrix and a second target matrix $\{|i-j|\}$ defining an $n \times n$ matrix of distances between equally-spaced positions along a continuum. Conceptually, the n objects are placed at these equally-spaced positions, and (because the entries in $\mathbf{Q}$ and $\{|i-j|\}$ are fixed) the usual correlation coefficient is maximized between the distances along the continuum and the proximities between the objects placed at these positions. (For a review of computational methods for approaching the QA task in such a data analytic framework, see Hubert and Schultz 1976.)

(b) Alternatively, instead of equally spacing objects in S along a continuum, a natural generalization for identifying $\rho^*(\cdot)$ would be through unidimensional scaling. Here, we would attempt to estimate an appropriate set of locations, in addition to identifying an optimal permutation $\rho^*(\cdot)$, by minimizing, for example, the least-squares loss criterion of

$$\sum_{i,j} (q_{\rho^*(i)\rho^*(j)} - |x_i - x_j|)^2 \tag{11}$$

where $x_1 \leqslant x_2 \leqslant \cdots \leqslant x_n$, and $\frac{1}{n}\sum_{i=1}^{n} x_i = 0$. So long as q_{ij} is strictly positive for all i and j when $i \neq j$, we may equivalently maximize $\sum_i (\sum_j q_{\rho^*(i)\rho^*(j)})^2$, and let the optimal coordinates be estimated as $\hat{x}_i = \frac{1}{n}(\sum_{k=1}^{i-1} q_{\rho^*(i)\rho^*(k)} - \sum_{k=i+1}^{n} q_{\rho^*(i)\rho^*(k)})$. (For suggested combinatorial optimization methods for the unidimensional scaling task, see Defays 1978, (for a branch-and-bound strategy) and Hubert and Arabie 1986 (for a dynamic programming approach).)

(c) Finally, and because satisfying the gradient conditions in Eqn. (10) might be considered only an indirect optimization goal in QA applied to unidimensional scaling, a more straightforward approach would directly attempt to optimize some index based on the violation/nonviolation of such conditions within $\mathbf{Q}_{\rho}^{*}$. This strategy has been suggested informally for decades (e.g., see Sibson 1971), and more recently using methods of global optimization based on dynamic programming in Hubert et al. (in press). Explicitly, we seek to maximize the difference between the

agreements and disagreements to the anti-Robinson gradient conditions in Eqn. (10) by maximizing

$$\sum_{1 \leqslant i < j \leqslant n-1} f(q_{\rho^*(i)\rho^*(j)}, q_{\rho^*(i)\rho^*(j+1)}) + \sum_{2 \leqslant j < i \leqslant n} f(q_{\rho^*(i)\rho^*(j)}, q_{\rho^*(i)\rho^*(j-1)})$$

where for $1 \leqslant i < j \leqslant n-1$,

$$f(q_{\rho^*(i)\rho^*(j)}, q_{\rho^*(i)\rho^*(j+1)}) = \begin{cases} +1 & \text{if } q_{\rho^*(i)\rho^*(j)} < q_{\rho^*(i)\rho^*(j+1)} \\ -1 & \text{if } q_{\rho^*(i)\rho^*(j)} > q_{\rho^*(i)\rho^*(j+1)} \\ 0 & \text{if } q_{\rho^*(i)\rho^*(j)} = q_{\rho^*(i)\rho^*(j+1)} \end{cases}$$

and for $2 \leqslant j < i \leqslant n$,

$$f(q_{\rho^*(i)\rho^*(j)}, q_{\rho^*(i)\rho^*(j-1)}) = \begin{cases} +1 & \text{if } q_{\rho^*(i)\rho^*(j)} < q_{\rho^*(i)\rho^*(j-1)} \\ -1 & \text{if } q_{\rho^*(i)\rho^*(j)} > q_{\rho^*(i)\rho^*(j-1)} \\ 0 & \text{if } q_{\rho^*(i)\rho^*(j)} = q_{\rho^*(i)\rho^*(j-1)} \end{cases}$$

2.2 Clustering/Partitioning/Hierarchical Clustering

Another very common task in ECDA is some variation on the theme of grouping objects in S based on a given proximity matrix $\mathbf{Q}$, where generally the groups formed should be internally cohesive and externally isolated or separated from the other groups. Depending on how the task is phrased, a number of variations are possible. One of the broadest interpretations of clustering would be to represent as well as possible a proximity matrix $\mathbf{Q}$ by the additive combination of the attributes defined by some to-be-identified collection of K possibly overlapping clusters or subsets of S. If for convenience, $\mathbf{Q}$ is keyed as a non-negative similarity matrix so large entries now denote the more similar pairs of objects, our objective would be to estimate a non-negative weight for each of the identified clusters and attempt a 'close' reconstruction of each proximity, say q_{ij}, by adding the weights for those subsets that include objects O_i and O_j (in addition to an overall estimated additive constant as well—a more detailed discussion of this additive clustering model can be found in Shepard and Arabie 1979). More mundane manifestations of clustering can be found in methods implemented in commercial software such as SPSS or SYSTAT, e.g., various strategies for identifying a single partition of an object set (such the k-means method) or complete partition hierarchies defined by collections of nested partitions that successively contain fewer and fewer classes (such as the well known agglomerative complete-link method).

Commemorative Objects

Commemoration refers to the mobilization of symbols to awaken ideas and feelings about the past. The word commemoration derives from Latin (*com* (together) + *memorare* (to remember): to remember together). Remembering together occurs in every sphere of life—family, association, occupation, community, and society—but its dynamics are most visible in the

largest, societal, sphere. Commemoration is society's moral memory, distinguishing events its members believe to be deserving of remembrance from those deserving of being merely recorded. Commemoration promotes society's sense of itself by affirming its members' mutual affinity and identity.

1. Commemorative Symbolism

Commemoration is based on the premise that historical meanings can be represented by means of objects and rituals, including scripture, icons, music, monuments, shrines, naming conventions, and ritual observances. These 'cultural objects,' embodying the meaning of the past in physical form (Griswold 1987), cover the social landscape:

(a) Commemorative scripture includes biographies, eulogies, poems, plays, and commentaries. Defining the moral rather than factual aspects of the past, commemorative texts are hagiographic and thus distinguishable from analytic history and chronicling.

(b) Music, consisting of anthems, hymns, and inspirational songs, aligns melodic and harmonic structures and lyrics to historical events in such a way as to dramatize the nature and extent of their significance.

(c) Icons, signs resembling what they represent, commemorate the past by bringing it to visual presence through paintings, statues, prints, photographs, motion picture film, and videotape.

(d) Monuments, including obelisks, antique temples, and war memorials, are designed to elevate the public imagination through grand structures bearing dramatic reference to grand events.

(e) Shrines—including birthplaces, residences, places of death, headquarters—play a key role in commemoration because they bring the individual into direct contact with sacred objects. Shrines are sacred because they are, by definition, 'containers' of relics (*scrinium* (case, chest)) associated with great events or used by great people.

(f) Naming practices make the past ubiquitous by incorporating its memory into the identity of businesses, streets, cities, towns, counties and states, rivers, and mountains.

(g) Commemorative observances (periodic performance of anniversary, centennial, and holiday rites) have been analyzed more extensively than other mnemonic forms, but their functions are no different: to maintain the vitality of the past, to prevent it from being forgotten and to revive what is essential in the collective consciousness. Through commemorative observance:

> the group periodically renews the sentiment which it has of itself and of its unity; at the same time, individuals are strengthened in their social natures. The glorious souvenirs which are made to live again before their eyes, and with which they feel they have a kinship, give them a feeling of strength and confidence; a man is surer of his faith when he sees to how distant a past it goes back and what great things it has inspired (Durkheim [1915] 1965, p. 420).

Commemorative observances, together with scripture, music, icons, monuments, shrines, and naming practices, comprise sign systems representing past events, recommending them as being worthy of contemplation, affording individuals a common legacy and identity by making history tangible and accessible to all.

2. Commemorative Networks

The combination of commemorative symbols conveys meanings that differ from meanings conveyed by any one symbol. To activate the commemorative process through story, song, icon, ceremonial observance, or other symbolic forms, therefore, is to activate memories that include but extend beyond the persons and events commemorated. Commemoration works by constantly pairing symbolic objects with one another, and the significance of historical figures and events change as they are placed in commemorative networks composed of new objects absent in previous networks.

During the Progressive Era (1900–1920), for example, visual images of George Washington were paired with contemporary and historical figures, including Theodore Roosevelt and Woodrow Wilson, with whom he could have had no actual contact. Commemorators identified him as one who would have supported Progressive Era reforms. In Washington's own political values, in fact, they found progressivism's roots. They named him the first Progressive and contrasted him with selfish businessman of their own time. The pairing processes fanned out broadly not only within a network of people whose prestige enhanced and was enhanced by Washington's, but also to networks of events and structures (notably, political and economic reforms and relentless condemnation of plutocracy). In such mnemonic webs, existing beliefs about Washington were organized, their institutional roots deepened, and a new and autonomous collection of beliefs about him accumulated. Common features of people and events with which Washington was symbolically connected were generalized to Washington himself. In this way, Washington changed through the nineteenth century from a conservative symbol of the social and economic status quo in to a liberal symbol of social and economic reform.

Commemoration, as Washington's case suggests, is a structuring process that partially overrides the qualities of its objects and imposes upon them its own content. The key to this process is not the mere act of pairing or coupling one historical actor with another;

it is the attribution to one actor of qualities of other individuals located in the same network of memory. Commemoration is creative because it fills in what is lacking in its objects, whether historical figures or events, by attributing to them the qualities of other figures and events deemed similar.

3. *Commemoration, History, and Collective Memory*

Commemorative symbolism is distinguishable from the historiography on which it is based. History, as French sociologist Maurice Halbwachs ([1950] 1980) defined it, seeks an objective standpoint to assess the sequence, importance, mutual relations, causes, and consequences of past events. It is 'situated external to and above groups' and looks to the past independently of their immediate problems and concerns. Once established, Halbwachs believed, historical knowledge remains stable—its stream of facts and demarcations 'fixed once and for all.' In contrast, commemoration remains significant only so long as it remains relevant (pp. 80–1).

Traditional societies possess no history. History emerges as tradition ends, social memory fades, and commemorative symbolism loses credibility. Early Christian leaders, for example, read historical chronicles, but their followers were illiterate and had no conception of 'historical preoccupations such as we think of them. … Their memories were tied to rites of commemoration and adoration, to ceremonies, feasts, and processions' (Halbwachs [1941] 1992, p. 222).

Pierre Nora, a French historian, shares Halbwachs' belief in the ultimate opposition between history and commemoration. Analytic history, according to Nora, deconstructs the sacred past; the *lieux de mémoire* (sites of memory) reconstruct it. *Lieux de mémoire* are ubiquitous and comprise every type of commemorative sign: not only monuments and shrines but also flags and anthems, sanctuaries and ruins, statues and busts, portraits and history paintings, coins and medallions, holidays and rituals (Nora 1997).

Two paths lead to two different notions of the past. History disenchants the past; commemoration and its sites sanctify it. History makes the past an object of analysis; commemoration makes it an object of commitment. History is a system of 'referential symbols' representing known facts about past events and their sequence; commemoration is a system of 'condensation symbols' (Sapir 1930, pp. 492–3) expressing the moral sentiments these events inspire. History, like science, investigates the world by producing models of its permanence and change. Commemoration, like ideology, promotes commitment to the world by producing symbols of its values and aspirations (Geertz 1973, pp. 193–233). The contrast between history and commemoration is not entirely clear cut. History always reflects the ideals and sentiments that commemoration expresses; commemoration is always rooted in historical knowledge. Commemoration is intellectually compelling, therefore, when it symbolizes values whose past existence history documents; history is morally compelling when it documents events that can be credibly commemorated. Analytic history and commemorative symbolism are interdependent constituents of collective memory.

4. *Theories of Commemoration*

Multiculturalism, postmodernism, and hegemony theory, each prominent in the intellectual environment of the 1980s, shaped the agenda for recent debates over commemoration and history. Whether commemoration is a process of construction or retrieval, contested or shared, a mirror reflecting the concerns of society or a lamp of practical guidance and moral precedent, a system of social attachment or social control—on these and related issues two theories have been brought to bear.

4.1 *The Politics of Commemoration*

In the theory of the politics of memory, commemorative activities appear as contests among differently empowered communities. Producers of commemorative symbolism, ('reputational entrepreneurs' (Fine 1996)), manipulate the attitudes of their audience in the service of society's privileged strata (Gillis 1994). The 'invention of tradition' was as a mode of social control during Europe's democratic revolutions (Hobsbawm and Ranger 1983); state histories and counter histories performed a similar control function in many authoritarian nations, while 'official' and 'vernacular memory' in the United States supported the interests of the elite and the masses respectively (Bodnar 1992). The second strand of the politics of memory literature assumes that power is diffused rather than concentrated and that commemorative objects emerge out of a context of cross-cutting coalitions, networks, and enterprises rather than a ruling elite's interest in maintaining its privilege. The fate of artistic and presidential reputations, Holocaust memories, place-naming and monument-making, and the organization of museums exemplify commemoration's role in pluralistic networks of interest and power (Olick and Robbins 1998).

4.2 *Commemoration as a Cultural System*

The theory of the politics of memory conceives commemoration as a reflection of power distributions, assuming that different elements of the past become

more or less usable as resources of various groups fluctuate. Commemoration thus appears to be made and remade in the service of changing interests and needs. The theory of memory as a culture system, in contrast, conceives commemoration as a pattern of symbolic forms that articulate present experience and perpetuate present understandings of the world. Commemoration, in this theory, is less a construction of a manipulative interest group than a symbolic frame in terms of which people confer meaning on their experience and find direction for their conduct. Reputational entrepreneurs (Fine (1996)), thus, perform more like priests than like manipulators, seeking to reaffirm beliefs they share with their audience. Accordingly, commemoration is not only a model *of* society—a reflection of its needs, interests, fears, mentality, and aspirations—but also a model *for* society—a program defining its values and goals and a frame organizing and assessing the moral significance of its experience. Commemoration affects social reality by reflecting, shaping, and framing it.

The distinction between commemoration's mirroring and modeling functions is analytic, not empirical: both aspects are realized in every act of remembrance. Commemorative objects must reflect current problems before they can program ways to deal with them, for people cannot be oriented by a past in which they fail to see themselves. It is commemoration's relevance as a model, however, that renders it a useful mirror, for people have no reason to look for themselves in a past that does not already orient their lives.

The coexistence of commemoration's modeling and mirroring functions is evident in its use. When Abraham Lincoln ran for the presidency, for example, Republican organizers 'campaigned down' to the people by mirroring their preferences with symbols of railsplitting and the frontier; but when Lincoln assumed the presidency, his supporters, wishing to portray him in a more dignified light, modeled his image after George Washington. They produced portraits of Lincoln gazing at a bust of Washington or standing beneath or next to Washington's portrait in the presence of familiar symbols of state. Lincoln himself launched military offensives on Washington's birthday and regularly compared his situation with Washington's. When Lincoln died, eulogists keyed his memory to that of Washington; mourners placed portraits of Washington beside his coffin and purchased prints showing Washington welcoming him into Glory. People commemorated Lincoln, as they did other actors and events, in ways that affirmed their values and enriched their lives, enabling them to comprehend and cope with a complex world and to render their experience meaningful. Lincoln's image was in turn modified by these new modeling and mirroring connections. Pairings of Washington's and Lincoln's images, as Emile Durkheim ([1915] 1965) would have said, 'do not confine themselves to revealing the mental state with which they are associated: they aid in creating it' (p. 262). Commemorative structures thus conferred on Lincoln's images a meaning it would otherwise not have had.

5. *Negative Commemoration*

Traditional commemoration transmits positive images of the past. Negative commemoration, marking events weighing on the present generation as sources of shame and dishonor and articulating regret for harm inflicted, arose during the late twentieth-century in connection with the new recognition of minorities' entitlements. Every real community, as is now recognized, is a community of memory, one that retells stories about men and women who have exemplified its ideals and values. Such stories include not only tales of shared suffering that create strong bonds of identity but also tales of suffering wrongly inflicted. Defined by these premises are the new commemorative politics of regret, embodied in new American narratives revealing George Washington as slaveholder and Abraham Lincoln as colonizationist wishing to deport the slaves he emancipated, and new shrines, monuments, and museums marking the era of slavery, maltreatment of minorities, and unpopular war (Wagner-Pacifici and Schwartz 1991). As these new commemorative modes reflect the erosion of boundaries that once separated racial, religious, and ethnic groups and once justified aggression within and between nations, they affirm the state's recognition of the dignity of every citizen.

6. *Memory of Commemoration*

Commemorative symbols are neither direct portrayals of the events they commemorate nor products of the concerns of the generations creating them; they are parts of an ongoing process of meaning-making. Since commemorative symbols refer to the memory of their own genre, their meaning includes not only the event being commemorated but also how it has been commemorated elsewhere and in the past. In other words, commemorations are 'path dependent'—shaped by their development as well as their referents. Therefore, differences between commemorations are not just matters of the politics of the present; they reflect the forms and media available at different times. Earlier commemorations affect the availability of resources and forms required for present commemorations (Olick 1999). Conceived in light of their generic predecessors, war memorials can be critical as well as reaffirming. The Korean War Veterans Memorial, as originally conceived by a supervisory committee hostile to the Vietnam Veterans Memorial's antiwar inspiration, had to be uplifting, suggestive of honor, pride, and dignity, evoking admiration and gratitude rather than self-contempt and grief. It had to be utterly different from the Vietnam Memorial in design and message. The Memorial Committee re-

jected all designs failing to fulfill these requirements (Schwartz and Bayma 1999). Comparing commemorations in terms of the history of their genres helps to explain their differences and leads to deeper insights into the various ways society contemplates its past.

7. *From the Politics of Commemoration to the Semiotics of Commemoration*

Pulling together the threads of this summary, we see that knowledge of commemoration grows in spurts—a brace of writings in Europe during the first half of the twentieth century, then a period of quiet, then an eruption of theorizing and research during the last two decades of the century. Emile Durkheim was the first sociologist to study commemoration and commemorative rites systematically, but it was Maurice Halbwachs, Durkheim's student, who formulated the broader concept of collective memory and pioneered its empirical study in the 1920s and 1930s. Like other students of public knowledge and belief, Halbwachs was jaded by the intellectual climate resulting from the First World War's destructiveness. A branch of the sociology of knowledge, the sociology of memory took root in a society where common values had eroded, large groups of people had become alienated from their own traditions as well as one another, and distrust infected all human relations. Halbwachs systematized doubt about the customary frames for understanding the past and the customary symbols for commemorating it.

Still an object of distrust and struggle, commemoration is widely conceived as a mask concealing the interests of the powerful; yet, this conception has new meanings because it is part of a new cultural environment. The 1960s and 1970s were years of disillusionment resembling those through which Europe passed when Halbwachs was writing. It was an era in which 'conflict theories' of social order replaced 'consensus theories,' an era in which traditional accounts of the past, as of everything else, were repudiated. Three overlapping intellectual perspectives—multiculturalism, postmodernism, and hegemony theory—articulate the connection between the cultural revolution of the 1960s and 1970s and contemporary interest in the 'construction' of the past, and these three perspectives still animate the politics of commemoration. During the last decade of the century, however, a new research trend arose, not replacing but superimposing itself upon and insinuating itself into the theory of the politics of commemoration. The 'New Structural Memory,' as Kerwin Klein (2000) calls it, arose in the United States and Europe, emphasizing texts and symbols and de-emphasizing older notions of memory based on the beliefs, attachments, hatreds, and fears of individuals. Michael Schudson's *Watergate in American Memory* (1992) was one of the first efforts to define explicitly The New Structural Memory, suggesting that perception of the past is not, as has been regularly assumed, a property of individual minds but is rather social, located in and shaped by tangible and even countable things—books, records, holidays, statues, souvenirs—in short, a varied and everchanging assemblage of mnemonic objects. 'Structural memory' has, in fact, less to do with structures than with the devices by which commemoration addresses the problem of meaning. Social scientists at the turn of the twenty-first century focus more intensely on this problem—commemoration as a source of cognitive and moral orientation, inspiration, consolation, and purpose—than ever before. The semiotics of commemoration is taking its place beside the politics of commemoration.

8. *Conclusion*

The meaning of commemorative symbols derives from their relationship to other symbols and symbolic patterns. Historians, it is true, also combine previously discrete units of knowledge to produce new understandings; but they do so within a methodological framework that defines proper and improper uses of evidence. In many places (mainly but not only in non-Western nations), historians trained in critical historiography still accede to pressures to produce gratifying images of the past (Shils 1981, pp. 54–62), but even in these nations history and commemoration, like science and ideology, remain different lines of work (Geertz 1973, p. 231): the former combines evidence, however selective or biased, to justify belief; the latter combines symbols to sanctify belief.

Commemoration and history are different but not separate lines of work, which is why they must not be radically distinguished. Commemoration 'requires the support of groups delimited in time and space' while history remains relatively autonomous (Halbwachs [1950] 1980, p. 84); yet commemoration cannot always be dismissed as a distortion of history. Commemoration is based on some invention and much exaggeration, but it is also constrained by the historical record: materials of the 'invented' past include facts as well as biases and interests. In democratic societies, at least, where all commemorative interpretations are open to criticism, constructions of the past must be undertaken within the limits of reality—limits no one can ignore without cost (Schudson 1992, pp. 205–21). Since the commemorative process starts with historical reality and improves it by de-emphasizing the inessential and emphasizing what is necessary to round out the ideal, commemorative networks do not deny history; they valuate history; they identify and lift morally significant events out of the historical continuum and set them apart from and above ordinary ones.

If the relevance of the past should erode, however, what would be the fate of commemoration? The

relevance of the past has diminished during the late twentieth century on two levels. First, the individual's connection to his or her society and its past is weakened by the discrediting of its metanarratives—its great legends and myths. Since the key feature of metanarratives is embodied in a plot structure that interprets events in a way that can be widely understood and shared, people require them, collectively and individually, to make sense of experience. 'Of what great story is my life and death a part?' is the question they ask in their effort to define themselves and the meaning of their lives.

Second, as the stories that society tells about itself are discredited, the orienting past tense of the individual's life is negated. Thus, 'pure and unrelated presents in time' and momentous 'psychohistorical dislocations'—erosion of the bond that once linked men and women to vital symbols of their cultural tradition—are at the core of contemporary temporality (Jameson 1984, pp. 480–1, Lifton 1993, pp. 14–17). That diminished engagement with the past distinguishes the postmodern era is a reasonable claim; however, the adjective 'diminished' must be underscored, for 'diminishings' are more difficult to describe and comprehend than disappearances. The role of commemoration is an ambiguous role defined by a 'residual' pattern of reverence and a 'dominant' pattern of affectively neutral admiration for the past and an 'emergent' pattern of indifference (Williams 1987). At question is whether the residual pattern is destined to disappear or whether it remains because it is not residual at all, but rather because it represents a fundamental requirement of society.

As residual patterns of belief often reflect efforts to renew ties to a past that emergent patterns challenge, we witness in the United States a great surge of monument building, beginning in the 1980s—the very decade in which revisionist history (conceding only the sins of the American narrative to be grand) matured. Thus, the millions who continue to admire historical achievements, seek information about them, and commemorate them, include those driven by currents of reaction against the erosion of the past and of tradition.

Commercial Banking

Commercial banks traditionally have performed three primary functions: they held time deposits (savings accounts), demand deposits (checking accounts), and they issued credit, primarily to firms but also to individuals. But commercial banks have played other roles as well, from the underwriting of securities to

providing a range of fee-based financial services to corporations. They have also been significant players in a range of national and international business communities, and their degree of power and influence in these communities has been the source of major controversy among scholars. More recently, a series of rapid changes have occurred in the commercial banking world that have raised questions about whether this institution will remain a distinct corporate form. In this article, research by social scientists on commercial banks is examined, focusing on their relations with nonfinancial corporations. Given the significant cross-national variation among banking systems and the legal environments within which they operate, emphasis will be primarily on the United States, although non-US examples will be referred to at various points.

1. *Financial Systems and Commercial Banks*

Zysman (1983) has suggested that there are two types of system into which most of the industrialized capitalist countries fall. In credit-based systems, such as those in France, Germany, and Japan, banks are the primary providers of long-term capital, and are permitted to own and vote stock in nonfinancial corporations. In capital market-based systems, as in the UK and the USA, securities issues (stocks and bonds), handled primarily by investment banks and insurance companies, are the principal sources of long-term debt, while commercial banks specialize in short-term debt. Gershenkron (1962) noted that the capital market-based systems are associated with relatively early industrialization while the credit-based systems are associated with later industrialization. Banks historically have played a particularly dominant role in the credit-based systems. But although there is no comparable period of bank influence in Britain, there have been periods of bank ascendance in the USA.

2. *The Rise of Commercial Banks: The United States, Germany, and Japan*

American commercial banks arose shortly after the Revolution, as businesses began to specialize and international trade expanded (Chandler 1977, pp. 28–31). The number of banks increased rapidly after 1790, to more than 200 by 1815. An important event in the development of American commercial banking occurred in 1832, when President Andrew Jackson refused to support a bill to recharter the Second Bank of the USA, a bank of national scope that had 22 branches located in several states. Three decades later, the National Bank Acts of 1863 and 1864 outlawed branch banking altogether (Roe 1994, pp. 54–9), and it was not until 1927 that American banks were allowed to branch even within states (Roe 1994, pp. 94–5). The resulting, relatively decentralized, commercial banking system is distinct from more centralized systems such as the one that developed in Germany in the late 1800s.

Despite antibranching laws, the leading US commercial banks became increasingly concentrated in the late nineteenth and early twentieth centuries. During this period, corresponding with socialist movements in Europe, and progressive and populist movements in the USA, a major chorus of analysts and critics emerged on both continents. In Europe, Rudolf Hilferding produced a Marxist analysis of what he called 'finance capital,' the domination of the German economy by a handful of leading banks. Bank power in both the USA and Germany emanated from the rapid growth and consolidation of industry, in which companies were increasingly dependent on the financing that the banks provided. The concentration of banking, and the alliances among the banks, made it difficult for nonfinancial corporations to leverage banks against one another, further increasing the banks' power. The American economy was dominated by a relatively small number of financiers who forged constellations of investment and commercial banks, leading industrial firms, and railroads. Louis Brandeis, in his classic *Other People's Money*, focused on investment banks as the centers of power during the period, but investment and commercial banks were not always easy to distinguish. Investment banks were permitted to hold deposits, and commercial banks were permitted to underwrite securities. Members of these alliances sat frequently on the boards of directors of multiple, nominally competing, financial institutions. George F. Baker, an ally of J. P. Morgan, sat on the boards of three banks and an insurance company.

Both German and Japanese banks developed later than those of the USA, beginning in the 1850s in Germany and the 1870s in Japan. By the beginning of the twentieth century, however, a handful of German and Japanese banks had become dominant actors in their respective economies, standing at the head of groups of companies, thus equaling or exceeding the power of American banks. The overwhelming power of the US banks began to ebb after 1912. The Clayton Act of 1914 outlawed director interlocks between competing firms, leading to a sharp decline in formal ties among the banks. The leading financiers of the period either died or retired, and although many transferred control to their sons or hand-picked successors, these second-generation leaders did not possess the power that their elders had enjoyed. Paradoxically, however, although US commercial banks suffered during the Great Depression, investment banks were more seriously affected.

A turning point was the Glass–Steagall Act of 1933, which forced commercial banks and investment banks to separate their activities. Commercial banks were

prohibited from underwriting securities, and investment banks were required to give up their deposits, which had been their primary source of capital. This set the stage for what some observers argue was a resurgence of bank power in the post-World War II period.

Although World War II severely disrupted both nations' economies, German and Japanese banks did not experience a similar decline in power. One reason for this is that, in Germany and Japan banks are permitted to hold equity in nonfinancial firms. Partly as a consequence of this, and partly because there was no equivalent to Glass–Steagall, banks in Germany and Japan have been considerably more involved than US banks in firm policy making. After World War II, the American occupational forces broke up the Japanese *zaibatsu* (business groups) but left the leading banks intact (Gerlach 1992). The German economy recovered quickly after the war and a small number of major banks remained dominant. Although most observers believe that German banks remain more powerful relative to industry than banks in the USA, there is now some controversy over how dominant their role is (Ziegler et al. 1985).

3. *Capital Dependence and Bank Power*

American commercial banking is stratified informally into national, regional, and local sectors. The national banks are led by a relatively small number of major money-center banks located primarily in New York but also in financial centers such as Chicago and San Francisco.

In recent years, as commercial banking has undergone major changes (described below), banks in areas such as Charlotte, North Carolina have emerged as among the largest. The national money-center banks are typically the leaders of major lending operations for the largest nonfinancial corporations. Regional and local banks, which make up the vast majority of US commercial banks, focus primarily on lending to mid-sized and small businesses.

Although the early American commercial banks were involved in long-term lending, US commercial banks generally have specialized in short-term notes of less than one year. Insurance companies have focused on long-term private debt, while investment banks have focused on the placement of long-term public bonds. A study by Go (1999) has shown that American commercial banks became more heavily involved in term loans of 1 to 10 years during the 1930s. Even prior to that, some large banks were involved in bonds as well as loans of up to 5 years. Given commercial banks' role as a source of corporate external financing, a number of scholars have assumed that their power over nonfinancial corporations was a function of the degree to which the latter were dependent on external financing. In their classic work, *The Modern Corporation and Private Property*, Berle and Means (1939) argued that the increasing profitability of large US corporations generally freed them from dependence on banks because firms were able to finance their investments with retained earnings. This view was accepted by the vast majority of social scientists into the early 1970s. The evidence for this argument was equivocal, however. A study by Lintner (1960) suggested that the use of external financing by American firms did not decline between 1925 and 1955. Stearns (1986) showed that the use of external debt financing by USA firms was at relatively low levels in the post-World War II period but that it began to increase around 1965, remaining relatively high into the early 1980s.

The evidence on the increasing use of external financing corresponded with a renewed focus on the power of commercial banks. This came from two sources. First, although unlike banks in Germany and Japan, US commercial banks had been prohibited from directly owning equity in other firms by the National Bank Act of 1863–4, in the post-World War II period they became increasingly active in managing corporate pension funds through their trust departments. As part of their fund management, banks invest in corporate stock, on which they have voting rights. A Congressional investigation in the 1960s led by Representative Wright Patman revealed individual bank trust department holdings of 5 percent or more in nearly 30 percent of the 500 largest USA industrial corporations. Despite some heavily publicized cases, it is unclear whether the banks actually used these holdings as leverage over corporate policy, as is believed to occur outside the USA, especially in Germany. Useem (1996), however, has suggested that institutional stockholders have become increasingly active in voicing their views to managers in recent years.

A second possible source of bank power was corporations' increased use of external financing. Mintz and Schwartz (1985) have argued that, given its value as a generalized resource, banks' control over capital has given them a broad 'hegemony' within the larger business community. Although they are rarely actively involved in company decision making, Mintz and Schwartz suggest that the banks are able to make broad policy decisions about the allocation of capital within the economy. As their evidentiary base, Mintz and Schwartz describe several examples of bank intervention in the affairs of nonfinancial firms. In addition, they show that the major commercial banks were the most central firms in the networks of director interlocks that span the leading US firms, a finding that has been replicated repeatedly across studies and over time (Mizruchi 1996). One could argue that the use of external financing does not ensure automatically that firms are dependent on banks. On the contrary, borrowing contains both tax benefits and, when interest rates are low, cost benefits. A study by

Mizruchi and Stearns (1994) shows, however, that even when controlling for the cost of capital, when retained earnings are high, borrowing tends to decline, and vice versa. This suggests, consistent with the arguments of a number of economists, organizational scholars, and sociologists, that firms will tend to avoid borrowing from banks if they have sufficient amounts of cash.

It is important to note that these same phenomena—reliance on external financing, ability to vote stock, and centrality in corporate interlock networks—have been used to suggest the power of financial institutions in the German and Japanese contexts. Gerlach (1992) argues that although Japanese firms became better able to finance investments with retained earnings in the postwar period, they remain heavily dependent on banks. Zysman (1983) suggests that German banks' control over virtually all sources of external financing, loans, bonds, and equity, along with their high direct equity holdings and willingness to use them gives them a high degree of leverage.

4. *Major Recent Changes in Commercial Banking*

Mintz and Schwartz's argument seemed to fit the German and Japanese cases quite well, but it was intended to apply to the USA. Although its applicability to the American case was always controversial, the argument was consistent with a considerable amount of evidence. Bank involvement in institutional stockholding had increased significantly since the 1950s, nonfinancial corporations' use of external financing had increased since the mid-1960s, and banks remained the most central firms in the corporate network from the early 1900s into the 1980s. Beginning in the early 1980s, however, a series of events occurred that altered the nature of commercial banking radically. Rapid changes in technology and the regulatory environment led corporations to reduce their reliance on banks for capital, as firms turned increasingly to direct borrowing through the issue of commercial paper. By 1994 the value of outstanding commercial paper in the USA equaled that of outstanding debt to commercial banks.

Meanwhile, the proliferation of alternative sources of savings and investment such as mutual, pension, and money market funds led individuals to reduce their deposits in commercial banks. In response to these losses, the largest commercial banks turned increasingly to high-risk lending, leading to several major bank failures and near-failures in the late 1980s and early 1990s. Both the number of commercial banks and the proportion of corporate debt acquired from commercial banks declined by one-third between 1979 and 1994 (Davis and Mizruchi 1999, p. 220). Large commercial banks responded to the loss of their traditional franchise by shifting their focus away from lending (especially domestic lending, which was no longer profitable) and toward financial services such as capital market services, foreign currency exchange, and derivatives. They also participated increasingly in securities underwriting, as legislation and lax enforcement slowly chipped away at the Glass–Steagall provisions. The largest commercial banks came increasingly to resemble investment banks. Bank profits, which had declined sharply in the late 1980s and early 1990s, rebounded by the mid-1990s. Both of these changes in bank strategies have had the effect of altering the social role of commercial banks within the American business community. As Davis and Mizruchi (1999) document, the largest banks reduced substantially the number of executives of major corporations appointed to their boards, thus losing their place at the center of the interlock network.

Two major developments of the late 1990s raise questions about the future of commercial banks as distinct entities. In April 1998, Citibank, the largest US commercial bank, announced a merger with Travelers Insurance, whose units included the investment firm of Salomon Smith Barney. This new megafinancial firm, called Citigroup, became the first corporation since Glass–Steagall openly to blend commercial and investment banking as well as insurance underwriting. In October 1999, the US Congress and the Clinton Administration reached an agreement and repealed the Glass–Steagall Act. The new legislation will allow financial corporations to offer a full range of services, from traditional lending to public stock offerings (*New York Times* October 23, 1999, A1, B4).

5. *The Future of Commercial Banking*

Given the tidal wave of changes occurring in the financial world at the the beginning of the twenty-first century, it is difficult to know whether commercial banks will continue to exist. Both the efficiency and control benefits of combining financial services under a single roof suggest that US commercial banks will move toward mergers with investment banks and other financial institutions, making them more like the 'universal banks' that exist in Germany and other countries. Of special interest to social scientists will be the extent to which these combinations lead to a resurgence in the power of US financial institutions. Regardless of the level of bank power from the beginning of the twentieth century to the early 1980s, it is undeniable that commercial banks became significantly less influential during the 1980s and 1990s. The effect of this anticipated integration of financial corporations on relations between financial and nonfinancial corporations will be an interesting process to observe.

Commodity Chains

Commodity chains follow specific commodities as they are moved over space to connect production with consumption. Commodities are seen as originating in regions of production and moving through networks of economic agents, as with producers, distributors and transporters, to regions of consumption. The commodity chain concept has potential for demonstrating the effects of consumption on labor and the environment. Armed with greater geographical knowledge, organized around the commodity chain concept, consumers can make choices that more fully consider the effects of consumption on workers and the natural environment.

1. Conceptions of Commodity Chains

Since the middle 1970s there has been a resurgence of interest in space conceptualized not as a homogenous expanse of territory, but as channels, networks, nodes and chains of connection. In economic geography the main interest resides in investigating the spatial organization of business networks (Yeung 1994). Related to this interest, commodity chain analysis differs in that analysis focuses on the commodity, rather than industrial organizations or networks of inter-firm relations. The geographical literature contains numerous references to concepts similar to commodity chains. For example, Harvey (1989, p. 101) implies the notion of a commodity chain in arguing the importance of knowing the effects of consumption on the conditions of production: 'We can take our daily breakfast without a thought for the myriad of people who engaged in its production. All traces of exploitation are obliterated in the object.' However, the commodity chain concept only began to be used formally in the middle 1980s. Three versions of commodity chain analysis can be discerned: global commodity chains, systems of provision, and commodity circuits. These versions have recently been criticized as limited in scope and applicability, and an expanded commodity chain concept proposed.

1.1 Global Commodity Chains

The notion of commodity chains has been developed in the world systems approach in sociology with extensions in the literature of economic geography (Hopkins and Wallerstein 1986 and Gereffi 1994). As characterized by the world systems approach, a commodity chain refers generally to a network of labor and production processes whose end result is a finished commodity (Hopkins and Wallerstein 1986, p. 159). Gereffi and his co-workers see inter-organizational networks linking households, enterprises, and states to one another within the world economy (Gereffi et al. 1994, p. 2). Global commodity chains stress the organizational scope of transnational production arrangements, that is the linkages between economic agents, such as raw material suppliers, factories, traders, and retailers. In this view, commodity chains have three main dimensions: (a) an input-output structure, in the sense of a set of products

and services linked together in a sequence of value-adding economic activities; (b) territoriality, as with spatial dispersion or concentration of production and marketing networks; and (c) a governance structure, in terms of authority and power relationships that determine how financial, material, and human resources are allocated and flow within a chain.

Two distinct types of governance structure are distinguished: producer-driven and buyer-driven commodity chains. In producer-driven commodity chains, transnational corporations or other large integrated industrial enterprises control the production system. In buyer-driven commodity chains, large retailers, brand-named merchandisers, and trading companies set up decentralized production networks in exporting countries, typically in the Third World. The latter pattern of trade-led industrialization is common in labor intensive, consumer goods industries such as garments, footwear, toys, household goods, consumer electronics, and a wide range of handcrafted items, such as furniture or ornaments. International contracting is generally carried out by independent Third World factories making finished goods, rather than components or parts, under original equipment manufacturer arrangements, and with specifications supplied by the buyers and branded companies that design the goods (Gereffi 1994, p. 219–22). In these studies firms comprise the main unit of analysis and unequal distributions of wealth along the chain are explained as outcomes of firm competition and innovation.

1.2 Systems of Provision

A second approach to commodity chain analysis derives from Fine and Leopold's (1993, p. 600) rejection of horizontal analyses of consumption that stress commodification and aestheticization connected with retailing, and their favoring, instead, of the vertical dimension of the system of provision—the commodity-specific chain connecting production, distribution, marketing, and consumption, and the material culture surrounding these elements. Different systems of provision result from distinct relationships between material and cultural practices spanning the production, distribution, and consumption of goods (Fine and Leopold 1993). This perspective allows for a more dynamic consideration of consumer behavior in economic transformations within advanced capitalist economies.

Some accounts argue that production is now consumer-driven (Piore and Sabel 1984), while others emphasize technological change or regulatory institutions in producing economic change (Harvey 1989). It has been argued that both sets of literature inadequately conceptualize consumption, and that a system of provision approach allows for a more balanced treatment of the relationships between production and consumption (Leslie and Reimer 1999, p. 405). Fine and Leopold (1993, p. 28) also recognize the changing relationships between the symbolic meanings of goods and their physical contents. Thus it is important to trace not only commodity movements over space, but also the discourses and representations operating in systems of provision.

1.3 Commodity Circuits

A third approach to commodity chain analysis, tracing commodity circuits, combines work in the political economy tradition with ideas derived from post-structural social theory. The notion of a circuit of culture has been used in examining the ways geographical knowledge of commodity systems is shaped and reshaped and in showing how particular cultural artifacts move through the circuit. Unlike the notion of a chain, circuits have no beginning or end, but instead Cook and Crang (1996) envision dense webs of interactions between all sites, with commodities interrelating with other goods as they travel. Rather than privileging one site, such as production, in interpreting the meaning of a commodity, explanation lies in combining a number of different processes. An appropriate politics of consumption recognizes the fragmentary and contradictory nature of the knowledges through which commodity systems are imagined (Cook and Crang 1996). Rather than assuming that consumers have little awareness of the quality and geographical origins of commodities, this approach sees commodity circuits constructed and reconstructed through consumer knowledge. This view might be criticized for eventually abandoning the concept of a chain altogether and for neglecting ideas of consumer resistance and activism (Leslie and Reimer 1999).

2. Recent Tendencies in Commodity Chain Analysis

Although useful in terms of conceptualizing the connections between firms and actors across space in the production of final outputs, these versions of the commodity chain concept fail to connect the sign of the commodity at the consumption end with labor and the natural environment at the production end. In not following through at the consumption end, world systems theory misses a vital opportunity to connect commodity chains with advertising, popular culture, and the geography of consumption. By not tracing firms' activities back to the conditions of workers, economic geography reduces labor to being yet another input in the overall production process, divorcing economic analysis from the politics of production. By not rooting commodity production in the natural environment, all these approaches fail to connect with political ecology, an important emerging

area in critical theory (Peet and Watts 1996). Significantly, these instances of neglect occur at the most politically sensitive sites along commodity chains, preventing the concept from uniting, in a comprehensive politics, consumption, culture, labor, and nature.

2.1 Expanded Version of Commodity Chains

In a more complex model of commodity chains, the effects of the commodity at the consumption node, the social and natural conditions at the production node, and the complex intersections of commodity chains at various intermediating and terminal points, are added to a simple model of commodity movement. This expanded version integrates the generation of cultural (signifying and representational) effects at the consumption node with the social and natural conditions at the production end of the chain, the purpose being to show the effects of one on the other, bringing home to consumers the results of consumption. In contrast to earlier theories, this expanded formulation sees commodity movements (the vertical dimension) connecting nodes that are conceived as places (horizontal dimensions) located at different positions along commodity chains. This emphasis on place lends the analysis potential for bringing together several aspects of the production and consumption of commodities. In this vein, the commodity chain is posited as a way of tying together material and signified realities, consumption and production, and activities separated by space, providing a fuller interpretation of the material world and the real, human actors who live in it (Hartwick 1998).

2.2 Consumption Nodes

At the terminal nodal point of consumption, the radiating image of a commodity produces a halo effect of socially constructed meanings. Such meaning systems can be analyzed in a number of ways, including the aesthetics of representation and consumer taste. The preferred theoretical tradition is the semiotics of Peirce (1931–5). In such a materialist social semiotics, a commodity has two meanings: a first-order meaning at the level of function; and a second-order imputed meaning at the level of symbolic effect. Semiotic analysis tries to reveal the social prescription of the meaning of a commodity. In a postmodern sign economy, first-order meanings, based in physical needs, have been transformed into second-order representational meanings, emanating from social status and cultural allusion (Gottdiener 1995). However, for a complete explanation, the conditions of production must be included within social semiotic analysis. Stark contrasts in material and cultural conditions so intensify second-order symbolic meanings that they mutate into a third, specifically geographical, meaning-form. Images are usually added to commodities at, or near, the organizational centers of global trading systems, where the producers of sign value share the cultural norms of the consumers. Underdevelopment, unequal exchange, profit flows and power differences, vastly different conditions of life, must be hidden behind the image of the commodity to give the impression that consumption is effortless and has no negative side effects. In general, adding social semiotics to commodity chain analysis expands the horizontal analysis of commodities at the consumption end and creates awareness of vertical linkages to producers (Hartwick 1998).

2.3 Production Nodes

The conditions of production at the other terminus of the commodity chain include the social relations of production, and also relations between workers and families, hence the reproduction of the household. This, in turn, consists of social relations of reproduction (gender, class, ethnicity) and social relations with nature, including the worker-family's reproductive use of subsistence land and resources. The complete set of the conditions of existence of the producers, and the full range of natural conditions of production that enter into the materiality of the commodity, and pass thereby into the distant bodies of consumers, are explored.

2.4 Commodity Bundles

Commodity chains articulate one with another at various nodal points of the intersection of their pathways. At the production end, commodities of prime significance form the conditions of existence for secondary commodity chains. At other significant nodes, processing points in particular, chains converge into commodity bundle that make up imaged complexes entering the consumption node—the entire complex combines to signify status, wealth, and power through radiating interconnected significations. As Glennie and Thrift (1993, p. 605) note, any commodity chain is characterized by leakiness, in both material and symbolic ways, which influences other commodity chains—they catalog the intertwining between commodities, advertising of linked products, consumer reflexivity, and consumption across several commodity systems. Nodes of consumption are thus points of convergence for series of imaged complexes of commodity chains. In this last sense, each purchase in the market is seen as culminating in an entire complex of commodity production and representation, linking together several lines of waged workers, unwaged reproducers of waged workers, and natural resources.

3. Commodity Chains and the Politics of Consumption

Geographical analysis centered on commodity chains connects the generation of cultural (signifying) effects within consumption to the real and material (social and natural) conditions involved in production. Deconstruction, understood in a geographical and materialist sense, uncovers these hidden dimensions of the commodity sign. Moving to a geographical focus on place broadens commodity analysis giving it greater political potential as a critical tool. Using this device, a series of local worlds are linked by connecting-chains into global systems. Commodity chains enable a greater awareness of the geographical implications of the political economy of consumption. Informed by commodity chain analysis, consumers learn to deconstruct, or critically analyze, the disconnected messages that bombard them by reconnecting images with material realities. Also the focus on people-in-places, as key nodal points along a commodity chain, broadens economic analysis so that social, cultural, and natural relations can be incorporated. This gives commodity chain analysis greater political potential as a comprehensive political tool. Formulated in this way commodity chains are said to constitute an analytical basis for a transformative politics (Hartwick 2000).

E. R. Hartwick

Common Law

The term 'common law' first comes into use in England during the thirteenth century. It referred to the 'common' repertoire of norms and understandings that had begun to be recognized across the whole realm during the latter half of the previous century as central government was becoming consolidated. These common understandings, which were seen to contrast with surviving customs of a simply localized character, became institutionalized as *law* as they were invoked to underpin the decisions of judges in the royal courts. So this evolving 'common law' claimed to represent the immemorial understandings prevailing in the social world, and was at the same time put to use as an instrument of rule by the courts as they developed into a distinctive branch of government. This primary sense of the term 'common law' has survived and continues in use, particularly as a means of contrasting this source from others which the English courts now draw on concurrently—'*statute*' and '*equity*.' However, the term has now acquired a general secondary sense in identifying the broader legal domain formed through the diffusion of English law under the process of colonial expansion. This common law world is contrasted with that occupied by the codified civil law systems of continental Europe directly inspired by Roman law.

1. Historical Development in England

While the common law is seen to originate in the everyday practices and understandings of the social world, its growth from the twelfth century took place in the context of dual, linked processes: the progressive

consolidation of central government, and the gradual emergence of a specialist legal profession. This growth was realized through the discursive formulation of 'law' in the pleadings of lawyers and the judgments given in the Royal courts. It was associated from an early stage, and remains associated today, with one primary assumption and a distinctive method. The assumption was that the common law sought to realize and secure the practices and understandings of everyday life (*immemorial custom*). The strength of this assumption can be illustrated through numerous examples, including: the continuing invocation of the *reasonable man* in arriving at the appropriate standard of care in respect of claims arising from civil wrongs (*tort*); the care taken to ascertain normal business practice in the area concerned when judging commercial disputes; and the deference accorded to the customs of conveyancers by courts dealing with property disputes. The method distinctive to the common law lay in the procedure under which lawyers recovered the rules to underpin their arguments, and judges to justify their decisions, from the records of earlier judgments. This procedure—the *doctrine of precedent*—was made possible by the maintenance from an early stage of semi-official written records (the *Year Books*) and subsequently sustained by private series of reports before official law reporting became institutionalized. Consistency in decision-making was reinforced by the understanding that courts should, wherever possible, follow their own previous decisions and were obliged to follow those of courts superior to them in the judicial hierarchy (the doctrine of *stare decisis*). This procedure can be contrasted with the mode of decision associated with the continental civil law world under which the judge seeks to ground a decision in an authoritative, ultimately codified, text.

These working practices which fashioned the common law were facilitated by the close relationship prevailing from medieval times between the judges and the specialist groups which ultimately became the legal profession. Notwithstanding the strong historical link between adjudication and the consolidation of government, in England there has never been a career judiciary. The higher ranks of the judiciary have been recruited exclusively from the legal profession, with appointment to the 'bench' representing the ultimate career stage of the successful lawyer. While some elaborate ritual, including the conferment of knighthood in the case of the higher judiciary, marks the transition from barrister to judge, and some formal distance is subsequently maintained between judges and their former colleagues, judges remain sociologically very much part of the professional group from which they emerge. They continue to belong to long-established networks of information exchange and support—often crossing generations—begun in the great private schools, continued at university, and subsequently prevailing in the collegiate groups to which barristers belong (the Inns of Court). So the courts can be just as easily seen as the apex of the legal profession as a specialized branch of government.

The common law, developed in the King's courts through resort, to precedent, has traditionally been contrasted with two other sources of law. The first of these has been described by legal historians as arising directly out of the formal working practices of the King's courts. These were characterized from an early stage by procedures requiring anyone who sought redress to bring the claim within one of a limited number of elaborate written formulas (known as writs). If some mistake were made in the pleadings, the claimant would be denied his remedy. Ensuing direct appeals for help to the King, which such apparent injustices gave rise to, led to the growth of a parallel remedial jurisdiction presided over by the Lord Chancellor. This jurisdiction—known as equity had a distinct body of doctrines, rules, and practices, and was long administered in separate courts.

Both the common law and equity evolved alongside, and are contrasted with, statute law—rules promulgated by the sovereign. While progressively larger areas have become at least partially regulated by statute—notably in the fields of crime, commercial law, and property—a comprehensive legislative scheme of the kind introduced through the great continental codes of the eighteenth and nineteenth centuries has never been attempted in England. This more limited role and reach of legislation provides a further contrast with the civil law regimes of continental Europe.

The 're-discovery' of Roman law in Italy during the eleventh century is generally presented by historians as having a limited effect on the growth of the common law in England, but England was in no sense isolated from this learning. Some of the clerics who accompanied William I to England were distinguished as scholars of Roman law, so Justinian's great *Digest* was well known there from an early stage. Holdsworth (1909) also makes it clear that Bracton, a senior judge writing in the mid-thirteenth century, used Roman law to fill the gaps left by his extensive repertoire of case histories. While Roman law provided part of the intellectual climate within which a unified legal order evolved in England during the mediaeval period, its use as a direct source was limited. Even during the English Renaissance, the legal historian Maitland (1907) notes that the common law was still characterized by 'an amazingly continuous persistence of medieval doctrine.' He attributed this durability to the presence of the collegiate groups—the Inns of Court—within which English lawyers associated. He saw the medieval Inns as 'schools of law' which provided arenas of communication within which young lawyers were taught and their seniors formulated a coherent repertoire of legal doctrine. He wrote. 'What is distinctive of mediaeval England is not parliament, for we may everywhere see in Europe assemblies of estates … but the Inns of Court and the Year Books that were read therein, and we shall hardly

find their like elsewhere.' By the time of the great continental codifications of the eighteenth and nineteenth centuries, which were closely informed by Roman law, the evolving understandings and practices of English judges and lawyers were already part of a largely autonomous, differentiated legal order. By then the common law tradition was too well set to be disturbed.

2. *Geographical Diffusion of the Common Law*

While originating in England, the common law has undergone wide diffusion as English settlers carried it with them abroad and government at Westminster imposed it upon annexed or protected territories in the course of colonial expansion. Across India, North America, Australasia, and considerable areas of Africa and Asia, the common law remains today a significant component, linking together a range of independent legal orders. Following the now ancient precedent of the USA, most former colonies have retained significant elements of the common law, justifying the shared label of 'the common law world.' But the sheer diversity of contemporary arrangements within this loose association inevitably makes any generalization hazardous.

English settlers establishing colonies overseas took with them the general law of England as it stood at the moment of first settlement. By this means, the common law was established as the foundational law of the USA and of those regions of what became the British Commonwealth which were subject to settlement. In these cases, very little recognition was initially given to the existing laws and customs of indigenous peoples. In those further territories which were conquered, annexed, or declared protectorates as the British colonial empire subsequently expanded, the statutes of general application, common law, and doctrines of equity in force in England at the time were typically imposed by Order in Council from Westminster. In these latter cases, notably in India and Africa, early recognition was given to diverse local legal orders encapsulated in the course of colonial expansion. In the case of Africa, this recognition extended to indigenous dispute institutions. Elsewhere, notably in Canada and Australasia, recognition of the prior arrangements of indigenous peoples was postponed well into the twentieth century.

Once English law, including its major common law component, had been received in a colony, it remained in force until repealed or modified by the local colonial legislature or courts—or by the overarching authority represented by Parliament at Westminster and the Privy Council (the ultimate appellate tribunal of the Empire). These initial linkages between the metropolis and the colonial world have had variable duration. In the case of the American colonies they were severed early on by the Declaration of Independence. During the twentieth century they progressively disappeared in the case of self-governing Commonwealth countries; but some former colonial territories have chosen to retain a final appeal to the Privy Council, and a very few colonies still remain.

Beyond the impetus given by the immediate necessity of explicit constitutional provision, the 'fresh starts' generated by the colonial enterprise resulted in vigorous, eclectic localized growth for the common law. In these new local contexts, the energy to attempt rationalization, even towards codification, was perhaps greater than in the metropolis. Major initiatives included the codification of wide areas of private law and the criminal law undertaken in India; the Indian Penal Code was subsequently reused in modified form in several other colonial territories. In the USA, with the particular problem of its numerous private law jurisdictions, a general attempt at rationalization has been the American Law Institute's *Restatement of the Law*. This initiative, now in its third generation of restatements, has brought together judges, lawyers and professors in the preparation of an agreed statement of common law across the state jurisdictions. In the same context, the great American law schools have, on the whole, self-consciously attempted to present an overall view of the common law in their teaching and research. Elsewhere across the post-colonial world the superior courts in different jurisdictions have become increasingly attentive to each other's formulations, indicating explicitly in their judgments that they are working together on a shared overarching fabric which is in the widest sense a common law.

3. *Theorization of the Common Law*

Attempts to 'theorize' the common law, in the sense of drawing together rules and procedure for the purposes of exposition and commentary, were made from a very early stage. Holdsworth (1909) even, proposed that Glanvil's compilation, prepared sometime towards the end of the twelfth century, 'marks the true beginning of the common law.' Judge Bracton's great treatise, compiled on the basis of 2000 cases which he had collected from the plea rolls, followed in the mid-thirteenth century. Both Glanvil and Bracton were deeply involved in what was becoming specialized, legal administration and for the remainder of the medieval period the common law continued to reside in practice, receiving discursive formulation only in the judgments of the courts and in authoritative commentaries. All the great legal texts of the period were prepared by practitioners whose learning was acquired through their work and in the context of their specialist associations, the Inns of Court.

Just as native legal theory in the medieval period concentrated on parochial commentary, that of the

early modern period continued to focus largely on the immediate practicalities at hand. During the constitutional crisis early in the seventeenth century, Chief Justice Coke eloquently prioritized the relative authority of judges, King (he 'hath no prerogative but that which the common law allows him') and Parliament. But Coke's arguments were not distanced speculation; rather those of a practical man, the holder of high office seeking to justify his position in the urgent context of struggles for power.

Prior to the mid-eighteenth century the common law had never been the subject of exposition and research in the English universities. English university teaching of the common law can be said to begin with the lectures which William Blackstone, the first Vinerian Professor, delivered at Oxford in 1758, and which were subsequently published in his famous *Commentaries* (1765–69). The *Commentaries* took more the form of popular exposition than scholarly treatise; but the account he gave provided a framework that would remain readily recognizable even 200 years later. In this work the common law takes pride of place as the law by which 'proceedings and determinations in the king's ordinary courts of justice are guided and directed.' The validity of common law doctrines, 'depending on immemorial usage for their support,' is determined by the judges. In reaching judgment, 'it is an established rule to abide by former precedents where the same points come again in litigation.'

It was only in the early nineteenth century that a body of specifically legal theory, focused on the common law tradition yet distanced from practice, began to develop in England. This body of theory links law firmly to government and maintains a consistent focus on adjudication. The link between government and law is established at the outset in the work of John Austin, the first Professor of Jurisprudence at University College London. In *The Province of Jurisprudence Determined* (1832), Austin presents law as the command of a sovereign directed towards members of a society in a 'habit of obedience,' with failure to comply being met with 'sanctions.' That central association safely in place, English jurisprudence turned to focus—virtually exclusively over the next 175 years—on providing theoretical foundations for adjudication.

The first modern attempt to provide a general theory of adjudication was made by Henry Maine in *Ancient Law* (1861). In this work, taking a broad, comparative, historical sweep, he insisted on locating the core of law in adjudication and in the emergence of rules underpinning judicial decision making. He began by mapping out a broad transition from small, kin-based groups to larger, territorial units. The very origin of social life was identified in the steering role exercised within a group of kin by the senior male agnate. These old patriarchs made decisions on an *ad hoc* basis; no consistent rules underpinned the decisions they took, yet government was supposed to be by adjudication by the senior male, before whom all disputes were brought. In the form of society that followed, numbers of these small groups of agnates became clustered together under chiefs, but the (sometimes fictional) assumption of shared kinship remained the basic organizing principle. Then came the territorial stage, in which members identified themselves through their common occupation of a defined tract of land, rather than through kinship. Around the end of the second stage and the beginning of the third, 'law' developed as rulers began to pronounce the same judgments in similar situations, providing their decision-making with an underlying set of rules. Later in the development of territorially-based societies, the settlement of disputes fell in to the hands of a specialized elite, who alone had access to the principles to be followed in their resolution. As Maine wrote: 'What the juristical oligarchy now claims is to monopolize the *knowledge* of the laws, to have the exclusive possession of the principles by which quarrels are decided.' There followed the 'era of codes,' and so on; but we can leave the developmental process at this stage.

Several important features are clear from this summary. First, there is the focus on dispute resolution and the foregrounding of a particular mode of intervention. For Maine there were no structural changes in the dispute settlement process over the fundamental stages of societal development. From the senior male agnate onwards, disputes were resolved by decision, handed down by a third party; there was no suggestion of negotiatory modes of settlement giving way to processes of third-party adjudication. Second, the presence of a normative basis for decision-making was the key attribute of law for Maine, and the emergence of this feature heralded the transition from the prelegal to the legal world. Third, there was the later development of specialization as legal rules became separated off from other rules operating in society. So, for Maine, social life is the product of 'government,' and the key variables lie in the identity of the third parties responsible for adjudication and in the evolving criteria underpinning decisions.

After Maine, the perfection of theories of law as adjudication occupied the jurisprudence of the common law world through the rest of the nineteenth century and much of the twentieth. Much of this scholarship was generated in North America where thoroughgoing re-examination was made of the doctrines of precedent and *stare decisis*. The greater part of this work remained within the traditional commentary mode of legal scholarship, exemplified by Goodhart's now classical attempts to refine the doctrine of precedent (1931). More ambitiously, scholars like Frank and Llewellyn of the legal realist school drew on sociological perspectives in questioning vigorously whether these doctrines actually operated in the manner claimed in native legal theory. They indicated the relative freedom of judges to distinguish

previous decisions they did not want to follow, suggesting that rules were drawn from the repertoire to justify desired outcomes, as opposed to determining what those outcomes would be. This iconoclastic strand survived on to the end of the twentieth century in the work of the critical legal studies movement.

One notable attempt to escape from the grip of adjudication, and to think about law unconstrained by the institutional shapes of the modern state, was made by Hart (1961). Rejecting Austin's (1832) command theory as simplistic and in some respects inaccurate, Hart's elucidation of law lays central emphasis on rules. One essential category of these is made up of 'primary rules' imposing obligations. The distinguishing mark of such a rule is the seriousness of the pressure to confirm to it 'Rules are conceived and spoken of as imposing obligations when the general demand for conformity is insistent and the social pressure brought to bear upon those who deviate or threaten to deviate is great.'

While Hart concedes that a society might exist with primary rules only, they alone do not constitute a legal system. For the step from 'the pre-legal into the legal world' to be made, these primary rules must be supplemented with 'secondary rules' of three kinds: rules of recognition—making it possible to identify what the primary rules are; rules of change—providing for the alternation of primary rules when the need arises; and rules of adjudication—empowering certain people to determine whether, on a given occasion, the primary rules have been broken. Most systems will also contain other secondary rules authorizing the application of penalties where primary rules are violated; but this further refinement is not seen as essential to a legal system.

Through the device of these secondary rules, Hart (1961) appears to disassociate his model from any parochial institutional content and invest it with considerable value for cross-cultural purposes. However, the escape seems to be illusory, leaving Hart's account of law firmly grounded in the institutions of the state and state-sponsored adjudication. He himself recognizes that the three categories of secondary rules imply, and require, the presence of legislative and adjudicatory agencies. While Hart struggled to marginalize adjudication by identifying law as an affair of rules, subsequent exegeses of his work hastened to represent his core idea as a theory of adjudication. It is significant, too, that his most influential successor, Ronald Dworkin, has consistently refocused the task of jurisprudence on understanding and justifying judicial decision-making.

Common Sense, Anthropology of

Common sense, taken for granted, obvious, self-evident, the only logical alternative: such labels place any challenge to a cultural orthodoxy at risk of annihilation by mockery. They are the terms of cultural power. Moreover, because they appeal to a universalizing rhetoric that brooks no possibility of exception within the known bounds of experience, they effectively disguise the agency that underlies that power. For this reason, they have even led critical analysts attempting to deconstruct the cultural specificities of common sense to treat the latter as established structures rather than as a work permanently, and unpredictably, in progress.

Thus, for example, in her justly famous explorations of 'self-evidence,' Mary Douglas (1966, 1975, pp. 276–318) presupposes the existence of a set of rules—a taxonomy—despite the ironic circumstance that even this assumption represents the common sense of the relatively stable, ordered world of bourgeois experience. Yet the genius of her approach should not be overlooked; indeed, it paves the way for this critique. Douglas shows how attributions of purity and pollution are defined in terms of failure to fit taxonomic schemes already in place; and the metaphor of place is central, for she defines 'dirt' as 'matter out of place' (1966, p. 48). In this reading, however, the conceptual cartography is already 'in place': the lineaments of the taxonomy are already known and accepted throughout the culture, often assumed in this approach to be a clearly bounded entity: 'Where there is dirt there is a

system' (Douglas 1966, p. 48). Such sharp delineation of boundaries, however, is itself a historically specific production of order created by agents exercising highly variable degrees of conscious volition, and commonly takes the form of the bureaucratic logic of nation states, for which the metonymic construction of the people as a social unit such as a kinship group serves to ground national identity in an apparently unchallengeable timelessness (Herzfeld 1992, 1997).

In such situations, the logic of ritual pollution and taboo may also infuse systems that claim the status of a universal rationality. While experience may show that democracies often fail to live up to their goals, for example, people often invent secular theodicies to explain failure—'it's the venality of those who have power, not the organizational structure itself'—rather than attempt to challenge the rationalizing rhetoric whereby those who manage the structures of power seek to perpetuate the status quo. Thus, rationality itself becomes a symbolic system, with its own hostility to the 'contamination' of alternative logics—as witness official hostility to, for example, New Age religious and medical practices (see Badone 1991, Danforth 1989). Here again, logical structure is mapped onto the distribution of power in such a way as to make seemingly deviant or alternative rationalities directly threatening to the bureaucrats and other power brokers of the state. Moreover the idea of a sharp mind–body, subject–object discrimination is so deeply embedded in the ontology of most educated Westerners and many others that in itself it comes—in the guise of an opposition between the sensible and the sensual—to constitute the very grounds of common sense in general.

Thus, Douglas's vision of common sense has the virtue of relativizing what might otherwise be taken as absolute and universal, but it can be extended much further through a conceptual shift of analytic emphasis from conceptual structure to the agency behind the deployment of rhetoric—to the uses, rather than simply the forms, of classification. This allows us to see why common sense so often appears to be static even when historical evidence shows it to have changed in content and logic: its authority appeals to assumptions of permanence but actually often rests on strategic opportunism. Since taxonomy constitutes the basis of knowledge, however, the realization that differing systems of classification both reflect and produce widely divergent understandings of how the world works was a crucial step in the process of relativizing the universalist intellectual claims that, in the West, find their popular expression in folk models of common sense.

Methodologically, it is those moments at which ethnographers are made to feel foolish that the locally dominant version of common sense makes itself felt. When, at last, I discovered that the shepherds among whom I was living in a Cretan mountain village were engaged in extensive, reciprocal animal theft and asked them why, they responded, as though it must have been obvious to anyone but an idiot, 'To make friends.' This baffling response provoked me to an entire ethnographic inquiry, in which I was able to show that, in an extremely demanding physical and social environment, agonistic relations that took the form of systematic, reciprocal animal theft provided en effective means of determining who would be both worthy to serve as 'friends' and tough enough to do so in a practically advantageous way.

Yet one of the criticisms made of the resulting study (Herzfeld 1985, cf. Gilsenan 1986, Loizos 1986) was that it overlooked both gender and (incipient) class inequality. In retrospect, I consider these critiques to be largely justified. A reflexive consideration of how I came to see the situation in the terms of the dominant group may now be of value in revealing the extent to which a structural view of social values can entail the uncritical acceptance of locally dominant models of common sense—a revealing convergence of anthropological generalization and local hegemony. My delight in 'discovering the logic of the system,' to use a phraseology popular in the structuralist era, obscured the clear evidence—which others were able to extract from my ethnographic descriptions—of inequalities, that such assertions of perfect reciprocity effectively masked by reproducing the image of an idealized past ('structural nostalgia,' Herzfeld 1997, pp. 109–38) in the less-than-ideal present (about which the villagers themselves had few illusions).

This example of how encounters between different notions of common sense produce ethnographic insight and can lead to a better understanding of the concealed operation of power is also useful for another reason. When we speak today of the exercise of power, we often—at least implicitly—mean a nation-state bureaucracy or a colonial state. But power is frequently diffused throughout a society in such a way as to be exercised at many analytically separable levels. The common sense of the village 'big men' was emphatically not that of the state, although its bearers called the latter into question by pointing out that the heroes of national independence had themselves been guerrillas known as 'thieves' (*kleftes*).

Notions of common sense infuse and legitimate claims to power at many levels. Such assessments of a culturally defined common sense as Bulmer's famous question, 'Why is the cassowary not a bird?' (1967), are thus not confined to the relatively 'harmless' zones of ritual and taboo. In a society in which it is said that harm will eventuate from any violation of taboo, the misuse of categories is never an insignificant matter. But in self-avowedly modern and rational societies, the issues take on a magnitude of scale that lends them particular force, although the logical principles remain fundamentally similar: virtually the same classificatory logic that we find in the taxonomic organization of cosmology also informs extremely violent practices of exclusion and even annihilation.

The theory of taboo enunciated by Mary Douglas in *Purity and Danger* (1966) has thus proved extremely useful in understanding the treatment of exiles and refugees (Malkki 1995) and of outsiders more generally (Herzfeld 1992). These expansions of her theory, in turn, have necessitated recognition of the kinds of *agency* involved in the activation of categories for specific social and political ends.

A similarly appreciative critique can be addressed to Clifford Geertz's approach to common sense (1983, pp. 73–93). Geertz represents common sense as a cultural *system*, utilizing a model through which he has exercised an enduring influence on the discipline. But if common sense is systematic, where does that quality lie? It must be in the rhetoric of those who invoke the idea of a unitary logic, rather than in the logic 'itself'—the cultural 'system.'

Akhil Gupta (1998) has shown with notable clarity how ideas of common sense reinforce hierarchy at several mutually encompassing levels. Drawing on his fieldwork in an agricultural village in western Uttar Pradesh, India, he shows how the rhetoric of science validates a particular view of common sense that supports the interests of the global economy at the expense of the villagers who are nonetheless expected to resign themselves to its authority.

The phrase 'common sense' implies universality, and in this respect shows that the concept originates in Enlightenment hopes of discovering a universal logic. Yet in the concept of sense, as in that of taste, the Cartesian separation of mind and body had not yet supervened in pre-Enlightenment times and does not seem particularly logical in many another culture (see Classen 1993, pp. 1–3).

Is common sense ideology? I would prefer to treat it, in Bourdieu's (1977) terms, as an example of *doxa*—that set of principles that both governs and is embedded in the culturally inculcated dispositions to which most daily routines are subject. It shares with *doxa* the quality of unreflexiveness: while it can be made the subject of explicit speech, for example, its authority depends on its immunity to questioning. In writing this entry, for example, I am questioning the Enlightenment presupposition of universality on which European notions of common sense are, at least implicitly, predicated.

But common sense is only revealed through practice. It is the invocation of common sense as a reason for doing things that gives it its ontological status in the world. A speaker who argues that something 'stands to reason' may wish to imply that what is invoked has universal status; but to the extent that this is the impression created, it simply testifies to the performative efficacy of the utterance. Thus, the task of the ethnographer is to document such utterances and to gauge their effect. In discussing the status of lying in rural Lebanon, for example, Michael Gilsenan (1976) demonstrates that calling the bluff of a liar by dint of another lie shows both what everyone knows (that lying in social life is inevitable) and that in the specific case a liar's failure to realize that he was being lied to showed him up as the less talented liar. Here common sense consists in realizing that everyone lies and not expecting to be believed oneself. Such a judgment would be considered a great deal less commonsensical in, for example, an academic debate (in which empirical reality probably approaches Grice's (1975) culture-specific maxims of conversation more closely than in virtually any other context (see also Briggs 1986, p. 83, for an assessment of these maxims and their relevance to fieldwork)). Especially in agonistic societies that find themselves advancing competing historical and cultural claims in the context of nation-state ideology, however, such notionally 'pure' commitments as the ideal of historical truth can prove more rhetorical and strategic than literal (see especially Shryock 1997). Moreover, the idea of a disinterested academic search for pure fact is itself riddled with rhetorical claims about both common sense and science, the latter often serving as the legitimating framework for a particular reading of the former. In other words, it is the local cultural rules that constitute the grounds for any appreciation of common sense; but it is the performance of social relations that provides the opportunity for the current understanding of common sense to be made manifest and graspable.

Finally, what of psychological inner states? According to the conventional anthropological wisdom, we cannot know the inner workings of informants' minds, still less generalize from these to the collective psychology of entire populations (e.g., Needham 1972, on 'belief'). Yet a degree of empathy seems to define one version of common sense, according to which the ethnographer usually manages to make precisely such intuitive judgments without difficulty and to the apparent benefit of the description overall (Leavitt 1996). To be sure, this may reflect the embedded common sense of the scholarly community rather than a careful analytical deduction: it implies an equivalence between empathy and knowledge. From another perspective, however, we may extrapolate the specific common sense of a given culture from informal judgments that reveal shared assumptions about what people think ('what they must think') under any given set of circumstances (e.g., Rosen 1995).

Implicit in the foregoing is a comparative project. If Leavitt is right in his demonstration that our own common sense allows us to accept what the logic of our profession prohibits, we see that, even internally, common sense does not necessarily possess the consistency or coherence it claims. More than that, however, contemplation of the limits beyond which we are not prepared to push our assumptions about shared human responses reveals significant cultural and historical differences about what constitutes common sense—what, in some contexts, constitutes the underlying ideology governing the use of language

itself. We may then prefer to adopt a posture in which the discipline of anthropology becomes, quite simply, the comparative study of common sense. In that case, however, the common senses in question are not unchanging systems but constitute symbolisms in use, and the questions anthropologists ask concern both the formal content of these symbolisms and the principles and contingencies governing their use. This methodology underlies the more serious attempts to produce a genuinely reflexive form of anthropology, one in which the cultural, social, and political presuppositions of ethnographic practice become part of the critical analysis of cultural relativism itself.

Communalism

The concept of 'communalism' is based on that of 'community' which has to be understood in relation to the concepts of 'nation' and 'civil society.' It derives its meaning from arguments about the place in modern society of communities of belonging. According to liberal, political theory, communalism is based on primordial attachments and stands in the way of the formation of a modern, civil society, in which individuals act as equals on the basis of their allegiance to the state in which they enjoy the rights and duties of citizenship. In modernization theories communalism signifies a hybrid phase between traditional society and modern society, since it combines modern democracy with political mobilization of religious communities in a plural society. Such theories make a sharp distinction between secular nationalism on the one hand and communalism on the other. Inherent in all these theories is an opposition between religion, seen as part of traditional society, and secular modernity. The fact that religious communities form a strong political force in modern societies all over the world cannot be understood in terms of standard modernization and secularization theories.

Communalism then, signifies a politics of belonging that does not emphasize the nation in all its diversity, but the homogeneous, religious community. It resembles the current notion of communitarianism in that it refers to a political agenda of communicative interaction within a particular community on the basis of shared 'habits of the heart,' but rather than emphasizing the defense of a 'common way of life,' it is much more aggressively antagonistic towards other, similar communities. It should be clear that the term communalism comes up as an alternative to national-

ism, both in theories which explain the failure of the nation-state to emerge in certain parts of the world and in theories which explain the demise of the nation-state under conditions of globalization.

Like the use of the concept of 'tribalism' in the study of African politics, 'communalism' is primarily used in the analysis of Indian society and politics and is seldom encountered in theoretical arguments of a more general nature. It refers to the articulation of religious communities into mutually antagonistic, social, political, and economic groups in India. Again, like 'tribalism' in Africa, communalism in India has a history as colonial theory with great social and political consequences. It emerges in the context of the colonial modernization of Indian society. The Indian population was classified, counted, and measured in terms of community. Notions of caste and religion were crucial in the census operations which took place on a regular basis from the 1870s. British colonial policies were strongly influenced by essentialist assumptions about the nature of Hindus, Muslims, and Sikhs. In their system of governance the British sought alliances with the 'natural leaders' of communities and, ultimately, this created a system of representation in which membership of a community took precedence over place of residence. Recruitment for jobs both in civil administration and in the military was also organized around notions of race, caste, and religious community. The notion of 'martial races' was specifically applied to the Sikhs, a religious community in the Punjab, North India. The British recruited only 'pure' Sikhs who were following the strict norms of what the British considered to be the proper Sikh faith. In this way the Sikhs became a dominant section in the Indian military until today, and a particular 'orthodox' form of Sikhism was promoted with great social and political consequences for the region.

The extent to which language politics was influenced by colonial ideologies of communal difference was also important. The medium of communication was supposedly related to communal identity. A major issue was the question of whether Hindi or Urdu should be the language of instruction and the language of government besides English. In the debates about it, Hindi came to be conceptualized as the language of the Hindu community while Urdu came to be conceptualized as the language of the Muslim community. In the later part of the nineteenth century Hindu leaders increased their attacks on Urdu and Indo-Persian culture by emphasizing the communal basis of the differences in script and vocabulary between Hindi and Urdu. A new vernacular literature emerged which attacked the joint Hindu-Muslim culture, as expressed in Urdu or the spoken vernacular, Hindustani. The principal arenas for the Hindi-Urdu controversy were schools and entry exams for government service. After the Partition of 1947 Urdu became the national language of Pakistan and Hindi, besides English, the main administrative language of India. The identification of language with religious community was also the ground on which the Sikh community after Independence started to demand a special status for the language of their sacred scriptures.

The legal structure of both colonial and postcolonial India has been greatly influenced by the notion of communal difference. Colonial law was grafted on Hindu and Muslim legal traditions which were interpreted and codified in a joint effort of British legal scholars and native religious specialists. Ancient Sanskrit texts, for instance, became foundational for the creation of Hindu civil law. Personal law in India until the present day is based upon communal difference. The contradictions between the claim that India is a secular state and the existence of communal laws can be briefly illustrated by the Shah Banu conflict of 1985. Shah Banu had been divorced by her husband according to Muslim customary law in 1978, but obtained alimony on the basis of a general criminal law against vagrancy. Her husband appealed to the Supreme Court arguing that Muslim law did not require him to pay alimony, but the court rejected that argument in 1985 with the further comment that the government should draw up a uniform civil code. Muslim organizations quickly responded to this judgment with country-wide agitations, claiming that Muslim personal law was in danger. The then Prime Minister, Rajiv Gandhi (1944–1991), gave in to their demands and overturned the Supreme Court decision by making a law which would no longer require a Muslim husband to pay alimony. This in turn was taken up by Hindu communal organizations which objected against the government's pro-Muslim stance, as well as by secular feminists who saw the government action as male chauvinism.

Communalist ideologies emerged in India in a variety of forms during the twentieth century. In the 1920s, V D Savarkar (1883–1966) published a book which connected Indian territory with Hindu identity and thus formulated a communalist ideology that made Muslims, Christians, and others into outsiders, at best second-rate citizens. His thoughts continue to play a significant role in the ideology of the Rastriya Swayamsevak Sangh (RSS), the leading Hindu communalist organization founded in 1925. This organization and its many branches are active in trade unions, political parties, and religious organizations, but it primarily tries to train young men in a military fashion to 'defend the Hindu nation.' The RSS has often been at the forefront of political violence against Muslims and Christians, before and after Partition. It was the driving force behind actions to demolish a sixteenth-century mosque in the Hindu pilgrimage centre Ayodhya in 1992, an event which made the political party with which it is connected into the leading party of the country.

On the Muslim side it is the Muslim League and the Jama'at-i-Islami which are, historically, the major communalist organizations. The Muslim League's

demand for a separate homeland for Muslims in the early 1940s began the political process which led to the Partition in 1947. The poet Muhammad Iqbal had formulated the wish for separation in his writings, but his main influence had been on Muslim students both in India and abroad. It only received political significance in the 1940s when Jinnah (1875–1948), the leader of the Muslim League, took it up. The speed with which the separationist movement gained support demonstrates the extent to which the political and social system in India was conducive to the communalist articulation of religious difference in India, with immense political consequences until the twenty-first century. The complexity of Muslim communalism can be demonstrated by the fact that the founder of the most militant Muslim organization in South Asia, the Jama'at-i-Islami—and as such the counterpart of the Hindu RSS—Maulana Maududi (1903–1979), was in principle against the formation of Pakistan. Partition, however, forced Maududi to move to Pakistan, where his organization became a redoubtable political force in campaigns for an Islamic constitution and laws against unIslamic practices. His revolutionary ideology had a great influence on the Muslim brotherhoods in Egypt and the Sudan.

Another major communalist development in India is the emergence of the Khalistan movement among Sikhs. Sant Jarnail Singh Bhindranwale (1947–1984), a young religious leader, created a large movement, popular largely among the urban youth, demanding a separate state for the Sikhs, Khalistan. It was repressed by the Indian army in 1984. The movement can be partly explained in terms of an identity politics in which Sikhs try to maintain the symbolic boundaries which divide them and the surrounding Hindu majority. These symbolic boundaries, such as the wearing of uncut hair and turbans for men, are only maintained if they are supported by the fact that Sikhs derive material gains from their membership, as they clearly did in the colonial period. The political and economic aspects of membership are intrinsic to the religious ones and it is therefore not useful to understand the Khalistan movement as either a religious or a political movement. It is like the Muslim and Hindu movements, a communalist movement which articulates the religious community in a political and economic way.

In the twenty-first century era theories of the decline of the nation-state emphasize the possibility of transnational, virtual communities which depend on new communication technologies. The extent to which these communities articulate politics of communal belonging that is not territorially bound is striking. This form of transnational communalism enables a politics which simultaneously connects very diverse issues in very different politics. The best example of this has been the so-called Rushdie affair, which started with the banning of the novel *The Satanic Verses* by the Indian government in 1988 under pressure from Muslim communalist leaders. This was quickly followed up by demonstrations, organized by leaders of 'the' Muslim community (mostly Indian and Pakistani) in the UK, and then followed by a call for the execution of the author by the self-proclaimed leader of the Muslims, the Sh'ite cleric and leader of the Islamic Republic of Iran, Khomeiny. The use of the notion of community in these political actions is widely varied, but simultaneously it allows some sense of unity across the globe. It is strongly tied up with migration to the North by members of religious communtities and thus with minority politics and secularism in the countries of immigration. At the same time it is engaged in communalist projects in the countries of origin, where these communities might constitute the majority, as indeed Sri Lankan Buddhists, Indian Hindus, and Pakistani Muslims do. It is this kind of transnational communalism, strongly supported by new media, which will become more important in the era of globalization. This should not be understood as the defense of primordial attachments in the face of modernization and globalization, but as completely new forms of community and identity politics.

Communes, Anthropology of

For purposes of anthropological investigation, 'commune' may be taken to refer to relatively small communities, which have set themselves up, typically self-consciously, as alternative to the wider social order, and embrace collectivism in some substantial fashion. They tend to be small enough to operate principally by virtue of face-to-face relations, they are inclined to hold resources and property in common, and usually, they favor communal decision-making for political purposes. This article treats the study of

such communities by professional anthropologists or ethnographic researchers.

1. 'Alternative' Communities

The great bulk of research on communes may be found in the disciplines of history, sociology, and psychology. Anthropological studies are relatively few in number, and only one, small book treats communes as a general topic (Hostetler 1974b). Considering that communes have much in common with the sort of small-scale community that anthropologists have preferred to investigate, it is curious that these scholars have not shown more interest in them. Like village communities, communes lend themselves to the kind of intensive fieldwork diagnostic of ethnography, and are especially accessible to the anthropological aspiration to research communities in the whole.

Perhaps one reason for the relative lack of anthropological attention is the consideration that in the social science literature, communalism has been largely associated with Western social settings. Whereas anthropology has focused on 'other cultures,' most (but not all) communes are not *other* in the relevant sense. They characteristically present themselves as essentially *alternative* to the societal orders in which they arise. However, in the present connection, significantly, the otherness entailed by such alterity can be misleading. For, as inverse and, in part or whole, utopian reactions to the dominant social order, such communities share with the latter rootedness in the same body of social thought. In the West this body of thought revolves around the question of the relationship between society and the individual, especially when that relationship is apprehended as a dualism. Seeing the dominant social order as primarily individualistic, communal societies propose to resolve the dualism to the contrary, by creating social and cultural conditions that ensure the valuational primacy of the collective over the individual. Typically, the realization of the primacy is keyed to institutional mechanisms that move the individual to grasp his or her self-identity primarily in terms of the collective.

2. Anthropological and Ethnographic Studies

The most substantial ethnographic studies of communes pertain to four different communal social settings: North American Anabaptist settlements, the Israeli kibbutz, Japanese communes, and the Soviet kolkhoz. Typically these studies take their cue from the presumptively alternative social nature of their subject, and accordingly tend to feature the way in which collectivism affects 'normal' institutions and practices, and the capacity of the community to withstand the opposing pressures of the surrounding social order.

2.1 The Hutterian Brethren

Hostetler's work on the Hutterites is exemplarily anthropological, in its ethnographic comprehensiveness and depth of cultural knowledge. He studied this people over a period of several years, and his publications (see especially Hostetler (1974a) and Hostetler and Huntington (1996)) provide rich descriptions of the 500-year history of the Hutterites, their worldview and critical system of Christian belief and practice, the colonies' economic, political, and domestic organization, and the difficulties experienced 'today' by this people in sustaining their unique communal way of life. But the principal focus of his research is socialization. Given the long-term survival of this social order under presumptively adverse external societal and cultural conditions, Hostetler supposed as the key to this evident success the inculcation of cultural values. Accordingly, he set out to examine the Hutterite child-rearing system. He finds that the system of socialization is remarkably effective for reasons of its ideological certitude, utter consistency, and understanding attitude toward modest forms of individual deviancy.

The system is predicated on the Christian belief in the absolute authority of God and the presumption of the primacy of communal order as the key to ensure the submission of the will of the individual self to the will of God. Human nature is seen as dualistically divided between carnality and spirituality. The former quality is understood as in need of firm submission to the latter, a condition meant to be realized by means of communal existence. All the institutional practices of the Hutterites, including of course the education and training of children, are designed to function strictly on behalf of this spiritual principle of hierarchical authority. In result, Hostetler concludes, the Hutterite's sense of individual self is only weakly distinguished from his social identity and is predisposed to self-denial and obedience to authority. In view of this analysis, Hostetler (in line with Hutterite opinion, and perhaps tautologically) is inclined to explain defection as a product of aberrant circumstances in which individuality emerges as an unruly force. These circumstances are, he suggests, associated with undesirable competition among family lines and the failure of these families truly to subject their autonomy to the social whole.

In his substantial monograph on the Hutterites, John Bennett (1967), like Hostetler, is interested in how this order of communal life perdures and maintains its traditional integrity, given the contrary nature of the surrounding social environment. But instead of socialization, Bennett focuses on the agricultural economy of the colonies and the impact of technological development. In line with the general tenor of Hostetler's account, he argues that for reasons of their sure sense of identity, extremely efficient man-

agement, well-formed social order, and rational approach to economic matters, these communities are exceptionally adaptable. More particularly, because they are very open to technological change but not to consumeristic influence, they are enabled to thrive without corrupting their traditional way of life.

Zablocki's philosophically rich study of the Bruderhof (Zablocki 1971), another deeply religious Anabaptist community, less traditionalist than the Hutterites, also constitutes an important contribution to the anthropology of communes. Zablocki is a sociologist, but by virtue of his intensive fieldwork in a single settlement, and his attention to the quotidian course of social events, his study is patently ethnographical. He, too, was interested in the relative success of the Bruderhof. He addresses this issue in terms of 'commitment,' a notion pertaining to the fusion of self-interest with the needs of the community and given currency in Kanter's *Commitment and Community*, a sociological study (contemporary with Zablocki's) of communes in general (Kanter 1972).

In addressing the question of the manner in which the Bruderhof creates and sustains the commitment of its members, Zablocki takes, in addition to the standard functionalism of Hostetler's and Bennett's work, a strong psychodynamic turn. Unlike Hostetler, whose approach to the question of commitment typifies the 'culture and personality' school of interpretation, Zablocki draws on psychoanalysis in a way that bears directly on sociological dynamics, not personality. His main finding is that the Bruderhof is characterized by an institutional structure the critical function of which is to call on and employ the ordinarily repressed psychodynamic energy of collective behavior in order to sustain commitment. Hence, when the community suffers a social crisis that threatens commitment on the part of members (such crises are, he finds, inevitable), this structure of resolution—a joyful prayer meeting of the whole—is brought into play, revitalizing commitment. In effect, he depicts a community keyed to something like Rousseau's 'general will' (a concept of 'commitment' if ever there was one), the difference being that in the Bruderhof this will is regarded as accessible (it is thought to pre-exist its concrete determination) only by means of the realization of a spiritual rather than rational or political unity. By arguing that this unity is brought about through collective behavior and affective effervescence, Zablocki charges Durkheim's famous but vague sociological thesis about the transcendent force of society, with a determinate psychoanalytical dynamic.

Underlying Zablocki's concern for commitment is a general concern about the relation between community and freedom. This concern is of interest to him for reasons beyond the question of the Bruderhof, as he finds that American society in general suffers from a need for community. Hence, for him the examination of the Bruderhof carries lessons for the society at large, the most prominent of which is the importance of distinguishing a kind of freedom that is nonindividualistic.

2.2 *The Israeli Kibbutz*

Melford Spiro's (1970) first book on the kibbutz continues to serve as an anthropological introduction to this secular communal society. It presents the community's historical beginnings, ideological principles, and institutional practices. It was originally intended to serve as a preliminary chapter to the earlier book resulting from Spiro's basic research project on the kibbutz, namely a study of socialization and personality development (Spiro 1965). Like Hostetler on the Hutterites, Spiro was intrigued by this communal enterprise's goal of recreating man in society's image, making him fit to live in social harmony (the kibbutz ideology's hoped-for 'New Man'). And like Hostetler, Spiro approached this problem as a question of the causal relationship between culture and personality, presuming that the personality of the founders' children must take its shape from the social arrangements fashioned by the parents. In particular, seeing the goal of communalism as essentially incompatible with conflict and hostility, Spiro sought to determine the degree to which kibbutz socialization and its system of 'collective education' were successful in eliminating the 'aggression drive' in the children reared in this way. This is the research theme around which centers his psychologically expert study *Children of the Kibbutz* (the title is an expression of a kibbutz ideological shibboleth), the major product of his research on this community (Spiro 1965). As a result of his inquiry he finds what he already anticipated in the epilog of his first book on the kibbutz and is consistent with his penchant for basic psychoanalytical theory: that aggression, being a universal drive, can be curbed but not eliminated.

Spiro's psychoanalytical naturalism receives even greater emphasis in his later study of women in the kibbutz (Spiro 1979), a topic presenting itself in the light of the ideological aim to establish equality between the sexes. Here he concludes, unequivocally, that gender–role differentiation is due to 'precultural' factors and therefore not subject to cultural elimination. In fact, the direction of Spiro's explanatory exercises was signaled, even before the publication of his first volume on the kibbutz, in a provocative article (Spiro 1954), the thesis of which is that the kibbutz had managed by cultural design to do away with the family in favor of the undiluted integrity of the collective whole. A few years later, however, retracting this thesis and foreshadowing his naturalistic universalism, he concluded that the family does constitute a distinct feature of kibbutz social structure (Spiro 1960). The merits of his psychological orientation aside, Spiro's work on the kibbutz is astutely and invaluably attentive right from the start to the stream of social

problems that bear on the place of the individual and run steadily beneath the ideological and, even, empirically minded self-presentation of this communal society.

In *Two Kinds of Rationality*, Evens (1995) treats the question of liberalizing change in a kibbutz in relation to democratic procedure and generational conflict. His phenomenological emphasis on practice and tacit knowledge sharply distinguishes his approach in the present connection. It leads him to look beneath the ideology for, rather than biological or psychological causes, contradictory understandings that are so taken for granted they predispose their hosts, whose self-identity cannot be told apart from these understandings, to certain behaviors. He traces the understandings in question to Rousseau's contractarian theory of the relationship between the individual and society, and then to the sense of man and generation given in the Hebrew myth of Genesis. Like other students of communal societies, Evens is moved to use his research as a basis on which to develop a theory of human conduct; in his case, one keyed to an ontology of ambiguity and a considered notion of ethics. In an earlier essay (Evens 1975), he examines a case of stigmatization in the kibbutz, in order to bring into relief the deepest meanings of the most basic social position in this society, that of 'member' or *chaver kibbutz*. He found that these meanings betray implicit, unreflected ideological expectations of failure in the face of perfectibilism, and foster defensive but disturbing social acts.

Allison Bowes's (1989) *Kibbutz Goshen* not only serves as a sound ethnographic introduction to the kibbutz but also analyzes prominent social problems characterizing the community in which she did her research. Problems of hired labor, competition over work roles, the re-emergence of familism, the sexual division of labor, and conflict between the generations are all subjected to eclectic but useful and empirically substantive sociological analysis. More broadly, turning a remedial eye on the very idea of ideology, she contends that the definition of these apparently troubled social circumstances as problems indicative of failure derives in large part from a misguided tendency to see kibbutz ideology as a set of fixed and decisive principles rather than a pliable and adaptive system of values.

The problem of work roles is the focus of Israel Shepher's (1983) ethnography of a kibbutz (see also Shepher 1980). He is concerned with the threat to the practice of equality posed by the development of permanent work roles, given increasing specialization in the kibbutz economy and the concomitant demand for expert workers. He argues that in so far as this trend is comprehensively applicable to every member, the creation of a structure of inequality based on work roles is precluded, since everyone is equally indispensable to his or her place in the labor sphere. In *Women in the Kibbutz*, Tiger and Joseph Shepher (1975) take up the question of sex–role differentiation. Their aim is to use the example of the kibbutz to arrive at universal truth in respect of the place of women in society. Like Spiro, they propose a naturalism, but their argument is sociobiological rather than psychoanalytical, keyed to the concept of 'biogrammar' or the genetic transmission of behavioral characteristics.

2.3 *Japanese Communes*

David Plath's work on utopian communities is of special interest because it pertains to a non-Western social setting. In a brief discussion, representative of the usual analytical focus on the struggle of such communities to flourish in the midst of contrary social and cultural conditions, Plath (1966) examines the tactics used by four Japanese communal societies to adapt to the ambient milieu without compromising their reformatory goals. However, in his perceptive epilogue to *Sensei and His People* (Sugihara and Plath 1969), a first-person narrative of a Japanese commune authored by the wife of the commune's charismatic founder and leader, Plath identifies suggestive differences between this and Western communal ventures. He observes that, having evolved spontaneously, Shinkyo (the name of the commune) cannot be regarded as an 'intentional community,' and he brings into relief the fundamental way in which this community is continuous with, not simply reactionary to, the ambient society. The commune got its beginnings in reaction to the formalism of Tenrikyo, a nineteenth century Japanese religious movement related to Buddhism (Shinkyo's founder had served at one time as a Tenri priest), as well as to the 'bossism' of the local village community. But its defining emphases—moral responsibility, self-sacrifice, mutual reliance, social equality, and spiritual/bodily cleanliness—are manifestations of the traditional values of rural Japanese society. In view of the overtly complementary relationship between Shinkyo and the surrounding community, Plath's exercise suggests that this commune, although radical by the actual standards of the state of things against which it reacted, practices a nonabsolutist communalism. As a result, by contrast to Western communitarian ventures, the identification with the social whole is not so much secured institutionally as left—not simply in the end but for all practical purposes—to the individual member's quotidian discretion.

2.4 *The Soviet Kolkhoz*

Caroline Humphrey's (1983) substantial social anthropological study of the Soviet collective farm or kolkhoz may be mentioned here but not really considered. For one thing, as a direct function of the state, the *kolkhoz* is neither alternative in the relevant sense

nor self-generating. For another, although one can learn much about the social and politico-economic life of Soviet collectives from Humphrey's study, it is more directly concerned with problems of social change deriving from the Soviet Union's need to integrate into itself ethnic minorities (in this case, the Mongolian Buryat) than with collectivism itself. As a result, it is difficult to place Humphrey's book directly in the literature on communes, and, apart from her extensive use of materials published by ethnographers and analysts native to the society in which she worked, she herself neither draws on nor mentions that literature.

3. Communes and the Significance of Anthropological Research

Given the intensive nature of ethnographic fieldwork, it is not surprising that the anthropological study of communes tends to be distinguished by sharp attention to the discrepancies between communal practice and ideological design. In staying acutely mindful of this question, the anthropologist is dwelling on a theme at least implicit in the very operation of such communities. The ideological presumption of dualistic opposition between the individual and society defines the communal endeavor as dependent on self-sacrifice for its success, thus projecting the endeavor as a trial of transcendence in the face of material adversity. The adversity is typically apprehended as a matter of the pressures exerted by the external social environment. It is also associated, by communards and researchers alike, with a naturalistic presumption of one kind or another—especially self-interest and individualism. The research interests of socialization, adaptability, internal conflict, women's and work roles, familism, crisis management, commitment, etc., revolve round the ideological picture of these communities as social experiments under hostile conditions, and amount implicitly to attempts at measuring the success or failure of the communitarian enterprise.

As informative as the anthropological focus on the gap between theory and practice is, though, it falls short of the unique advantage anthropology has to offer, for it tends to confine the anthropologist to the communal endeavor's ideological social compass. That compass misleads, in part but significantly, by the presentation of itself as alternative or 'other': it is after all very much an integral function of the social universe against which its alternance is defined. In principle, however, even if working 'at home,' the anthropologist takes his or her direction from a more radical otherness, one that cannot be reduced to what is already known, at least not without disrupting or altering the latter. Thus, Plath's work in Japan may well disclose a communalism that is not dualist in the received (Western) sense of the term, and Evens's on the kibbutz, digging deconstructively beneath the ideology to a nondualist mythic core, begins to rethink the very idea of the difference between theory and practice, away from its implicit perfectibilism and towards a relativism that serves to reform 'ethics' as the very name of human existence.

Given the radical way in which they tend to betray a dualism of the individual and society, communal orders constitute exceptionally fertile ground for anthropological study. Because they thus magnify a fact that ordinarily gets taken for granted, their study helps explain, as Durkheim asserted of exceptional ('pathological') social phenomena, the norm. By the same token (the conspicuous disclosure of individual–society dualism), since the relation between the individual and society is also a predicative question for social science inquiry, the study of these societies critically orients self-examination into anthropology's own tacit foundations.

Communication and Democracy

Democracy can be defined in many different ways. This is one reason why so many different kinds of democratic states have existed. It can be an empirical scientific term, referring to the common people's participation in the political decision-making process, but it can also be a normative ideological concept referring to an ideal political system. In order to make historical and international comparisons possible, the term 'democracy' is used here in the empirical scientific sense, referring to the phenomenon by which all eligible members, directly or indirectly, participate in the decision-making process of the society to which they belong. Here the term democracy is not used for an ideology or a political goal.

The first half of this article reviews how the development of communication technologies, and the spread of both communication media and education among the masses, contributed to the evolution of democracy. The second half of this article deals with how modern communication media, especially mass media, function in a pluralistic democracy.

1. History

1.1 Democracy before the Mass Media Age

In major civilizations before the seventeenth century, the majority of the population was illiterate, and in early medieval times so were some European kings. The Vatican initiated a campaign in 527 AD to increase the number of literate priests. Even in late sixteenth century England, the illiteracy rate was as high as 80 percent among men and 95 percent among women (Parker 1980).

Under such constraints, 'democracy' as defined above was possible only in small communities or societies in which individual members could discuss the issues face to face. The 'direct democracy' of the ancient Greek city-states is the best known example of this. However, a long list can be made of other ancient and medieval civilizations with similar systems or practices: the first century German tribes (according to Tacitus), the Swiss cantons, the New England town meetings, and *yoriai* (meeting) in traditional Japanese villages.

While small-scale direct democracies at the city or village level existed, democracy at the empire, kingdom, or state level did not exist anywhere in the world before the seventeenth century. The main reason for this is that it was technically impossible.

1.2 Evolution of Democracy as a Result of Mass Printing

The illiteracy rate in Europe dropped rapidly in the seventeenth century. In England it declined to about 55 percent for men and 75 percent for women by the early eighteenth century (Parker 1980). This was true in some non-Western countries as well. In Japan, for example, the illiteracy rate was very high before the seventeenth century, even among the elite *samurai* (warrior) class. Peace during the early seventeenth through the nineteenth century, however, gradually 'civilized' ordinary people. As early as the late seventeenth century, Ihara Saikaku (a popular novelist, 1642–93) describes an illiterate *samurai* in one of his novels as 'sadly behind the times' (Dore 1965).

A natural consequence of an increasingly literate population was an ever increasingly open expression of political opinions and criticisms by middle-class intellectuals: low-ranking aristocrats, rich farmers, successful merchants, and so forth. The almost predictable response from the traditional political elite was repression, which was very severe and cruel in the sixteenth and seventeenth centuries but became gradually less so during the following two centuries. During this time, at least some constructive opinions and policy suggestions by middle-class intellectuals gradually came to be tolerated and incorporated into the policy-making considerations of the political elite.

This process started in England, with the reinstatement of a parliament in 1640 that demanded assurances against a resumption of the 'absolute monarchy' of Charles I, and spread to Western Europe and North America. Similarly, although later and slower, changes took place in some non-Western countries as well. For example, Japanese media historians point out that the control of publications by the central government became more relaxed and less widespread during the nineteenth century compared with the seventeenth century, due chiefly to the remarkable increase in the number of publications, which included private news

media such as the *kawaraban*, the first of which was established in 1615. By the early nineteenth century nationwide networks for the distribution of private primary school (*terakoya*) textbooks had been established, and political books banned in Tokyo flowed unhindered to distant and remote areas of the country through the textbook distribution pipeline (Konta 1977).

The increase of publications intensified the need for intellectuals and experts in the government bureaucracy who could understand and evaluate all of these published books and documents. This was especially noticeable in the fiscal, monetary, agricultural, and foreign policy areas as well as in the judicial system. Consequently, experts and scholars serving government came to be recruited based on their merits and competence rather than on their lineage. Specialization led to the creation of government agencies that dealt with defined and narrower policy areas. This division of responsibility within the new 'meritocratic' establishment meant the greater participation of lower ranking people in the political decision-making process.

As Cooley ([1909]1993, p. 75) stated, 'Printing means democracy, because it brings knowledge within the reach of the common people; and knowledge, in the long run, is sure to make good its claim to power.' This is equally applicable to the histories of both the East and the West.

1.3 Crisis of Democracy in the Mass Media Age

As discussed above, premodern undemocratic governments assumed that the masses should not participate in the political decision-making process; therefore they suppressed publications that criticized them and also any efforts at free expression on the part of their subjects. However, they did not attempt to operate their own mass media to influence the masses. This only began to happen with the emergence of new types of undemocratic governments that resulted from the development of mass media. Most of them took advantage of democratic tenets, such as free elections and freedom of expression, to seize power. Once they had seized power, however, they abolished or drastically restricted those fundamental democratic rights and became dictators. With a twisted logic, some of them persisted in calling their regimes democratic because the majority of the population once supported them. Fascist, Nazi, ultra-nationalist, militarist, communist, and radical socialist governments in the twentieth century all belong in this category.

When newspaper readerships were limited to well-educated middle-class intellectuals, they contributed to the evolution of democracy (as Cooley [1909]1993 points out); however, when newspaper circulation expanded further to include the general masses, newspapers sometimes changed to engines of mass agitation and exerted a dangerous influence on national policies.

In the past, nearly every modern democracy has had some experience of this. For example, it is well known that the sensationalism and jingoism of the William Randolph Hearst newspapers were responsible for the Spanish–American War of 1898. The British newspapers were largely held responsible for the unreasonably onerous reparations imposed on Germany at Versailles following the First World War (Nicolson 1969).

Chauvinistic, ethnocentric, and racist newspapers helped undemocratic political parties to seize power in Germany and Italy. In Japan, even though both the Emperor and the civilian government tried to curb Japan's military actions in China, many newspapers supported the military (to expand their circulation) and helped them take over the government.

When socialist or communist parties (hereafter 'socialist' includes communist) took power in Russia (1917), in China (1949), and many other countries, the majority of the masses were still very poor and illiterate. So when socialist governments emerged as the result of violent revolutions they were at first regarded as another variation of democracy, because the revolution enabled the traditionally repressed classes such as farmers and manual workers to participate, for the first time in their history, in the political decision-making process at the national level. When these socialist governments were first established, they were vulnerable and feared a counter-revolution by reactionary feudalistic forces. As they firmly believed that justice and truth based on Marxist socialist scientific theories were on their side, they did not permit any political parties other than their own, nor any antisocialist expressions, nor a free and open press, and certainly not free and secret elections. Socialist governments operated their own propaganda machines to educate the masses in an effort to catch up with the more economically and technologically advanced capitalist liberal democracies.

The socialist system that started off as one more variation of democracy, however, soon became more and more undemocratic as the power of the state came to be monopolized by a handful of the socialist party elite. These elites gradually evolved into special privileged classes such as the 'nomenclature' in Soviet Russia. In the most extreme cases, such as those in North Korea and Romania, the position of head of the state was completely privatized and was passed on, or an attempt was made to pass it on, to the head of state's son. The maintenance of a dictatorship by the socialist party elite depended on the strict control of mass communications, and widespread surveillance and coercion by the secret police.

Although these dictators managed to control the domestic mass media, it became harder to control the inflow of information from foreign countries as

communication and transportation technologies developed. Contact with foreigners through tourism, conferences, letters, the telephone, and other communication channels steadily increased in all socialist countries.

People trust the mass media only if their contents are congruent with their own experiences and observations. If the output of the mass media and the people's direct experiences and observations are incongruent over a long period, the credibility of the mass media is gradually lost. If the government operates the mass media, the credibility of the government is then jeopardized.

Based on the recognition of this reality, the Soviet Union leadership started the liberalization of information, called *glasnost*, in the late 1980s. The initial purpose of this policy was to allow free flows of information, a free press and freedom of speech within the socialist democratic system. Soon, however, it became obvious that a one-party dictatorship could not coexist with the policies of *glasnost*.

Wherever there is a free flow of information, freedom of the press and free speech, many divergent political ideologies and policies emerge and compete with each other for public support, thus making it impossible to maintain a one-party dictatorship. Some of these parties might be ethnocentric, racist, fascist, or even fanatical, and therefore undemocratic as the socialists have always claimed. However dangerous they might be, they do constitute a part of a modern 'pluralist democracy' that many countries in the world, including former fascist and socialist countries, have reached only by paying the high cost of social unrest, wars, and violent revolutions.

2. *How Do Communication Media Function in the Modern Pluralist Democracy?*

What is evident from a historical review of the relationship between the forms of communication (especially mass media) and the power elite is that in any society with a well-educated population criticisms of government policies and demands for participation in the political process are bound to be heard. There are only two ways to deal with this eventuality: either to suppress these criticisms and demands or to coexist with them. Historically, political leaders of almost all the countries in the world have chosen the former option at first. In countries where printing developed earlier than in other parts of the world, however, the latter choice, coexistence, was preferred, but only after much struggle and bitter experience. Thus, 'free criticism of the government,' which is practically the same as 'freedom of the press,' became the paramount prerequisite for a modern pluralist democracy.

In modern societies where communication technologies are highly developed and the freedom of the press is permitted, mass media have to compete not only with each other but also with all other forms of communication media and information flows. If a mass medium loses credibility with its consumers, it will lose their support. Under the capitalist market system this could lead to financial ruin, whereas under a one-party dictatorship this could mean the loss of the people's trust in the party and a subsequent toppling of the government.

As discussed elsewhere (see *Influence: Social*), the mass media appears to have some influence on individual attitudes, opinions, and behavior under certain conditions. However, even if it is proved that people are influenced by the mass media that they are regularly exposed to, the political implications for society as a whole are not quite clear because the mass media in pluralist democracies represent such a diversity of opinion. As long as the mass media remain diverse, their influence on actual policy and decision making is unclear. The political implications of mass media's influence on individual opinion become clearer only when the entire mass media become monolithic or united in a common cause. In what kinds of situations do mass media coalesce their opinions and have a marked influence on government policy and decision making?

2.1 *Agenda Building*

For the reasons mentioned above, the persuasive effects of a particular journalist or mass media company on political leaders are limited and may be marginal. However, when the mass media continually dwell on problems that the government is supposed to have solved but has not, due to negligence, then they can have a direct impact on government policies.

This phenomenon usually takes place in areas such as the environment, the rights of minority groups, and the handicapped. These issues tend to be ignored or forgotten partly because they do not always have powerful lobbying groups to promote them. Just by pointing out the existence of these problems through their investigations, the mass media sometimes succeed in mobilizing government agencies and politicians into creating a solution. This is the 'agenda-building function' of mass media's 'investigative reporting.'

2.2 *Enforcement of Social Norms*

It is said that while the police and prosecutors enforce laws, mass media enforce morals and ethics. There are many immoral or unethical acts committed for which people may not be arrested or prosecuted but which they do not want exposed. Money and sex scandals are typical examples. Lazarsfeld and Merton (1960) called

this social function of the mass media 'the enforcement of social norms.' The power of the mass media is so feared by political leaders just because celebrity scandals are more newsworthy than those of ordinary people.

Personal scandals do not always stay that way. When they are perceived as symptomatic of 'organizational corruption,' the subsequent revelations can have a direct impact on government policies. The introduction of competition into traditionally monopolistic areas, and drastic reforms of government organizations and systems, are often the result of widely reported exposés of such organizational corruption.

2.3 Mass Media–Public Opinion Congruence

Apart from basic social norms, public opinion is clear and decisive on certain issues. Taxes and war or military involvement are good examples. On these issues, the mass media tend to follow public opinion (partly because of their fear of losing circulation or ratings) and the mass media as a whole become less diverse as a result. Competition among relatively monolithic mass media further reinforces public opinion, and their combined demands and criticisms of the government become intensified. The term 'climate of opinion' has been used to explain this pressure. Under these circumstances, the government is often obliged to concede to the wishes of the mass media–public opinion alliance. This alliance is democratic in principle and, therefore, usually desirable. As described above, however, the possible danger of such an alliance in a mass society should not be ignored.

Communication and Social Psychology

Human communication is both social and cognitive because it is a process by which individuals exchange information and influence one another through a common system of symbols and signs. Compared with the study of language more generally, the study of the psychology of language is relatively new, and, when it did emerge as a field in the middle of the twentieth century, more attention was paid to understanding the psychology of grammar than to understanding language use or communication *per se*. Moreover, what attention was paid to understanding communication reflected mostly a cognitive perspective rather than a social perspective. The social psychological perspective on communication, then, is a very recent development within the study of language.

The social psychological perspective on communication complements the more purely cognitive perspective (Cherry 1957, Shannon and Weaver, 1949). The cognitive perspective treats communication skills much like language skills by identifying a set of procedures, mechanisms, and operations by which information is transmitted from some source to some recipient. The social psychology of communication emphasizes the fact that communication also involves social motives and has interpersonal consequences beyond information reception. From a social psychological perspective, communication is a social action that shapes reality, and not just a device for transmitting information from one location to another. Communication is action (see Searle 1969), and action is 'social' in so far as its subjective meaning and orientation takes other people into account. By the communicator and the audience taking each other into account, communication both creates new knowledge and constructs a shared reality (see Higgins 1992). The nature and functions of communication—what it is and what it does—reflect the fact that it is a social action.

From a social psychological perspective, communication is an interpersonal interaction, a game with interaction rules and social motives. The constraints on communication are not just the basic information to be transmitted or the information processing capacities of source and destination. There are, in addition, the social rules of appropriate communication, the social context of communication, and both what the communicator intends the message to do to

the audience and what the audience infers about the communicator's intentions. The social psychology of communication is also concerned with the social consequences of communication, including how communication influences audiences' and communicators' attitudes, impressions, attributions, and memory about the message topic. Since the 1950s, social psychological researchers have discovered several phenomena that reveal the different ways in which communication as a significant social action shapes the world in which we live.

1. *Taking the Audience Into Account*

Communicators do not simply encode some set of information and then transmit it to a destination. They choose how to formulate their message by taking the characteristics of the audience, including their audience's situation, into account. When another person is the topic of their message, they will encode the same information about that target person differently depending on what they think is the audience's attitude toward that person or what they think the audience already knows about that person, including what information they share in common with the audience. For example, people give different directions to a destination when talking to a 'local' than to a 'foreigner'. Communicators will even convey different information at the same time to more than one audience when they have a different relationship with each audience, such as using expressions that will have a different meaning to an in-group member than to an out-group member (see Fleming 1994). Communicators also take the audience's context into account, such as describing a target person differently depending on the context of other people from whom the audience must distinguish the target (e.g., Manis and Armstrong 1971; for a review, see Krauss and Fussell 1996).

When communicators take their audience into account in formulating their message, they are constructing a representation of the topic of the message that is shaped by their audience. This audience-shaped representation itself has effects beyond the original information to be transmitted. It can change communicators' own knowledge and attitudes, including their own attitude toward themselves (i.e., their self-esteem) if they spontaneously communicated a favorable image of themselves to others. It has been found that communicators' own evaluations of a target person, and what they remember about the target person's behaviors, will change over time to match the evaluative tone of the message they communicated about that person weeks before, a message that was originally designed to take into account the audience's positive or negative attitude toward the target person. Thus, what communicators end up saying about a target person in order to suit a specific social context ends up becoming what they believe about the target person after a period of time. This 'saying is believing' effect exemplifies how communication as a social action can shape people's world (see, for example, Higgins 1992).

2. *Taking the Communicator Into Account*

Audiences also do not simply decode information transmitted by some source. They believe that the message was a social action. Thus, they infer that the communicator chose to formulate the message in a particular way and that this choice is significant. They infer, for example, that communicators tailor their message to suit the attitude of the audience, and adjust accordingly their judgments about what the communicators truly believe (for reviews, see Higgins 1992, Krauss and Fussell 1996).

Messages are intentional acts, and inferring the communicator's intentions is critical to understanding the meaning of the message (see Grice 1975). A central assumption about how conversations should be conducted is that all information contributed by the participants during the conversation should be relevant to the goal of the conversation. When one participant in a conversation breaks this rule, it can create problems for the other participants. It has been suggested, for example, that the poor performance of participants in some decision-making studies could be because the experimenters in these studies broke this conversational rule of relevance by providing information to the participants when communicating to them that was not relevant to the participants' decision task. If the participants assume that the experimenter is following the rule of relevance, they will use the irrelevant information the experimenter has communicated to them and perform poorly (see Schwarz 1994). In order to understand the full meaning of a message, audiences must understand not only what information is actually transmitted in the message, but also infer what meaning the message conveys given a particular communicator and particular context. The meaning of a message is influenced by the communicator's characteristics because the audience uses these characteristics to draw inferences about which meaning of a word or phrase was intended by the communicator. For example, an audience would infer a different sport for the word 'football' depending on whether the communicator was known to be British or from the USA. By also taking the context of communication into account, audiences make different attributions about the communicator's intentions in producing a message, which changes the meaning of the message (see Hilton 1995).

Because messages are intentional acts, they provide information about the communicator and not just information about the message topic. Information about the communicator, in turn, can influence the

illocutionary force of a message—its perceived purpose and effectiveness as an action (see Searle 1969). The effectiveness of a persuasive message, for example, does not depend solely on the informativeness of its content, such as the quality of its arguments. It also depends on the characteristics of the communicator (e.g., perceived expertise, attractiveness) and the nature of the relationship between the communicator and the audience. Thus, both the meaning and the impact of a message are influenced by audiences' taking the characteristics of the communicator and the context of communication into account.

3. *Messages as Strategic Actions to Influence the Audience*

The significance of messages and the responses of audiences to them are not restricted to their symbolic meaning. As social actions they can be used strategically to imply causality and generalizability or to signal relationships. They are socially important as well as meaningful. Thus, they have significance both as signals and as symbols. Recent research has shown that interpersonal language has a number of inference-mediating properties. This research is based on a model of interpersonal language by which an objective and quantitative analysis of the language used is possible, such as how abstract or concrete the message is (see Semin and Fiedler 1988).

Subtle and relatively small differences in the level of abstraction of a message convey differential inferences to audiences. For instance, systematic variations in abstraction level of a message lead audiences to draw different inferences as to whether the behaviors of a person are influenced by situational factors or due to his or her personality makeup. Concrete representations of events lead people to think that the behaviors of an actor were due to situational constraints, whereas depicting the same event abstractly leads people to think that the behaviors were due to the personality makeup of the actor.

Applications of these findings in communication contexts have shown the role that strategic language use plays in influencing the types of inferences audiences make. One instance is the transmission and maintenance of stereotypes. For instance, it has been shown that behaviors that are consistent with stereotypic expectations are communicated at a higher level of linguistic abstraction compared with behaviors that are inconsistent with expectations. When audiences receive such messages, one finds that expectancy-consistent messages lead to the conclusion that these behaviors were due to enduring personality factors. In contrast, unexpected behaviors are depicted with concrete language, suggesting that such behavior is situationally constrained and thus unlikely to be repeated. This effect has been shown to be mediated by the level of abstraction of the messages. Diverse research findings demonstrate that subtle and implicit properties of language, such as abstraction, are strategically used, albeit unconsciously, in the composition of messages with a view to influence audience inferences. More importantly, these subtle linguistic cues in messages have been shown to influence the audience as intended but without their knowledge.

4. *Audience Responses to Messages as Signals of Relationships*

Just as communicators can influence their audience through strategic language use, audiences can respond to messages in ways that influence communicators. These responses can be verbal or nonverbal and they can be intended or unintended. One basic set of phenomena concerns the different ways in which audiences can influence communicators' functioning by signaling their relationship to them (see Giles and Coupland 1991). If the members of a social group, for example, perceive their social identity to be threatened by how members of a different social group communicate with them, they might respond by displaying behaviors that accentuate the difference between the two groups, such as exaggerating their distinct accent or using expressions that are distinctly associated with their own group.

Communicative acts and styles, such as speech rate, pausal phenomena, utterance length, facial expressions, gaze, and so on, are used when responding to others' communicative acts to accentuate differences (divergence) and reduce differences between groups (convergence). These are strategies by which individuals adapt to other people's communicative behaviors toward them. When communicators respond to different people whose social status and education vary, and whose power and closeness relationships to them vary, they will modify their use of phonology, median word frequency (an index of formality), and other language features in order to signal similarity with whoever is their current communicative partner. In communicative interactions, both the communicator and the audience use verbal and nonverbal actions to manage the discourse, to signal and control the relationship, and serve other interpersonal goals (see Giles and Coupland 1991).

Research on the social psychology of communication has increased our understanding of the role of communication as social actions that influence both partners in the social interaction. Both communicators and audiences take each other into account in producing and comprehending the message, and in so doing change the meaning and significance of the message beyond its content *per se*. Both communicators and audiences use communicative acts to influence their communicative partner. These role-taking and social influence processes have

consequences for communicators' and audiences' attitudes, attributions, and memories, and thus communicative acts shape people's understanding of the world in which they live.

Because communication is a social action that shapes understanding, it concerns a critical motivation–cognition interface. Variables reflecting the motivation–cognition interface have received relatively little attention, however. For example, do 'saying is believing' effects depend on communicators' being motivated to share reality with their audience? Are the consequences of message production on the communicator different depending on their motives for producing it, such as to transmit information, to make a good impression, or to entertain the audience? The social psychology of communication can make further contributions to understanding language use by studying more explicitly the role of social motives in communication. All self-regulation involves trade-offs, and thus communication must involve trade-offs among different motives. How the problems of trade-offs are solved and how the solutions influence the nature and consequences of communication are major questions for future research.

Communication and Transportation, History of

The history of communication refers to a broad and loosely integrated field of historical research which includes parts of the history of transport, traffic, communication, media and information techniques. It is a relatively young field and a new point of view within historical science. Some aspects have been partly studied by historians—economic historians in particular—for a long time, especially the role of new technologies in transportation and traffic, and the history of the railways, ships and automobiles, and telephone and telegraph. Since the 1970s new questions and combinations have arisen with respect to the revolution of communication (including computation, multimedia, and the Internet) and these have given an impetus to broader research.

1. Overlapping Concepts

The term 'communication' was first used in England within the sectors of transport, commerce, and trade immediately before the Industrial Revolution. It was the time of extension of the road system with turnpike roads, new attempts at canal building, and improvement of the British postal system. The improvement of roads, the regulation governing the use of rivers, the erecting of canals, and improvements of coaches and cars, boats, river- and ocean-going ships, were aimed at more transport capacity, the reduction of high costs of transportation and the widening of local and regional markets to national and international dimensions. The Industrial Revolution from the 1820s onwards completed the possibilities of transportation with the construction of railroads and steamships and communication was improved by telegraph and telephone.

Today these forms of facilitating the services of commerce, trade, and tourism—including the later inventions of automobiles, progress in the building of roads, and the airplane—are described under infrastructure and its technical equipment. There is therefore an overlap between infrastructure and communication, and the last term has become more

and more subsumed under the name of 'media.' Communication nowadays is only partly concerned with matters of transport and traffic, and there is danger of a one-sided contraction of the content of this term, because the media and media devices are only partly subsumed under infrastructure.

Economists, especially those in public finance, normally define communication and transport as a necessary prerequisite for development and growth, calling it 'infrastructure,' (Hirschman (1958), Tinbergen (1962), Jochimsen (1962, 1966)). Before one can produce anything for a broader market, one needs transport and communication. The term 'infrastructure' is a word that originally came from French railway-idiom and was adopted by NATO after World War II. Later economists used it as a new term. Good 'material infrastructure' includes the communication possibilities of roads, canals, railways, ships, and, of course, all media equipment. But 'infrastructure' includes not only 'material infrastructure,' it also refers to 'immaterial infrastructure,' or learning, education, schools at different levels, universities, research institutes etc. The role of communication in the diffusion of knowledge and information is evident. According to Kuznets (1959, 1965, 1966) the infrastructure was one of the most important prerequisites for the European Industrial Revolution. It guaranteed stable economic growth, the international and regional division of labour, and made an impact on specialization and on more, and higher economic, social and cultural integration.

Today 'communication' is used especially in connection with the media. The development of the media since 1970, culminating in the Internet, necessitated a new classification of all items of media techniques and their former use: from the human voice to messengers, to ballad singers or actors in a theatre; from writing, handwritten codices and letters to printing in books, pamphlets, newspapers and posters or typewriting; from pictures, drawings and paintings to photos, and since the late 1990s scanning possibilities; from messages given through drums, written on stones, papyrus, parchment and paper to transmission by telephone, telegraph, film, radio and TV, CD-Rom, DVD, the computer and the Internet. As a result, the discipline of journalism has widened its scope to all the mass media and even studies their history.

There is also an overlap with the term 'information,' which is especially stressed by economics and business sciences as an important outcome of communication. Since the 1960s 'information' has been seen as the 'new immaterial resource' in physiology, sociology, psychology, pedagogy, linguistics and information science, ethnology, political sciences and law, and, last but not least, in a bundle of technical sciences.

In economics, for example, it was F. A. Hayek (1968) who described markets as spontaneous networks of information over goods and services. In a competitive market the prices make it possible to have and to use more information than normal, and of course much easier, faster, and cheaper. Market prices in normal (competitive) situations provide very precise information about shortages and abundances, qualities, monopoly and so on. Business scientists study the organization of firms and the optimization of information within the business entities and stress information as an important factor of production.

As Pool (1963) points out, communication is a fundamental necessity for human social action. Therefore we can distinguish between: (a) interpersonal communication = information exchange within an individual person; (b) intrapersonal communication = information exchange between two or more persons; and (c) media-bound communication = exchange of information between media producers and media consumers (in mass consumption). Since the 1980s communication has come to mean not only information between human beings but also between computers.

The development of communication and transportation possibilities show in the very long run a dramatic widening of the abilities and capacities of human communication. From the stages of primarily personal experience of communication by ears and eyes it shifted to a secondary system which is technically arranged and represents 'artificial' communication (S. Krämer (1997)). Today this 'artificial' communication has reached a peak in the new media possibilities of TV, the PC, and the Internet. McLuhan (1964) points out that individuals recognize their environment primarily through the media, which increasingly use the new techniques of electronically transmitting and storing information. His diagnosis is that 'the medium is the message.'

According to N. Luhmann (1981) social systems can be defined as the possibilities of human beings (in their time-space related contexts) to take part in the experiences, procedures, and activities of the society. Their ability to participate is, however, dependent of the availability of communication and transport equipment and techniques. Religious and political barriers or facilitations, problems of economic and social inequalities and, of course, the complex of good or bad 'property rights' play a role.

The historical sciences, i.e., political, social, and economic history, as well as the history of technology, study the causes and consequences of the communication process from antiquity to modern times. As communication and transport are important prerequisites of development and globalization, one has to examine very thoroughly the rise of the West to see how it obtained leadership over the East. To a large extent this leadership originates from better and new infrastructure and the organization of transportation and the media. Every step of European development since the Middle Ages can be seen in connection with the big spurts and crucial points in the improvement of each new media and in infrastructural equipment.

The European case also seems to show that, with the improvement of media and transportation, an upgrading displacement of the state and old elite went hand in hand with an increasing participation of human beings in communication. N. Elias (1939) in his famous book on civilization has pointed out the strict limitations of monopoly power in western societies. This freed the way for more and more social groups and individuals to use communication and transportation techniques. From the *cursus publicus* of the Roman Empire, which was only open for the purposes of the state to the new postal system at the beginning of Early Modern Times; from the cavaliers' tours of the nobles and the commercial journeys of single merchants to mass tourism, from illiteracy to dense school systems; from the handwritten codices of the monks to Gutenberg's Bible and Jerry Cotton; from the transport of gold, silver, silk, and amber to the transport of bulk goods over the whole globe; from the limited diffusion of knowledge and messages by fire signals, letters, etc., to a worldwide web in a 'global village' with 'global information infrastructure.'

1.1 Phases of Development in Europe

Historians and media specialists think that within western culture one can find four revolutions and periods in communication and transport development: (a) the Middle Ages (especially from eighth–fourteenth century AD); (b) the Early Modern Times (fifteenth–seventeenth century AD); (c) the onset of and then the Industrial Revolution (eighteenth–first half of the nineteenth century AD); and (d) the Communication Revolution, beginning in the last decades of the twentieth century.

M. Weber (1896) in his famous article upon the decay of the Roman world sees one main cause of its decline in the communication and transportation complex. He argues that all ancient high civilizations from China, Mesopotamia, Egypt and the Greek world were river- and shore/coastal-oriented civilizations. The failure of the Roman Empire was to go deeper and deeper into the European continent. Though the quality of Roman road building was very high and a relay system, changing tired for fresh horses, enabled people to cover distances as far as 300 km a day, the ancient *cursus publicus* had not enough impact on common trade, commerce, and communication, as it was not open to the common man.

The Middle Ages and the Early Modern Times in Europe found new answers and, in the long run, more stable solutions in communication, and prepared the way for the great spurt of European civilization which, from the sixteenth century onwards, left behind the older and richer civilizations of Asia. The Middle Ages from the tenth and eleventh century AD onwards developed a feudalistic system with a weak State and government, but strengthened local and regional authorities. At this time dense networks of more or less autonomous cities were created in which trade and handicraft was defined as a primary privilege of the citizens, and new, dynamic dimensions of good 'property rights' were introduced to the manors. New communication and information techniques and systems were tested. We can see this in regional and interregional trade with new types of merchants and new commercial institutions (such as fairs and marketplaces, trade guilds, commercial law, special organizational forms of storing, borrowing and changing money—all these were the outcome of perpetual communication). The consequences were a very rapid diffusion of technical knowledge in mining, architecture, handicraft, and agriculture.

This new system was also open for inventions from the Orient, the Arabs and the Islamic world, and accepted new insights from China and India. Technical inventions which revolutionized communication and transportation were the horse collar (tenth century, used in China since 450 AD) and the stirrup. From 1200 onwards the diffusion of the use of Arab numbers began and made trade much more easier. The compass and the compass needle (China 1075) at about 1200 improved navigation. Though the quality of the techniques of Roman road building could not be attained, the opening up of roads to everybody was a big improvement on the *cursus publicus* in the ancient Roman world. In about 1380 cities, religious orders and guilds introduced the new system of sending messages regularly and for long distances by private postal institutions.

Predominantly face-to-face communication using primarily oral means of information shifted more and more to a written-media stage. The monasteries and the first universities with already-formed libraries had a great impact on learning and knowledge. From the midst of the fourteenth century onwards the improvement of shipping on the rivers by constructing canals and canal locks began. Measuring time took on new dimensions with the invention of more precise clocks with wheels at about 1330. From the midst of the fourteenth century we can find clocks on the towers of churches. In 1510 the first pocket watches appeared.

The Early Modern Times brought about the second revolution of communication in Europe. The adoption of Chinese navigation techniques was completed; the compass freed the way for discoveries and the exploration of the New World. Trade in mass goods began. This became easier when plantations began to produce 'fungible goods' (like tea, coffee, cotton, and tobacco), which enabled a new trade on commodity markets.

The production and the use of paper and the idea of the movable type for printing (Johannes Gutenberg 1397–1468)—also of Chinese origin—brought about the shift from a written to a printed culture. Books now could be printed at a relatively low price and in

large numbers. The woodcut print (firstly used in 1400) and the copperplate print (firstly used in 1446) now could be combined with this new printing technique. Pamphlets were printed and could be easily distributed. Political and religious controversies, teaching, and learning took on new dimensions. Newspapers were introduced. The monopoly of science and information was broken up. The book became important for the unlimited storage and diffusion of information. The pamphlet was used for political discourse and opened up possibilities for participation in political and religious debates, and the newspapers opened the way to inform a growing number of readers about recent events in society.

The sovereigns of these territories reorganized their postal system and widened communication possibilities. For example in 1486 'Kurfürstliche Botenanstalt in Brandenburg.' In 1490 the postal system in the German Reich was reorganized under Maximilian I, and in 1516 the Vienna–Brussels postline was introduced, while the Brussels–Rome postline introduced in 1522 of the Thurn & Taxis Vienna-Nurenberg. The new communication advantages cleared the way for a European expansion over the Atlantic and created a second West in the New World of America.

The third revolution began before the Industrial Revolution and influenced the period up to the present day in three stages. In the first stage the mercantile system introduced more regular traffic, a regular postal system, and supported canal- and road-building. Milestones in France included the 'Canal du Centre' between the Loire and the Saône (1555) and the 'Canal du Midi' between Southern France and the Atlantic (1666–1681). Soon after, many canals in German territories, in the Dutch Lands and in England were built. The introduction of railways from the 1820s and 1830s onwards, the intensive use of steamships from the 1850s and 1860s onwards, and the common use of telegraph, telephone and the overseas cable since the 1850s–1870s marked the second step, which reached its peak in a highly integrated world economy before World War I.

The automobile and new road building, especially in the form of highways; and the victory of the street over the railway and the airplane widened communication and transportation possibilities following the interwar period. This brought greater reductions in the regional differences in prices, greater allocations of production and resources, more division of labour, mass production for wide national and foreign markets, standardization, and the unification of languages, morals, and tastes. The third step began in about 1970 with the 'postindustrial phase' or 'age of information.' The multimedia revolution brought the technical inventions of ISDN, the mobile phone (cellular phone), the fax, the PC and the Internet (www, on-line and e-mail), and digital forms of TV, broadcasting and printing. The economic consequences were e-commerce, direct banking, more foreign investment in many countries, and a very sharp decrease in the share of costs for information and transport, globalization, digital traffic engineering, and teleworking. The socio-cultural consequences were teleteaching, networked scientific community, and telemedicine.

1.2 Historiographical Trends, Further Research, and New Fields

The historiography of former times seldom studied communication and transportation. Since the turn of the nineteenth century economic history reached an independent status and transportation problems were described under the aspect of commerce. In the period before World War I in nearly all industrialized countries the first technical museums were erected. They had a great impact on the study of the history of technology and innovations, especially railways, cars, automobiles, ships, airplanes, and information devices like the telephone and telegraph. The history of technology became a new subdiscipline within economic history. In the last few decades the science of journalism has widened to a science of media and examines all media, especially mass media, in a historical context. Today a modern history of communication has to combine all these fields in cooperation with other social and economic disciplines.

There are, of course, many possibilities for further historical research in the field, e.g., studies into the regional, national, and worldwide diffusion of communication and transportation techniques; the social consequences of media revolutions; the impact of the media and the transport revolution on political situations and military conflicts; the access to communication and information techniques; religious and political control and inhibition of communication (censorship); the effects of the transport revolution within economic development; the role of official and nonofficial statistics in information about economies; the consequences of changing communication and transportation in mass tourism, leisure, and hobbies. Other possibilities include the rise of special cultural forms, traditions and customs concerning, for example, letter writing, traveling by coach, railroad, automobile, ship and airplane, and studies of the intensification of communication in personally written, and in digital communication.

Even completely new fields can be developed under the aegis of communication. One example may be the invention of the European 'financial intermediation' in banking and stock exchange. It can be seen as an important new way of communication in the economic and business sphere of the seventeenth and eighteenth centuries.

How to finance firms and enterprises and how to finance states and their budgets—these are the important questions in every modern economy. In former

times people who had large savings and lent to the state or to private entrepreneurs could not get back the money before the end of the agreed term. So, normally, the only possibility was to hold large stockpiles of money without being able to lend it in order to remain liquid at any one time. This problem was shared by wealthy individuals and institutions, such as insurance companies, managements of orphans' properties, etc. No civilization before had managed these problems adequately until Europe founded new ways of communication to bring together lenders and borrowers. There are four points that stress this information and communication revolution in banking since the seventeenth century.

(a) Since the period between the fifteenth and seventeenth centuries, communication and information has improved through investment in new roads, cars, ships, canals and new media techniques. The unification and standardization of goods also brought improvement, especially through the creation of 'fungible' goods: where one item stands in quality for all the other pieces of this product. Markets could thus be transformed partly into markets with 'fungible' goods. The exchange in products for certain metals, and for certain crops, especially tropical plantation crops like cotton, tea, coffee, sugar, etc., was born. This facilitated economic communication enormously. As the qualities of these goods were defined *ex ante* and were well known, merchants could deal in great volumes of these goods and articles without bringing them physically to the markets. Transaction costs were thus dramatically reduced.

(b) In combination with stock exchanges the experiences with 'fungible' goods were transferred in the seventeenth century to the financial sector. Creating fungible bonds for the state and public authorities (instead of individual obligations for single lenders in former times which could not easily be transferred to other capitalists) pulled hidden private stockpiles of wealth into the public economy and brought the money into the hands of sovereigns and governments. This idea spread to fungible shares for enterprises. Now it became possible to erect big enterprises in the form of joint stock companies. The first joint stock companies were firms within the trading sector, followed by companies in infrastructure and communication, in the banking system and last of all in big industrial firms.

(c) The next point in this development was the improvement of the financial mediation of banks. A new type of bank developed which brought together people who had money but did not need it at the time and people who had no or too little money and wanted to make productive investments in business. The 'goldsmith bankers' of London were the first to succeed at this business, because they found out that the communicative role of a bank has to be the transformation of risk, of terms, and of size. Fungibility and the new communicative role of banks became the main motor for a 'financial revolution' as precondition of the Industrial Revolution.

(d) Since the beginning of the twenty-first century new steps in financial communication have been made, especially in the context of the PC and internet systems. New generations of financial products have arisen, including e-banking and worldwide speculations on stock exchanges.

Communication: Electronic Networks and Publications

Historically, the basis for scholarly communication has included a variety of publications, such as scholarly journals, newsletters, conference proceedings, monograph series, and books. Face-to-face communication took place via conferences, workshops, colloquia, and other events. Purely audio communication was primarily restricted to telephone communication and radio broadcast. Video and film captured image, speech, and event for live broadcast and delayed replay.

However, electronic networks have expanded means of communication and publication, first via CD-ROM, local area networks, and since the early 1990s and later (depending on network development in the world) via global networks including the Internet. The Internet protocol enables digital communication via email, FTP (File Transfer Protocol), chat rooms for simultaneous, interactive electronic communication, and video conferencing for educational and consulting purposes. Publication can be instantaneous with the completion of a document, image, or data set by using hypertext formats (HTM, HTML), PDF, PostScript, or even text (ASCII) formats coupled with placement in the World Wide Web. Hypertext references allow linking between cited and related items. Electronic publishing (e-publishing) includes both self-publishing and refereed publishing in various forms directly on the Internet or in an electronic journal with access via the World Wide Web. Publishers of refereed and nonrefereed scholarly journals are increasingly providing digitized versions parallel to the print journals, and new 'digitally borne' journals available only in electronic form (for instance *Journal of Electronic Publishing* (http://www.press.umich.edu/jep/), *First Monday* (http://www.firstmonday.org), *Psycholoquy* (http://www.princeton.edu/~harnad/psyc.html), and many more; NEWJOUR (http://gort.ucsd.edu/newjour/NewJourWel.html) has listed all new electronic journals since 1995; Charles Bailey also provides the *Scholarly Electronic Publishing Bibliography* with periodic updates at http://info.lib.uh.edu/sepb/sepb.html; see also *A Field Guide to Sources on, about and on the Internet: Electronic Publishing* at http://www.cc.emory.edu/WHSCL/electronic.publishing.html) are originating from scientists, learned societies, and university presses.

Electronic publication has permeated all fields of traditional publication formats: e-books, e-journals, e-zines, electronic proceedings, newsletters, electronic theses, and especially digitally prepared encyclopedias (see Pang 1998, Miller 1998) offer the added multidimensional aspects of integrated active hyperlinks between related concepts, articles, references, citations, graphs, and tables, as well as home pages of authors and institutions. This augments the linear reading and information-seeking methods of the past, provided that the objects 'pointed' or linked to are available in digital form. The hypertext format contributes to more efficient, timely, and economical revision especially evident in encyclopedias, multimedial works, and complete websites built on the concept of combining information building blocks or content units to produce webpages by 'spontaneous generation' at user demand.

Similarly, a single work such as an article can become a 'dynamic document' which allows continuous additions, alterations, and comments also in the form of an attached discussion list. This procedure is changing the nature of the publishing paradigm both in the sense of a fixed 'date of publication' and in the finalized or 'closed' state of the information content in this work (examples of dynamic documents include the experimental journal *Living Reviews in Relativity* (http://www.livingreviews.org)).

The basis for digital connections are the electronic networks established within the framework of the Internet protocol (TCP/IP) and expanded to its present state in the World Wide Web. Electronic networks began in the 1950s and were developed by the Defense Advanced Research Projects Agency (DARPA) particularly for military defense purposes well into the 1980s, with some academic institutions in the USA included by merit of their involvement in defense research. The 'Internet' was then opened to include higher-education institutions in the USA at the end of the 1980s, as well as other US research libraries and schools. As of 1991, other institutions could also use the Internet, including non-US educational institutions and commercial enterprises.

This created new possibilities for global communication, scientific exchange, and building of international collaboratories, as well as enabling rapid dissemination of scientific results. The business world also recognized the potential of the Internet for e-commerce. Booksellers, publishers of all sorts, corporations providing educational programs, as well as other entrepreneurs, have developed business strategies which integrate the electronic communication and hypertext publication possibilities of the Internet. As a result of this development, certain aspects of free

access to information, as supported by libraries worldwide, have been commercialized, and new questions of licensing and ownership of intellectual property have been raised. Issues of electronic piracy, copyright, and protection of intellectual property have taken on new dimensions and demand new techniques to assure quality control, validity, authenticity, and ownership rights.

Similarly, the economics of scholarly publishing, sometimes referred to as a 'crisis in scholarly publishing,' have promoted the transition to electronic publication. In particular, the US Coalition for Networked Information (CNI) (http://www.cni.org), established in 1990 as a result of the opening of the Internet to general academic institutions, has dedicated itself since its inception to the analysis of the system of scholarly communication and its transformation through the effects of networked information transmission. CNI-initiated cooperation between university libraries and commercial publishers resulted in the first electronic journals project, TULIP (**T**he **U**niversity **Li**censing **P**rogram), in which pricing models and availability of electronic journals were tested (see Lynch 1995).

The nature and scope of the Internet as a distributed information network challenges traditional tasks associated with libraries, free access to information, and also the author–publisher relationship. Issues of 'access versus ownership' of scholarly articles through restrictions of licensing agreements could make publishers' servers the sole repositories of scholarly works. This also evokes a vehement controversy between certain segments of the academic community over 'who owns scholarly publishing' (Bacharach et al. 1998), Odlyzko (1995, 2001), Harnad (1995a), and others support the concept that the author and the author's institution, having supported the research and researcher, 'own' the information and have the right to archive it on an institutional e-print server, as well as to offer it cost-free to the scientific world via the institutional server, the author's homepage, or similar free-access mechanisms.

Thus, the original concept of 'open' access was synonymous with 'cost-free' access to information which is necessarily changing to access often with a price. Most publishers of electronic journals do not allow copies of the electronic files to be given to non-licensed users in the way that paper copies of non-subscribed journal articles were made available via interlibrary loan. Thus, certain aspects of scientific communication can no longer function without corresponding licensing agreements at the user's institution or immediate payment (pay-per-view) via credit card.

In addition, scholars were often frustrated by long delays from the time of submission to time of publication. The ensuing conflict of interests within the scientific community has given way to the extensive participation in preprint servers and to self-publishing or 'self-archiving' (see Harnad 1995b). Originally based on FTP-Archives (Gardner 1990) for scientific articles, the first preprint server, the so-called 'Ginsparg-Server,' originally developed at the Los Alamos National Laboratory in 1991 by Paul Ginsparg to allow researchers in high-energy physics immediate access to scientific articles without the delay of peer-review and publication schedules. Since then, other subject-oriented eprint servers patterned after this server have evolved (NCSTRL, REpec, CogPrints, PhysNet, MathNet). In 1999, representatives from these servers plus representatives from research libraries and digital library initiatives in the USA met to discuss a cooperative project to create a retrieval mechanism for all eprint servers. Originally called the Universal Preprint Service (UPS), this evolved into the Open Archives Initiative (OAI) (http://www.openarchives.org) which has determined a standard set of metadata and a harvesting protocol for search and retrieval of the metadata from all participating eprint servers, including not only self-archived articles, but also electronic theses (see also the National Digital Library for Electronic Dissertations and Theses (http.//www.ndltd.org)) and other formats of electronic scholarly information.

Another response to the development in scholarly publishing is the increased participation of university libraries and learned societies in alternative initiatives such as SPARC (Scholarly Publishing and Academic Resources Coalition (http://www.arl.org/SPARC/); see Johnson 1998, Rosenzweig 1999). Over 175 (at the beginning of 2000) research institutions, college and research libraries, consortia, and library associations from North America, Europe, Asia, and Australia in SPARC pool their resources to produce high-quality scholarly journals on a purely electronic basis. The intellectually high quality, but significantly cost-effective, scholarly journals created by this group challenge overpriced commercial competitor titles while preserving the academic tradition of quality through peer review.

Electronic publications have the potential of citation-linking from one electronic work to the full text referenced. This, however, has implications connected not only with standardization of technological markup, but also with cost and access to the full texts of the referenced works. 'Click-through,' or direct, access from a hyperlinked reference or concept in one electronic work in a publisher's or institutional server to another server where the targeted item is stored may be inhibited by licensing regulations or be subject to conditions negotiated (or not negotiated) by the responsible institution.

As a results of such restrictions for education and scientific research, the US Government supported development in 1999 of several subject-oriented e-print servers, PubMed, PubScience, and PubMedCentral (http://www.nih.gov/about/director/pubmedcentral/pubmedcentral.htm). These develop-

ments, in addition to those evolving out of the scientific communities, challenge prevailing publishers' policies for licensing scientific information while also providing mechanisms for free access to article information on a subject-based, as well as on a global and interdisciplinary, level.

To counteract this, about 25 publishers world-wide collaborated to develop the 'Cross Ref' service (http://www.crossref.org) which would allow reference-linking and click-through licensing agreements. This publishers' consortium has determined a standard set of bibliographic, content, and naming values (Digital Object Identifier, metadata), a common navigation tool (search engine), and a pricing scheme to facilitate direct access via references to full texts in other publishers' servers based on composite licensing agreements with all participating publishers or on a payment schemes ('pay-per-view,' 'pay-per-print') at point of use.

A major research study on the changing paradigms of scholarly publishing, the Open Journal Project, began in 1996 under the eLib Programme in Great Britain and has been expanded as of 2000 under the joint JISC–NSF International Digital Libraries Research Programme in the 'Open Citation Project' (http://opcit.eprints.org/). The 'Open Citation Project' will establish electronic reference links from 100,000 papers in the Los Alamos arXiv e-print server (http://arXiv.org) to the corresponding electronic full texts on other sites (publishers' servers as well as other noncommercial sites). In conjunction with the Computer Research Repository (CoRR), a considerable number of nonelectronic resources in the cited physics, mathematics, and computer science literature will be integrated, also demonstrating procedural aspects of connecting electronic and nonelectronic documents via citation-linking as an enhancement of the information value of electronic resources (see Hitchcock et al. 1998, 2000).

Electronic publication formats also have the potential for long-term archiving of scholarly publications combined with global access. In 1995, the Johns Hopkins University Press (JHUP) cooperated with the Milton S. Eisenhower Library with funding from the Andrew W. Mellon Foundation and the National Endowment for the Humanities (NEH) to digitize full-text scholarly journals from JHUP in the Project MUSE (http://muse.jhu.edu/muse.html). By 1999, 46 peer-reviewed JHUP journals in the humanities and the social sciences were available via a searchable database. This database will continue to be expanded to include all JHUP journals.

The JSTOR project (**J**ournal **Stor**age—The Scholarly Journal Archive), in which back volumes of journals in philosophy and the humanities have been digitized to facilitate electronic access and navigation, has developed a new, collaborative payment model (see Guthrie 1997a, 1997b). Member libraries pay an initial fee based on the size of the parent institution and number of students and faculty, as well as an annual fee for individual use. Thus, the consortium of library customers supplies the funds which allow continued maintenance of existing digitized journals, as well as seed-funding for systematic scanning, processing, and integration of further complete sets of other selected journals.

Standardized archiving procedures for scholarly publications in electronic form have not yet been achieved. The archival function of digitizing print volumes at key subject-oriented institutions can provide the respective scientific community with an electronic repository of materials which the publishers would not find financially feasible to digitize. Further use of digitization and development of standardized metadata for digital preservation are incorporated in the CEDARS Project in Great Britain (http://www.leeds.ac.uk/cedars/) which addresses strategic, methodological, and practical issues of digital preservation of information resources. Various projects in Australia, the USA, Germany, and other countries are also working on these issues.

The quality of content management and information provision through electronic publishing in any format is dependent on a variety of new concepts: standardized metadata, licensing terms and conditions governing access, citation-linking, subject-specific search engines and archival servers, intellectual design, and new forms of visualization of scientific knowledge. Metadata initiatives (for instance, the Text Encoding Initiative (TEI) (http://www-tei.uic.edu/orgs/tei/), the Government Information Locator Service (GILS) (http://www.gils.net/), the Encoding Archival Description (EAD) (http://lcweb.loc.gov/ead/), and the Dublin Core Metadata Initiative (DCMI) (http://lcweb.loc.gov/ead/) are some of the most notable; see also the IFLA Electronic Resources Bibliography for 'Digital libraries: Metadata resources' (http://www.ifla.org/II/metadata.htm)) parallel traditional library cataloging categories while accommodating new meta-information needs for resource discovery, search and retrieval, access and availability schemes for digital and non-digital items. Various projects, such as the Electronic Text Center of the University of Virginia or the Gutenberg Project (a world-wide collaboratory for digitizing literary classics and making them available in electronic format), were instrumental in promoting the transition from print to electronic texts and creating text-mark-up metadata schemes. Other metadata schemes implement structures for payment and access models (terms and conditions), and facilitate processing of remuneration and payment channeling of artist's honoraries or performance fees to the appropriate recipients, for instance in the fields of music and art (e.g., the Interoperability of Data in e-Commerce Systems).

Studies on the acceptance and use of electronic publications show that the natural and biomedical science communities demonstrate greater acceptance

and frequency of use of electronic-information resources (see The International Coalition of Library Consortia 1998, Rusch-Feja and Siebeky 1999). The social and behavioral sciences are less accepting of electronic resources due to often substantially longer articles and later integration of computers in these fields. There are also cognitive and behavioral reasons relating to qualitative assessment of use and acceptance of electronic information resources. Further research on digital presentation of scientific results, visualization techniques, and design aspects to heighten readability of electronic resources and render ease of interpretation of complex data sets, especially in the natural sciences, can be expected in the coming years. New developments in information retrieval and search precision, automated collection of metadata, and personalized information brokers in complex information portals will add value to electronic publications which surpasses that of print equivalents and will create new dimensions for electronic publishing and scholarly information in a networked environment.

Communication: Geographic Aspects

1. *Defining the Field*

Communications geography, which includes mass communications and telecommunications, considers the movements or flows, directions, and volumes of information between and among persons and areas. The communication may be within households and neighborhoods as well as firms, organizations, and states. While elements of information transfer have always been inferred components in human geography, for example, in the diffusion of religion or the diasporas spreading colonialism, it was during the 1960s and 1970s that the spatial components of communication began to receive serious attention. These decades, at least in the wealthy and industrialized worlds, experienced rapid urbanization and growth in tertiary sector employment and growth. They were associated with a postindustrial economy and society. The key employment categories in the services economy were retail, wholesale, and international trade, transportation, government, finance, health care, and education. Also leisure activities, telecommunications, printing and publishing, education, and the media experienced growth. For those social scientists studying these services, a refinement was needed; the term quaternary sector identified those in information and communications industries and services. Sociologist Daniel Bell in his 1973 *The Coming of the Post-Industrial Society* used this term in describing the economic/social transitions that were occurring in American society.

2. *An Emerging Field of Inquiry*

Those early geographers who developed this specialization came from backgrounds in economic, social, and urban geography. Some were interested in transportation networks, others in urban social behavior, and still others on the social impacts of Information and Communications Technology (ICT). During this same time geography was experiencing disciplinary shifts, including the emergence of social-behavioral geography, which utilized some concepts, models, and theories from psychology and sociology, and then humanistic geography, with close ties to history, literature, philosophy, and the arts. Human geographers in both spheres were interested in the ways people communicated, media producers, the diffusion of information, power issues associated with information production, how places were presented, and the ways information geographies might be mapped.

Some of the initial work by behavioral geographers applied the Shannon–Weaver model to geographical contexts. This model dealt with the flow of electronic information from its source to its destination. That flow could be person-to-person (face-to-face) or person-to-area (television reporter transmitting news to national or global audiences) or area-to-area (from a government to major trading partners). Many channels as well as barriers or filters could influence the transmission of information from its source to its final destination(s). The term gatekeeper was introduced and could be applied to a newspaper editor, owner of television stations, or government agency censoring reports to its population. The spatial dimensions of information flows, both interpersonal and corporate, were studied, as were the impacts of mass media. Geographers also mapped information and communication structures, including the newspaper sheds (circulation areas) and the media sheds for radio and television stations.

A major theoretical line of inquiry during the 1960s was the 'diffusion of innovations'; it was introduced to European and North American geographers by Swedish geographer Torsten Hägerstrand (1967) who used the concept to describe and predict the adoption rates of agricultural innovations. Rural sociologist Everett Rogers (1962), with his work on the social dimensions of diffusion, also influenced geographers' thinking. Diffusion research identified individuals as being innovators, early and late adopters, or laggards. Geographers examined the diffusion of crops, diseases, institutions, revolutions, and consumer purchases. Maps at varying scales depicted adoption rates. Some studies described patterns; others used sophisticated mathematical models to predict adoption rates.

One of the first publications in communications geography was *Human Geography in a Shrinking World* (Abler et al. 1975), which included discussions on space-adjusting technologies, tyrannies and human freedom, monocultures and minicultures in the media,

bureaucracy and alienation, and futuristic scenarios. Several authors discussed how these technological changes affected households, firms, and organizations. There was also interest in how to display 'shrinking world' concepts cartographically. Three additional concepts that formed the basis of discussion were time–space convergence, cost–space convergence, and human extensibility; the first referred to the rate places were 'moving closer together' in relative time, for example, with faster transnational phone calling capabilities, and the second, how lower costs reduced the friction of distance in placing calls or mailing items from the US east coast to the west coast. Over time the costs to communicate from place to place became more uniform, that is, distance ceased to be a barrier to communication; standardized postal rates in a country represent a good example of complete cost–space convergence. Human extensibility relates to the networking features of an individual, institution, university, government, or nongovernmental organization (NGO).

Communications geography continued its ascendancy during the 1970s and 1980s with contributions coming from geographers with backgrounds in the social sciences and humanities and with ties to rural and urban sociology, psychology, computer science, but also telecommunications, film studies, literature, architecture, the social impacts of technologies, and future studies. The role of mass media in promoting popular culture, news reporting, the place settings and images in film and television documentaries, state boosterism, travelers' writings, and landscape representation in the popular literature were common themes (Burgess and Gold 1985, Zonn 1990). The experiences of authors, painters, photographers, lyricists, and film directors were studied to communicate to readers the meanings of places and landscapes.

Cartography was also changing from a technique focusing on how best to display and represent data, whether pen-and-ink methods or automated mapping, to the construction and interpretation of maps, that is, their power, meaning, identity, and interpretation. Maps became more than displays of information, but products in which information is communicated with social meanings and where the author/cartographer (whether a scholar, company, or state) conveys different messages to readers. Context was important. The colors, languages, symbols, and projections are all elements of visual 'communication.' Maps were also designed for the visually and color impaired. Visualization became a concept associated with the presentation and representation of information, whether maps or graphs. Maps were but one subject of texts and discourses studied by social theorists in geography; these poststructuralists also investigated the constructions of wilderness paintings, landscape poetry, city boosterism, and foreign policy, all examples where power was important in communication (Barnes and Duncan 1992). Social theorists in geography benefited from the writings of linguists, philosophers, intellectual historians, and landscape architects.

Paralleling social theory contributions in communications geography in the early 1990s were case studies on specific countries, firms, communications networks, and the social impacts of ICT. A volume that highlighted these developments was *Collapsing Space and Time: An Introduction to the Geography of Information and Communication* (Brunn and Leinbach 1991), which contained chapters on telecommunications and regional development, ICT and religious broadcasting, banking, medical services, and distance learning, and the notion of the 'electronic cottage' or homeworking. What these authors and others writing in the early 1990s failed to grasp was the blossoming of GIS (Geographical Information Systems) and the rapid diffusion of the Internet and WWW.

3. *Current Research*

Speed, volumes, networking, and accessibility are the keys to understanding the geographies of the Internet. The net is a medium to send, receive, analyze, store, disseminate, manipulate, and map large amounts of print, sound, and visual data to, from, and about households, firms, organizations, institutions, and states. Developments are occurring in banking, real estate, education, health care, entertainment, and tourism, all of which are information based. The traditional information and communication services such as journalism, broadcasting, and telecommunications are also affected by these high tech developments. While the Internet and WWW have diffused to many parts of North America and Europe, large areas of the developing world remain unwired. An entirely new international lexicon has developed, including virtual community, cyberspace, cyberplace, chat-rooms, all terms relating to communication, place, and identity. Children and adults are learning these terms and how to use the technologies at the same time, sometimes elders learning from youth. Most materials (print or on-line) published about the Internet are in English as Internet communication is dominated by American English. Non-English users are almost forced to learn English if they want to communicate and interact in electronic space. Geographers keep apprised of developments in ICT not only by attending conferences and workshops, but also through GEOGCOMM, a listserv operated from the University of Kentucky, the IGU (International Geographical Union) Commission on the Geography of Information Society, and the journal *Netcom* (Networks and Communications Studies).

Much of the recent research by geographers addresses issues about cyberspace, electronic commerce, telecommunications, and social impacts. For example,

some geographers are investigating the geographies and geometries of virtual places, electronic scholarly communities, the virtual geographies of the military, children's games, how states are using the WWW to promote themselves to potential investors and tourists, and the uses of GIS by emerging democracies, NGOs, revolutionary and hate groups (Pickles 1995, *Geographical Review* 1997). Others are examining the meanings of electronic space, human rights in an electronic state, telecommunications and governance, global 24-hour banking, and ICTs in peripheral rural areas to promote grassroots economic development (Wilson and Corey 2000). Urban geographers are investigating how telecommunications are transforming urban spaces and systems, high tech industrial location in an information age, the diffusion of innovations, teleworking, gender and work, and the role of the state (Graham and Marvin 1996, Wheeler et al. 2000). Mapping communications in an electronic age and the meanings of accessibility in the information age are additional topics (Janelle and Hodge 2000, Dodge and Kitchen 2001). E-commerce has been studied with regard to financial services, recruiting, regulatory problems, and diffusion in developing countries (Leinbach and Brunn 2001).

The electronic worlds of the fax, email, chat-room, and WWW are changing the strategies for industrial location, how governments define and regulate public goods, how consumers purchase goods and services, and how individuals behave. High-speed lines move money (itself information) in split-second time around the world 24 hours a day. Time zones lose their meaning. Students, scholars, community organizers, and governments can request information and have it often the same hour or day. Companies, cities, and states can use the WWW to promote themselves almost anywhere (where there are connections) and to anyone (who has an operating machine). 'E' services, now existing in banking, health, entertainment, tourism, education, and religion, keep carving out niches.

4. Dilemmas and Future Directions

While advances in high tech communications are diffusing rapidly throughout the developed worlds, and rich nodes in the developing worlds, geographers and others remind us that low tech communications and geographies and 'digital divides' remain much in evidence for most of the world's population. Some of these recent innovations have not diffused globally, nor will they, as they may not be desired or welcomed by some societies and individuals. Some states attempt to block these ICT, which is difficult; others cannot afford to construct fiber optic networks or satellite receiving stations, and still others seek to construct filters to screen out undesirable information for their citizens, children, or politically dissident groups. What is emerging alongside rapid advances in communications technologies (toward more wireless communities and miniaturized devices) is a widening gap between the 'have and have-nots' within cities, countries, and the world. The long-term social, political, and spatial consequences of these 'ICT gaps' remain largely unknown, but they are receiving the attention of geographers and others.

A number of troublesome philosophical and methodological issues surface when conducting research on these topics. They include the availability, reliability, and cost of data from public and private sources, privacy issues when individual household or firm data are sought, and the appropriateness of Western models when constructing theories and describing or explaining results. One also needs to keep in mind the role of the state in gathering the data and publishing them in tabular, digital, or cartographic form. Transnational corporations are also major producers and consumers of information about individuals, groups, societies, and physical environments. Medical, employment, income, and family history data can always be manipulated for evil purposes by rouge states, organizations, or corporations.

Among the questions being raised about the human dimensions of technological change are not only what ICTs tell us about human life and society, but also children and adults, girls and boys, women and men, and those with learning and physical disabilities and impairments (color, visual, dexterity, hearing). These are populations and groups who exist in all societies that merit continued study by those with interests in cartography, visualization, GIS, social theory, E-commerce, geopolitics, grassroots democracy, and teaching second and third languages. We also would benefit from investigating what is happening to humans as we communicate in and outside of cyberspace. What happens to our identity as we become geolimnal selves? And what does this mean? Recent research in communications and information geography is beginning to addresses these practical and philosophical questions.

Communication: Philosophical Aspects

S produces the sounds 'It's snowing' in the presence of *A*, and *A* instantaneously comes to know that it is snowing. *S* has *communicated to*, or *told*, *A* that it is snowing, and, as a result of *S*'s speech act, *A* came to know that it was snowing. Philosophical interest in communication turns on four interrelated questions. The first is about the logical structure of communication or, more specifically, about whether communication is a relation that holds among three things just in case the first communicated the second to the third. The second is about the explication, or analysis, of communication. The third is about the role of communication in the explication of linguistic meaning. The fourth is about how knowledge is acquired by communication. The questions are interrelated in that answers to any one question may constrain answers to one or more of the others.

1. *The Logical Structure of Communication*

The issue about the logical structure of communication can be explained in the following way. The verb 'to love' stands for a two-place relation, a relation that holds between two things just in case the first loves the second (temporal considerations are ignored for simplicity of exposition). This is indicated by the fact that if we take a sentence like

(a) Al loves Betty

and replace its singular referring expressions with variables, we obtain (what logicians call) the open sentence

(b) *x* loves *y*.

This indicates that the verb 'to love' stands for a two-place relation, a relation that holds between two things just in case the first loves the second. Similarly, we can say that giving is a three-place relation that holds among three things just in case the first gives the second to the third, because from a sentence such as

(c) Al gave that book to Betty

we obtain the three-place open sentence

(d) *x* gave *y* to *z*.

The issue concerning communication is whether we can likewise start with a sentence such as

(e) Sally communicated that it was snowing to Abe

and obtain the open sentence

(f) *x* communicated *y* to *z*.

If we can, then a further issue is about the sort of things that can occupy the *y* position. That is, what sort of *things* are the things we communicate, if communicating is represented by (f)? There is a philosophical issue about the logical structure of communication because there is disagreement about how to answer both questions.

The *prima facie* case for taking communication to be a three-place relation is simple: it is the obvious way to account for the fact that (e) entails

(g) There is something that Sally communicated to Abe—to wit, that it was snowing.

A possible reason to resist this first thought emerges when we ask what manner of *thing* is this thing, *that it was snowing*, which would be the entity Sally communicated to Abe if communication is a relation expressed by (f). For it is apt to appear that things communicated are what philosophers nowadays call *propositions*—mind- and language-independent entities that have truth conditions but are not in space and have no physical properties whatever. The trouble is that many think there are good reasons not to believe that such things exist (e.g., Quine 1970).

It must, however, quickly be said that the immediate source of concern here is not with communication *per se* but with *that-clauses* in sentences such as (e) and 'Sally believes that it is snowing'—that is, with expressions of the form 'that *S*,' where '*S*' holds the place of a sentence in the indicative mood. More generally, the concern is with what (for historical

reasons we need not go into) philosophers call the *problem of intentionality*. Do that-clauses refer, or purport to refer, to *entities* that are believed and communicated, or do they have some other semantic function? While this is a problem that can be stated without specific reference to communication, a complete account of communication presupposes its resolution. Until we understand the semantics of that-clauses, we will not know what communication is. But there is no universally accepted solution to the problem of intentionality, and for every position in logical space there are philosophers who occupy it. For about one-third of the twentieth century, the American philosopher Willard von Orman Quine had so effectively stigmatized propositions that most philosophers were too frightened to believe in them; but philosophy has recovered from Quine's influence, and most philosophers today feel that the case for propositions is stronger than any against them. At the same time, there is disagreement among propositionalists about the kind of propositions we believe and communicate. Here one finds two dominant views. The *Russellian view* (after the British philosopher and logician Bertrand Russell) holds that propositions are made up of the objects and properties our beliefs are about, while the *Fregean view* (after the German philosopher and logician Gottlob Frege) holds that propositions are made up of (what are nowadays called) *concepts*, or *modes of presentation*, of the objects and properties our beliefs are about. But even among Fregeans there is disagreement about the nature of concepts, and it is not clear whether the difference between the Russellian and Fregean views is in practice anything more than alternative styles of bookkeeping, since Russellians agree that concepts are crucial to the individuation of thoughts and acts of communication. In what follows I shall assume, which I believe to be correct (Schiffer in press), that communication is a relation holding among a communicator, a communicated proposition, and a person to whom that proposition is communicated, without prejudice as to whether those propositions are Russellian or Fregean.

2. *The Explication of Communication*

How can the communication relation be explicated, or analyzed? One question that falls under this rubric concerns what we can know *a priori* about the *concept* of the communication relation. The strongest view here holds that *a priori* conceptual analysis can arrive at a correct, informative, and noncircular completion of the schema

(h) Necessarily, for any agent x, proposition p, and agent y, x communicates p to y if, and only if, … .

Those influenced by the late British philosopher J. L. Austin, such as the American philosopher John Searle, hold that a completion is possible that appeals to rules that are constitutive of the practice of communicating, in the way that the rules that define chess are constitutive of that practice, but none of these theorists has, to my knowledge, made any serious attempt actually to complete the schema, and in any case there are persuasive reasons to think that the appeal to 'constitutive rules' is mistaken (Austin 1975, Searle 1969, Schiffer 1972).

The only serious attempt to provide a complete *a priori* analysis of communication has been by the late British philosopher H. P. Grice and by others who sought to improve on his attempts (Schiffer 1972, Bennett 1976, Grice 1989). Three things are distinctive of the Gricean program. First, it attempts to define communicating p wholly in terms of the communicator's audience-directed intentions, included in which is her intention to get her audience to believe p. Second, the means by which the audience is intended to arrive at his belief is by taking the communicator's perceptible act (e.g., her uttering certain sounds) as evidence that she performed that act intending to get her audience to believe p, and then to take her having that intention as evidence that she herself believes, or believes she knows, p, and then taking her believing (she knows) p as good evidence that p is true. So, when Abe came to know that it was snowing as a result of Sally's telling him that it was snowing, his knowing is due to his having adequate evidence—viz., the fact that Sally believed (she knew) that it was snowing—for the fact that it was snowing. Third, linguistic meaning—the meanings of natural language expressions—was then to be defined in terms of the now reduced notion of communication (or, more accurately, in terms of a reduced notion of speaker meaning that includes telling as a species of speaker meaning). In the end, one would have a reduction of the semantic to the psychological, which, we shall later notice, would set the stage for a reduction of psychological facts to physical or topic-neutral facts—facts, such as the fact that one event was caused by another, which do not entail but are consistent with there being no nontopic-neutral facts other than physical facts. (*Functional* facts are topic-neutral facts that pertain to the causal or counterfactual relations relating internal states to one another and to sensory input and behavioral output.)

Conceptual analysis of the kind practiced by Griceans is now generally regarded as *so* twentieth century. In addition to this general skepticism about definition-seeking conceptual analysis, there are specific problems with the best efforts in the Gricean tradition. It has proved very difficult to state nonsemantic conditions that are jointly sufficient for communicating that such-and-such; the complexity of the analyses inevitably proffered in the attempt to get sufficient conditions makes one doubt that ordinary speakers have the supersubtle intentions those accounts ascribe to them; and, related to these

problems, it seems that if we subtract from a speaker's intentions her intention to be telling her audience that such-and-such, we are not left with enough non-semantic propositional attitudes (i.e., thought states that have propositional content) in terms of which one could define communication (Schiffer 1987, pp. 242–9). Armchair reflection on the concept of communication can yield important necessary truths about communication, but it is doubtful if it can yield a definition, let alone a definition in wholly non-semantic terms.

Much more influential than attempts to define communication have been attempts to show that communication facts, like all other intentional facts, stand in a relation to physical facts which renders the intentional facts naturalistically respectable. But there is no universally accepted view about what is required to render the intentional a respectable part of the natural order. Some philosophers insist that intentional properties and relations be identical with physical properties and relations. Such an identity need not be discovered by *a priori* conceptual analysis; it could have as its model the *a posteriori* identification of, e.g., heat with molecular motion. Yet this insistence seems chimerical when the intentional relations are relations to propositions. For the idea of a *physical relation* to *propositions* is evidently incomprehensible (what on earth could be a physical relation to the proposition that $1^2 + 1^2 = 2$?). More promising is the idea that propositional-attitude relations like believing are functional/causal relations. If there are such identifications, it is doubtful that they can be discovered by *a priori* conceptual analysis, and the reasons for supposing that there are *a posteriori*, scientifically discoverable identifications of propositional-attitude relations with particular functional/causal relations are considerably less than compelling, typically based either on implausible views about what is required by the 'unity of science,' the way in which the various special sciences are related to one another and depend on fundamental physics, or on a naive conception of what is required for propositional-attitude properties to play the causal/explanatory roles that they evidently do play.

A weaker position, but one accepted by many, is that while intentional relations cannot be identified with physical or topic-neutral relations, nevertheless all intentional facts *supervene* on non-intentional facts in that there could not be two possible worlds that were identical as regards to their non-intentional facts but not as regards their intentional facts. This position faces the challenge of having to offer some sort of explanation of the supervenience relation that anchors the intentional in the non-intentional, rather than taking that supervenience simply as a brute, inexplicable fact (Schiffer in press).

Finally, there are those who are content to hold a neo-Cartesian dualism wherein the intentional does not supervene on the nonintentional but does play the causal-explanatory role it appears to play (Bealer in press). The trouble with this view, however, is that it is very difficult to see how the intentional could plausibly play its causal role without the sort of reliance on underlying physical facts which the dualism precludes. Those who hold the neo-Cartesian dualism will doubtless appeal to *causal relations* between intentional states and their underlying physical states, but the difficulty just alluded to is precisely that of making sense of there being psychophysical causal laws or mechanisms capable of sustaining the alleged causal relations.

3. *Communication and the Explication of Linguistic Meaning*

What is it for marks or sounds to have meaning in a given population? Obviously, it has something to do with how the members of that population use, or are apt to use, those marks or sounds. If what we are concerned with is meaning in a public language like English or French, then it is reasonable to think that the use of those marks or sounds in *communication* looms large in the answer. On this much all agree, and David Lewis (1983) has provided an elegant framework for posing the further questions about the explication of linguistic meaning and the role of communication in it. Think of a language as an abstract object that may or may not be used by anyone; more specifically, think of it as a mapping of sequences of marks or sounds onto those things that are sentence meanings—propositions, perhaps, or, more likely, abstract entities that determine a specific kind of speech act and propositional content. Then the problem is to say what relation must obtain between a population of persons and a language so conceived in order for that language to be a language of that population. It is likely that this question enjoys no neat answer in terms of a single set of necessary and sufficient conditions, but it is probably not unreasonable to suppose that sufficient conditions can be stated that in fact explain what it is by virtue of which particular languages are used by particular populations. Such sufficient conditions will include communicative speech acts, but, what other kinds of speech acts? Can a unified account of speaker meaning be provided which subsumes all relevant speech acts? If so, are the Griceans right in claiming that those speech acts can be explicated in wholly psychological terms, thereby yielding a reduction of all public-language semantic facts to psychological facts? How exactly will the relevant kinds of speech acts enter into the account of what makes a language a language of a given population? Will some notion of *convention* be needed here? If so, what sorts of conventions, and how is the relevant notion of convention itself to be explicated? There is little agreement on how these

questions should be answered, and, anyway, philosophers have lately lost interest in the questions. Of much more contemporary interest is the explication of meaning in systems of mental representation, and it is not plausible that that explication needs recourse to communication (Field 1978, Schiffer 1987).

4. *Knowledge by Testimony*

Knowledge by testimony is the knowledge gained via communication; it is knowing something because it was told to you. The liveliest issue at present about communication concerns the nature of this knowledge. It is a lively issue because a certain view that was more or less taken for granted has been challenged. In order to understand what is at issue, we need to see what the assumed view was, what objections have been brought against it, and what new view, or views, of knowledge by testimony has been proposed in its place.

If one knows *p*, then *p* is true and whatever justifies one in believing *p* is what elevates one's true belief to knowledge. Accordingly, disputes about the nature of knowledge by testimony are disputes about the kind of knowledge-providing *justification* for one's believing *p* when one knows *p* by virtue of having been told *p*. The long-standing view that has been challenged is that this justification is just the ordinary sort of empirical justification one has whenever one knows something because one has adequate empirical evidence for it. There is no established view about the exact nature of such knowledge, but part of the traditional view is the idea that there is a single set of topic-neutral epistemic principles that determine when one is justified in the truth of any given proposition to be evidence for the truth of any other given proposition. Examples of knowledge gained in this way would be one's knowing that Smith murdered Jones on the basis of such-and-such DNA and fingerprint evidence; one's knowing that one's cat had been on the kitchen table on the basis of seeing cat hairs on the table; one's knowing that a smoker had recently been in the room on the basis of seeing a smoldering cigarette in the ashtray; and so on. In the case of communication, the idea, applied to an example, is that when Abe comes to know that it is snowing because Sally told him that, his knowledge-providing justification is his taking Sally's utterance of 'It's snowing' to be adequate empirical evidence that it was snowing, and that his so taking it is based not on any special faculty or principles of testimony but on ordinary empirical knowledge together with general inductive and deductive procedures. The Gricean conception of communication, as ordinarily conceived, presupposes this evidential view of knowledge by testimony. On this view, the key ingredient in Abe's coming to know that it is snowing is that he takes Sally's utterance to be evidence that she believes she knows that it is snowing, and his taking her having that belief to be evidence that it is snowing. None of this is to say that Abe is consciously thinking thoughts, or making inferences, about what Sally thinks, any more than you are consciously thinking the thoughts, or making the inferences, involved in your inductive justification when you see the smoldering cigarette and instantaneously conclude that someone has recently been smoking in the room. On this conception, knowledge by testimony *reduces* to knowledge gained by other means—by perception, memory, demonstrative, and non-demonstrative inference—and no more requires special epistemological mechanisms or principles of its own than does, say, knowledge gained by police detection.

Philosophers who reject the traditional conception of knowledge by testimony do so for two reasons: first, they have reasons for thinking that it cannot account for all that we know by testimony, and second, they have at hand an alternative conception of knowledge by testimony. As regards the direct objections to the traditional conception, Coady (1992) argues that if we took away all of an agent's knowledge based on testimony that itself did not depend on other knowledge by testimony, there would not then be the wherewithal to provide adequate empirical justifications for beliefs based on testimony. Tyler Burge has objected that while in gaining knowledge by testimony we rely on a presumption of reliability, we 'need not engage in reasoning about the person's qualifications to be rational in accepting what he or she says, in the absence of grounds for doubt' (Burge 1993, p. 469). This is evidently the sort of consideration also at work behind Robert Audi's claim that knowledge by testimony is

> 'typically not inferential. Certainly when trusted friends speak to us on matters we have no reason to think are beyond their competence, we normally "just believe" what they tell us.' (Audi 1998, p. 132)

Those who reject the traditional view hold that knowledge by testimony, in the typical case, is immediate and non-inferential. Sometimes this is developed via an analogy with the way in which perceptual knowledge is thought to be immediate and non-inferential (Coady 1992). According to Burge (1993), we have an *a priori* entitlement to belief what we are told immediately without argument or evidence, unless there are stronger reasons not to do so.

The direct objections are not persuasive. Coady presupposes that if knowledge by testimony were inferential (in the sense in which taking one thing to be evidence for another is inferential), then the inferences involved would rely on general beliefs about the reliability of testimony. This is unwarranted. On the most plausible inferential account, the crucial thing on which interlocutors rely is their commonsense knowledge of what would explain a given person's having a certain belief. Abe, for example, comes to believe that

it is snowing because he comes to believe that Sally believes she knows that it is snowing, and, using his general knowledge about the sorts of ways one is likely to acquire such a belief, Abe believes that it is very unlikely that Sally would have her belief if it were not snowing. The status of the relied-upon folk psychological theory may be taken to be on all fours with the status of the commonsense physical theory we rely on in forming our beliefs about the movements of physical objects.

As for the Burge–Audi objection, if believing what someone says off the bat, or not needing to engage in reasoning about a person's qualifications, were a reason for taking knowledge by testimony to be nonevidential, we could easily be shown not to have most of the evidential knowledge that we have. What 'reasoning' is one actively and consciously engaged in when one immediately concludes from the sight of a wet sidewalk that it recently rained, or when one immediately believes that one's Vermeer has been stolen upon seeing that one's alarm system has been disabled and that one's back door is wide open? Whether knowledge is based on inference from evidence is not about the actual movement of thought, the considerations one actually ponders; it is about the structure of beliefs that sustain one's conclusion. What justifies our beliefs about the rain and the Vermeer, and what justifies our taking those examples to be examples of evidential knowledge, is that they involve inferences to the correct explanation. One takes the wet streets to be evidence that it rained because one believes that the streets are wet *because* it rained; one takes recent rain to be the correct explanation of why the streets are wet. Likewise, when one sees the disabled alarm system and open door, one immediately and unhesitatingly makes an inference to the explanation whose ingredients include the intentional disabling of the alarm by a thief whose motivation was to get the only thing of value in the house and who successfully made his escape, Vermeer in hand, via the back door.

Likewise, when Abe unhesitatingly accepts Sally's statement that it is snowing, he instantaneously makes an inference to an explanation of her utterance which entails that she believed she knew it was snowing and that part of the explanation of this is that it was snowing. Proponents of the non-evidential view will concede that Abe would not believe that it was snowing if he also thought either that Sally did not believe that or that her belief was not partly explained by the fact that it was snowing, but they will then claim that it is not necessary that Abe actually believe that Sally had her belief or that she had it because it was snowing. This is a mistake; Abe need not consciously ponder any thoughts, but he must have the beliefs in question, just as you must actually have the belief that the streets are wet because it rained when you see the streets and instantaneously form the belief that it rained, even though, so to say, that belief need never have consciously crossed your mind. Nor does it matter that Abe should form his belief while knowing next to nothing about Sally. For suppose you now learn, in whatever way you care to imagine, that I believe I know that my middle name is 'Richard.' Even if you only know me as the author of this article, you would almost certainly yourself believe that my middle name is 'Richard.' Why so? Because, as you know, it is extremely unlikely that a philosophy professor who is coherent and sane enough to write this article would be mistaken about his middle name. On the other hand, your knowing that I believe that the law of excluded middle is not determinately true or that so-and-so will win the next US presidential election probably would not significantly affect your beliefs about those propositions.

Philosophers who reject the evidential view may do so because they are mistaken about what is required to know something on the basis of an inference to the correct explanation. Two points seem relevant in this connection. First, in forming one belief a person may be relying on another belief even though the second is merely tacit, never brought to conscious thought. When you see the wet streets and actively believe that it rained during the night, you probably at no time entertained or actively believed that the streets are wet *because* it rained last night; yet you believe that all the same and would not believe that it rained last night if you did not. Likewise, Abe, in coming to believe that it snowed, probably does not actively believe that Sally would not believe that it snowed if it had not snowed, but he does have that belief and would not believe that it snowed if he did not. Second, a seven-year-old child may know that it rained on the basis of her perception of wet streets, and this because he/she knows that the streets are wet *because* it rained. But how does our seven-year-old know *that*? It is unlikely that he/she spent any time actually considering alternative explanations of the streets' wetness. The fact is, I submit, knowledge-providing justification is easy to come by in cases like this; we are relaxed in our ascriptions of knowledge in such cases, at least when nothing more is at stake. We count the child as knowing because we think he is right and because we do not think there is an alternative explanation of what made the streets wet that is a plausible competitor. Come to think of it, what is true of the child is true of most adults, or else we have very little evidential knowledge. We count someone as knowing, on the basis of his perception of wet streets, that it rained even though if asked to rule out alternative explanations of the streets' being wet he would not be able to articulate much of anything.

All that is required for knowledge by testimony to be evidential is that when we are justified in believing p because we were told p, then, roughly speaking, we are also justified in believing that the speaker would not have told us p unless she believed she knew p and that she would not have that belief if p were not the case. Moreover, as already indicated, to be justified in

thinking that someone would not have told us *p* if she had not believed (she knew) *p* need not require any special antecedent knowledge of the speaker's honesty or reliability. I am giving a talk on an unfamiliar campus and ask an unknown professorial-looking man where Blah-Blah Hall is. He points to a visible building; I head off in what I am confident is the right direction. But how did I know he was not lying, crazy, mistaken, etc.? By inference to the correct explanation; the assumption that he is expressing his belief, etc., is entailed by my tacit explanation of why he pointed and spoke as he did.

One who holds that Abe has non-evidential knowledge by testimony that it is snowing might concede that Abe has a justified true belief that Sally believes it is snowing in part because it is snowing, but yet insist that his justification is not good enough to yield knowledge. This is not very plausible. Abe knows that *if* it is snowing, *then* Sally believes it is snowing in part because it is snowing. So in order for him not to know the consequent of the conditional he knows, it would have to be possible—since it is agreed that Abe knows it is snowing—for one to know [*p* and if *p*, *q*] and not know *q*. And while there are indeed those who are willing to hold that this is possible (Dretske 1970, Nozick 1981), it remains extremely counterintuitive and is widely rejected.

I now know that the cup before me is red. I also know that its being red is the correct explanation of why I am having the visual experience I am now having. Yet my knowing that the cup is red may in this case be overdetermined, both direct *and* based on the evidence of my visual experience. In this case it is not unreasonable to suppose that, in addition to my evidential knowledge that the cup is red, I also have immediate and nonevidential knowledge that the cup is red. For it is not unreasonable to suppose that, given the way we are built as information processors, my having my visual experience would cause me to believe that the cup was red even if I did not have the conceptual wherewithal to form a belief about my sensory experience or its causes. This is evidently the moral to be drawn from the perceptual knowledge of certain animals and very young children. But knowledge by testimony seems disanalogous in an important respect. While very young children seem to believe what they are told even though they are conceptually unable to form beliefs about the beliefs of speakers or about the etiology of those beliefs, it is also the case that it is very difficult to see how there could be communication in public language by creatures who did not have a fairly rich commonsense propositional-attitude theory that allowed them reliably to ascribe beliefs to others and to form reliable hypotheses about the etiology of those beliefs. What we can conclude is that when an adult gains knowledge by testimony, it is because she knows that the speaker believes (she knows) the communicated proposition and that she has that belief in part because the communicated proposition is true. Whether anything like knowledge by testimony could occur in mature creatures who did not tacitly form such beliefs about the beliefs of speakers is perhaps to some extent an open question. If it is possible, then perhaps we should allow that knowledge by testimony is overdetermined; but whether or not it is overdetermined, the knowledge by testimony actually gained by mature persons is arguably evidential.

Communication, Two-step Flow of

The concept of the 'two-step flow of communication' emerged from *The People's Choice*, the 1948 American voting study conducted by Paul Lazarsfeld and his colleagues at the Bureau of Applied Social Research of Columbia University. They observed that: 'ideas often flow from radio and print to opinion leaders and from

them to the less active sections of the population.' Thus, the flow of information and influence from the mass media to their audiences was suggested as taking place in two steps: from the media to the opinion leaders and from them to the public. This model certainly called into question most of the assumptions of the 'powerful media' notion by revealing the limits of media influence while highlighting the role played by personal influence and especially by certain individuals—the opinion leaders. These ideas caught the attention and imagination of a new generation of researchers who opened up a new theoretical and empirical vista.

1. *The Emergence of the Concept*

Beginning with *The People's Choice*, Lazarsfeld and his colleagues were occupied with a series of panel studies on the role of mass communication in the making of decisions in various areas (voting, consumption, public issues and others). The researchers focused on the impact of campaigns in the media and were surprised to find that interpersonal communication had a stronger impact on individual attitudes than the mass media alone. Moreover, they found that certain individuals were more central and influential in their groups, often acting as intermediaries between the mass media and the public. In comparison with the rest of the population, these individuals were found to be more exposed to the mass media. Thus, if personal influence was so important and if it was executed mainly by certain individuals who were more exposed to the mass media than the people they influenced, then it could be postulated that there was a two-step flow process from the media to the opinion leaders and from them to their followers. These intermediaries, called Opinion Leaders, could allow messages to pass through (backing them with their own personal authority), strengthen or weaken them, or block their passage entirely. This became the 'two-step flow of communication' model.

The most thorough and systematic examination of the two-step flow model and the notion of opinion leaders was the Decatur Study (after the community in which it was conducted). The study's procedures and findings were published in *Personal Influence* and represented one of the most impressive early documentations of the opinion leadership concept (Katz and Lazarsfeld 1955). The research focused on four areas of decision making in daily life: marketing, fashion, public affairs, and movie selection. By isolating specific changes of opinion and identifying the influences that allegedly produced them, the researchers located the individuals who were mentioned most frequently as the source of influence. As this was a pioneering study, Katz and Lazarsfeld applied various methods and measures to locate and identify the opinion leaders. Briefly, there are two ways to locate opinion leaders in specific areas of influence. One is through the testimony of those whom they have influenced. The other is through a self-designation procedure in which respondents themselves are asked about their influence on others. To verify the 'self-designating' answers, the researchers requested the confirmation of the persons mentioned as advice-seekers. Two-thirds confirmed the contact and the topic. Although the researchers were satisfied with this 'validation,' it is far from being an acceptable measure of validity and indeed attracted later criticism.

The early studies on personal influence and opinion leadership resulted in several attributes related to opinion leaders (Katz 1957). Let us briefly review the main ones: (a) Opinion leaders are found at every social level and in most areas of decision making, influence people from the same social level. (b) Opinion leaders are found in both of the sexes, all professions, all social classes, and all age groups. (c) Opinion leaders tend to be more involved in various social activities and social organizations and occupy central positions in their personal networks. (d) Opinion leaders are considered to be experts in their field, but this is informal recognition by close friends, relatives, co-workers, colleagues, and acquaintances. (e) Opinion leaders are more exposed to the mass media than nonleaders. (f) Opinion leaders are more interested, involved, and updated in the field in which they are influential. (g) Opinion leaders tend to be monomorphous, that is, they are usually experts in one area but rarely in various areas (i.e., polymorphous). (h) Opinion leaders manifest a specific communication behavior insofar as they are more involved in formal and informal personal communication than nonleaders. (i) Opinion leaders are usually well aware that they serve as sources of information and influence for others.

Since the introduction of the two-step flow model and the opinion leadership concept, numerous studies have sought to advance both the understanding and applicability of these ideas. Already by the early 1970s several hundred of these studies were available and the number has continued to grow steadily (for a review of almost 1,400 of these studies, see Weimann 1994). Thus, the 1960s and 1970s may be considered as the 'Golden Age' of the research on opinion leaders, yielding convincing empirical evidence of the opinion leaders concept in various areas: marketing and consumer behavior, fashion, politics and voting, family planning, science and scientific innovations, agriculture, and health care.

2. *Criticism of the Model*

The model's theoretical and practical appeal crossed the boundaries of disciplines, societies, and cultures. It

attracted researchers from medicine to politics, marketing to family planning, AIDS prevention to clothing fashion, and agriculture to birth control. However, the concept has been a subject of growing criticism. The weaknesses and shortcomings of the original conceptualization of opinion leadership, and especially that of the two-step flow model, were exposed by several studies which combined theoretical, ideological, and methodological aspects (for a review, see Katz 1987).

2.1 *Theoretical-ideological Criticism*

The media, according to the Columbia research tradition, were not as powerful as was assumed, once the public was found to be more active, less lonely, and less vulnerable. Defended by their selective consumption of the media and by the selective mediating function of the opinion leaders, people could fend off media influences and protect their attitudes, preferences, and values. The limited effects of the media as a central element in the opinion leadership and two-step flow concept became the main source for the theoretical-ideological criticism directed at this paradigm. Gitlin (1978), for example, rejected the two-step flow model and the functions related to the opinion leaders. The opinion leader is celebrated, he argued, because administrative researchers study proximate causes which are accessible to their patrons, the media organizations themselves, and the dominant values of the capitalist society. The ideological-theoretical bias of the two-step model, according to this criticism, is manifested in a set of assumptions: (a) *Commensurability of modes of influence*: the impact of the mass media was presumed to be comparable to personal influence, with the two 'forms of influence' regarded as functionally equivalent. (b) *Power as distinct occasions*: the measurement of influence by studying discrete incidents in a 'behaviorization of power.' (c) *Commensurability of buying and politics*: the areas of marketing, politics, fashion, and movie-going were perceived as comparable within a single theory and measurable by a single method. (d) '*Change*' *as the sole dependent variable*: influence was identified by the occurrence of 'attitude change,' disregarding the case of reinforcement as an effect or the prevention of change as an effect. The latent power of the media to prevent changes and maintain the status quo should not be regarded as a residual category, but as a major function and a powerful effect.

2.2 *Empirical-methodological Criticism*

The empirical-methodological weaknesses cited (see Weimann 1982) include the following aspects: (a) Ignoring the evidence of direct flow from the media to the public. (b) Ignoring horizontal flow among leaders or among followers. (c) Ignoring the more-than-two-step flow, or 'longer chains of influence.' (d) The use of a crude dichotomy between leaders and nonleaders instead of applying continuous measures of leadership. (e) Standardization of measurement for information flow and influence flow. (f) Standardization of measurement across domains, disregarding the variance across domains of decision making. (g) The use of short timeframes, far from reflecting the long-term, cumulative impact of media messages.

3. *The Paradigm's Fight for Survival*

The wave of criticism led to a decline in the popularity and attraction of the original concept and almost to its total collapse. However, the paradigm's 'fight for survival,' through a dynamic exchange of arguments, criticism, response, and debate, resulted in several modifications of the original model.

The first amendment to the two-step flow of communication was the introduction of multistep rather than two-step flow. This allowed the inclusion of other optional directions of flow, such as horizontal (among leaders, among followers) and vertical (leaders to followers, active to inactive); direct (linking two actors directly) and indirect (linking actors through a third party or a chain of intermediaries); and downward (leaders to followers, media to public) and upward (from opinion leaders to media, followers to influentials, marginals to centrals). Another important modification was the introduction of continuous measures of opinion leadership and their validation (e.g., Noelle-Neumann and Csikszentmihalyi 1992, Weimann 1991, 1994).

Finally, the most promising development is the merging of the model with modern network analysis (Weimann 1989). The developing theory and methodology of network analysis, combined with modern technologies of data processing, namely high-speed computers, special programs for sociometric data analysis, and such sophisticated mathematical procedures as matrix algebra and sociometric topology, has facilitated the study of large communities. It has also contributed to 'modernizing' the concepts of personal flow of media messages, opinion leadership, and flow of influence. Sheingold (1973) called for the use of social networks data as a 'resurrection' of the Columbia research agenda, and indeed much research on social networks in recent decades has focused on the role of influentials or 'centrals,' applying various structural measures taken from the network analysis procedure. These new developments have linked the two-step flow model with other theories and concepts, such as the Agenda-Setting process (e.g., is there a two-step flow of agenda setting?; see Weimann and Brosius 1994, Brosius and Weimann 1996) and have thus contributed to revitalizing some of the notions of the two-step flow model.

Communicative Competence: Linguistic Aspects

The term 'communicative competence' has come to be applied both to the knowledge that speakers have about how to use their linguistic repertoire, and to their degree of success in doing so. As such, the history of its evolution is entwined in the often heated debates about 'competence' and 'performance' in the emergence of interactional sociolinguistics and the ethnography of communication within sociolinguistics (see *Sociolinguistics*), and in the gradual definition of pragmatics in the context of linguistic and sociolinguistic theory (see *Pragmatics: Linguistic*). In addition, it has been used extensively in the applied linguistics field of language teaching and testing.

1. From Whence comes Communicative Competence?

In the mid-to-late 1960s, revolution was brewing in American linguistics. Noam Chomsky was busy sweeping away the structuralist approach to linguistics, which had resulted in catalogs of observations that overemphasized the diversity of languages, and, he felt, obscured the essential similarity between languages. After all, he reasoned, learning one's language (the singular 'language' is deliberately chosen here) is a natural human capacity; whatever allows young children to learn Navajo or French or Swahili, must, at root, be the same. There must be some underlying language capacity, common to all humans, which, when combined with experience of particular languages, results in a system of linguistic knowledge for those languages. Chomsky deliberately idealized the knowledge he was trying to describe, assuming for the sake of argument (and scientific advance) that all speakers of a language shared the same knowledge.

From these early speculations grew the notions of competence and performance (Chomsky 1965). Competence describes the knowledge that a speaker has of his or her language, the knowledge which underlies the production and comprehension of that language. Importantly, for Chomsky, competence is not, and has never been, an evaluative term. He uses it instead of the term 'knowledge' to avoid suggestions that knowledge of language is, or might be, conscious, when in fact knowledge of language is largely tacit and unconscious. So, his use of competence is not the ordinary use of the term, and must not be interpreted as contrastable with incompetent on some evaluative scale. Chomsky further argued that language behavior, actual utterances coming out of the mouths of speakers and being understood by hearers—performance—was but a poor reflection of underlying competence, beset as it could be by slips of the tongue, alcohol or novocaine induced slurring, and other physical impediments of various kinds. Thus, for Chomsky, the competence vs. performance distinction was very unevenly balanced, with all the richness and interest on the competence side, and just behavioral mishaps on the other.

This characterization incensed sociolinguist Dell Hymes, who was very interested in how young bilingual children choose which language to use and when, and how all speakers modify their language(s) depending upon the context in which they are using them. He had

been gradually evolving a way of looking at language in use which he called the 'ethnography of communication,' and which focused on the social meanings created and negotiated between people in communication. He emphasized the shortcomings of most of the sociolinguistics of the time which focused on statistical analyses of large populations, and argued for a focus on the blow-by-blow organization of interpersonal communication. Even though Chomsky was similarly rejecting the impersonal cataloging of linguistic facts, and was putting the focus on the task of the individual as a learner of any humanly possible language, Hymes felt that Chomsky's idealization of the language capacity as something possessed by a monolingual, and stripped of all the variation he observed in the behavior of even a single individual moving among different contexts of use made a mockery of what language was all about for him. Hymes was not prepared to follow Chomsky down a path which led to linguistics being seen as part of cognitive science; he was firmly committed to language as a social and behavioral phenomenon.

In reaction to Chomsky's coinage of the term competence, therefore, Hymes created the term 'communicative competence' which he intended to subsume and extend Chomsky's notion. The most celebrated quotation from Hymes is

> A child capable of any and all grammatical utterances, but not knowing which to use, not knowing even when to talk and when to stop, would be a cultural monstrosity. (Hymes 1967, p. 16)

He thus argues that the fundamental problem is

> to discover the underlying communicative competence that enables members of a community to use and interpret the use of language, and to provide a formal description that is a theory of that competence. (Hymes 1967, pp. 17, 18)

It is worth noting that the term was 'in the air' at the time. Not only was it beginning to be used in the field of second and foreign language teaching, but Campbell and Wales (1970) used it in connection with language acquisition. They are usually credited as having coined the term independently, although Hymes (1992) suggests that they might have indirectly got it from him by talking to the people he was talking to at the time.

2. *Hymes' Communicative Competence*

Hymes' notion of communicative competence was born out of a belief that acts of speech, such as promising or asserting or denying are produced and understood within the context of particular 'speech events,' such as conversations, lectures, or marriages, themselves occurring within particular speech situations within a speech community. The particular value that a speech act has is determined by the layers of context within which it is embedded. Importantly, the context includes not just objective factors such as who is speaking, where, and when, but subjective factors, such as what participants in a speech event believe themselves to be doing, and how they 'take' what is said to them. These speaker/hearer beliefs vary both individually and culturally, and cannot be ignored when trying to understand what a speaker means by an utterance. Cultures vary, for example, in how they view the loquacious individual, in the extent to which information is power, and to what status they accord the language of infants. Factors such as these significantly affect the microsociolinguistic world of interpersonal communication. Thus, for Hymes, it was fundamentally important that such factors be properly integrated into linguistics and that 'sociolinguistics' come to be synonymous with 'linguistics.' Since then, communicative competence has come to cover all aspects of language use, including text cohesion and coherence, rhetorical organization, speech act organization, register variation, dialect variation, and so on.

3. *Reactions and Counter-reactions*

The term communicative competence was accepted with alacrity by many other influential sociolinguists, including John Gumperz, Susan Ervin-Tripp, and Michael Halliday. The field of sociolinguistics sustained rapid advances as a result, seeing itself increasingly at loggerheads with formal linguists, which retained its focus on sentence-level grammatical issues. However, Chomsky was not unaffected by the firestorm. In his book *Rules and Representations* (1980) Chomsky refers to 'pragmatic competence,' and defines it as follows.

> Furthermore, the person who knows a language knows the conditions under which it is appropriate to use a sentence, knows what purposes can be furthered by appropriate use of a sentence under given social conditions. For purposes of inquiry and exposition, we may proceed to distinguish 'grammatical competence' from 'pragmatic competence,' restricting the first to knowledge of form and meaning and the second to conditions and manner of appropriate use, in conformity with various purposes. (Chomsky 1980, p. 224)

It is clear that, although he is not using the term communicative competence, he has many, if not most, of the key elements of it (see also *Pragmatics: Linguistic*). Moreover, he situates 'pragmatic competence' in relation to 'performance':

> Theories of grammatical and pragmatic competence must find their place in a theory of performance that takes into

> account the structure of memory, our mode of organizing experience, and so on. (Chomsky 1980, p. 225)

This quotation is important, because when Chomsky first proposed the 'competence' vs. 'performance' distinction, sociolinguists could see that their concerns did not fit into his restricted notion of competence, which meant that if they were anywhere, they must be part of what was at the time a very impoverished notion of 'performance' (slips of the tongue, etc., see above). So many writers, trying to find a place for communicative competence have seen it as part of a theory of 'performance,' and argued for it as such, despite the clear division Chomsky makes in the quotation above. The result is an ambiguity in the literature between communicative competence as knowledge and communicative competence as ability or skill for performance. This has meant that the term has sometimes been interpreted very cognitively, and at others very behaviorally, and at yet others, systematically ambiguously.

4. *Communicative Competence as Ability/Skill*

Despite the originally stated intention to make communicative competence match 'competence' as a formal description of what a person who knows a language knows, many writers have used the term in an evaluative sense in which various kinds of communicative competence are seen as being on continua from incompetence to competence. For example, in educational circles, communicative competence has often been used as one measure of a learner's success. The work of Basil Bernstein, for example, has usually been seen as suggesting that children from certain kinds of background are likely to be, in fact, communicatively incompetent in the terms defined by school success (Bernstein 1990). Children who cannot use the language in the ways expected by the school suffer from the effects of this incompetence. Similarly, in work by Cummins (1984) and others, bilingual children have been claimed to be communicatively incompetent to the point of being labeled semilingual because their ability to use each of their languages satisfies native speakers of neither language, who find them communicatively 'incompetent' in both languages.

In second language acquisition studies (see below) concerns with making second language learners competent users of the language have driven a range of studies under the umbrella of communicative competence. In all these sub-fields (and there are many others), the evaluative sense of communicative competence plays the main role. It is worth asking whether the ambiguity in the term's use is problematic or not. The answer is likely to depend more than anything on one's philosophical stance with respect to the nature of knowledge. Is knowledge something represented, something separate from behavior, or is knowledge simply the term we give to the capacity to act? This in turn depends on one's approach to the division between cognitive science on the one hand, and social and behavioral science on the other. For those who wish to see the two fields come together, the ambiguity of the term, straddling as it does the border between them is perhaps to be encouraged. For those, however, for whom cognitive science is a fundamentally different enterprise, in which behavior is the outward manifestation of knowledge (whether represented declaratively or through connectionist networking), the issue is more fundamental.

5. *Communicative Competence in Language Acquisition*

A range of different fields have used, and developed, the communicative competence notion. Two will be discussed briefly here: the sub-fields of first-language acquisition and of second-language acquisition.

In first-language acquisition, studies on very early communication prior to the emergence of real language (at a point where gestures and single 'words' are all the child has at his or her disposal) were particularly popular in the 1970s, and still continue in work as diverse as that trying to determine whether chimps can be said to have a communicative competence or that which aims to discover what kind of communicative system deaf children will invent if they are not presented with an acquirable language. Work with older children has focused, and continues to focus on how children develop the range of means to express speech acts, how they choose between styles of speech, how they switch between languages and dialects, and so on (cf. Romaine 1984, which also has an interesting discussion of the concept of communicative competence). There are also those interested in children who for one reason or another appear to have a relatively intact ability to communicate in the face of severe disorders to the linguistic system, and in those who have the reverse pathology, being capable of producing correctly structured utterances, but with severely disordered abilities to use language appropriately. These dissociations, if they truly exist (and current debates show divided opinion here), raise a range of epistemological questions about the status of linguistic competence in relation to pragmatic or communicative competence. General introductions to child language development, covering the issues listed above among many others can be found in Foster-Cohen (1990, 1999).

Considerable energy has been put into trying to model communicative competence correctly within the field of second language testing and second language acquisition. For language testers, interested in the evaluation of communicative competence (used

evaluatively, of course), it is vital that all the parts of the notion be laid out and defined, so that testers can be sure that they know what they are testing. Most discussions in this context make reference to Hymes' work, although the initial use of the term communicative competence in this context appears to have been independent of him. At first, communicative competence for language teachers meant simply an ability to get a message across in the target language, to be capable of 'spontaneous expression.' However, when Hymes' work became known, many language teachers adopted the more broadly sociolinguistic sense of the term, and argued that teaching the social meanings of second language expressions are as important as teaching the structures

Michael Canale and Merrill Swain are perhaps the best known for expanding the notion of communicative competence for those interested in second language acquisition in an article published in 1980. There they distinguish between 'grammatical competence' (syntax, morphology, lexis, semantics and morphology), 'sociolinguistic competence,' and 'strategic competence.' Sociolinguistic competence covers both sociocultural rules of how to use linguistic expressions appropriately, and rules of discourse, that is how to string utterances together appropriately to produce a contribution (written or spoken) that a native speaker would recognize as well-formed. Strategic competence covers both verbal and nonverbal communication strategies that allow a nonnative speaker to get over communication problems due to inadequacies in either grammatical or sociolinguistic competence, or due to performance limitations.

More recently, Lyle Bachmann (1990) has reemphasized the dynamic nature of communicative ability. The negotiation of meaning between participants in an interaction, emphasized in sociolinguistics by Michael Halliday from the early 1970s and in language teaching by Sandra Savignon from the early 1980s, picks up on the idea of the 'emergent properties of events' noted by Hymes when the communicative competences of two individuals come in contact. Bachmann's model overtly places performance mechanisms within communicative competence which he, of necessity, calls 'communicative language ability,' having given up the original competence vs. performance distinction with which Chomsky and Hymes began. Although designed for language teachers and testers, Bachmann's discussion lays out particularly clearly the range of knowledge and abilities that a communicatively competent language user must control.

6. *Communicative Competence and Pragmatic Competence Revisited*

It was noted above that Chomsky's definition of pragmatic competence bears strong resemblance to Hymes' definition of communicative competence. However, it must not be forgotten that the perspectives of the two are still quite different. Whereas Hymes' is interested in accounting for the diversity in language behavior, Chomsky is interested in the similarities across individuals, in discovering the universal properties which make us human. A similar mindset can be seen among all those who are interested in pragmatic competence as an account of human understanding of communication. Sperber and Wilson, in their account of pragmatics known as 'Relevance Theory' (Sperber and Wilson, 1986, 1995), focus on the inferencing procedures that individuals use to interpret utterances in context. They view their enterprise as explicating a cognitive approach to communication, and can as such be seen as providing a theory of communicative competence in the Chomskyan sense, but not in the Hymesian sense.

However, this theory is entirely compatible with the range of facts which a sociolinguistic account of communicative competence sees itself as needing to account for. Just as grammatical theory has shown its capacity for accounting for cross-linguistic, cross-dialectal, and idiosyncratic features of languages, so a good theory of pragmatics should be able to show how human communication works across similarly diverse individuals. Gumperz (1997) calls for such a general theory when he invokes the work of Jürgen Habermas on communicative competence. Habermas is interested in 'the universal conditions of possible understandings' between people, ultimately in the political and social realities created through communication; but Gumperz argues for a definition of communicative competence as

> the knowledge of linguistic and related communicative conventions that speakers must have to initiate and sustain conversational involvement … Studies of communicative competence, therefore, must deal with linguistic signs at a level of generality which transcends the bounds of linguists' grammatical systems and must concentrate on aspects of meaning or interpretation more general than that of sentence content. (Gumperz 1997, pp. 40, 41)

Sperber and Wilson would certainly agree. A concern for a general theory of human understanding, then, drives researchers from widely divergent backgrounds and training, and with significantly different assumptions.

Communism

Karl Marx famously began his *Manifesto of the Communist Party* (1848) with the words, 'A spectre is haunting Europe—the spectre of communism.' If that was an exaggeration at the time and for most of the nineteenth century, it became a significant reality in the twentieth century. The Bolshevik Revolution of 1917 in Russia saw the establishment of what came to be called by Communists 'the world's first socialist state.' For Communists themselves, 'Communism' meant both an international movement concerned with overthrowing capitalist systems and establishing a new social order and a society which would exist only in the future, 'communism' (with a lower case 'c'). It referred, in that second meaning, to the final goal of political and social development—the withering away of the state and the creation of a utopia in which the need for hierarchy and coercion would no longer exist. Instead, there would be a society of equals in which people would live harmoniously and collectively administer their affairs. Karl Marx (1818–1883) had, not surprisingly, very little to say about how this projected society of the future would work and only once distinguished between an initial and higher stage of communism. V. I. Lenin (1870–1924), who led the Bolshevik Revolution in Russia in 1917 and became the founder of the Soviet state, made a firmer distinction between what he called 'socialism' and 'communism.'

Soviet theorists continued to describe their system as 'socialist' and, as the years passed, the ultimate goal of 'communism' receded ever further into an uncertain future. However, the main instrument of rule within the Soviet Union, and subsequently within other 'socialist' countries, was the Communist Party. Most objective analysts of those systems have, with good reason, chosen to call them Communist rather than socialist. The term, 'socialist,' embraces a far wider range of social movements and governments than those which owed their allegiance to Marxism–Leninism (as the Soviet codification of the works of Marx and Lenin became known). Communist Parties were far from having a monopoly on the understanding of socialism and, indeed, in many countries—most notably, in Western Europe—socialist parties of a social democratic type competed throughout the twentieth century (generally with more success) with Communist Parties for the working-class vote.

While there were some important differences from one Communist country to another during the political heyday of Communism—a forty-year period between 1949 and 1989, when more Communist states existed than at any other time before or since—they had enough in common to constitute a distinct subset of the world's political systems. Five defining characteristics can be discerned to differentiate them from other totalitarian or authoritarian regimes and, much more fundamentally, from pluralist systems in which from time to time political parties calling themselves 'socialist' held governmental office. The first of these defining characteristics was the *monopoly of power of the Communist Party*, for which the euphemism employed in Communist states, especially after the death of Stalin, was 'the leading role of the party.' (In Stalin's time the term, 'the dictatorship of the proletariat,' was used to signify this phenomenon. In a peculiar conflation of social categories, it was taken as axiomatic that in the Soviet Union the Communist Party embodied the will of the proletariat.) The supreme authority and unchallengeable hegemony of the Communist Party was a given of Communist systems, although how much power was concentrated in the hands of a ruling group within that party and

how much in the hands of a single leader varied over time and from one Communist state to another.

The second defining characteristic of a Communist system was *democratic centralism*, a key concept embodied in the published rules of Communist Parties which, in practice, signified centralism to the virtual exclusion of democracy. Although often distinguished by Communist theorists from 'bureaucratic centralism' (which meant officials acting in a high-handed way, without any consultation with those lower in the party hierarchy), democratic centralism, in political reality, stood for a highly centralized, strictly disciplined party with extremely narrowly interpreted rights of intra-party debate. The slightest criticism of the party leadership from below and any horizontal, as distinct from vertical, links between party organizations were stigmatized as deviations from democratic centralism and harshly punished.

State, or at any rate non-capitalist, *ownership of the means of production* constituted the third defining feature of Communism. In Yugoslavia, a system of supposed self-management was developed which differed from the unadulterated state ownership of industry characteristic of the Soviet Union, most of Eastern Europe, and also of China until late in the twentieth century. Exceptions to state ownership were occasionally made in agriculture—Poland, for example, maintained an essentially private agriculture throughout most of its Communist period, in contrast with the collective and state farms to be found in the USSR and elsewhere—but not for industrial production.

The fourth defining characteristic of Communism was *the declared aim of building communism—a society in which the state would have withered away—as the ultimate, legitimizing goal*. This theoretical aspiration was not part of the operational code of a Communist system and in terms of everyday politics was far less important than the 'leading role of the party' or 'democratic centralism.' It was, nevertheless, of great ideological significance. In the early years of the Soviet Union, and among some Communist Party activists in the earliest stages of establishing a Communist system, the goal of building a classless society was of motivational and inspirational significance. Thus, if the first three defining characteristics of Communism are also the three key structural features of Communist systems, the goal of building communism was primarily of doctrinal importance. It had an important place in Leninist ideology and it was this goal-oriented vision which distinguished Communist systems, not least the Soviet one, from societies in which governments were formed by democratic socialist parties whose aspirations did not go beyond enhancing fairness and reducing social inequality. If in politics there is, in Oakeshott's (1962) words, 'neither starting-place nor appointed destination,' a party could hardly claim the right to rule on the grounds that it knew how to guide society to the ultimate goal. It was, however, because Communist theoreticians claimed that there was an appointed destination—that of communism—that they could justify the permanent exercise of the leading role of the Communist Party. It was, Lenin himself had argued, that party alone which possessed the theoretical insight and political experience to guide less advanced citizens to this harmonious, classless society.

A fifth defining feature of Communism was the *existence of, and sense of belonging to, an international Communist movement*. For the Soviet Union, leading that movement was a matter of profound ideological and practical significance. It helped to underpin the legitimacy of the Soviet state in the eyes of many of its inhabitants and was also an instrument of state power. Many foreign Communists, especially in the period before the Twentieth Congress of the Soviet Communist Party in 1956 when Nikita Khrushchev (1894–1971) revealed some of the crimes of Stalin, (most notably, the mass arrests and executions of communists between 1936 and 1938), believed that a genuinely new society was being built in Russia and were ready to follow the twists and turns of the 'general line' emanating from Moscow. The first cracks in the unity of the international Communist movement occurred when Tito's Yugoslavia broke with the Soviet Union. The Yugoslav Communists were denounced by the Cominform, the successor to the Comintern as the Soviet-dominated organization of international Communism, in 1948. Vastly more encouraging for adherents of Communism had been the coming to power of the Chinese Communists in 1949. Yet, notwithstanding significant contributions by Soviet engineers and other specialists to China's development in the 1950s, the relationship between the two most populous of Communist states was to turn sour by the end of that decade. The next major breach within the international Communist movement after that between Moscow and Belgrade turned out to be the Sino-Soviet dispute. There were important ideological differences in which the Chinese were critical of what they saw as Soviet 'revisionism' (of Marxism–Leninism), but also resentment on the part of China's Communists of the Soviet leadership's taking for granted that the USSR was 'more equal than others' within the international Communist movement. The overwhelming majority of Communist states took the Soviet side against Mao's China, as most of them were essentially client states of the USSR. However, international Communism could never be the same again after a country of the size and importance of China had broken with the first Communist state and had called into question the Soviet 'leading role' within that movement.

Nevertheless, there remained the 'Soviet bloc' in Eastern Europe. The Albanian and Yugoslav Communists had made their own revolutions and there were no Soviet troops in Czechoslovakia when the Czech Communists seized full power in February

1948. In most cases, however, the European Communist systems owed their existence to Soviet force of arms. These countries had been liberated from Nazi occupation only to have their freedom of political choice rapidly curtailed as local Communists were brought to power and subsequently kept there by Soviet willingness to support their rule by further armed intervention, if necessary. The Soviet invasion of Hungary in 1956 and of Czechoslovakia in 1968 put an end to political changes which were backed both by reformist Communists and by the majority of the populations of these countries. The crushing of the 'Prague Spring' defined the limits of reform for East Europeans for a further twenty years.

Soviet leaders and their counterparts in Eastern Europe in one sense recognized the fragility of their regimes inasmuch as they devoted vast resources to surveillance of dissident groups and to maintaining as rigorous a censorship as was possible. They could not, however, prevent ideas from crossing national boundaries, even by jamming foreign radio (as they did for most of the post-Second World War Communist era). Communist political elites, in some countries more than others, made pragmatic adjustments to doctrine, while all the time finding suitable quotations from Lenin by way of justification.

In response to the relative failure of Communist economic development—as the Soviet Union and the East European countries not only fell further behind the most advanced Western economies but failed to keep pace with the newly-industrialized countries of Asia in an era of technological revolution—the USSR, with the coming to power of a leader a generation younger than his immediate predecessors, Mikhail Gorbachev (1931–), embarked on a reformist course from 1985. Although the initial impetus to change was the declining economic growth rate, Gorbachev was soon giving priority to political reform over economic reform and radically revising Soviet foreign policy in ways which led to the end of the Cold War. By, however, removing the threat of armed intervention which had hung over the East European states for decades, he left the Communist regimes there to stand or fall on the basis of winning the support of their own peoples. This they manifestly failed to do, and in the course of 1989 virtually all the Central and East European countries which had been under Communist rule became independent and non-Communist. The unification of Germany and the end of the German Democratic Republic followed a year later.

The almost entirely peaceful ending of Communism in Eastern Europe had serious implications for the Soviet Union itself. It emboldened those who sought national independence in the most politically alienated of Soviet republics, especially the Baltic states, and the salience of the national question, on top of economic problems and the political tensions engendered within an increasingly divided Soviet elite, threatened not only the Soviet system but the survival of the Soviet state. Indeed, Gorbachev's initial aim of reforming the system had given way in 1988–89 to more far-reaching change from above, amounting to systemic transformation. The collapse in December 1991 of the Soviet state, as distinct from the dismantling of the system, was, however, very much an unintended consequence of radical reform. Two-way contagion between pluralistic reform in the Soviet Union and democratizing change in Eastern Europe and between the assertion of national independence in East-Central European states and in the Soviet Union's republics played an important part in producing the collapse of the USSR.

Personal political rivalries were also of significance. Boris Yeltsin (1931–) played the Russian card against the Union, partly in order to get Gorbachev out of the Kremlin and himself inside as the unrivalled President of Russia. Hard-liners within the Soviet leadership attempted to reverse the Gorbachev reforms, and especially his Union Treaty that would have devolved great powers to the republics, and mounted an attempted coup in August 1991. It began with the placing of Gorbachev under house arrest in his Crimean holiday home and ended a few days later with the arrest of the Chairman of the KGB, the Minister of Defence, the Vice-President and their collaborators. It also had the unintended consequence of hastening the breakup of the USSR which the putsch had been mounted to prevent.

In 1985 there were 23 Communist states in the world. A decade later there were at most five—China, Cuba, Laos, North Korea and Vietnam. Yet these states no longer had all the attributes of Communist systems outlined earlier. In particular, there was no international Communist movement worthy of the name, nor was there even much lip-service to the building of communism. Moreover, in the most important of these countries, China, great concessions had been made to the market, and allegiance to Marxism–Leninism was becoming increasingly tenuous. To the extent that these states retained, in their very different ways, enough features of Communism to be so defined, then at the beginning of the twenty-first century almost a quarter of the world's population lived under Communist rule. But the fact that China has by far the largest population of any country means that approximate figure disguises the extent and political significance of Communism's decline and fall. If idealists and professional revolutionaries could in the nineteenth century, and during much of the twentieth, believe that this was humankind's path to a more radiant future, such illusions at the start of a new millennium had been confined to what Marx called 'the dustbin of history.'

Communism, History of

The notion of communism has been used in three different ways. First, since antiquity communism has been referred to ideas relating to advanced forms of socialism advocating the need to organize societies as communities owning means of production and consumption. Second, the term communism signifies political movements with 'bolshevism,' an extreme faction of Russian social democracy, as their protagonist since 1903. Third, communism denotes a political and socioeconomic system of state introduced for the first time in Russia in the year 1917. Following the three different interpretations of the word communism, researchers concentrated their work on:

(a) the idea of social and political thought,

(b) state political systems with particular emphasis on dictatorship (totalitarian ideas), and

(c) economic systems, especially nonmarket economies, planned economies and autarchies.

Research on communist political movements and systems of state has been complicated seriously due to changes in time and space since both have existed for almost 100 years and have manifested themselves in different cultural zones of the world, most intensively, however, in Europe and East Asia.

1. The Idea

The ideas of communism have surfaced since antiquity and have been present throughout the Middle Ages, the Renaissance, the Enlightenment, and the French Revolution. The proponents of communism resorted to moral or economic arguments advocating the need to organize societies as communities owning means of production and consumption. These ideas were adopted by some socialists in the nineteenth century. Marx and Engels published their '*Communist Manifesto*' (1848). To substantiate his ideas Engels drew on the then studies on primitive societies as representative of classless communities (the natural state of society was disrupted by the division into social classes). However, the notions of socialism and communism were sometimes used interchangeably in the nineteenth century. When social democracy developed in many countries, socialists hardly ever used the notion of communism, whereas anarchists resorted to it occasionally (Kropotkin's anarchocommunism).

Communist ideas have acquired a new meaning since 1918. They became equivalent to the ideas of Marxism–Leninism, that is, the interpretation of Marxism by Lenin and his sucessors. Endorsing the final objective, namely the creation of a community owning means of production and providing each of its participants with consumption 'according to their needs,' they put forward the recognition of the class struggle as a dominating principle of a social development. In addition, workers (i.e., the proletariat) were to carry out the mission of the reconstruction of the society. Conducting a socialist revolution headed by the *avant-garde* of the proletariat, that is, the party, was hailed to be a historical necessity. Moreover, the introduction of the proletariat dictatorship was advocated and hostile classes were to be liquidated. In the following decades communist ideas have been subject to dogmatizing, on the one hand, and, on the other, to current political pressures. Paramount importance was attributed to the 'classics,' namely to Marx, Engels, and Lenin, as well as Stalin during his rule. It was only the later 'classics' (i.e., Lenin and Stalin) who were believed to be entitled to correct and amend the views of the earlier 'classics.' The communist ideology was expanded to include new components such as an exemplary role of the USSR and 'the principle of exacerbating the class struggle parallel to the building of socialism' (Stalin), which was called into question after 1953. In the years to follow the idea of a peaceful coexistence of socialism and capitalism as well as that of a peaceful transition to socialism were added. Some differences have surfaced between communist ideas endorsed in the USSR and the Soviet

bloc, in Yugoslavia, where social and economic aspects of self-government were regarded as significant features of the communist ideology, and in China, where Maoism became a revolutionary ideology of the suppressed 'Third World' directed against capitalist metropolics (Harrison 1972) as well as of the 'rural guerrilla revolution' (Cohen 1964). Some West European countries endorsed the ideology of Eurocommunism, i.e. a transition to socialism, which complied with all rules of democracy and renounced the dictatorship of the proletariat. On the whole, the ideology gradually lost its momentum in the countries governed by communists, particularly in the Soviet bloc. A much greater significance was attached to this ideology by groups opposing the Soviet-style communism. In the late 1960s some milieus of 'the new left' in Europe and America formulated the ideas of communist spontaneity, which were in opposition to capitalism and bureaucratic communism.

Many researchers have treated communist ideas mostly as one of the interpretations of Marxism. Popper (1945) wrote about the division of Marxists into radical (communist) and moderate (social democratic) wings. Walicki (1995) claimed that Leninism and Stalinism 'were dominant forms of the Marxist ideology of the 20th century.' In his work on Marxism Kolakowski (1978) handled the ideas of Leninism as one of the interpretations of Marxism, yet in some areas he saw them as a departure from Marx's original views. An even clearer division of communist ideas from Marxism was drawn by Furet (1995). Although he did not deny that these ideas had originated from Marxism, Furet pointed to other sources of origin such as Russian populist ideas.

2. *The Political Movement*

When in 1903 the Russian Social Democracy split into two groups, the majority faction was called 'Bolsheviks' and the minority 'Mensheviks.' The Bolsheviks in 1912 formed a separate party, an organization of active revolutionaries. Although the principle of democratic centralism was introduced, in practice the system was centralist and devoid of any traces of democracy. Furthermore, violence was endorsed as a fundamental means of political activity. All these features could be accounted for by the situation in Russia, where the parliamentary system was in its infancy and despotism ruled unabated. The Bolsheviks came to power in Russia in 1917, whereas in 1918 they transformed themselves into a communist party. Since 1918 communist parties emerged also in other countries, mostly as a result of a split within socialist parties. In 1919 the Communist International (Comintern) was set up and it soon became centralized and dependent, as a matter of fact, on the Russian (or later Soviet) party. The terms 'communism' and 'bolshevism' were still used interchangeably and 'bolshevisation' came to denote the process of following suit and imitating the example of the Russian party.

Communist political movements manifested themselves most intensively in Europe and in China. They kept changing their political profiles adopting to the then current situation on the international arena (e.g., under the pressure of the 1929–1933 crisis), but, above all, complying with interests of the Soviet Union. In the 1930s this compliance was linked with Stalin assuming the role of the undisputed leader of the international communist movement. Opposition groups were excluded from the movement. One of the few groupings which remained active were the proponents of Leo Trotsky, a prominent party leader expelled from the Soviet Union. However, in the late 1930s, when faced with the threat of fascism, communist parties started to endorse the slogans of parliamentary democracy and entered into cooperation with socialists and even nonsocialist democratic parties (the 'People's Front').

When the Soviet Union entered into an agreement with Germany in 1939, communist parties all over the world declared their neutrality towards both parties in World War II. This policy was subject to a drastic change following the 1941 German invasion of the Soviet Union. Only then did communist parties come to regard the struggle against fascism as their priority and fostered the idea of forming the National Front. The idea, however, was rarely put into practice for several reasons including dependence of communists on the Soviet Union (although Comintern was dissolved in 1943) and their aspirations to play a dominant role in the resistance movement.

When World War II was drawing to an end communist parties took over power in the countries in which the Soviet army was present as well as in Yugoslavia and Albania. In the countries occupied by the armies of the Western allies, communists frequently entered into ruling coalitions. With the escalation of conflict between two political blocs and an upsurge of the 'cold war,' communist parties in the West went into opposition. The Soviet control over the international communist movement was strengthened anew in 1947 when the Information Bureau of Communist and Workers' Parties (Cominform) was established comprising the largest European parties. A year later the first serious conflict between parties came to the fore, when the Yugoslav party was condemned by Cominform. The victory of the communist party in China in 1949 (and later in Vietnam and Cuba) laid foundations for subsequent decentralization of the communist movement.

The process of decentralization took place gradually following the death of Stalin in 1953, who three years later was accused of great atrocities. The escalation of the crisis in 1956 brought about the dissolution of Cominform, and resulted in reforms in Poland and a revolution in Hungary. The 1960s witnessed a conflict between the Soviet and the Chinese parties

during which some other parties attempted to take advantage of the situation and gain independence. Yet another crisis, triggered by the intervention of the Soviet bloc in Czechoslovakia, resulted in the adoption of Eurocommunist ideas by some West European parties in the 1970s. At the same time, small communist groupings emerged in the West drawing on the experiences (or rather their own visions of the experiences) of China, Vietnam, Cuba, or Yugoslavia. Further crises in the international communist movement were linked to the Polish conflicts of 1980–1981. In the 1980s both ruling and opposition communist parties showed symptoms of decay. After the collapse of communist systems in Europe nearly all communist parties rejected their former ideological and organizational principles and transformed into socialist or social democratic parties.

In the countries ruled by communists a considerable number of works on the communist movement was published, yet their content was subject to control. The most important publications had even an official character (*The History of the Communist Party* 1938). Little changed in this respect in the communist historiography after the 'destalinization' although the party ceased to stress the official character of publications, relying heavily on the censorship and monitoring of publications. These publications rarely contained reliable information, featuring mainly interpretations devoid of any critical approach and containing hagiographic accents.

Many publications were written by representatives of the communist opposition, who embraced the fundamentals of communism yet criticized the political line of Stalin and his successors, as it was in the case of the Trotskyists. Some of these texts resembled political commentaries and contained different information not included in the official and semi-official communist literature. This trend comprised also publications based on extensive studies (e.g., Deutscher 1949, 1954, 1959, 1963).

Works by noncommunist authors fall into yet another category of literature relating to the history of the working-class movement. Although this literature contained fewer political commentaries, it demonstrated a strong socialist bias. From a left-wing socialist perspective, communism, in spite of all its shortcomings, was perceived as a proletariat movement close to socialist ideas and as a potential ally in the socialists' struggle against the bourgeoisie (e.g., Braunthal 1960). Right-wing socialists, on the other hand, saw it as a hostile force striving to exert influence over the same social class. In recent decades, however, the history of the workers' movement encompassing the history of the communist movement has become subject to more academic research.

Amongst authors who dealt with the communist movement there were some who came from within the party ranks as well as those who broke free from its legacy (Borkenau 1938, 1953). Others were emigrants from countries governed by communists, who drew on their life experience and language skills (Fejtö 1974). One should also consider here expert publications of academic institutions which dealt with communism as a sideline political movement within a larger scope of interests relating to the so-called Sovietology.

3. *The Political and Socioeconomic System*

Communists themselves are more prone to call it a socialist system. For the first time, such a system was introduced in Russia after 1917. The principles of it were outlined by Lenin before the victory of the revolution, yet his work on this subject was published only when the Bolsheviks came to power (*Gosudarstwo i rewoljucija* 1918). Two principles were of particular significance: (a) the state has to resort to violence in the political and social life, and (b) elements of a centralized bureaucracy, that is, record keeping and monitoring, play a key role in the organization of the economy.

In the Soviet political system the leading role was assigned to the centralized communist monoparty devoid of any traces of democracy within its ranks. All organizations were subordinated to the party and headed by its members. Moreover, the party exercised control over all publications and mass media directly or through state departments (e.g., censorship).

The state authorities at all levels reported to party organs. Initially the state authorities were organized in a hierarchical structure of councils with some chosen representatives of lower level sitting on the councils of a higher level. Following the establishment of the Soviet Union in 1922, the party and state authorities were to function according to the principles of a federal state. The 1936 constitution provided for general elections at all tiers of power. In practice, however, soon after communists came to power they introduced the principle of nominating from above, a principle that applied to both the party and state authorities. The approval of such nominations in public elections was a mere formality.

This political system was adopted after World War II in all communist countries. In the Soviet bloc, which included European communist countries (with the exception of Yugoslavia since 1948 and Albania since the 1960s) as well as Mongolia and North Korea (for a couple of years), there were initially informal methods of control from Moscow. System monitoring was exercised through the Cominform and Soviet advisers or directives sent to high-ranking officials. Since 1956 methods of control were restricted and formalized by means of political and military structures of the Warsaw Pact, as well as structures of the Council for Mutual Economic Assistance (COMECON). The remaining communist countries enjoyed a full or partial independence. Yugoslavia carried out some transformations in its political system, introducing

elements of a limited federalism and a local government.

Gradually the centralized systems began to crumble on international and state levels alike. Retaining its leading role, the USSR had to take into account more and more frequently the positions of the countries within the Soviet bloc. Following the crisis in Czechoslovakia and the invasion of the country by the Soviet bloc, the Brezhnev doctrine was proclaimed (1968) asserting the right of the communist community to intervene when any of its members demonstrates 'anti-socialist degeneration.' Several countries of the Soviet Block and China managed to hand down some power to regional levels.

A considerable autonomy was enjoyed by the police, and above all by security services. They gained a strong position in the period of widespread repression in the Soviet Union (collectivization and 'big cleansing' in the 1930s) as well as in the countries within the Soviet sphere of influence (in the late 1940s and early 1950s) and in China (during the cultural revolution). Furthermore, security services attempted to exert a still greater political influence also in other periods.

Another pivotal element of the system was the army. In the Soviet Union it owed its position to the role played in introducing the system and in World War II. Later it was a key means supporting the rivalry between superpowers and political blocs as well as the Soviet expansion in the countries of the Third World. Similarly, in China and Vietnam, the army was the co-creator of the system. In Poland the army won a particular importance in the face of the imposition of martial law in 1981. On the other hand, party officials feared an excessive degree of independence of the army, which had far-reaching repercussions in the Soviet Union during repressions directed towards army officials in the 1930s.

Since 1953 several communist countries, particularly those belonging to the Soviet bloc, witnessed recurring political crises. They were triggered by people's rising democratic aspirations influenced by examples emanating from Western democracies, by the lack of respect for national sovereignty and, to a large extent, by a growing economic crisis and a low standard of living. Another precipitating factor was the disillusionment as to the application of communist ideas in practice. Communist officials adopted the formula of 'real socialism' as a form of the existing system hindered by historical limitations on the road to the socialist and communist future.

The economy in communist countries was subordinated to politics. Nationalization was implemented in all spheres of economic life. Although agriculture and, to some degree, trade and small production were formally owned by cooperatives, they were supervised by the party and state administration. There were only negligible relics of private ownership with the exception of Poland and Yugoslavia where agriculture remained in private hands.

Centralized state planning functioned on the basis of 5-year plans, the allocation of raw materials and means of investments, regulated prices, and rationing commodities for sale. A top priority was the needs of the state, which resulted often from an international policy. A particular emphasis was placed on the development of heavy industry and reservoirs of raw materials, neglecting other branches of production. In the face of constant shortages and a crippled economy, many goods intended for production and consumption were subject to different forms of rationing. The state's monopoly on foreign trade along with slow technological progress, a limited exports potential and, consequently, import deficit led to a form of economic autarchy. Yugoslavia's economy demonstrated a slight divergence from this general pattern after the introduction of self-government in enterprises. Moreover, Yugoslavia fostered more extensively mechanisms of the market economy and managed to avoid autarchy. Nonetheless, it put a limit on foreign investments and failed to develop technological innovations.

Communist systems which were created almost exclusively in poorly developed or underdeveloped countries, demonstrated initially a high rate of economic growth. The rapid industrialization combined with urban development was based on extensive factors such as a cheap labor force. However, as these factors were gradually exhausted, the growth rate began to decline and the standard of living stabilized at a low level. Among other factors which aggravated the crisis were the growing costs of the arms race and political rivalry between superpowers and blocs.

From the late 1950s attempts were made to overcome the crisis. On the one hand, restraints of the arms race were accepted (the Helsinki Agreement of 1975, treaties on nonproliferation of nuclear and conventional weapons) and, on the other hand, planned economies were transformed slightly by introducing in them elements of a market economy and stimuli of a technological progress. In spite of a successful arms race reduction the costs of armaments and political expansion still exceeded the economic potential of communist countries, whereas the introduction of elements of market economy generated strong resistance of the bureaucracy in the state and the party administration.

The 1980s saw not only a growing opposition against the political system but also an ever stronger conviction of an upcoming defeat shared by communist officials. The need to conduct economic reforms called for a more extensive popular support, which was possible to achieve thanks to political reforms. Political reforms were pursued to a limited extent in the Soviet Union (economic *perestoyka*) accompanied by political *glasnost* – transparency) and in Poland (the 'round table' talks, an attempt to achieve a compromise with the opposition). Finally, the attempts to carry out limited reforms of the

economic system were doomed to failure. Coupled with a disintegrated political system, they led to the collapse of communism over the years 1989–1991.

In China, however, the authorities resorted to extreme means of repression against the opposition (the massacre at the Tian'anmen square, 1989). They were then successful in effecting its economic reforms encompassing devolution; privatization of agriculture, small- and medium-size industry, and trade; as well as the introduction of elements of market economy. The country managed to restore a fast rate of economic growth and development creating openings for foreign investments linked with the import of new technologies. The future will show the results of these reforms.

Communist researchers into the political and economic system concentrated their work mostly on its premises rather than on reality. A distinct character was noticeable only in the discussions before the 1930s which touched upon the 'Asiatic system of production.' These works tackled directly the prospects of building of the communist system in China, and, indirectly, they reflected some ideas on the political and economic system in Russia. Amongst basic characteristics of oriental societies they featured a dominating role of the state in the economy and, consequently, the durability of absolutist and bureaucratic tendencies. This concept was raised in discussions in the 1920s by Wittfogel. He broke away later with communism and came to regard the Soviet Union as a follower of Asian despotic systems (1962).

Later, the communist authors emphasized the class conditioning of the system. Many works presented a mystified picture of common interests of the state and society. They referred also to the notions of 'People's Democracy' or 'Socialist Democracy' (as a state of equal opportunities). Communist publications are of little academic value, yet sometimes they can communicate significant information.

In the noncommunist literature as a whole there were prominent publications which dealt with communist systems within a wider historical framework. In particular, they referred to the connections between the history of Russia and of the Soviet Union. The principle of a historical continuity was propagated (Kucharzewski 1948, Pipes 1990, 1993, Besançon 1980). This conception was often accompanied by a tendency to view communist systems as something superimposed by the USSR upon other countries.

The notion of totalitarianism was used initially in Italian fascism, later by researchers whose works dealt with German national socialism. In the wake of experiences and the atmosphere of the 'cold war', communist systems were regarded by some researchers as one of the forms of totalitarianism (Arendt 1951, Friedrich and Brzeziński 1956). Arendt saw the roots of totalitarian systems above all in the current demise of human values and the crisis of principles underlying the existence of societies and individuals. Friedrich and Brzeziński focused mainly on the techniques of wielding power and the totalitarian syndrome.

Concrete studies of the system were heavily influenced by the concept of totalitarianism (Fainsod 1953). The concept of communism as a form of totalitarian systems was undermined to some extent as a result of growing tendencies towards decentralization and curbing repression. Researchers started to concentrate more on the differences between communist countries as well as on the fact of how inconsistent their respective systems were (Brzeziński 1960). Another approach to communism stipulated that the system was an attempt to implement utopia invented by doctrinaires (Heller and Niekricz 1982, Malia 1994). There were also other interpretations of the communist system according to which it was a peculiar way to modernization concerning in particular the Third World (Schurmann 1966).

Some authors treated communism above all as a system of genocide. Political commentaries on the subject emerged before World War II. Afterwards, scientific studies were preceded by documentary literature (Herling-Grudziński 1951, Solzhenitsyn 1974). A different interpretation claimed that Stalinism was only a criminal distortion of the communist system (Medvedev 1971). In the 1960s, Conquest (1968) published monographs on various aspects of genocide in the Soviet Union. Most recently an international team has tried to apply a comprehensive approach to this problem (Courtois et al. 1997).

At present, communist systems exist exclusively in the Far East and in Cuba. These areas require further studies devoted to their specific character and ability to stand the test of time.

Communist Parties

Originating after the Russian Revolution of November 1917, communist parties developed into a distinctive organizational form with a characteristic political ideology and an integral personal identity for their members. Modeled deliberately on the example of the Russian original, those communist parties that had remained faithful to the Soviet Union generally either declined or underwent radical transformation when the Soviet state collapsed in 1991.

In March 1918 Vladimir Lenin urged his victorious 'Bolshevik' ('majoritarian') faction of the Russian social democratic party to reconstitute itself under the name 'All-Russian Communist Party (bolsheviks),' known by its Russian initials as the RKP(b) and later renamed communist party of the Soviet Union. By this act of renaming, Lenin meant to signify that the former Bolsheviks would oppose replacement of Tsarist rule with parliamentary social democracy in Russia. They would stand instead for establishment of a 'dictatorship of the proletariat' as a deliberately coercive device for prohibiting political activity in pursuit of any goal other than communism, defined by Karl Marx as a society combining contribution according to ability with consumption according to need.

A year later Lenin convened his supporters together with foreign sympathizers resident in Moscow and a few delegates from other socialist parties who managed to make their way to the Russian capital, where they established the 'Communist International,' or Comintern. At its Second Congress in August 1920, this organization's leaders laid down the '21 conditions' which gave definition to the identity of communist parties. The three most important conditions obligated communist parties to practice democratic centralism, organizational exclusivity, and defense of the Soviet Union. 'Democratic centralism' came to mean that in a communist party, all local organizations, and all individual members must obligate themselves to comply with directives of a national directorate. This 'centralist' principle was to work in combination with the 'democratic' principle that the national directorate (called a 'Central Committee') must be elected by delegates from the local organizations and accept information from them about their local activities. Because the centralist principle included the Central Committee's right to nominate the sole candidate for obligatory election by the local organization ('committee') as its leader, in fact democratic centralism conferred on the Central Committee the right to select its own electors.

Organizational exclusivity obligated the communist party to separate itself from any socialist party, prohibiting joint membership in the two parties. Accompanying this requirement was a demand that even where communist parties could operate legally, a

communist party must maintain a clandestine organization for illegal revolutionary activities.

All members of communist parties were further required 'to render every possible assistance' (Daniels 1984) to the Soviet state, especially against the policies of their own governments. Lenin's ultimate successor Joseph Stalin would in 1927 transform this expectation into a definition of communist internationalism as the readiness 'unreservedly, unhesitatingly and without conditions … to defend the USSR' (Stern 1990). By imposing internal discipline enforced by the right of central leaders to remove local opponents, an organizational split with other Marxists, and a Russia-centered conception of the party's mission, the 21 conditions required foreign communist Parties to reprise the organizational history of the Soviet exemplar. As communist Parties emerged around the world, encouraged both by the success of the Soviet Party in establishing Russia's independence from foreign domination and by clandestine monetary subsidies from the Soviet comrades, they became identifiable by their adherence to a common political ideology known as Marxism–Leninism. Of course from the very beginning Marxism–Leninism existed in many variants. The 21 conditions were themselves an effort to enforce a minimal degree of uniformity on diverse conceptions of communist identity. Adherence to the ideas of 'Marx, Engels, Lenin, and Trotsky' characterized the Trotskyists who soon broke off in a 'Fourth International' whose adherents still exist (winning 5.3 percent of the vote in the 1995 French presidential election). 'Marxism–Leninism–Maoism' became the ideology of the Chinese Communist Party and of the splinter parties that broke off from national communist parties after the Chinese definitively split with the Soviets in 1963. Italian communists continued to be influenced by the ideas of Antonio Gramsci, whose independent conception of the reasons why the working class in industrial countries remained politically quiescent bore far more democratic implications than Lenin's own explanation of worker passivity. Until Stalin's death, the Soviet Party referred to its own ideology as 'Marxism–Leninism–Stalinism.'

Despite this diversity, communist political thought has generally shared certain core elements. Communists have classed their own political thinking as 'theoretical' in contrast to the 'ideological' programs of other political parties. They have affirmed a theoretical postulate identifying political parties with the economic interest of classes. This postulate defines 'class' as joining all persons who make their living in the same way and 'class interest' as the perpetuation of that way of making a living (as opposed, for example, to increasing the incomes of the individuals who compose a class). The same postulate identifies each communist party with a 'proletariat,' as the class of persons who earn their living by selling ('alienating') their labor to someone else. Communists have generally insisted that in the long run the proletariat can only avoid the fate of mass unemployment if it succeeds in overthrowing capitalism, i.e., the system of buying and selling labor as a commodity. In the short run, state ownership of industrial enterprises has tended to be regarded as a means of maintaining the proletariat against capitalist pressure. Communists are further distinguished from other Marxists by a view that agricultural smallholders are likely to be promising allies in shortening the road to the abolition of capitalism. Finally, both the long-run goal of abolishing capitalism and various short-run interests of the proletariat have been considered achievable only by a 'vanguard party,' one which relies on theoretical analysis to identify the interests of the proletariat rather than consulting the proletarians themselves. Where they engage in electoral competition, communists have seen their task as educating voters in the voters' true interests rather than responding to expression of interest by voters. Where they have acquired control of the state, communists have portrayed their task as preventing other parties from deceiving the proletariat by running their own independent candidates.

Because of the commitments to democratic centralism and to the theoretical self-understanding as a vanguard party, communists could only be 'cadres,' although in a sense distinct from the usage of this term introduced into political science by Maurice Duverger. By a 'cadre party' Duverger meant a nineteenth-century association of notables, who drew their personal identities from birth or achievement and saw the party as a device to help win contests for office (Duverger 1963). To a communist, 'cadre' took its meaning from Lenin's conception of the party member as a full-time professional revolutionary. A communist cadre, at least ideally, has derived his or her personal identity solely from self-transformation into an agent of the party. Democratic centralism provides that every party member may immediately be redeployed, regardless of his or her personal will, to any place or duty at the discretion of the central party authority. This total commitment gave an integral, all-or-nothing quality to the personal identity of a communist. As Stalin once told the Soviet Central Committee, 'Either you are nothing in the eyes of the party or you are a party member with full rights' (Arch Getty and Naumov 1999). Ken Jowitt has argued that this integral conception of personal identity accounts for communist parties' difficulties in attracting adherents in industrial societies, contrary to Marx's expectation that only these societies were ripe for communist ideas, because the complexity of industrial society encourages people to develop identities contextualized to varying situations. Conversely communist parties were more successful in attracting adherents in agrarian societies where less social diversity and more rigid subordination limited the fragmentation of selfhood (Jowitt 1992). Integral identification of the self with the party makes more comprehensible both the ex-

ceptional violence practiced by many communist parties, in whose eyes the victims were 'nothing,' and the extraordinary selflessness displayed by communists in such movements as the World War II Resistance against German occupiers or struggles for civil rights and economic justice in many countries. Where communist parties managed to gain control of the state, it is questionable whether they remained 'parties' at all. Communists became the rulers of the Soviet Union, eight countries in Eastern Europe, China and five other Asian countries, and Cuba. If by a 'party' we mean an organization that competes for political power by supplying candidates for executive or legislative office and by maintaining a coalition among its candidates after they win, then it is questionable whether ruling communist parties qualified. Of course a monopolist may be said to compete, so successfully as to exclude all rivals. But ruling communist parties performed three functions not usually associated with political parties, acting as territorial administrations, personnel offices for their governments, and ultimate policy makers. In the Soviet Union, the first secretary heading each local party committee was the ultimate authority over all government activity in the territory assigned to the committee. The highest ranking local government official was a subordinate of the first secretary, sitting as a member of the committee's bureau acting under the first secretary's direction and likely, at a later stage in his career, to be promoted into the position of first secretary. The first secretary was expected to exercise his plenipotentiary authority by recommending appointment or dismissal of all officials within the territory, with the exception of those officials whose appointment or dismissal could be recommended only by some higher party committee. The Political Bureau ('Politburo') of the Central Committee in turn 'recommended' policies to the appropriate government agencies, enforcing compliance with its policy recommendations by exercising its right to making binding recommendations about appointment or dismissal of the relevant officials. Where communist parties did not secure control of the state, they also did not practice these methods of rule, but at the same time their overt identification with the practice of complete penetration of the state hampered their electoral campaigns by stimulating suspicion among voters accustomed to distinguish party activities from conduct of government.

The collapse or transformation of many communist parties after the fall of the Soviet Union in 1991 resulted from their close identification with the Soviet State. Decline was not solely the result of the disappearance of monetary subsidies on which many parties had subsisted and others had drawn. From the beginning communists had conceived themselves as those Marxists loyal to the Soviet Union and ready to accept its authenticity as the revolutionary workers' state. Communist parties had repeatedly lost members or suffered organizational splits whenever events had dramatized the discrepancy between the emancipatory ideals of Marxism and the practices of the Soviet rulers. Such events as executions of senior Soviet officials in 1937–8, the 1939 Molotov–Ribbentrop pact with Nazi Germany, Nikita Khrushchev's 1956 denunciation of Stalin's crimes against the party and the crushing of the Hungarian uprising that resulted, the invasion of Czechoslovakia in 1968, and the suppression of the Polish labor movement Solidarnosc in 1980–1 had impelled waves of resignations from communist parties around the world. The reciprocal denunciations in 1963 by the Chinese and Soviet parties led to formation of parallel Maoist parties in most countries where communist parties existed. While the reforms known as *perestroika* championed by Mikhail S. Gorbachev after 1985 briefly encouraged some foreign communists loyal to the Soviet party, popular uprisings against ruling parties in Eastern Europe in the fall of 1989 and the defeat of the August 1991 coup against Gorbachev led many foreign communist parties to reconceive their identity. Lenin had said that the adoption of the name 'communist' was far more than a formal act; in East European states formerly ruled by communist parties, remnants of those organizations hurried to relabel themselves 'socialist' or 'democratic socialists,' while the independent-minded Italian Communist Party preferred 'Democratic Party of the Left.' Although the pattern of decline was mixed, with the independent Communist Party of Spain retaining its name and gaining adherents, the once powerful French Communist Party, noted for its loyalty to Moscow, found its support among voters dwindling, with former supporters deserting to the Socialists or even to the far-right National Front. Just as communist parties as a distinctive form of political organization had originated with the Soviet State and developed their identifying features by emulating Russian forms, so the collapse of the Soviet order ended the cohesiveness of communist parties as an identifiable phenomenon.

Communitarianism: Political Theory

Characteristic key elements of communitarian theory are the following five points: a hermeneutic methodology, criticism of what was called atomistic individualism, an Aristotelian concept of the good in opposition to rights, the renaissance of the idea of community, and a renewed insight into the relevant political function of civic virtues. Communities can be defined as webs of social relations that encompass shared meanings and shared values. Families may qualify as minicommunities, villages often are, although not necessarily. Communities need not be concentrated geographically, like the scientific community. Especially traditional communities are not necessarily places of virtue, but they can be oppressive, monolithic, and authoritarian. So a main problem for communitarian authors is to find overarching criteria to avoid accepting automatically any commonality of shared self-understanding as a good community (Etzioni 1998, p. XIV).

In the 1980s, a group of political theoreticians—Charles Taylor, Michael Sandel, and Michael Walzer—challenged what they perceived as excessive individualism by the insight that individuality is based and dependent on social context. The radical liberal idea of an 'unencumbered self' was criticized as self-refuting, because it fostered antisocial behavior with the tendency to undermine its own social preconditions.

The academic and public impact of communitarianism has come about for two reasons: it seemed to give a theoretical answer to the most important political philosophy of the time, for example, the individualist liberalism of the renewed contract theory of John Rawls and others. The second reason is even more important: politically, communitarianism was a critical reaction against the 'liberalism of greed' of the Thatcher and Reagan years, so it became attractive to the New Democrats and New Labour as a rhetoric to win back the votes of the middle classes. In the early 1990s, Etzioni and others decided to take these ideas from the campus to the larger society. They founded the journal *The Responsive Community* and tried to establish communitarian ideas as a recognized third way of political thinking between liberalism and conservatism. Different from former communitarian ideas in the tradition of Ferdinand Tönnies (*Gemeinschaft und Gesellschaft*), Robert Nisbet, and Martin Buber, the new communitarians pointed out that a responsive community tries to avoid any authoritarianism and oppressiveness against the individual. The old communitarians privileged social bonds and traditional small communities over the individual. Communities in their definition were villages, small cities, some religious sects, and tribes. Asian communitarianism overemphasizes social harmony. The new American line of communitarian thinking concentrated much more on the question of balance between individual rights and social responsibilities. Individual autonomy and the common good are to be brought into a new equilibrium. It tried to add a sense of the social and communal preconditions of social integration to rights-centered liberalism and liberal neutrality.

The anthropologic key concept of modern communitarian thinking is Taylor's idea of humans as self-interpreting animals (Taylor 1985b). Modern identity is based on inescapable frameworks of interpretation, which provides the background language for strong evaluations of right and wrong, good and evil, higher and lower. The quality of this framework is decisive for the quality of the society. Sandel radicalized this idea and transformed it into an argument against Rawlsian liberalism: the original position as a metaphor for justice, where nobody knows about his or her later social position before a decision is taken, is not only practically impossible (Rawls would agree), but also theoretically undesirable, because this conception of justice would lead to a world inhabited by morally neutral people without any character. Persons without loyalties to their family, their community, nation, or people are in Sandel's view persons without character. MacIntyre emphasized the missing foundation of liberal theories of justice. Even more, modern concepts cannot provide any motivation to act morally, because they are not based on fully responsible persons, but only on character masks such as the manager, the therapist or the Kierkegaardian aesthete.

This anti-Rawlsian criticism was not conclusive, because his principles of justice were not meant to shape the whole person, but only their behavior in the political realm. Even more, Sandel did not take into account the possibility of a person taking a distant stand from their community. So the foundations of Sandel's (and, as traditional virtues are concerned, MacIntyre's) criticism seemed to be rooted in old-fashioned communitarianism without reflection of the fact that modern American society can be interpreted as the social basis for some kind of responsive individualism. Both Sandel and MacIntyre were uncomfortable with the label 'communitarian,' but their ideas belong to the present discussion of the concept.

A quite different kind of communitarian theory was developed by Walzer, who is also uncomfortable with

the term, but refers to the same set of methods and ideas. In his *Spheres of Justice. A Defense of Pluralism and Equality* (1983) his social criticism and his ideas for reform lean on the hermeneutic interpretation of commonly shared values. The well-known tension between shared values and social practice is sufficient to legitimize social reform. Walzer's method differs on the one side from liberal Kantian or Rawlsian social constructionism, and on the other from conservative belief in the objectivity of traditional values (social ontology). Justice is only possible if it takes into account the differentiation of spheres. Different modes of distribution have to be applied concerning membership and citizenship, political power, security and welfare, money, office, education, recognition, kinship, and love. There is no general theory of justice, but a special justice for each of these spheres. What is considered as just depends on commonly shared and publicly discussed opinions about the criteria of justice.

The liberal-communitarian debate of the 1980s and early 1990s seems to be over at present. Those who decided to stick to the label 'Communitarians' now call themselves liberal communitarians or communitarian liberals, such as Selznick (1992) and Etzioni (1996). The central idea is that, in a modern society, common values and virtues can only be developed by freely consenting individuals, not by the state or by pressure from religious movements of the fundamentalist denomination.

Selznick's 'communitarian liberalism' draws on the social philosophy of John Dewey. Morality is always community based. Character and integrity are relevant for the function of large organizations, including the state. A proper understanding of communities implies diversity and pluralism as well as social integration. It has to have a strong sense of a common good. Thus, Selznick combines sociological functionalism with the value-based traditions of American pragmatism. His interpretation of the term 'covenant' means a self-defining commitment, and an act of faith and resolve by the individual. It is prepolitical, foundational, and consensual. Liberal neutrality misses this aspect, and is based only on institutions for the purpose of social integration. Conservatism, on the other hand, tries to overload institutional processes with value orientations. The communitarian third way tries to restore values and virtues as functional prerequisites of the civil society.

Bellah and co-workers (1991) try to describe the state of American society and to make statements about its long-term viability through insights into its mores and the climate of opinion. They lean on Alexis de Tocqueville's *Democracy in America* (1835), which seems to be a key text for most communitarians. The results of the study are communicated in terms of eloquent sadness: the self-destruction of the liberation promises of modernity and the retreat from public engagement into the private sphere of the family and friends is stated by many of the interviews. Most of them articulated a profound yearning for the idealized small town, which can be interpreted as a yearning for meaning and coherence, for commitment and community. The social ecology is not intact if there are no communal answers to the extreme fragmentation of modern everyday life. The ubiquitous language of individualism, in which American self-understanding normally is articulated, limits the ways in which people think and cuts off the opportunity of a broader orientation (once called 'civic virtues,' Bellah et al. 1985, p. 290). Because of their option for more substantive ethical identities and more active political participation Bellah and co-workers were labeled as communitarians. They preferred to describe their position in a slightly different way to avoid the risk of being misunderstood, privileging only small face-to-face groups such as families, congregations, and neighborhoods, and of being opposed to the state and all the other larger structures that dominate life at the start of the twenty-first century. They insist that freedoms and a Good Society depends on institutions, and they are critical that many individualistic Americans have trouble understanding and accepting social and political institutions (Bellah et al. 1991).

Etzioni's main criticism of liberal political theory is the negligence of the social preconditions that enable individuals to maintain their psychological integrity, civility, and ability to reason. On the other hand, he distances himself from those communitarians who hold that as long as a community has agreed on a set of values, these are the ultimate criteria as to what is morally appropriate (Etzioni 1995, p. 17). The central problem is to establish criteria for the evaluation of the internal value system of different communities. The question is: how to avoid perspectivism and relativism, and to develop criteria to rule out authoritarian and oppressive community values. In the first place, internal democracy of the community is the criterion. But additional criteria are needed, because a majority in a specific community might violate individual and minority rights. The second criterion is a substantial process of consensus building within a community. Beyond any particular community, the values of a society as a whole are a framework within a higher order of legitimacy; that is, the application of the Constitution, especially the Bill of Rights. The third level is the cross-societal moral dialogues, in which the societal values have to be legitimized against others. The fourth criterion is the global community. But even the global community might act oppressively, as it did when women were excluded from voting worldwide until the end of World War I. So the last resort for the dissenting individual is the clearly communicable self-evidence of some core values.

All these criteria have in common that they are based on moral dialogues of different reach, not on ontological values or on artificially constructed value systems. The communitarian approach is the support

of concrete societal and, if necessary, cross-cultural moral dialogues. Of course, they have to be limited to a set of core values (Etzioni 1996, p. 237). Through these reflections Etzioni tries to overcome the restriction of traditional communitarian thinking to limited communities and to bring into discussion the notion of a global community. These are questions the world-wide discussion of communitarian ideas has made inevitable. Communitarian approaches have to solve the question: Which community? What kind of community? Who belongs and who does not? This will be important especially for further discussions on the problem of multiculturalism (cf. Taylor et al. 1992).

The discomfort with the label 'communitarian' seems to be a general characteristic of many authors in this field, with the exception of Etzioni. Communitarianism seems to be a permanent, accompanying phenomenon to liberalism, but can hardly stand on its own. The traditional social structures of community orientation have been dissolved by the processes of modernization, individualization, and fragmentation. Attempts to restore or invent dense forms of social integration as an answer to modernity such as communism, fascism (*Volksgemeinschaft*), or some forms of Islamic fundamentalism are discredited because of their atrocities and their contempt for individual rights. Thus, in modern, technology-based service economies, communitarianism is only acceptable as a reflexive admonition to care more about the common good, but not as a coherent and mobilizing social ideology. So the prediction follows that communitarian ideas in a moderate form of social self-reflection and social integration programs will be a permanent subdominant melody in the chorus of further modernizing societies, because it meets a fundamental human demand for social integration on a theoretical level.

Communitarianism, Sociology of

Communitarianism is a social philosophy that favors social formulations of the good. It is often contrasted with liberalism, which assumes that the good should be determined by each individual. To the extent that social institutions and policies are required, these should be based on voluntary agreements among the individuals involved, expressing their preferences. In contrast, communitarians view institutions and policies as reflecting in part values passed from generation to generation. These values become part of the self through internalization, and are modified by persuasion, religious or political indoctrination, leadership, and moral dialogs.

1. A Brief History

The term 'communitarian' was first introduced in 1841, to mean 'of, pertaining to, or characteristic of a community or communistic system; communitive.' It

has been infrequently employed since then until the middle of the twentieth century.

Among early sociologists whose work is focused on communitarian issues (but did not draw on the term) are Ferdinand Tönnies, especially his comparison of the *Gemeinschaft* and *Gessellschaft*; Emile Durkheim's studies of socially integrating role of values and the relations between the society and the person; and George Herbert Mead's work on the self. Other early relevant sociological works are those of Robert E. Park, William Kornhauser, and Robert Nisbet.

In the 1980s communitarianism was largely advanced by Charles Taylor, Michael Sandel, and Michael Walzer. They criticized liberalism for its failure to realize that people are socially 'embedded,' overlooking the fact that people can have a strong attachment to their societies. They lamented liberalism's focus on the individualistic concept of self-interest.

Asian communitarians argue that to maintain social harmony, individual rights and political liberties must be curtailed. Some seek to rely heavily on the state to maintain social order (for instance, leaders and champions of the regime in Singapore and Malaysia), and some on strong social bonds and moral culture (as Japan does). Asian communitarians also hold that the West's notion of liberty actually amounts to 'anarchy'; that strong economic growth requires limiting political freedoms; and that the West uses its idea of legal and political rights to chastise other cultures that have inherent values of their own.

In 1990 a new school of communitarianism was founded. Among its leading scholars are William A. Galston (political theory), Mary Ann Glendon (law), Thomas Spragens Jr. (political science), Alan Ehrenhalt (writer), and sociologists Philip Selznick, Robert Bellah and his associates, and Amitai Etzioni, who wrote books that, in 1990, laid the foundations for responsive (democratic) communitarianism.

According to Selznick's (1992) *The Moral Commonwealth*, communitarianism seeks reconstruction of liberal perspectives to mitigate the excesses of individualism and rationalism, and to encourage an ethic of social responsibility. In community there is an irrepressible tension between exclusion and inclusion, and between civility and piety. Thus community is not a restful idea, a realm of peace and harmony. On the contrary, competing principles must be recognized and dealt with.

Responsive communitarians, a group founded by Amitai Etzioni, took communitarianism from a small academic discipline and introduced it into public life, as well as recast its academic content. Its tools were *The Responsive Communitarian Platform: Rights and Responsibilities* a joint manifesto summarizing the guiding principles of the group; an intellectual quarterly, *The Responsive Community*, whose editors include several social scientists; several books; position papers covering issues such as shoring up the family, organ donation, health care, and bicultural education; and numerous public conferences, op-eds, and a web site (www.gwu.edu/ ~ ccps).

2. *Basic Principles*

Responsive communitarianism assumes that societies have multiple and not wholly compatible needs, in contrast to philosophies built on one core principle, such as liberty for libertarianism. Responsive communitarianism assumes that a good society is based on a balance between liberty and social order, and between particularistic (communal) and society-wide values and bonds. This school stresses the responsibilities people have for their families, kin, communities, and societies—above and beyond the universal rights all individuals command, the focus of liberalism.

While a carefully crafted balance between liberty and social order defines a generic concept of the good society, communitarians point out that the historical-social conditions of specific societies determine the rather different ways a given society in a given era may need to change to attain the same balance. Thus, contemporary Japan requires much greater tolerance for individual rights, while in US society excessive individualism needs to be curbed.

Communitarians also pay much attention to the relationship between the self and the community. Political theorists depict the self as 'embedded', which implies that the self is constrained by the community. Responsive communitarians stress that individuals who are well integrated into communities are better able to reason and act in responsible ways than isolated individuals, but if social pressure to conform rises to high levels, it will undermine the individual self.

Communitarians pay special attention to social institutions. Several of these form the moral infrastructure of society: families, schools, communities, and the community of communities. Infants are born into families whose societal role is to introduce values and begin the development of the moral self. Schools' role is to further develop the moral self and to remedy moral development if it was neglected or distorted by the family.

Communitarians emphasize that children reared in well-functioning families and schools will still not be sufficiently equipped for membership in a good, communitarian society. This is a point ignored by those social philosophers who assume that once people have acquired virtue and are habituated, they will be adequately guided by their inner moral compass. In contrast, communitarians assume that commitments to moral values tend to deteriorate, unless these are continuously reinforced. A major societal role of communities is to reinforce these commitments of their members. This is achieved by the community's 'moral voice', the informal sanctioning of others, built

into a web of informal affect-laden relationships, that communities provide.

Studies indicate that Americans in the 1980s often avoided speaking up on moral issues. The work of Robert Bellah and his associates has been particularly influential here, demonstrating the rise of first expressive and then instrumental individualism, and their negative effects. Many Americans, and to some extent members of other Western societies, embraced the liberal ideology that what is morally sound is to be determined by each individual, and one should not judge the acts of others. Very large increases followed in crime, drug abuse, divorce, and loss of trust in public institutions and legitimate authority and fraying of social bonds.

Within this context responsive communitarians point out that if a society has communities whose social webs are intact, who share a moral culture, and whose members are willing to raise their moral voice, such a society can rest its social order largely on moral commitments rather than on the coercive state. That is, the moral voice can reduce the inevitable tension between liberty and social order and enhance both.

3. *Critiques and Responses*

Critics argue that the concept of community is difficult to define. In response, Etzioni defined community as an amalgam of a web of affect-laden relationships among a group of individuals, who also share a commitment to a set of shared values and mores, who have a shared history and identity—in short, a particular culture.

Other critics claimed that the population of contemporary societies is concentrated in cities and is geographically highly mobile, and thus bereft of community. Communitarians respond that communities persist in many city neighborhoods, often based on ethnic or religious ties. Moreover, communities need not be residential; members can be spread among nonmembers. For instance, homosexual groups often constitute communities even if they are not all neighbors. Also communities exist at work, among professionals and even in cyberspace.

Critics maintain that communities are authoritarian and oppressive. Communitarians respond that communities vary in this regard. Contemporary communities tend to be relatively democratic, given the relative ease in which people can relocate as well as shift their loyalties and psychic investments among various communities of which the same person may be a member, for instance, at home and at work.

Critics point out that communities tend to be homogenous and exclude people who are different. Communitarians respond that communities must respect laws that ban discrimination on racial and other grounds, but argue that given the considerable human benefit of community membership, a measure of self-segregation should be tolerated.

The fourth element of the needed institutional structure is the community of communities. Responsive communitarians have noted that communities need to be bound socially and morally into more encompassing entities, if violent conflict among them is to be avoided. Society should not be viewed as composed of millions of individuals, but as pluralism (of communities) within unity (the society). The existence of subcultures does not undermine societal unity as long as there is a core of shared values and institutions.

4. *Civic and Good*

Most recently, following the growing popularity of the concept of civic society, Etzioni argued that it is insufficient from a communitarian viewpoint. This is the case because civic society tends to be morally neutral on all matters other than the attributes citizens need to make them into effective members of a civic society, for instance, to be able to think critically. In contrast, a good society seeks to promote a core of substantive values, and thus views some voluntary associations and social activities as more virtuous than others.

In the same vein, communitarians argue that while everyone's right to free speech should be respected, some speech—seen from the community's viewpoint—is morally highly offensive and when children are exposed, damaging, For instance, the (legal) right to speak does not render verbal expressions of hate (morally) right.

While sociologists made numerous contributions to altered communitarian thinking, this philosophy challenged sociology to face issues raised by cross-cultural moral judgments. Sociologists tend to treat all values as conceptually equal; thus sociologists refer to racist Nazi beliefs and those of free societies by the same 'neutral' term, calling both 'values'. Communitarians use the term 'virtue' to indicate that some values have a high moral standing because they are compatible with the good society, while other values are not and hence are 'aberrant' rather than virtuous.

In the same vein, communitarians reject the claim of cultural relativism that all cultures command basically the same moral standing, and do not shy away from passing cross-cultural moral judgments. Thus, they view female circumcision, sex slaves, and *hudud* (chopping off the right hand of thieves) as violations of liberty and individual rights, and abandoning children, violating implicit contracts building into communal mutuality, or neglecting the environment, as evidence of a lack of commitment to social order and neglect of social responsibilities.

5. Public Voice

The discussion up to this point focused on responsive communitarianism as a social philosophy, its social science propositions and ethical implications. Responsive communitarians also have been playing a considerable public role. They are best understood as a new environmental movement, one concerned with the well-being of society rather than nature. Like environmentalism, communitarianism appeals to audiences across the political spectrum. The record shows that their influence extends from the moderate social democratic left (especially Tony Blair and Bill and Hillary Clinton) to the moderate Tory right (including public figures such as Kurt Biedenkopf in Germany and David Willetts in the UK). Green parties are also among those who often embrace communitarian concepts.

Communitarian terms have become part of the public vocabulary in the 1990s, especially references to assuming social responsibilities to match individual rights, while the term 'communitarianism' itself is used much less often. The number of articles about communitarian thinking in the popular press, increased twelvefold during the last decade of the twentieth century.

Communities of Practice

The term 'community of practice' is of relatively recent coinage, even though the phenomenon it refers to is age-old and social scientists have talked about it under various guises. In a nutshell, a community of practice is a group of people who share an interest in a domain of human endeavor and engage in a process of collective learning that creates bonds between them: a tribe, a garage band, a group of engineers working on similar problems.

1. Definition

Not everything called a community is a community of practice. A neighborhood for instance, is often called a community, but is usually not a community of practice. Three characteristics are crucial.

1.1 The Domain

Since a community of practice is focused on a domain of shared interest, it is not merely a club of friends or a network of connections between people. Membership therefore implies a minimum level of knowledge of that domain—a shared competence that distinguishes members from other people. (You could belong to the same network as someone and never know it.) The domain is not necessarily something recognized as 'expertise' outside the community. A youth gang may have developed all sorts of ways of dealing with their domain: surviving on the street and maintaining some kind of identity they can live with.

1.2 The Community

In pursuing their interest in their domain, members engage in joint activities and discussions, help each other, and share information. That is how they form a community around their domain and build relationships. Having the same job or the same title does not make for a community of practice unless members interact and learn together. The claims processors in a large insurance company or the students in American high schools may have much in common, but unless they interact, they do not form a community of practice. The Impressionists, for instance, used to meet in cafes and studios to discuss the style of painting they were inventing together. These interactions were essential to making them a community of practice even though they usually painted alone.

1.3 The Practice

A community of practice is not merely a community of interest—people who like certain kinds of movies, for

instance. Members of a community of practice develop a shared repertoire of resources: experiences, stories, tools, ways of addressing recurring problems—in short a shared practice. This takes interactions over time. A good conversation with a stranger on an airplane may give you all sorts of interesting insights, but it does not in itself make for a community of practice. The development of a shared practice may be more or less self-conscious. The 'windshield wipers' community of practice at an auto manufacturer makes a concerted effort to collect and document the tricks and lessons they have learned into a knowledge base. By contrast, nurses who meet regularly for lunch in a hospital cafeteria may not realize that their lunch discussions are one of their main sources of knowledge about how to care for patients, even though in the course of all these conversations, they have developed a set of stories and cases that become a shared repertoire for them to think about and discuss new cases.

1.4 A Familiar Experience

We all belong to communities of practice. They have been around for as long as human beings have learned together. At home, at work, at school, in our hobbies, we belong to several communities of practice at any given time. And the communities of practice to which we belong change over the course of our lives. In fact, communities of practice are everywhere.

Theoreticians often wonder whether the concept of community of practice is an analytical category, whether it exists only in the theoretician's mind, or whether it refers to actual social structures in the world. The answer is that it is both:

(a) The extent to which any social structure is a community of practice is not something that can be determined in the abstract. Is a family a community of practice? What about a group of workers? A sports team? An orchestra? A classroom? This is always an empirical question that can only be resolved by analyzing the way the group operates. In this sense, the concept is an analytical category.

(b) Yet, you can go into the world and actually see communities of practice at work. Moreover, these communities are not beyond the awareness of those who belong to them, even though participants may not use this language to describe their experience. Members can usually discuss what their communities of practice are about, who else belongs, and what competence is required to qualify as a member.

Communities of practice are a familiar experience, so familiar perhaps that it escapes our attention. Yet when it is given a name and brought into focus, it helps us understand the world better. In particular, it allows us to see the social world as structured by engagement in practice and the informal learning that comes with it, rather than more obvious formal structures such as institutional boundaries.

2. Theoretical Applications

Why have many social scientists found the concept of community of practice to be a useful unit of analysis? Well, if you want to understand broad issues such as culture, identity, and learning in terms of the processes by which people create systems of meanings, then it is useful to consider a unit of analysis where these processes involve a direct experience of engagement for participants.

Communities of practice break down the traditional dichotomy in social theory between perspectives that give primacy to structure (history, culture, myths, or class, of which moments of life are mere instantiations) and perspectives that give primacy to immediate experience (local interactions, of which broader structures are an emergent property). A community of practice is a mid-level unit of analysis that combines both elements. It is neither an abstract structure nor a passing experience. Unlike a culture, it is within the reach of individual participants. Members of a community of practice contribute to the development of the practice through direct engagement in their community. Unlike momentary interactions, however, a community of practice has an enduring character as a social structure. It can therefore accumulate collective cultural resources over time. It is an elementary structure that has all the characteristics of social life—the 'cell' of cultural production and reproduction.

Social scientists have used the concept of community of practice for a variety of analytical purposes, but the primary use of the concept has been in learning theory. The concept originated in studies of apprenticeship (Lave and Wenger 1991). People usually think of apprenticeship as a relationship between a student and a master, but studies of apprenticeship reveal a more complex set of social relationships through which learning takes place—with journeymen and more advanced apprentices. The term community of practice was coined to refer to the community that acts as a living curriculum for the apprentice. Then researchers started to see these communities everywhere, even when no formal apprenticeship system existed.

As a basis for a general social learning theory, however, the learning processes of a community of practice are not limited to training novices. The practice of a community is dynamic and involves learning on the part of everyone. The shared competence defined by the community is always in interplay with the experience of members. Sometimes, as in the case of apprenticeship, it is the competence of the community that pulls the experience of the novice until the novice has a full experience of competence. Sometimes, members bring new ideas and insights: it is their experience that pulls the competence of the community along. One can think of learning as a tension between competence and experience (Wenger

1998). Whenever either starts pulling the other, learning takes place. Learning so defined is a dynamic, two-way relationship between people and their communities. It combines personal transformation with the evolution of social structures.

While the concept of community of practice has been most widely used to analyze learning and the social organization of knowledge, it has also been useful for investigating other aspects of the social world: the construction of subcultures as a form of institutional resistance (Eckert 1989); the reproduction of social classes (Willis 1977); the formation of identities as trajectories through communities of practice and multimembership combining the simultaneous influence of multiple communities (Wenger 1998); local meanings and linguistic change through engagement in shared practice (Eckert and McConnell-Ginet 1992).

It is often useful to look at a social entity—a culture, a linguistic group, a 'social world' (Strauss 1978), an organization—as a constellation of communities of practice. Such social entities are best understood, not as a uniform group, but as a complex set of interconnected communities of practice, each with its own local 'mini-culture' as it were. Such a perspective makes it possible to understand local differences as well as the processes by which broad patterns are recreated in practice. The overarching entity then is the emerging property of interactions within and among local practices (Wenger 1998, Brown and Duguid 2000).

3. *Practical Applications*

Beyond social theory, the concept of community of practice has found a number of practical applications in business, organizational design, education, and civic life.

3.1 *Business Organizations*

The concept has been adopted most readily by people in business because of the increasing need to focus explicitly on knowledge (Wenger et al. 2002). Initial efforts had focused on information systems with disappointing results. Communities of practice provided a new approach, focused on the social structures that could best assume ownership for complex and dynamic knowledge with substantial tacit components. A number of characteristics make communities of practice a natural fit:

(a) Unlike training or research departments, they are not separate units. Rather they pervade the organization, since people belong to communities of practice at the same time as they belong to their business units or teams.

(b) Communities of practice address the informal and tacit aspects of knowledge creation and sharing, as well as the more explicit aspects.

(c) They allow a much closer connection between learning and doing, while still providing structures where learning can accumulate.

(d) In a time of globalization and disaggregation, they create connections among people across institutional boundaries and potentially across the globe.

From this perspective, the knowledge of an organization lives in a constellation of communities of practice each taking care of a specific aspect of the competence that the organization needs. However, the very characteristics that make communities of practice a good fit for stewarding knowledge—autonomy, practitioner-orientation, informality, crossing boundaries—are also characteristics that make them a challenge for traditional hierarchical organizations. How this challenge is going to affect these organizations remains to be seen.

3.2 *Education*

In business, focusing on communities of practice adds a layer of complexity to the organization—a kind of orthogonal structure focused on knowledge, while the core structure of the organization still focuses on business processes and results. But they do not imply a restructuring the whole system. Schools have been a bit slower at adopting the concept of communities of practice because sharing knowledge is already their main activity, and adopting communities of practice as a basic organizing principle implies a deeper rethinking of their structure. In educational circles, the hope is that communities of practice could bring the experience of schooling closer to everyday life along three dimensions.

(a) *Internally*. How to ground school learning experiences in practice through participation in communities around subject matters?

(b) *Externally*. How to connect the experience of students to actual practice through peripheral forms of participation in broader communities beyond the walls of the school?

(c) *Over the lifetime of students*. How to serve the lifelong learning needs of students by organizing communities of practice focused on topics of continuing interest to students beyond the schooling period?

From this perspective, the school is not the privileged locus of learning. It is not a self-contained, closed world in which students acquire knowledge to be applied outside, but a part of a broader learning system. The class is not the primary learning event. It is life itself that is the main learning event. Schools, classrooms, and training sessions still have a role to play in this vision, but they have to be in the service of the learning that happens in the world.

More generally, the concept of community of practice has promise in suggesting ways to organize

societies around issues and functions. The US government and the World Bank are experimenting with these approaches by connecting people across cities and countries with practice-based communities that complement place-based communities. New technologies such as the Internet have extended the reach of our interactions beyond the geographical limitations of traditional communities, but the increasing flow of information does not obviate the need for community. In fact, it expands the possibilities for community and calls for new kinds of communities based on shared practice.

Community Aesthetics

Just as politics was significant in the definition of modernity, aesthetics might well become the mark of postmodernity. Aesthetics is understood, of course, in its etymological sense: that we all 'feel.' Such aesthetics is the foundation of the community, the foundation of what once was called the postmodern 'tribe' (Maffesoli 1996a).

Aesthetics implies an impulse to live that cannot but offend fixed minds, which are only able to witness and analyze average thoughts and average ways of life. But aesthetics reminds us that our being is an event, or even advent. To return to the opposition between modernity and postmodernity, one can say that in the case of the former, history follows its course, whereas in the case of the latter, the event emerges. It intrudes. It forces its way and it does violence. Hence its irrevocably brutal, unexpected, and constantly astonishing characteristics. Here again, one is confronted by the difference between the tonality of drama or dialectic which postulate a possible solution or synthesis, and the tonality of the tragic that is intrinsically *aporic*.

The advent is singular. But its singularity is rooted in an archaic timeless substratum. The 'archaisms' in question are, of course, rethought according to the present, they are experienced in a specific way, but with the origins always kept in mind. Event–advent? For sure, what is qualitatively, intensely experienced, works to bring out what has always been present within our being, be it individual or collective. We can refer to Heidegger on this point, and to the attention he paid to a postmetaphysical thought, applying himself to bringing out the most 'simple' that serves as a substratum to human existence. But we can also refer to Leibnitz who, in his 'principle of indiscernible,' works to find a balance between absolute difference and repetitive identity (Vattimo 1990, p. 21). Between the two, the romanticism or the philosophy of life enhances the tragic aspect of the present, along with its demand, its impulse to live, and the sense of urgency it exudes.

Is this not characteristic of the astonishing contemporary attitudes, based on aesthetics, caring little or not at all about the consequences of their acts? Plural families, and successive and transient love affairs are proof of such behavior in the domain of emotion. Political changeability or ideological variations exemplify it as far as public life is concerned; the acceptance of the anarchical laws of production and, at the same time, the extraordinary suspicion towards them, attest to it in what can be called the economical disorder. An atmosphere of unconcern pervades the whole thing, not furthering the worry about the future but, on the contrary, an urge to live in the present according to a way of being that, during the ages, has developed progressively.

If we try to define this kind of aesthetic environment, we can compare it to an eternal paganism. A paganism that works to grab hold of life, grasps what it offers, anything that turns up. A pagan exuberance devoting itself to using the delights of the present, leading a daring, bold life; a life penetrated by the freshness of the fleeting, precarious, and, therefore, intense instant. In his analysis of Machiavelli's opposition to Christianity, Fichte speaks of his 'general impiety' Fichte 1981, p. 48). It seems that we can extrapolate what he says from his paganism. For it is clearly the essence of Christianity that we find again in the political sphere, in the economical conception of existence, or in the

quest for security that the various social institutions offer.

It is precisely this type of 'Christianity' against which the contemporary impiety rebels. The youthful aspect of its agitation, the 'freshness' of its rebellions, its exacerbated search for intense pleasure, multiform, in the present, all combine to make it view the 'ancient world' as its original homeland. 'Ancient world' should, of course, be understood in a metaphorical sense; that is to say, as anything that contravenes the various 'categorical imperatives' formulated by modern moralism, be they of a sexual, economical, or ideological nature. This return to the ancient—to the archaic—is a feature of postmodernity. As if, beyond a mere parenthesis, for better or worse, in the everyday life or in paroxysm, in a subdued way or, on the contrary, in destructive excesses, we are rediscovering the sublime quality of the beauty of the world. Only this beauty matters, so we may as well delight in it for what it is, even at the cost of submitting to its terrible, formidable laws that we have to accept anyway, which cannot but evoke the theme of *amor fati*, the important consequences of which can be estimated in a Nietzschean spirit.

It is as they wake up from the Promethean dream that more and more people choose to behave in a Stoic spirit. A generalized stoicism according to which that upon which we have no power becomes indifferent. And thus the *amor fati*, thanks to which our fate is not only predetermined but also accepted, even appreciated as such. That attitude generated a certain form of serenity that can seem paradoxical, but which is actually at the basis of various and numerous demonstrations of generosity, mutual aid, voluntary help, and humanitarian actions that stem from social life, and that even tend to multiply. For the acceptance of that which can go hand-in-hand with the concern to take part in that which is: not to bring it under control, but to accompany a given so that, possibly, one makes it give the best of itself. This is the aesthetic logic, described briefly. Thus, realization of the self or of the world no longer consists in a simple economical action, but blossoms in ecological interaction. That may be the way to switch from the Hegelian and Marxist control that is a feature of modernity, to what Bataille calls 'sovereignty,' a sovereignty working on structural reversibility and this is, more than anything else, the sign of pre- and postmodern eras.

If we apply it to the contemporary world, such 'proclivity' does not fail to secrete an undeniable wisdom. A wisdom that is nonactive without being passive, bringing out the tendency that, at a certain point, is inscribed in the reality in question. Thus, to use an idea (Maffesoli 1996b), moralism and necessity are replaced by a 'deontology' that takes situations earnestly and behaves consequently. Moralism rests on the injunction to be this or that. The individual has to submit themself to the plan that has been decreed *a priori*; society is also compelled to become what the intellectual, the politician, the expert thinks it has to be. Quite different is the deontology that adapts to a general tendency, that is heedful of the (spirit of the moment); in short that is in keeping with the opportunities of the present.

Only situations matter. Such immanentism does not imply indifference but, on the contrary, a constant conscience, an awareness of what is: the world, the other, the social. In short, we could talk about a 'co-presence' towards otherness under its various modulations. A variable intensity of 'co-presence,' but integrating the entirety of being, and no longer only this or that part or characteristic.

To reconsider a famous theme already brought up to date by Dodds, we can recall the role of the *daïmon* in the Greek tradition. Of course, Socrates put forth his own *daïmon*, and we can consider that it was a generalized belief that no one could ignore. But the interesting point we want to underline within the scope of this discussion is the tight link that exists between the *daïmon* and necessity, the role of which is so important within the science of ancient culture. In a word, we can say that a much greater number of things depend on necessity than the individual's own nature. It is that very fact that is expressed in various ways in tragedies: we are more acted upon than we really act ourselves. Fate is there—omnipotent, merciless—directing the individuals in spite of their own will in the direction of what has been written down. Here again, it is a matter of a certain form of predestination. To quote just one example out of many, the whole myth of Oedipus is based on such a 'necessity,' with the extreme consequences we know of.

Indeed, community aesthetics only encourages the rise of the impersonal. What is at stake in such a repetition of fate is the very negation of the philosophical foundation of the modern Western world: free will, the decision of the individual or social groups acting together to make History. The great fantasy of universality is the natural consequence of this. Opposed to that, the assertion or reassertion of cyclical systems invalidates such a free will (Dodds 1959, p. 51). The various mythical 'orients' that intrude into postmodernity take up with the impersonal powers again, and the inescapable aspect of action. Be it the various philosophies, or more simply the Buddhist, Hindu, or Taoist techniques, or African clairvoyance, directly confronting the telluric forces, or the Afro–Brazilian cults of possession, without forgetting the multiple New-Age practices, or quite simply the fascination astrology holds over people. All of this emphasizes the fact the individual is, at worst, only the plaything, and at best, the partner of forces that exceed him, and to which he knows he must adapt.

Expressions of this contemporary mythology can be seen in science fiction films, pop videos, sometimes even in advertisements. These expressions reveal the relativization of the free will by the supra-individual 'force.' Of course, strong minds laugh at this, but the

resonance is undeniable. It taps into the social imagination, ensures the success of folklore shows and historical reconstructions, inspires crowds to visit places of pilgrimage, and makes best sellers of rites-of-passage novels. We can call this the 'ethics of the aesthetic,' another way of asking the question posed by medieval alchemists who wondered about the *glutinum mundi*, the glue of the world that ensured that whatever the case, there was something rather than nothing, and that this something was coherent. The 'glue of the world' is, therefore, an impersonal force, a vital flux, in which everything participates in a mysterious attractive correspondence.

There are numerous poets, artists, and utopians who have celebrated such an attraction. It is possible to make a social anthropological reading of it. This is suggested through the term 'orgy,' that is to say, shared passion, social empathy. Or even, by distorting the expression of Durkheim, one could speak of an 'organic solidarity,' meaning that, whether willingly or not, everyone is, essentially, part of a whole that makes one what one is. In short, we only exist because the other, my close relation, or the Other, the social, gives me my existence. I am as I am because the other recognizes me as such. Such an assertion might seem shocking, but is this not, empirically, how, from the smallest to the largest, societies function. Such an 'effect of structure' is well described by Marie Douglas, in her book *How Institutions Think*, (Douglas 1992, p. 12). It enables us to understand that whoever does not submit to such recognition is rejected, stigmatized, or marginalized. Their exclusion is due to the fact that they don't have 'the smell of the clan,' or don't want to acquire it.

Thus, above and beyond individualism, whether theoretical or methodological, empirical social life is only the expression of successive sentiments of belonging. You are a member, part of, you integrate, participate or, in common parlance, 'you belong.' Even if during the good periods of modernity there was autonomy, distinctness, affirmation of an individual identity or class, today all that is only a deception, illusion, simulacrum. Sociology of the orgy (Maffesoli 1991), that is, order of the fusion, even the confusion that determines that everyone exists according to a principle of heteronomy.

With this in mind we can understand the return in force and resonance of the emblematic figures and other daily archetypes that exist in contemporary society. The phenomenon of 'fan' groups among the young generation is only one of the extreme forms of these multiple memberships, which they are not aware of. Thus one 'participates' magically with such and such a rock singer, sporting idol, religious or intellectual guru, or political leader. A participation that generates a quasi mystical communion, a common feeling of belonging. Gilbert Durand, commenting upon the major tragic figures, like Don Giovanni, emphasizes that they become pure 'objects.' More objects than subjects as they only exist in the mind of others, they become an 'ideal type' (Durand 1982, p. 207).

We can pursue this analysis by noting that these 'major abstractions,' these archetypes, tend to multiply, even to democratize themselves. Increasingly there are small major figures. Ultimately, each postmodern tribe has its emblematic figure just as each tribe, strictly speaking, possessed, and was possessed, by its totem. In both cases identity, free will, individual decision, or choice can be asserted or demanded, but they are dependent on the identities, decisions, and choices of the group. Note, moreover, that these archetypes regain force and vigor at the same time as the tragic atmosphere of the moment is affirmed. There is a correlation here that deserves consideration.

Instead of being opposed, irreducibly, instead of being exceeded, according to a dialectic and dramatic mechanism, in a soothing synthesis, freedom and necessity are, at certain moments, experienced in a 'contradictory' tension, which is what is called a conflicting harmony. This, of course, recalls the mystic tradition, or the philosophy of Hinduism, but, also, the process of individuation, as described by Jung (1980), in which the 'I' is used and experienced as an object of the Subject that encompasses it. This is an experience of the self that does not destroy the empirical individual, the 'I,' but which, on the contrary, raises it; that is to say, takes it up into a larger whole. Hence the intensity and jubilation of the tragic situation, of the Nietzschean *amor fati*: to be free in a necessity full of love (Aurigemma 1992, p. 250). In short, a form of dependence full of tranquillity in which the individual becomes fulfilled in a state of 'being more' in which he is revealed to himself.

We can see what these situations of 'being more' could be in contemporary society. Great gatherings, all kinds of crowds, multiple trances, mass sporting celebrations, musical excitements, religious or cultural effervescence. All these things raise the individual to a form of plenitude that has none of the colorlessness of economic or political functionality. In each one of these phenomena there is a sort of magic participation in the strange, strangeness, in a global nature that exceeds individual particularity. A global nature which is sacred, and in which each person receives communion. Is this an irony of the tragic, or 'ruse' of the collective imagination, returning this numinous dimension to the social circuit that modernity believed it had evacuated from social life? Re-enchantment of the world? Yes, in so far as one assists, undeniably, in the surpassing of simple utility, even instrumentality, whether this is individual or social.

In such a perspective, the world and the individual do not become, progressively, what they have to be according to a programmed finality, but, one could say, the 'befall' (*adviennent*) to what they are. The archetype, is as it were, only an aide in this revelation, something that serves as developer, used to bring out

what is already there. It is in this sense that there exists a strict relationship between the tragic dimension of the archetype and the accentuation of a cyclical conception of time.

This structural proximity between the archetypal procedure, the collective unconscious and the cycle stems from the fact that, to use a formula of Jung, all 'vital processes follow their own inner laws.' To take the example of the unconscious, you cannot make progress by forced marches, it comes 'in its own time.' Like a spring which trickles, gushes forth or dries up according to its own rhythm, the emergence of the unconscious flow can never be predicted with complete certainty.

We could also establish a connection between this and the fact that, like in alchemical thought and in the dynamic of the unconscious, there is something circular, better, spiralesque in the production of images. They do not obey the mechanic linearity of simple reason, but follow a series of convolutions, which particularly complicate interpretation. Indeed, there is a labyrinthine structure that exists in both the unconscious and the world of images. And if the former has been invested predominately by intellectual interpretation, this is not the case for the latter, which is still ignored, looked down upon, or marginalized by thinkers, at least by those that defend a strictly nationalist point of view.

It is certain that the convolutions or even, if we refer to a Jungian theory, the 'circumambulations,' describe the slow circular work that everyone makes in order to achieve, bit by bit, the realisation of what can be called 'greater being,' which is the work of a whole lifetime (Jung 1980, p. 145). The Tibetan *mandala* is a good illustration of this for the Oriental tradition, just as the myth of the quest for the holy grail expresses it in the Western tradition. In both cases there is repetition, cyclical movement and a tragic conception of life. The archetypal figures always proceed by recurrences, they always refer to a mythical time that is nondatable, the time of our stories and legends: 'at this time,' *l'illud tempus*.

This is striking in the case of mythical illustrations strictly speaking, of which there are many examples to be found in literature, cinema, theater, or song. But this phenomenon of timelessness, of cyclical or tragic accentuation is noticeable, also, in the daily or, *a fortiori*, show-like performance of contemporary stars. The *puer aeternus* that Michael Jackson, for example, represents; the depraved repentant that Madonna represents; or more prosaically, the divine rogue illustrated by the contemporary 'trader'; without forgetting the aggressive heroes of the sports world; all of these emerge from a re-enchantment of the world that has a strong repercussion in the collective unconscious. These figures don't create anything specific, they only repeat anthropologically rooted characters or ways of being. It is this cyclical aspect which means, moreover, that they are raised on a pedestal. And it is by communing in these redundant productions, by identifying in them, that everybody, at the end of a long initiation, which most of the time is nonconscious, exceeds oneself, 'has a ball,' in an aesthetic manner, in something surpassing confinement, or the shrinking, in the small individual 'I.'

Whether in empirical expressions of contemporary art or, and they are not necessarily very far removed, mythical contradictions, it is important to reveal a fundamental recurrence. Lévi-Strauss and Gilbert Durand have greatly insisted on this aspect: repetition, and the 'do-it-yourself' correlative to it, is at work in the great spiritual works of humanity (Durand 1980, p. 130). To a certain extent this repetitive aspect, whether a Nietzschean 'eternal return,' a writer's obsessive idea, a musician's typical musical phrase, a painter's 'touch,' the never-ending theoretical digression of a thinker, even the recognizable ritornello of a singer, all of these things underline the presence of the timeless in history, a sort of immobility in movement.

It is having in mind the redundancy of myth and the repetition in daily creations, without forgetting, of course, that which is at work in everyday life, that we can understand the part of intimate emotion secreted by the familiarity of phenomena, situations, ideas etc … which return with regularity. It is this that characterizes community aesthetics. '*L'habitus* as analyzed by Thomas of Aquinas insists on the structuring aspect of the established custom. The metaphor of the 'fold' that Deleuze offered to reflection is a way of bringing the resonance of habit up to date. All these things show that individual or collective improvement is not necessarily progress without end, as modern pedagogy has postulated, but can, at certain moments, be carried out with an awareness of what is recurrent: customs, myths, and rites, the habits of a given society. This is exactly what a premodern society offered, and it is possible that in postmodernity it has regained importance once more.

Community Economic Development

The terms community, economic, and development each has a clear meaning. Community usually suggests a defined geography with a set of people who hold common history, beliefs, or regard for the territory in which they reside. Economics refers to the workings of capital, i.e., money within institutions and among individuals to create or control wealth. Finally, development refers to a process by which institutions, organizations, or individuals gradually transform from their current state to something bigger or at least different from the original state. Each of these words when fused together takes the form of a new notion of local economic development. Community economic development is a branch or arena of local economic development with a different set of intents. Community economic development is several things in this context. It is a set of beliefs or a movement; an arena of practice; a set of tools or methods; and finally, a set of government programs. For these reasons, when the term community economic development is used it conveys a set of refined principles and practices. As a result for a catholic understanding of the field of community economic development each of the above notions needs to be discussed.

1. The Movement: People Based Economics

Community economic development focuses on distressed or economically disadvantaged communities as zones of action. That is, community economic development has a strong bias toward place. Depressed geographic and socially bound areas have been left behind by the normal processes of economic change (Goldsmith and Blakely 1992). As Goldsmith and Blakely 1992 show in their analysis of urban American disadvantaged populations reside in areas or regions of considerable wealth. But in many areas wealth is unequally distributed among the people creating conditions of observable poverty and neglect for those people and place that do not share the same economic advantages. These communities are deeply divided with: separate assets; separate opportunities; and are separate physically and socially isolated places within the larger national and international economy. Other scholars in the industrialized world have made similar observations. The basic thesis of community economic development is to address this situation, not entirely by the re-capture or redistribution of wealth from the larger society but through the creation of new wealth within these disadvantaged communities.

As Habersfeld, a leading community economic development practitioner (1981, p. 8) puts it clearly, 'residents of low income communities want development which promotes their interests.' Habersfeld describes these interests as the ability to build community capital by: (a) creating productive work for the residents of the distressed neighborhoods in their community or close by; (b) providing local goods and services for the community with local ownership wherever possible; (c) acquiring the same resources as other communities in the city or country with respect to governmental infrastructure that enhances the appearance and livability of the area; (d) generating new wealth through locally based and owned enterprises; (e) reducing the communities' dependence on external resources such as national and local government programs; and, (f) providing the residents with the experience and exposure to present themselves at the neighborhood level as equal participants in the larger city and regional politicoeconomic processes (Habersfeld 1981, p. 8).

Thus community economic development is based on a very strong and clear belief structures or a philosophy aimed at a people–location axis. This philosophical position is the basis for a movement that places the community's social development or social capital formation at the center of the economic process. In this sense it differs from other forms of economic development that focus almost exclusively on the wider economic transactions in the macroeconomy and assume that they will affect everyone within the economy. The stress on community or neighborhood as the target for economic development is also unusual because general economic theory does not recognize place or particular groups of people as central variables. In essence, community economic development is a movement based on the concept that the basic resources in poor communities can be enhanced to generate new opportunities and wealth within the community.

2. The Practice of Community Economic Development

The practice of economic development aims at developing, attracting, and retaining or capturing economic activity for a designated locality. Economic activity equates to increased tax base, jobs, and the resources to pay for civic goods ranging from roads to symphonies or museums. Economic development practice is devoted to attracting outside capital as the central means of improving the regional or local economy. In fact, incentives (discussed later) are offered as inducements for firms to move from existing locations to new places. This form of economic development assumes

that almost all forms of job and tax-generating activity is of benefit to the community that successfully induces it.

Community economic development does not subscribe to the above practices of moving or stealing firms from other locations. The reasons for this are simple. First, in most situations when a firm moves it takes with it skilled resources and leave behind unemployed workers in need of jobs. In essence, to produce wealth in one place, another is impoverished. This is not to say that firms should not move for economic reasons such as gaining access to better raw materials, human resources, or customers. However, the premise of community economic development is that net new wealth needs to be generated not merely transferring jobs from one place to another. Second, community economic development presumes that new economic activity needs to fit the human resources in the distress community (Blakely 1994). By fit, we mean that the jobs or the activity will absorb the local population with only minor training or access to locally available raw materials or markets.

Community economic development practice eschews the notion that all jobs are good jobs and that any economic activity is better than none. The reason for this is that too many low income communities have been victimized by corporatist activities that use their territory and resources and that do not benefit the locals. Countless examples can be cited where low income residents were promised jobs in new plants only to see the workforce imported by the new employers. Or in other instances, poor communities have been displaced or entirely destroyed by new shopping malls or plants designed to serve them. A classic case of this type of capital over community is the sad story of Poletown in Detroit which was razed for a new Chrysler autoplant that was supposed to employee several thousand local people (Wylie 1990). In the end of the plant never produced the anticipated jobs and the community was lost. There are many Poletown illustrations such as the London Docklands and other places around the world, where community life has been sacrificed for economic activity.

Community-based economic development practice rejects the notion that a community must be destroyed to be saved. Rather the goal of community economic development is to forge new economic activity out of the assets in the distressed community. Harvard Business Professor Michael Porter in a seminal article in the *Harvard Business Review* argues that inner city low income areas are indeed capable of generating their own new wealth (Porter, in Boston and Ross 1995). Porter argues that '… inner cities occupy what should be some of the most valuable locations in their respective regions, near congested high cost areas, major business centers, entertainment complexes, transportation infrastructure, and communication nodes. As a result, inner cities can offer a competitive edge … (Porter, in Boston, p. 305). Porter's thesis is consistent in many respect with other community economic development scholars prospective on distressed communities. However, not all of them share his enthusiasm for expanding the basic supplier industries such as food processing and local serving firms. Friendly community economic development scholars suggest that Porter's assessment is too glib. Professor David Sawicki, one of the most knowledgeable scholars in the field of economic development says, 'What the policy debate does not need is yet another model of urban redevelopment that raises unrealistic expectations about what can be accomplished and which directs potentially productive players (young, black, business school graduates) into private sector initiated activities without real roots in the inner city.' (Sawicki and Moody 1995, p. 75.)

The real issue is how the ghetto or any low income community possesses a sufficient resource base for any form of economic development. Michael Teitz, a leading policy scholar, who is sympathetic to locally based economic development suggests that neighborhoods or even larger communities within a city are not relevant units to focus on for development purposes. He argues that, '… neighborhoods by their very nature are problematic as a target for economic development strategy, insofar as the strategy is intended to generate economic activity and employment directly within their boundaries.' (Teitz 1989, p. 112.)

So clearly, the advocates of community based economic development practice have to provide tangible evidence that the locus of such development can be targeted at the distressed community level. My own assessment is that the notion of community targeting can be too drawn too finely. What every disadvantaged community must be able to do, is to connect itself with the growing sector of the larger regional economy. Community economic development practice then is to find ways to increase the value added productive capacity of the under-performing communities and their residents. This requires, as I suggest, in my book *Planning Local Economic Development* (Blakely, 1994) strategies that build long term institutional capacity with low income neighborhoods through instruments like Community Development Corporations to help guide the local community resources so that they can play a role in the wider economy. My perspective is shared by Avis Vidal (1992), the leading community development scholar, who suggests that these institutional vehicles build the human social capital that can link distressed areas by forging the necessary combination of political and economic links to the larger region.

3. *The Tools of Community Economic Development*

Economic development is almost always described by laypersons and even some professionals in term of the

tools. For example, tax reductions or low cost land incentives, a tool of economic development, is frequently called the economic development strategy for a city or region. Clearly, these tools are very visible. But the tool means very little without a more compete and well refined strategy. In community economic development the tools are aimed at dealing with the underlying pathology of the people and the place. There are three types of tools used to deal with community economic revitalization. These are: (a) locality development—improvements in the physical character and appearance of low income areas; (b) human capital formation—increasing the skill levels and capacity of low income individuals to gain employment or start businesses to serve their communities; and, (c) finally, social capital or capacity building—building new institutions and organizations that increase the political and economic institutional capacity of the community to develop and manage its own resources.

3.1 Locality Development Tools

Distressed communities are not attractive places. There are very observable conditions in disadvantaged areas in which the community lacks a viable economic base. The signs of this include boarded up storefronts, deteriorating public infrastructure such as streets and sidewalks, and visible criminal activity. These are the symptoms of the problems. But much like human disease, the symptoms must be arrested before a full effort can be launched to eradicate the problems. Another observable condition is idleness. Working age men and women are on the street during employment hours with no 'place' to go, or economic activity to attach them to the larger community. Again, this situation is symptomatic of closed factories or a lack of employment opportunities in the area.

Community economic development strategies attempt to deal with both the perceived, that is observable, as well as the real underlying situation. At one level, there are a host of community economic development tools aimed at dealing with the physical appearance of distressed areas. Some of these are well known, such as commercial facade improvement and community or neighborhood commercial revitalization projects. These programs use a variety of local initiatives aimed at bringing about physical revitalization of dilapidated building stock. Some projects do no more than provide paint and offer small loans for owner repairs and rehabilitation of their premises. Government agencies or services in the area attempt to re-do their facades to look less institutional, in character, thereby appearing safer, more lively and wholesome to passers by. More recently, new strategies called business or neighborhood improvement districts are being employed to reach the same ends. In these programs local merchants and sometimes residents agree on a small tax assessment as dedicated fund to do civic improvements and provide enhanced police services to the neighborhood. This tool is employed in communities of all economic strata. Improvement siatricts are now being touted as a new approach to ghetto physical revitalization. One of the major attributes of this approach is the degree of business and citizen involvement that it stimulates. This approach works where there is still a cadre of active local merchants with the resources to help get the activity started and with the energy to maintain it. In some communities the improvement district program is merged with community policing which incorporate the local residents as well as the merchants.

Physical based planning is a heavy component of many of the more recent tools like the enterprise and empowerment zones. The zone notion aims directly at targeting the place–people link in community economic development. No matter which name is used the basic notion is to provide government tax relief and other incentives to fix up or reclaim inner city or distressed are a land and buildings for re-use as business venues. Under most of these programs new businesses that employ local residents receive tax breaks or very low interest loans to use or expand an underutilized site. In addition to these tax incentives a firm locating in the targeted zone will receive special tax relief for every local worker hired.

There is some evidence that these strategies work under certain conditions. For example, New York City has seen a resurgence of many low income areas in dying neighborhoods using a combination of tough police actions to deter any forms of low level street crime and an aggressive clean up and fix up programs. The New York approach has been widely imitated across the United States in major cities with generally good results. However, some critics complain that the problems do not go away, but are merely shifted to even poorer neighborhoods in the city. Homeless advocates claim these programs have made the plight of the homeless even less tolerable since they target the homelessness and offer no alternatives for the vulnerable homeless populations.

3.2 Human Capital Formation

One of the most important companion tools for community economic development is employment development. Job creation is critical. As a result, a wide variety of approaches have been devised to improve the skill base of distress community residents. These approaches range from basic skills and English language training to job interviewing skills and even new business advice. Community-based job training programs run the gambit from those that provide specific training conducted on the employer's site to

pre-employment counseling and support services. (Fitzgerald 1999).

Job training does not presume that there are, or will be, enough jobs available or suitable for the residents of low income areas. One reason for this is the very high level of ex-offenders among the population. Another is that too many of the best jobs are too far away or the skills requirements too high for the local workforce. Nonetheless it can be argued that increasing the work effort in low income communities, especially moving low income people off welfare is as important to reduce the cycle of dependency. As Lawrence Mead, the architect of welfare to work argues, 'increasing the work effort of dependent populations leads to greater sense of personal worth, a reduction in idleness and crime.' (Mead 1989).

One means of combating the loss of jobs in a community is to help start more local high quality businesses that can serve the community. Low income areas have many of the same service needs as high income areas. Therefore, it makes sense to assist low income residents to start new locally serving businesses. Timothy Bates, a leading small business scholar, suggests that one road to economic revitalization is for more of the low income residents to form new businesses that they own and operate (Bates 1995). This notion is clearly incorporated in the numerous minority ownership programs of the Small Business Administration. Nonetheless, few successful American minorities own or operate businesses in the ghetto (Bates 1995). The notion is that the minority owned and operated business will tend to select staff of color from the community where the firm is located in much higher proportion than their Caucasian counterparts operating in the same locale. Still another reason for promoting minority business ownership in low incomes areas is to create wealth in the distressed community. Real wealth can translate into investments in the same area and new job formation for future generations.

3.3 Social Capital Development

Social skills are the root of economic capacity. It is clear that most economic gains are made through some form of collective action. This can be as simple as joining a club or organization composed of other successful people to forming a corporation. While this seems obvious, it has been overlooked in much recent scholarship. Low income communities are not only bereft of jobs and businesses, they seldom have any organizations. The clearest illustration of this is to examine the town entry signs in small towns across the United States. In well-to-do prosperous communities the city limit sign is accompanied by a larger welcome sign with the names of significant community business and professional organizations such as the Rotary, Lions, Kiwians, Future Farmers, and the Chambers of Commerce as well as similar organizations. These organizations are the bedrock for firm or professional entry into the community. In low income areas of a city or poor small towns there are few or no organizations, other than the church. Unfortunately, the social network necessary to develop and carry an idea to fruition is not present. As a result, one of the latest movements in community economic development is to assist distressed communities build internal networks that can work as systems of mutual assistance within the community.

Forming social capital is sometimes called capacity building among foundations and government agencies. It is a very old notion going at least back as far as the US Department of Agriculture Cooperative Assistance Programs, which started just prior to the Great Depression of the 1920s and 1930s. The basic idea is to help the low income community develop institutional skills similar to the advantaged communities. In most instances this entails the formation of a community development corporation or CDC. The CDC acts as an umbrella agency that organizes local business, assist neighborhoods in social and community services, and helps start community revitalization efforts. The role of CDCs in community economic development is well documented elsewhere. (Vidal 1992). The fundamental idea is to create the CDC, along with a network of other organizations to create a social base for collective action among the disenfranchised in low income residents. This is not an easy task. Lack of trust, envy, and a general sense of apathy must be overcome to trigger community social capital formation.

4. Government Community Economic Development Program

Government programs in community economic development go back to at least the early industrial era. Tenement and poverty area clearance and clean up schemes have been part of national, state, and local level to transform low income areas. The most well recognized community or neighborhood level programs were launched with Jane Adams at Hull House in Chicago at the turn of the twentieth century. The aim of Hull House, later called the Settlement House Programs, was to provide professional interventions in a community in a way that assisted the community leaders in helping themselves. As this idea was refined new programs emerged to accomplish many of the same goals. In England, Local Housing Councils took on similar roles with the low income workers.

Similarly, throughout Europe and particularly in Scandinavia programs were designed in the 1930s to eradicate the worst slum conditions. All of these programs have very similar components. Usually they

provide some basic services for the low income such as housing or home repairs. Additional services are organized by group or community workers to assist the residents form self help devices. These devices range from buying, farming, or business cooperatives to help poor communities meet basic needs for local control and ownership. Today cooperatives have grown into major institutions from this community economic development base. In the United States and throughout Europe, cooperatives operate banks, insurance companies, health services, and even telephone and electric power companies.

Another aspect of government programming has been the designation of special distressed neighborhood or community economic zones. The earliest of these in the United States were community action councils in designated poor neighborhoods in the 1960s. These community action councils were part of the War on Poverty. The concept was that targeting these areas for special government assistance would stimulate business relocations to them and thus increase local employment and capital formation. The most recent incarnation of these zones is called, e.g., enterprise or empowerment. The theory is that altering the tax breaks and employment incentives the area will become attractive for business relocations and expansions. Similar programs have been proposed and adopted in the United Kingdom, Australia, and several Asian countries including China with varying impacts. Green (1991) and several other scholars have questioned the validity of this approach. His work shows that special tax measures are seldom a reason for a firm to change location. In reality there are many factors, chief among them is the quality of nearby human resources (Blakely 1994).

Small and minority and low income business formation has been an important component of virtually all community economic development initiatives. More recently, government program efforts in this area have borrowed from the Bangladesh and the Basque Region of Spain experiences of group lending strategies called microlending. This approach blends both social capital and business formation into a single approach. The micro-loans programs provide small seed capital to a group of borrowers who may enter in different enterprises or may even use their small loan (US $100–US $5000) capital to buy clothes for work. The requirement is pledge and guarantee repayment as a group. The group component creates the social capital that is so frequently missing in other efforts. The group members learn to trust and rely on one another for other networks and to use one another's expertise as needed via bartering arrangements. This approach has had very good results in most of the places that it has been introduced. Another variant of this is the host of government programs that aim at community banking and other capital retention programs. Community Development Banks have been formed with the specific intent and mandate to help create new businesses in low income areas. These banks have government direct support through special underwriting or loans and some funding from traditional banks as part of a government requirement for licensing.

The efforts described above do not represent all government efforts in the field of community economic development. In some cases, government programs have community economic development as a secondary or lower consideration. Further, new government programs are spawned to meet new circumstances such as welfare reform. The range or type of programs described above represents a classical typology rather than an exhaustive list. This type of program is seen in most of the industrialized world in one or more of these forms.

5. *Summary*

Community economic development is a distinct movement. It is part of local economic development; however, it has three distinctly different goals. First, it is based on the concept that there is a link between the conditions of distressed places and those of the people in them. That is, it is important to deal with the social as well as the physical conditions of a place to successfully introduce new economic options and opportunities. Second, it adheres firmly to the notion that interventions in the community or territory must build new capacity or institutional vehicles that have political skills and economic ability to deal effectively with the wider region. Finally, effective community economic development rests on the building of internal–indigenous resources of the local people—through increasing their skills and their capacity to generate their own economic wealth.

Community Environmental Psychology

Research in community and environmental psychology emphasizes the powerful role of the everyday social settings where individuals live, work, and learn in shaping human development and behavior. This body of research also emphasizes the dynamic nature of the inter-relationship between individuals and social contexts. Social settings can be described in terms of three underlying sets of social climate dimensions: relationship dimensions, personal growth or goal-oriented dimensions, and system maintenance and change dimensions. Research findings on social settings may be organized according to four social ecological principles: environmental press, setting interdependencies, matching models, and a transactional view.

1. Historical Development

Psychological research on social settings has been guided by a *social ecological* perspective. The social ecological perspective emphasizes the powerful role of social context in shaping behavior and the dynamic nature of the inter-relationship between individuals and social contexts. The historical roots of research on social settings trace to Kurt Lewin's *field theory* (Cartwright 1951) developed during the 1930s and 1940s. Lewin argued that behavior is determined by the concrete situation that exists at the time the behavior occurs. During the 1950s, Barker's (1968) *Ecological psychology* presented a conceptual and observational framework for research on social settings. In contrast to psychology's traditional emphasis on person-based variables, Barker showed how the temporal and spatial characteristics of the everyday settings where individuals live, work, and learn mold participants' behavior.

Since the 1960s, both community and environmental psychology have pursued research on contextual determinants of behavior (Walsh et al. 1992). Community psychology focuses on the influence of the social environment, whereas environmental psychology focuses on the influence of the physical environment. The overlap of community and environmental psychology involves the study of social processes in physical settings—the psychology of social settings like the home, the workplace, and the school. Bronfenbrenner's (1989) *ecological* approach to human development has added a fuller understanding of how the characteristics of one type of setting, such as the family, are altered by other factors in participants' lives, such as occupational and educational settings.

Moos (1994) has developed integrated assessment procedures to measure the social climates of family, work, educational, and other social settings. Moos described social settings in terms of three underlying sets of social climate dimensions: relationship dimensions, personal growth or goal-oriented dimensions, and system maintenance and change dimensions (Table 1). Relationship dimensions assess the quality of personal relationships in a setting; that is, how involved people are, how much they help one

another, and how openly they express their feelings. Personal growth or goal orientation dimensions tap the directions in which an environment encourages personal change and development. System maintenance and change dimensions measure how orderly and organized a setting is, how clear it is in its expectations, how much control it maintains, and how responsive it is to change.

Research findings on social settings may be organized according to four social ecological principles: environmental press, setting interdependencies, matching models, and a transactional view. Environmental press and setting interdependencies describe how social settings affect behavior. Matching models and a transactional view describe the dynamic interplay between individuals and social settings.

Table 1
Social climate dimensions in family, work and educational settings

	Relationship dimensions	Personal growth dimensions	System maintenance and change dimensions
Family setting	Cohesion	Independence	Organization
	Expressiveness	Achievement	Control
	Conflict	Intellectual-Cultural	
		Recreational	
		Moral-Religious	
Work setting	Involvement	Autonomy	Clarity
	Co-worker cohesion	Task orientation	Managerial control
	Supervisor support	Work pressure	Innovation
			Physical Comfort
Educational setting	Involvement	Task orientation	Order and organization
	Affiliation	Competition	Rule clarity
	Teacher control		Teacher control
			Innovation

2. *The Psychology of Social Settings*

2.1 *Environmental 'Press'*

Traditional approaches to the prediction of behavior rely predominantly on demographic and person-centered variables. Yet, individuals are profoundly affected by the 'press' of the social settings in which they are embedded. For example, high family support, independence, social integration, and organization are associated with better psychological adjustment and more self-reliant and active coping. Family support may have especially protective psychological effects when family members face life crises and transitions (Pierce et al. 1996).

Child and adolescent development is fostered in families that encourage independence and provide modeling for instrumental and social skills, whereas it can be impeded in families that emphasize achievement in the context of conflict and accommodation to restrictive rules. For example, youth in more cohesive, expressive, well-organized, and socially oriented families are more likely to have higher self-confidence and social competence. Youth in families that value independence and achievement tend to be assertive and self-sufficient, whereas those in supportive and well-organized families tend to have a more even temperament. In contrast, a strong emphasis on achievement in the context of high family structure and a lack of cohesion is associated with depressed mood. Family conflict tends to engender behavior problems and impulsivity.

Four aspects of the work climate have been associated with employee distress and lack of mental and physical well-being: high job demands, insufficient opportunity to participate in decision-making, high supervisor control, and lack of clarity about the job and criteria for adequate performance (Karasek and Theorell 1990). In general, occupational distress is most likely when job demands are high and employees have little discretion in deciding how to meet them. When individuals are allowed to make decisions about their job, high work demands can be stimulating and can foster active problem solving and innovation.

The quality of interpersonal relationships at work can moderate these associations. Supportive relationships with co-workers and supervisors strengthen the salutary effects of autonomy and task orientation and moderate the adverse effects of highly demanding and constrained work settings. In general, co-worker cohesion and supervisor support promote better job attitudes and morale as well as higher work motivation and commitment. However, cohesion without task focus diminishes satisfaction and productivity, whereas the combination of high support and moderate structure promotes these outcomes.

Similarly, the most effective schools are supportive as well as task-oriented (Fraser and Walberg 1991). Educational settings need to emphasize student performance, but not at the expense of engagement and support. Supportive relationships with teachers and classmates and an emphasis on student participation in well-organized classrooms foster student morale, motivation to learn, and academic self-confidence. Students in task-oriented classes that set clear academic goals in the context of supportive relationships are especially likely to do well on standard achievement tests.

Learning environments characterized by competition and control with low support often lead to student anxiety and higher absence rates. Although significant achievement gains can occur in classes that emphasize task performance and competition and are lower in warmth, such classes are less successful in fostering student creativity and continuing motivation to learn. Students in flexible classes that encourage more individual initiative are more willing to work independently and have lower absenteeism.

2.2 Setting Interdependencies

The boundaries between social settings are permeable; the social settings where individuals live, work, and learn are inextricably related to one another (Parke and Kellam 1994). Sometimes the influence of one social setting can amplify that of another setting. For example, youngsters do better in classrooms with rules guiding interpersonal interaction that are similar to those they experience in their families (Booth and Dunn 1996). Youngsters from cohesive families obtain better grades in cohesive classes; those from structured families do better in structured classes; and those from *laissez-faire* families obtain better grades in *laissez-faire* classes. Similarly, stimulating home environments that are oriented toward learning independently help to predict more positive attitudes toward school and better academic achievement. Students in family and educational settings both of which are characterized by high support and structure tend to have the most positive academic self-concepts.

Likewise, the influence of the workplace is an important aspect in understanding family functioning in a broader social context (Eckenrode and Gore 1990). One pattern of work–family interaction involves positive carryover; personal gratification and positive experiences at work can enrich family life. Family members of individuals who enjoy their work tend to experience their families as more involving and supportive. Moreover, because parental work environments can influence the family climate, they may indirectly affect child functioning through their impact on family life. For example, fathers' positive work relationships have been associated with better family relationships and, in turn, fewer child adjustment problems.

At other times the influence of one setting can counteract that of another setting. Thus, family and school effects can be oppositional when there is discontinuity between the home and the school. For example, the academic underachievement and high dropout rate of children from families of low socioeconomic status may be due in part to a discontinuity between their home and school environments. Parents who are less educated are less likely to mirror teaching and learning processes that are similar to those that occur in school, such as praising and interacting with their child around mastering new knowledge.

Similarly, the work–family interface often involves negative carryover from the workplace to family life. Highly demanding, conflict-laden job situations often elicit a pattern of tense family interaction. For example, fathers' work stressors are related to fathers' depression and, in turn, to more family conflict and children's adjustment and physical health problems. Stressors in the workplace are especially likely to generate family distress among individuals who have more family-related demands. Thus, the association between work expectations, such as taking on extra duties and finishing job tasks by doing overtime, and perceived overload tends to be progressively stronger among single employees, those who are married, and those who have children.

3. Person–Setting Interaction

3.1 Matching Models

Considerable evidence documents the powerful connections between features of social settings and individuals' well-being, performance, and personal development. However, part of the influence of social settings depends on the personal characteristics of the individuals who experience them. Thus, according to *person–setting matching models*, adaptation is viewed in terms of the match or congruence between the environmental demands of a particular setting and an individuals' unique pattern of personal vulnerabilities and strengths. For example, individuals with few personal vulnerabilities generally adapt well except in settings with unusually high demands (Fig. 1). Conversely, those with many personal vulnerabilities typically adapt poorly except in settings with exceptionally low demands. Individuals with an intermediate level of personal vulnerabilities tend to adapt poorly in settings that tax areas of vulnerability, but adapt well in settings that emphasize areas of strength.

For example, moderate emphasis on system maintenance factors helps to promote ego control among individuals who need a well-structured setting. However, a strong emphasis on system maintenance factors, especially among developmentally mature and internally oriented persons, restricts individual growth and can foster passivity. Similarly, expressive relationships typically promote morale. However, highly independent or introverted persons who prefer fewer social bonds can feel hemmed in or overstimulated by interaction-oriented settings.

When individuals invest themselves in a setting, they are likely to be especially vulnerable to disruptions in that setting. For example, environmental demands that match an individuals' vulnerabilities in a highly salient setting are associated with more adverse health risks. Involvement in more settings leads to the development of a more complex self-system and provides protection against pressures and disappointments in any one setting.

More generally, social settings tend to maintain or accentuate individual preferences and attitudes that are congruent with dominant setting characteristics. The more intensive, committed, and socially integrated a setting is, the greater is its potential impact. Thus, when person–setting mismatch occurs, homogeneous settings exert the strongest pressure on incongruent individuals to change in the direction of the majority. A heterogeneous setting in contrast has

more diverse influences and provides participants with a wider choice of options.

3.2 A Transactional View

Thus far, we have described a passive process by which people find themselves in settings that mold their behavior. However, people are both influenced by and in turn influence social settings. Individuals select and build environmental niches that maintain and accentuate their dominant personal dispositions. Thus, the psychology of social settings adopts a *transactional view* that emphasizes the reciprocal, two-way interaction between the person and the environment (Stokols and Shumaker 1981).

In part, individuals create microenvironments that then 'reciprocate' by fostering personally preferred attitudes and behaviors. For example, people avoid some settings and, on the basis of their needs and dispositions, choose to participate in others. In turn, these chosen settings are likely to influence people to change in desired ways. Further, individuals' mood and behavior may alter the settings they function in, such as when a depressed individual's hopelessness and lack of enthusiasm leads to a reduction of support from family members and co-workers.

The Conceptual Level (CL) matching model integrates a transactional view with a person–setting matching model. According to the CL model, more mature individuals are better able to organize their environment. Those who are less mature need the stabilizing influence of a well-structured setting. In general, people who want to explore and shape their environment and who exhibit a strong need for independence profit more from less structured environments. For example, internally oriented individuals do better in more flexible environments, whereas externally oriented individuals tend to adjust better in well-structured settings.

Human–environment optimization describes the overall process whereby individuals and groups strive to achieve optimal environments that maximally fulfill their goals and needs. For example, organizational consultants and program evaluators use change-oriented interventions to institute organizational development programs in work and educational settings and clinicians apply such interventions to promote healthy family settings. More generally, through a long-term process of group and community participation and collaborative decision making, each individual can help to shape social values and the ensuing evolution of new settings.

4. Current Directions

Interest in the psychology of social settings has experienced a resurgence in contemporary research on

Figure 1
A matching model predicting psychological adjustment as a function of both environmental demands and personal vulnerability (adapted from Zubin and Spring 1977) (copyright 1977 American Psychological Association; reprinted by permission of the author)

psychological stress (Goldberger and Breznitz 1993). The social ecological principles that have guided the study of social settings are central to contemporary models of the stress and coping process. The social settings where individuals live, work, and learn can be significant sources of distress. Stressful settings, such as demanding work environments that allow little control, explain a wide range of behavioral and health outcomes. Moreover, linkages between settings can markedly increase stress responses, such as when a pileup of work demands exacerbates chronic family strains.

At the same time, an appreciation of the dynamic nature of the inter-relationship between people and social settings provides insight into some ways individuals can reduce or avoid distress. Social settings are sources of adaptive resources, such as social support from family members and colleagues at work, that can operate as stress resistance factors when stressors occur. In addition, *stress-diathesis* (vulnerability) models can help to educate individuals to seek settings where their adaptive capacities best match setting requirements. Finally, transactional models of coping (Lazarus and Folkman 1984) underscore how active, problem-focused coping strategies can help individuals to manage stressors successfully and even to grow psychologically through stressful encounters.

Community, Expression of

Social identities are made up of people's overlapping, mutually reinforcing, competing, and conflicting memberships in a variety of communities. When people claim community membership they are simultaneously expressing their personal and social identities. The meanings of community membership, to both members and outsiders, take on a very intense personal weight as statements about who people are and how they should be treated. Communities are seen as the repositories of values, and the claim to community itself takes on a moral force in much contemporary discourse. In the process of expressing their identities and positions through community membership, and of expressing their judgements of others through *their* inclusion in or separation from community, people deploy markers of community such as locality, kinship, place of origin, nation, ethnicity, religion, age, gender, language, values, or resources as ways to express their position in a moral and social universe. Not all social categories or groups are communities, but when people use what they have in common with others to say who they are, they are expressing community.

Utopian communities have always been explicit and self-conscious expressions of a vision of human nature and potential. Descriptions from Plato to Rousseau and Huxley and practical attempts from the Diggers to the Spanish Anarchists and contemporary communes, have all been occasions for expressing a vision of what people are and should be, and for individuals to express their own potential and aspirations (Kanter 1972). The new communitarians within academia continue this tradition with their call for community formation as a counter to the fragmentation of postmodern life (Etzioni 1993).

1. Moral Expression and the Imagined Community

At least since the Enlightenment, there has been a concern among social philosophers with demographic, cultural, and economic change and the consequent demise of community. Durkheim, Marx, Tonnies, and Weber disagreed about the nature of the transition from community to mass society (*Gemeinschaft* to *Gesellschaft*), and they disagreed about the inevitability and desirability of rending traditional bonds and patterns to replace them with rational calculation and contract. But these classic social theorists all agreed that a profound transformation of social relationships was taking place before their eyes, replacing the ascribed statuses of communities regulated by custom with the statuses achieved by individuals.

In his preface to the second edition of *The Division of Labor*, Durkheim argued that as increasing division of labor expands the scale of society and diminishes the centrality of territorial social organization, new social groups must take the place of territorial units. 'A society composed of an infinite number of unorganized individuals … constitutes a veritable sociological monstrosity'—not only undesirable but impossible. There must be 'a whole series of secondary groups' that can 'drag' individuals into 'the general torrent of social life' (1964, p. 28) and that have 'a moral power capable of containing individual egos' (1964, p. 10). What must be added to Durkheim's formulation is the way that the moral power of communities is not only constraining of individuals but also expresses their identities, fears, and ambitions.

Anderson's (1983) influential concept of the 'imagined community,' with its paradigmatic representation in the newspaper reader who reads alone but is assured of a community of fellow readers, illuminates the ways that community membership expresses identity, to both oneself and to others. Imagined communities share features of reference groups in distinction to interaction groups or face-to-face communities. As Anderson's example of the newspaper reader suggests, developments in technology have undermined whatever geographical basis communities have ever had. Telephone, radio, television, and the Internet have made a commonplace of expressive communities without face-to-face interaction or geographic closeness and have made possible a huge variety of meaningful identities expressed through community with others. However, the impact of technology on community has not been determinative, but rather has been mediated by culture and by individuals.

Though technology has been important in the proliferation of these communities, it is important to remember that dispersed religious and political communities are ancient social forms. The medieval Christian church, the Jewish diaspora, and the community of scholars are familiar examples. Islam has, for over a millennium, been a community that both provides and expresses identity to millions. Mecca has been an orienting location for all practicing Muslims, and for many it has been a place of pilgrimage, but Mecca has been overwhelmingly a symbolic and expressive location. Mecca is the center of the Islamic world not because the Islamic community lives there in face-to-face interaction but because it is the symbolic focus of a community of faith.

When the poet Rupert Brooke wrote: 'If I should die, think only this of me:/That there's some corner of a foreign field/That is for ever England' or when the Psalmist sings of Jerusalem and members of three faiths claim Jerusalem as a sacred city, or when millions of Muslims face Mecca to pray, they are all addressing places that are physical localities, but also deeply elaborated symbols of national or religious communities.

2. *Community and Individualism*

One proposed alternative to physical locality as the basis for community is the ego-centered network. Wellman (1999), for example, argues that the researcher should begin with an individual and work outward, documenting the network of 'personal communities' and mapping the interconnections. Personal communities are 'loosely bounded, sparsely knit networks of specialized ties' (Wellman 1999, p. xiii). Where individuals act as agents constructing these networks, which vary from person to person, quantitative network analysis has become an effective, specialized way of studying them (Fischer 1982).

These personal communities, by definition, have neither the existence independent of a particular individual nor the moral force of the communities envisioned by Durkheim. Ego-centered networks are indisputably central elements of society, but they differ from expressive communities in important ways. In particular, looking at society as made up of networks or communities implies a different emphasis on the relationship between individuals and society (Gans 1988). While network analysis proceeds from individuals whose identity is not problematic, depictions of community stress the ways in which individual identities are constituted by membership and exclusion. It is the morally coercive or normative community expressing a vision of the common good that transcends individual interest that is mourned by those who feel that modern society, particularly in the United States, has lost a sense of community (Bellah et al. 1991).

Throughout history, people have expressed themselves through community. In the nineteenth century United States, a time of great economic and political change, working men and women practiced community with little regard to the ideological implications of their behavior. In their everyday lives, they transcended the tension between the group and the individual by acting in consort—to make bedding for each other at quilting parties, to care for a sick person in their midst while acutely aware they might later demand services in kind, and to create actively a community of accountability and mutuality (Hansen 1994). The gendered division of labor in these communities meant that women exercised a great deal of influence in an arena where power was not denied them, as it was in the public realm. Their actions became self-conscious only when they intentionally mobilized people to become political, as in the abolitionist and temperance movements, or religious, as when they felt God called them to a higher cause and they sought to convert others to Christianity. Through their everyday practices they constructed community and molded the expressive dimensions of their culture. The social sphere created through daily practices was both a source of secure identity and an expression of values capable of exerting discipline and excluding 'outsiders' or 'deviants.'

Seeing community as simultaneously expressive of identities and as something to be expressed reorients discussion away from an easy opposition between individualism and community. Symbolic communities connect people together through a common cause or identity, as in the African-American community (Bruggemann 1995), the community of people with disabilities, or the people listed in the *Social Register*. Symbolic communities, so far from requiring face-to-face interaction, frequently include the dead, as in lineage groups, ancestral lines, the community of martyrs, or communities of scholars who share intellectual 'ancestors.' Shared values or beliefs, ex-

pressed or manifested through ethnicity or nationality, or the symbolism of a shared history or a common cause, have also proven effective bases for community expression and as rhetorical levers in political actions. The symbolism invoked in using the term 'community' may be as much a rallying cry as a description of a social entity.

3. *Methodological Implications*

The opposition between 'community' and 'individualism' seen in much social theory has received a perverse reinforcement from the pervasive individualism of a great deal of social science research, especially in the United States. If 'street corner ethnography' does not capture the spatially dispersed communities of modern societies, research using random samples of isolated individuals also misses important elements of community. By starting with individuals and asking about their attributes, survey research necessarily misses the connections between individuals and the supraindividual social elements that are defined by the *nonindependence* of their members. Communities of orientation, reference, and memory have normative force and behavioral implications, but do not take obvious physical forms. They may, therefore, be invisible to both observers and participants. The same is true of the negotiated and directive, not entirely voluntary, communities facilitated by rapid transportation and easy communication in which people are embedded and that constitute such central features of modern social organization.

For many people in the United States, their high school graduating class provides an example of a community that is neither localized and face-to-face nor entirely voluntary but that still expresses important aspects of their identity. The public school has been the pre-eminent expressive institution of the secular democratic republic, transmitting the moral ideals and ideology of the society. The time children spend in high school is a period of intense face-to-face interaction with a community larger and more diverse than they have known before at an age characterized by identity formation and role confusion.

After the rite of passage of graduation, the face-to-face community becomes spatially dispersed and socially fragmented, but the graduating class endures as a reference group and expression of identity to self and to others. Interviews with Americans who have graduated from high school are studded with comparative references to former classmates who had or had not done well and to those who served as the concrete manifestation of 'people like me' (Townsend 2002). Classmates share histories and normative judgments, and make of themselves, and of each other, characters in morality tales they tell themselves. The meanings of belonging and exclusion are subject to revision and negotiation, but the community has an existence independent of any one of its members. Individuals may attempt to opt out, but the remaining members continue to hold them up to evaluation, and use them to symbolize their own sense of who they are and who they are not.

The salience of high school graduation as an expression of identity in later life is clearly class-specific. Professionals with advanced degrees, for whom high school graduation was a first step rather than a culmination, frequently dismiss the importance of an event which is for many others a significant achievement and the realization of an aspiration. For them, others who graduated from the same professional training institution may constitute a more important community of reference than their peers in high school. The specific features of expressive communities differ between situations and over time, but the social processes underlying them are general.

4. *Contradictions of Community—Gender, Race, and Unequal Access*

While the notion of community necessarily expresses what the members have in common, the concept and rhetoric of community is frequently used to divide, to exclude, and to justify differential treatment and access. British colonialists in Africa, for example, invented traditions, communities, and expressive forms for themselves in order to symbolize their own cohesion in spite of spatial dispersion and to lay claim to a higher social status than they would have been entitled to in Britain itself (Hobsbawm and Ranger 1983, Ngugi wa Thiongo 1981). At the same time, Britain's policy of indirect rule imposed tribal structure on complex indigenous social formations. The language of the tribal community was then used to control Africans' political and economic lives. In the period since the end of colonialism in Africa, ethnicity has replaced tribalism as the dominant expressive language about community, although Africans continue to inhabit a variety of identities. The language of ethnic communities is used to advance, and to conceal, a range of interests and identities based on generation, class, gender, nation, and continued external domination of the continent (Werbner and Ranger 1996).

The dynamic between an inclusive expression of identity and a concealment of internal divisions—'belonging' as a source of community solidarity and as a device to silence dissident expression—is played out in many social movements based in expressive communities. The Black Power and Women's Liberation movements in the 1960s and 1970s are powerful examples of the potential for mobilization on the basis of commonality and shared identity. They selected for people who shared political perspectives and ethnic and gender identities, but the inclusiveness that was their source of strength required that internal difference be obscured by expressions of unity.

Historically, women in the west were excluded from politics and the public sphere, though they found greater opportunities to exercise freedom and power in the social sphere, which was more egalitarian, but not free of gender hierarchies (Hansen 1994). White women mounted a campaign to gain access to the public sphere by focusing on women's suffrage. They called for a united womanhood, and appealed to a common degradation and a shared circumstance. As with activists 100 years later, the suffragists simultaneously excluded those who did not fit their conception of womanhood—women of color, working class women, immigrant women. In the second wave of feminism of the 1960s and 1970s, the similar rallying cry that 'sisterhood is global' was premised on a biased and exclusive identity. The empowerment achieved through mobilization and the increased sense of entitlement wrought discord among women because of the exclusivity that lay at the heart of the movement. Ironically, in reaction to the appeals to a universal womanhood that masked multiple and profound differences, many groups of women organized themselves as members of new communities of women with distinctive identities.

5. *Debate Over the 'Demise of Community'*

Currently, a vocal public and a broad spectrum of policy makers lament community demise. At the same time, social researchers are finding a renewal of civic participation and vitality in communities that appear invisible from a distance. The debate itself is an important expression of how Americans want to define themselves as a culture. Political conservatives worry about losing control over local government and school districts, which they see as repositories of community values. Political progressives worry about the depleted ranks of those wanting to and willing to mobilize for social change. Policy makers and grass roots activists worry about the low density of people in neighborhoods and what that means for the crime rate. With so many people working so many hours, who has the time or inclination to contribute toward the greater good of society, or at least to those beyond the household and kin network?

Observers concerned about the decline of community emphasize its moral centrality and the social values conveyed and expressed through community membership. Wilson (1996) argues that inner-city majority-Black neighborhoods suffer a crisis in community most acutely. With the removal of jobs that pay a living wage, the exit of middle- and working-class workers decreases the cultural and social capital those inner-city neighborhoods need to build and express a sense of community. An economically diverse neighborhood has citizens who model behavior that conforms to the values of the dominant culture and who work within the community to fight crime and cultural malaise and improve services, including public education.

Arguing that the decline of community is a major problem for Americans as a whole, Putnam (2000) provocatively characterizes the crisis in community life as a problem of 'bowling alone.' Putnam's analysis of civic participation, volunteering, sports leagues, and church-going shows a consistent decline over the past half-century. Putnam is also concerned about the loss of the social capital that is generated by invigorating community involvement. On the other hand, Sirianni and Friedland (2001) find an increase in citizen activism at the local level in battles over the environment, healthcare, and the media. They argue that looking only at engagement in 'traditional institutions of civic integration' such as the PTA, the NAACP, and the Elks, misses new forms of civic renewal that are dedicated to problem solving on the local and state levels, that are national in scope, and that express the new communities brought into being by new circumstances.

Concern about the loss of community is not new, but Wellman (1999) asserts that whenever researchers have set out to study communities, they have found them to exist and to be thriving. Perceptive observers have consistently found people expressing their identities through community membership, and asserting their places in communities, in situations where conventional wisdom has pointed to a lack of community—in locations such as suburbs, street corners, homeless shelters, and old people's homes where the physical situation was alleged to make community impossible, or among stigmatized groups who were alleged to lack the cultural resources to express community identity.

All participants in the debate acknowledge the importance of widespread economic change, capital mobility, international movements of people, urbanization, and the increasing entry of women into the paid labor force in transforming the shape of communities. Philipson (2002), for example, asks whether an increasing commitment to corporate workplaces might be colonizing not just workers' time, but their emotional loyalties, eroding independent community life by trying to meet employees' extracurricular needs while absorbing all their waking time. The question remains, however, whether community is declining or transforming.

6. *Continued Vitality of Communities*

The importance of expressive communities increases as locality recedes as the basis for social organization. Since community is essential for human existence, the task is to observe not the 'decline' but the *transformation* of the foundation of communities. In the global movements for the independence of East Timor or the end of apartheid in South Africa, for instance, we see several ways in which communities are both

expressed and expressive. In the face of exile, apartheid divisions into 'tribes' or 'peoples,' and forced prevention of assembly and movement, Black South Africans expressed themselves as a community. The expression of this community helped to forge a united movement. At the same time, international opponents of apartheid expressed moral outrage, and this expression became the basis for a global community. In South Africa and internationally, expression was vital to the creation of other aspects of community such as organizing efforts, congresses, publications, fund raising, and political action. The expression of community, of common interests and identities transcending differences and separations, was one of the most powerful rhetorical weapons of the movement.

Similar mutual reinforcements of symbolic expression and community action occur in a wide variety of situations where the basis for community is the expression of values and identities, and in which, once expressed, the community takes on a life of its own and becomes a potent symbol in its own right. Expressive communities, whether they are long standing or new, confront individuals as already existing, though amenable to change. By their allegiances to these communities, people take on and express a social identity.

Community Genetics

Community genetics is a set of activities at the interphase of medical genetics and community medicine aiming to maximize the number of people benefiting from medical genetics while at the same time minimizing potential harm (Ten Kate 1999).

Clinical disciplines, including clinical genetics, are portrayed by the doctor waiting in his/her office for (a call from) the patient with his complaints and worries. Community medicine, including community genetics, is characterized by an anticipatory, proactive attitude and the large numbers of individuals that are approached. The health care worker, who is worried about the people in the community, leaves his/her office and searches for the people who are at risk, but do not know this yet, or do not know where to go with their worries.

While community medicine brings these characteristics to community genetics, medical genetics brings its expertise in genetics, but also its sensitiveness to ethical issues as respect for autonomy of the individual, beneficence, non-maleficence, and justice.

Although in the above definition the emphasis is on the application side of community genetics, the field has also a strong research side. Research is indispensable to find out what the community needs, and to evaluate the effects of the efforts to meet these needs.

The following activities belong to the field of community genetics.

1. Genetic Screening

Genetic screening is the application of a test on people for the systematic early detection or exclusion of a

hereditary disease or a heritable predisposition to a disease in the participant or in his or her children (see *Genetic Screening for Disease-related Characteristics*).

2. Genetic Education

Genetic illiteracy is widespread. How can people decide on participation in genetic screening programs, pre-pregnancy consultation, or clinical genetics services, if they do not understand the basic principles of genetics, and have misconceptions? There is thus a strong case for sharing basic genetic knowledge with the community (Jallinoja and Aro 2000). The general public should not be the only target, the professionals and policy makers also need to be considered. Apart from genetics, the education program should focus on the meaning of probabilities and on ethical aspects, in which respect for autonomy and solidarity should be stressed.

3. Pre-pregnancy Consultation

Many clients for clinical genetics services are referred when they are pregnant, with problems that better could have been solved before pregnancy. Evaluating a family history, diagnostic work-up of consultants and family members, and consultation of other experts may take more time than the ongoing pregnancy allows. During pregnancy there are less options available for the pregnant woman and her partner, and decisions have to be taken in a short time. The options are not restricted to prenatal diagnosis, termination of pregnancy or continuation, but also include the possibility of refraining from pregnancy at all, and sometimes also pre-implantation genetic diagnosis, artificial insemination by donor, or egg-cell donation. Moreover, some preventive measures have to start before pregnancy. Folic acid supplementation for the prevention of neural tube defects such as spina bifida or anencephaly, for example, should be started at least four weeks before conception and continue for eight weeks after conception. Controlling maternal diabetes and choosing medications, if needed, that are the least harmful to the expected child, should also start before conception. The same applies to correcting dietary insufficiencies and refraining from smoking, alcohol and drug consumption. Even if there is no indication for increased risk pre-pregnancy counseling would give opportunities for education about risks of advanced parental age, or over consumption of vitamin A, and about prevention of, e.g., toxoplasmosis and neural tube defects. Notwithstanding all these advantages, a systematic offer of pre-pregnancy counseling to all couples who wish to have a child has nowhere been effectuated on a satisfying scale (Schrander-Stumpel 1999).

4. Genetics in Primary Care

Clinical genetics centers are scarce and have few resources to meet such needs as pre-pregnancy consultation for the whole population, or to answer all questions people might have about genetics. Pre-pregnancy consultation should be readily available in the neighborhood of the couples considering pregnancy. The same applies to answering genetic questions that might arise outside the reproductive setting. In developed countries, primary care is very accessible and is an obvious first line for handling these tasks. This is especially the case in countries were primary care is the gatekeeper to facilities, such as clinical genetics (Hayflick and Eiff 1998). With the discovery of hereditary cancer genes like BRCA1 and BRCA2, the number of questions to primary care physicians because of a family history of cancer, have increased markedly. However, there is a problem. The developments in the field of genetics are fast, and there are only a limited number of routine situations. Education of professionals about genetics alone will not be sufficient, since its content will soon be outdated. A solution is to exploit the possibilities of the Internet for the support of primary care.

5. Genetics for Disadvantaged People

The majority of people are not living in developed countries. For these people, the education of primary care physicians is not a solution. Other approaches are needed for these people. An example of one other approach is the genetic nursing system that has been developed in South Africa, where some remote hospitals, which generally have a serious lack of medical doctors, have at least one local nurse who has received some training in genetics (Christianson et al. 2000). These nurses, who have substantial contact with the local population, can recognize frequent disorders and perform genetic counseling. More difficult cases are presented to a hospital-visiting clinical geneticist.

Disadvantaged populations are not only living in the third world, but are present in developed countries as well. Groups of immigrants with a culture and language that is different from the resident population do not easily turn to clinical genetics services. Belief systems and social systems, religious and ethical convictions, traditions and usual practice are possible impediments. Special attention is needed for immigrants to also profit from genetic information (Penchaszadeh and Puñales-Morejón 1998).

6. Access and Quality of Clinical Genetics Services

Although clinical genetics can be clearly distinguished from community genetics, the presence of clinical

facilities, their accessibility and their quality is a concern of community genetics (Harris and Reid 1997). Genetic education, genetic screening, prepregnancy consultation, genetics in primary care, and genetics for disadvantaged people all presuppose that there are answers to difficult questions and for genetic diagnosis which can be easily found.

7. *Monitoring*

Monitoring of the population with regard to genetic and congenital diseases, but also for unwanted potential side-effects of the use of medical genetics, e.g., insurance problems, is desirable. Monitoring can be done by continuous registration or periodic surveys. When timely detection of sudden changes in frequencies are of interest, continuous registration is preferable. Periodic surveys, however, in general are less expensive. A problem with registers of congenital anomalies is the relative rareness of many of the disorders. This limits the statistical power of individual registries. Power may increase by joining international networks, such as the European Registration of Congenital Anomalies (EUROCAT) or the International Clearinghouse of Birth Defect Registries (ICBDR) (Reefhuis et al. 1999).

8. *Conclusion*

Community genetics is a multidisciplinary field. It differs from clinical genetics by its community orientation. It is not population genetics or genetic epidemiology. Population genetics and genetic epidemiology serve to increase our understanding about the behavior of alleles in populations and the contribution of genes to disease. Both fields produce information that is extremely important for community genetics. Community genetics applies this knowledge, together with the contributions from clinical genetics, psychology, sociology, educational experts, law, ethics, patient organizations (Kent 1999), and the community.

The term 'community genetics' is a new one, first mentioned in literature in the 1990s (Modell and Kuliev 1998). Separate community genetic activities, however, have a longer history. The term is useful since it gives a clear label for a coherent field within the universe of health care. It helps to delineate clinical genetics and it conveys a positive answer to those who express fear for eugenic tendencies and genetization. This answer is: 'Yes, it is possible to apply genetics to the benefit of the community by serving the individuals in it, without intention to improve the gene pool or the health of future populations.' This is one of the reasons why the name community genetics should be preferred above the term 'public health genetics' (Khoury et al. 2000). The other reason is that classical outcome measures in public health are uptake, compliance, and reproductive choices. Community genetics prefers to measure outcome in terms of improvement of autonomy, empowerment of people, perception of benefit, decrease of harm, and increase in justice.

Community Health

Although the term 'community health' is used frequently in health-related textbooks, scientific articles, and publications of international organizations, pre-

cise definitions of 'community health' are hard to come by. The term is often not clearly distinguished from related terms such as 'community medicine,' 'community health care,' 'preventive medicine,' or even 'public health.' Nevertheless it is possible to identify essential elements in the general concept of community health which are common to most uses and which differentiate 'community health' from traditional biomedical and individual-based approaches to health. This article reviews the uses of the term 'community health' in the health field, discusses common themes implicit in its use, and summarizes some of the ways the concept has been reflected in recent research and practice.

1. *Multiple Uses of the Term 'Community Health'*

Perhaps because the term was originally adopted in the medical field, it has often been used to refer primarily to health services provided in the community (for example in community health centers or by means of health visitors) as opposed to more traditional institutional settings such as hospitals. Early on it was also used to refer to the provision of health services by the community (i.e., through services organized and funded by the community itself, rather than through the mechanisms of traditional private medical practice), especially services intended to prevent or control the spread of disease and attend to the 'medically indigent.'

Other uses of the term community health have been much broader. The term community health or community health care has also been used as a synonym for the community-oriented primary care movement pioneered by the work of Sydney Kark in South Africa in the 1940s and 1950s (Kark 1981). Community-oriented primary care involved the provision of health care in geographically defined communities through a coordinated system of community health centers. However, it was conceived as much broader than the simple provision of health services in or by the community. The approach included community participation and organization, a multidisciplinary and team practice, a broad approach to the determinants of ill health including social and cultural together with biological factors, and built in monitoring, evaluation, and research (Susser 1999).

Community health (or community health care) has also been used as a synonym for another imprecisely defined term, community medicine, which emerged in the 1960s in the United States as part of a general movement in academic centers towards 'community-based approaches' to health care. Community medicine was defined as the assessment of health needs and provision of health care to defined population groups as distinct from the prevailing system based on the individual patient. It implied the provision of both curative and preventive services as well as the use of epidemiologic techniques in assessing the needs of population groups, in setting priorities and in the assessment of the results achieved (Lathem 1976). The community medicine movement was associated with the creation of departments, centers, and programs in community medicine (or community health) in many universities. Although multidisciplinary teams were sometimes emphasized, community medicine was clearly conceived as a domain or subspecialty of the medical profession. In Great Britain, the term community medicine was officially established in the early 1970s as a distinct medical specialty and defined as a branch of medicine concerned with populations or groups rather than with individual patients, requiring special knowledge of epidemiology, organization and evaluation of medical care, and the medical aspects of health service administration.

The term community health (and community health promotion) has also been used to refer to the local, collaborative efforts of the public and private sectors in the prevention and treatment of disease. This perspective highlights the participation not only of the medical profession and allied health professions but also of schools, families, workplaces, and the public sector (Green and Ottoson 1999). Key characteristics of this use of the term are notions of local diagnosis and action as well as intersectoral and collaborative approaches between public and private partners. This conception distinguishes community health from traditional clinical practice on one hand (which focuses on the individual patient) and from population health (or public health) on the other hand (which focuses on the population as a whole).

Although sometimes distinguished from 'population health' because of its focus on local diagnosis and action, community health has also been used to refer to the health of populations generally. In this sense the term is synonymous with modern uses of the term public health. Originally 'public health' was sometimes used to refer to health services provided by governmental agencies or to government prevention campaigns (such as vaccinations) and environmental interventions (such as sanitation). More recently, however, public health has been used more broadly to refer to 'the combination of sciences, skills, and beliefs that is directed to the maintenance and improvement of the health of all the people through collective or social actions' (Last 1995).

2. *Common Themes Underlying the General Concept of 'Community Health'*

Despite the many different and often imprecise uses of 'community health' in the literature, it is possible to trace several underlying themes implicit in its use. The first concerns how health and disease are concep-

tualized: health is a state of complete physical, mental, and social wellbeing and not merely the absence of disease or infirmity (WHO 1978). In addition, health and disease are perceived as extremes of a continuum of health states, rather than as dichotomous categories. The consequences of this conceptualization of health and disease are that interventions to improve health should include not only the diagnosis and treatment of disease (usually emphasized in traditional medical practice) but also health promotion and disease prevention activities.

A second theme refers to the determinants and causes of ill health. Community health approaches take a broad view of the causes of ill health-including not only those emphasized by traditional biomedical approaches such as individual susceptibility, individual exposures to disease-causing agents, and health behaviors (e.g., smoking, drinking, diet, and exercise), but also characteristics of the physical and social environments of the places where people live and work. Health and disease are therefore no longer thought of as matters exclusively (or even predominantly) of individual characteristics or individual choice, but rather as conditioned by broader social and economic forces which affect the resources that individuals have and constrain the choices that they can make. For this reason community health approaches often emphasize intersectoral approaches to health promotion and disease prevention and treatment. Improving health requires not only traditional health care interventions (early detection, diagnosis and treatment) but also health education (e.g., through health promoters, the school system, or mass communication), interventions on the physical environment (e.g., sanitation, pollution reduction, improvement of recreational spaces), reorganization of work (reduction in exposure to noxious physical or chemical environments, improvement of the psychosocial work environment), and even economic and social policy interventions. Thus a community-health approach requires collaboration of the traditional health sector and public health agencies with many other sectors.

A third characteristic of community health which stems directly from the recognition of the multiple causes of disease is the emphasis on a multidisciplinary approach to the study of health problems and to their solution, bringing together not only traditional health practitioners (such as doctors and nurses) and biological scientists, but also public health practitioners, epidemiologists, health educators, and social scientists. Community health integrates personal health services with environmental, health policy, and social policy approaches, and draws on both quantitative and qualitative research.

A fourth underlying theme in community health emphasizes the importance of local determinants and local action. While recognizing society-wide determinants of health, the importance of local determinants, and the need for local needs assessment, local decision making, local priorities, and local action is stressed. The emphasis on local diagnosis and action is closely linked to the importance of local control and the need to recognize the specificities of communities in both assessing needs and designing and implementing interventions.

A fifth characteristic is the key importance of community participation, that is the active involvement of the community in all stages of the community health process, including identification of health needs, establishment of priorities, development and implementation of interventions, and evaluation of their effects. Community participation implies more than sporadic consultation with community leaders or participation of community members in the implementation of interventions. It requires direct involvement of the community, its representatives or its institutions in all aspects of the decision making process. However, the importance of community participation, and the extent to which true participation in the decision-making processes has actually existed in community health programs, has been the subject of much debate.

Finally, and perhaps most importantly, use of the term community implies recognition of the construct of community, or more generally of populations, as fundamental in understanding the causes of ill health. However community is defined, there is implicit recognition of the role of social interactions and social organization in shaping the attitudes of individuals and the choices that they make. The determinants of ill health can be conceptualized not only at the individual-level but also at the population, group, or community level. This notion is in stark contrast to the dominant paradigm in medicine where methodological individualism and the idea that disease itself and all its determinants are best conceptualized and measured at the individual-level is paramount. Thus, interventions can be targeted at communities themselves (as well as at community organizations or institutions), rather than focusing on individuals as is done in traditional medical practice. Another key idea that distinguishes the community health approach from that of traditional medical practice is that the object of study (and intervention) is not only the individual patient but also the community or population. Thus the practice of community health requires the ascertainment of health problems and needs not only in individuals but also in communities or populations.

3. *The Concept in Recent Research and Practice*

Many of the underlying themes of community health have appeared in health-related research and in health care and public health practice over the past few years. Three research-related areas in which elements of the community health paradigm have emerged are the investigation of community-level determinants of

health, the evaluation of community interventions (community intervention trials), and the notion of 'community-based' research. In public health practice, community health themes have formed the basis of the primary health care approach and have recently emerged in some aspects of the healthy cities and healthy municipalities movements.

3.1 Community-level Determinants of Health

The 1990s saw an increasing empirical investigation of community-level determinants of health and the extent to which community characteristics are related to health over and above the effects of individual-level factors. Research on community effects is part of a resurgence of interest in the group-level, macrolevel, or ecological determinants of health. It is related to a larger critique of the dominant paradigm in health research which implicitly assumes that all disease determinants are essentially individual-level attributes (Duncan et al. 1998, Diez-Roux 1998). Recent empirical investigations of community effects on health have focused on geographically-defined communities or neighborhoods. For example, a series of studies have now documented a relation between neighborhood socioeconomic context and health outcomes, including mortality, disease prevalence, and health behaviors (e.g., Haan et al. 1987, Davey Smith 1998, Robert 1999). These associations often persist after controlling for the socioeconomic characteristics of individuals, suggesting that characteristics of areas or neighborhoods *per se* may be important to health.

The recent development of the statistical technique of multilevel analysis, which allows the simultaneous examination of group-level and individual-level factors (Duncan et al. 1998, DiPrete and Forristal 1994), has greatly stimulated empirical research in this field. However, there has been relatively little conceptualization or empirical examination of the specific features of areas that may be relevant or of the mechanisms involved (MacIntyre et al. 1993). Potential intervening factors may include the physical characteristics and resources of neighborhoods as well as features of their social environments. In addition, research in this field still faces important conceptual and methodological challenges before firm inferences can be drawn regarding the presence and relative importance of neighborhood effects (particularly with regard to the role of individual-level social position). These challenges include better definition and characterization of communities or neighborhoods, specification of their relevant features, elucidation of the processes through which neighborhood factors may operate, and examination of the ways in which neighborhood factors may interact with individual-level characteristics.

3.2 Community Interventions

Closely linked to the notion of community determinants of health is the idea that interventions to improve health and prevent disease may be more effective if they target communities rather than (or in addition to) the individuals within them. Although the importance of community interventions such as improved sanitation has long been a basic tenet of public health, the idea that interventions to prevent chronic diseases such as cardiovascular disease should also focus on the community level only emerged in the last two decades. The rationale underlying the need for community interventions is that many health-related behaviors (such as smoking, sedentary lifestyle, and diet) related to today's prevalent chronic diseases are promoted and maintained by the physical and social environments of communities. Thus, by addressing community environments directly, and by modifying prevalent social norms, community interventions may be more effective than traditional individual-based one-on-one approaches (Syme 1986). In addition, by targeting the entire community rather than just individuals above an arbitrarily defined 'high risk' cut off, community interventions have the potential for shifting the entire distribution of risk and thus preventing a larger amount of disease (Rose 1985). The community intervention approach represents a radical departure from the traditional clinical approach which focuses only on individuals at highest risk and 'decontextualizes' risk behaviors by ignoring their broader social determinants.

Community intervention trials or their variants have been conducted in a variety of settings over the past 20 years including geographically defined communities, workplaces, and school (Sorensen et al. 1998). Examples of the types of interventions implemented as part of community intervention trials include health education activities, mass media campaigns, education of health professionals, screening, physical activity programs, and labeling in grocery stores and restaurants. Although some community intervention studies for the prevention of cardiovascular disease have found significant effects (Puska et al. 1985), the empirical evidence of program effects in these studies is generally modest (Koepsell et al. 1995, Fortmann et al. 1995). The presence of society-wide trends that make it difficult to detect program effects, the relative absence of interventions at the structural, macro or policy level, and the lack of significant community participation may account for the mixed results of some of these community trials.

3.3 Community Participation and Community-based Research

Many of the ideas underlying the concept of community health are also expressed in what has been

termed 'community-based research' (or 'community-centered research') (Israel et al. 1998). A key characteristic of this approach is the explicit recognition of the concept of community as a fundamental category in public health research, where community 'is characterized by a sense of identification and emotional connection to other members, common symbol systems, shared values and norms, mutual, although not necessarily equal, influence, common interests and commitment to meeting shared needs' (Israel et al. 1998). The notion of community includes not only geographically defined neighborhoods (which may or may not qualify as communities under the previous definition) but also, for example, geographically dispersed ethnic groups with a sense of common identity. Key elements of community-based research include: (a) building on strengths, resources and relations that exists within communities as part of health research; (b) collaborative partnership and the active participation of community members and representatives in all aspects of the research process; (c) the reciprocal transfer of knowledge, skills, capacity, and power; (d) the integration of knowledge and action, and (e) a broad approach to the determinants of health including not only the characteristics of individuals but also community characteristics and broader structural factors. Although often noted as an ideal approach to research in public health, true community participation has been infrequently implemented in health research, so its impact has yet to be determined.

3.4 The Primary Health Care and Healthy Cities/Communities/Municipalities Movements

Many of the constituent elements of 'community health' were reflected in the 'primary health care' approach formalized by the World Health Organization in 1978 (WHO 1978), which drew in part on community-oriented primary care (Kark 1981). As defined by WHO, primary health care extends beyond the provision of basic health services or first contact clinical care to environmental, economic, and social interventions which may have an impact on health, and emphasizes community participation and the need to eliminate inequalities both between and within countries. Primary health care was put forward as the primary strategy for achieving the goal of health for all, and was adopted by the health sectors of many nonindustrialized countries. Elements of community-oriented primary care were also adopted in some industrialized countries as illustrated for example, by the community health center program in the 1960s in the United States (Sardell 1988). Themes of the 'community health' paradigm have also recently emerged in the Healthy Cities, Healthy Communities, and Healthy Municipalities movements initiated in Canada in the 1980s, and subsequently adopted in the United States and by the Panamerican and World Health Organizations. Although the philosophical orientation, sponsors, and activities of these projects have varied substantially, they share the basic idea of challenging communities to develop projects to reduce inequalities in health and access to health care, and to develop healthy public policies at the local level through a multisectorial approach and increased community participation in health decision-making (Flynn 1996). They emphasize local government, decentralization, community involvement, and developing a broad range of strategies to address the social, environmental, and economic determinants of health. The evaluation of the effects of primary health care and related strategies on health outcomes is complex. Empirical studies are scarce, although there is some evidence that comprehensive and integrated approaches (such as those advocated by the primary health care movement) may be more effective and efficient in improving health overall than selective and vertical approaches (Taylor and Parker 1987).

4. Limitations and Implications of the Concept of Community Health

Ambiguities in exactly what 'community health' is intended to mean has led some to urge caution in the use of the term. For example, community health has often been associated with the organization and delivery of health care for the poor, despite the fact that it has been postulated as a framework for understanding the causes of ill health and a strategy for improving health in the population as a whole. The concept of 'community participation' has also been misinterpreted. For example, health education campaigns in the community, periodic gatherings with community members to inform them of ongoing activities, or even simply hiring community members for routine tasks at the health center has been taken as an indication of the 'participatory' nature of the program. There has been much debate around the concept of community participation itself, whether participation has been more than simply symbolic, and the extent to which it has been distorted, manipulated, and rendered rethorical (Ugalde 1985). The relationship between 'community health' and medical practice has also been contested. For example, despite formulations of the concept that emphasize the multiple determinants of health and the need for intersectoral approaches, community health has often been viewed as a branch or specialty of medicine, as clinical practice with a population or community base (where population or 'community' may refer simply to the group of patients that a particular medical practice sees).

The use of the term 'community' has also been problematic because 'community' is rarely precisely

defined, and has sometimes been used to refer to any group of persons. Moreover, the use of 'community health' in place of 'population health' or 'public health' has been criticized because the term 'community' conjures up ideas of consensus and equality (an idealized notion of community which may often not exist in reality), and in so doing may obfuscate the fact that population health (and public health) is strongly influenced by inequality (Popay 1996). It has also been argued that the use of 'community health' as opposed to 'public health' or related terms such as 'social medicine' has contributed to a desocialization and parochialization of the concept. The use of community medicine (or community health care) as a synonym of public health perpetuates the idea of public health as a subdivision of medicine rather than medicine as a subdivision of the broader public health (Anonymous 1985). Others have noted that by focusing on 'community' the concept emphasizes local action and shifts attention from the need to address larger scale social and structural determinants of health. The emphasis on decentralization in some formulations of the community health paradigm has not always been accompanied by true changes in decision-making power. In addition, it has often been associated with ideas of financial autonomy and self-sufficiency, sometimes with the intent of reducing government outlays, with potential consequences for the availability of resources at the local level and equity. In Latin America, the concept of 'collective health' which emerged in Brazil in the 1970s (*saúde colectiva* in Portuguese) has been used as an alternative to the terms 'public health' and 'community medicine,' reflecting a critique of the perceived biomedical reductionism and burocratization of the 'public health' and 'community medicine' approaches dominant in developed countries. The 'collective health' movement emphasized the social nature of the health-disease process, as well as the contribution of the social sciences (together with other disciplines) to knowledge and practice in the field (Silva Paim 1992).

5. Conclusion

Despite many ambiguities and reductionisms, the broadly defined philosophy of community health has been progressive in the health field because it recognizes the role of 'community' or more generally of interactions between persons in groups, social relations, and social organization in influencing people's health. Thus, it transcends the approach dominant in clinical medicine which reduces health and its determinants to a biological and individual phenomenon, and recognizes that each person is a member of multiple groups, communities, or populations (e.g., social classes, racial and ethnic groups, occupational groups, neighborhoods) and that characteristics of these groups are crucial in shaping that person's health over and above his or her individual characteristics. Moreover, it emphasizes the need for a multidisciplinary and intersectoral approach. Under the community health paradigm, the prevention of illness and death is no longer viewed purely as a matter of medical intervention, it is no longer a monopoly of doctors and health care providers. Health and disease are viewed not only as biological, but also as fundamentally social phenomena. Because of their recognition of the social and economic determinants of health, their concern with equity, and their strong emphasis on community participation, community empowerment, and community action, community health movements have been frequently linked to broader social movements, and to calls for social change and political action.

Community Organization and the Life Course

Communities and, more specifically, neighborhoods are one of several central social settings that affect human development. Approaches to neighborhood theory and measurement are first reviewed, followed by a discussion of neighborhood effects on children and adolescents and on adults and the elderly. The article concludes by highlighting new directions for research, policy, and practice.

1. *The Ecology of Human Development*

A fundamental proposition of developmental science is that social contexts affect human development. Most theories on social contexts seek to identify which attributes of a single context are developmentally positive or negative. Most theories emphasize the composition and structure of a setting. While this approach is useful, it is limited in that it says little about the processes that have a more direct impact on individual development. For theories to be maximally predictive and generalizable, they must also address processes. This is especially important because some effective or ineffective processes may be more common in settings with certain compositional or structural characteristics. Ultimately, attention must also be paid to the ways in which multiple contexts jointly affect development during particular life periods and over the life course as a whole. The approach advocated here is therefore in line with recent advances in ecological, life-span, and life-course frameworks (for a review, see Settersten 1999). These frameworks emphasize the multiple proximal and distal settings in which development takes place, the connections between these settings, the proximal and distal processes that occur within them, and how these settings and processes change over time.

2. *Theoretical Models of Neighborhood Effects*

Neighborhood effects on physical, psychological, and social outcomes may be tied to the composition and structure of neighborhoods, the social processes that occur within them, or specific combinations of composition, structure, and process.

Several theoretical models have guided most inquiry in this area, namely contagion models, models of social disorganization, models of collective socialization, competition models, models of relative deprivation, and institutional models (see also Furstenberg and Hughes 1997, Mayer and Jencks 1989). These and other models need not be contradictory; indeed, they may be complementary.

'Contagion' or 'epidemic' models suggest that those exposed to neighbors who engage in negative behaviors will themselves be more likely to engage in similar behaviors (e.g., Crane 1991). In these models, the assumption is that neighborhoods of low socioeconomic status (SES) are characterized by more problematic behaviors. Presumably, this also extends to attitudes, beliefs, and values. The focus of these models has almost exclusively been on the contagion of negative phenomena, not positive phenomena.

Models of 'social disorganization' suggest that neighborhoods with high levels of social problems become disorganized, which in turn results in deviant behavior at the individual level (e.g., Skogan 1990). Recent work on 'collective efficacy' has advanced

these models (e.g., Sampson et al. 1997). Social organization is bound explicitly to collective efficacy, which depends on neighbors trusting each other, sharing values, jointly monitoring and supervising youth, and intervening on behalf of the common good. As such, these also become models of 'collective socialization' in that the entire community takes responsibility for socializing its residents.

Models of 'relative deprivation' or 'social comparison' are models in which the presence of advantaged neighbors, in particular, becomes problematic for those who have less because individuals evaluate their own standing relative to that of others. For example, if children and families view themselves to be at a disadvantage, they may not be motivated to achieve and they may labeled negatively by their peers (Furstenberg and Hughes 1997). These models may also emphasize 'competition' or 'cultural conflict,' in that neighbors or peers are viewed as competing for limited resources.

Finally, 'institutional' models suggest that it is not the kind of neighbors that matters most, but instead the resources, services, and organizations available in a neighborhood (e.g., McLaughlin et al. 1994). Proponents of these models generally assume that higher SES neighborhoods have greater and higher quality organizations, services, and resources than lower SES neighborhoods, and that these are ultimately very beneficial for human development.

There are also models that downplay and even dismiss the likelihood of neighborhood effects altogether. These models, common in economics and anchored in theories of rational choice, assume that people do not base their decisions on what their neighbors value or how their neighbors behave. Instead, people base their decisions on their personal interests and circumstances. As long as individuals are able to find others who hold positive standards, they will be able to form positive lives. From this standpoint, the relative concentration of positive values and behaviors in a neighborhood is not as important as their mere presence.

3. *Conceptualizing Neighborhoods*

How neighborhoods are approached in research, policy, or practice will depend on how they are conceptualized. Neighborhoods may be conceived as sites, networks, cultures, or perceptions (Burton et al. 1997, Gephart 1997). The most common approach is to consider neighborhoods as sites and focus on their social and physical makeup. In these cases, the neighborhood unit is most often a set of block groups, zip codes, or census tracts; and data are drawn from a variety of largely official sources (e.g., census, crime reports, vital health statistics, social service agencies, school records). Recently, Sampson and Raudenbush (1999) also found innovative techniques for gathering systematic first-hand data via 'windshield' surveys.

When neighborhoods are approached as *networks*, the focus is on intimate ties, social relationships, and patterns of interaction. When neighborhoods are approached as *cultures*, the focus is on the behaviors, outlooks, rituals, and languages that characterize a neighborhood. Of course, neighborhoods can also be understood as *perceptions* and through the subjective experiences of neighborhoods as sites, networks, and cultures. Regardless of how neighborhoods are conceptualized, individual-level data are most often gathered through survey and interview methods and then aggregated. Indicators may be objective or subjective, quantitative or qualitative, static or temporal. There are strengths and limitations associated with each conceptualization of neighborhood, and the relevant unit to study and data to gather will depend on the outcomes or processes of interest.

4. *Measures of Neighborhood Composition, Structure, and Process*

Most studies of neighborhood effects have relied on single indicators or built composite measures of neighborhood composition. These have largely been based on secondary public sources, especially the census. Most research has focused on factors related to SES (e.g., percentage of families in poverty, median family income, percentage of male joblessness, median educational attainment of adults, percentage of adults in professional or managerial positions). It has also been common to emphasize racial composition (especially percentage of Black) and intersections between racial composition and indicators of SES. A few characteristics have also been used to index neighborhood commitment and stability (e.g., percentage of families in same dwelling for 5+ years, percentage of residents who own their homes).

Other researchers have built more informative measures of neighborhood structure and even process. These are most often based on individual-level survey data that are then aggregated. These studies have turned attention to dynamics around social cohesion, social control, social support, and disorganization, and to the availability of various types of resources, adult participation in local organizations, and stability in and satisfaction with the neighborhood. The most advanced research has attempted to link neighborhood composition, structure and process. For example, Wilson (1996) emphasizes the larger economic conditions that result in joblessness; the flight of middle-class families to the suburbs that reduces resources and investments from local and state governments; and the declining marital stability of families that results in a shortage of positive male role models.

These and other factors produce a local ethos that undermines social consensus and social control and produces social isolation. Similarly, Brooks-Gunn et al. (1993) suggest that the percentage of local adults who work in managerial and professional occupations affects the development of youngsters in positive ways because these adults are more likely to promote conventional attitudes and behaviors.

5. *Neighborhood Effects on Children and Adolescents*

Most scholarship has focused on the impact of neighborhood environments on the social outcomes of children and adolescents. Early childhood and late adolescence seem especially important periods in that they involve significant shifts in both family and school settings and individuals in these two periods differ in the degree to which they are susceptible to influences outside of the family (Brooks-Gunn et al. 1993). Neighborhood influences on development early in life also seem particularly important in that positive or negative effects may cumulate over time, generating further advantage or disadvantage over the life course.

Despite significant interest in neighborhood effects on the development of young people, research has not shown consistent or sizable effects (for overviews, see Gephart 1997, Mayer and Jencks 1989). (This may also relate to measurement problems, some of which will be highlighted in the conclusion of this article.) In childhood, neighborhoods have been shown to affect cognitive functioning, behavioral problems, child maltreatment rates, low birth weight rates, and infant death rates. In adolescence and early adulthood, neighborhoods have been shown to affect delinquency, drug use, school achievement and dropout, teen childbearing, health status, joblessness, poverty, self-efficacy, personal commitment to conventional attitudes and behaviors, and having conventional or delinquent friends.

Most literature is focused on negative outcomes (and on how to prevent negative outcomes) rather than on positive outcomes (and on how to foster positive outcomes). It is also focused on adolescence. Little attention has been paid to neighborhood effects on the development of adults outside of their early 20s. The exception to this trend relates to the other end of the life course: old age.

6. *Neighborhood Effects on Adults and the Elderly*

In the field of gerontology, there has been longstanding interest in the fit between older people and their environments. Where the subject matter of this entry is concerned, this fit relates to how residential environments might be designed or redesigned to better accommodate the physical, psychological, social, and economic changes that often accompany aging. It also relates to the challenges of relocation in later life, as significant numbers of older individuals move to nursing homes, government-subsidized apartments, or other residential settings. Indeed, many institutions for older people are explicitly aimed at achieving a sense of 'community' by design. These and other factors may lead to age segregation (rather than age integration) in residential and other environments, a phenomenon that has garnered attention in recent literature on aging (see Uhlenberg and Riley 2000).

Even those who age 'in place' have seen their neighborhoods through significant change, and often for the worse. Along these lines, there is also a tradition of research on crime and the elderly, both in terms of fear of crime (e.g., Ferraro and LaGrange 1992) and actual victimization (e.g., McCabe and Gregory 1998). The personal circumstances of many older people also constrain their residential options and their ability to move (especially health, marital and financial statuses). Recent scholarship on aging has also emphasized the differing needs and circumstances of rural and urban elders (e.g., Coward and Krout 1998) and the important roles that neighbors and satisfaction with neighborhood play in determining well being (Phillipson et al. 1999). Indeed, older people may be more likely to feel the absence of community and more likely to benefit from community life (Lucksinger 1994).

Relative to scholarship on childhood and adolescence, scholarship on neighborhood effects on older adults is significantly less advanced. While important research has been conducted on both ends of life, there is little research on the many decades between. Scholarship on adult development and aging should evaluate whether the models developed on childhood and adolescence can be extended to early adulthood, midlife, and later life, and how existing models must be reconsidered or examined anew to better understand development during these three periods.

7. *New Directions for Research, Policy, and Practice*

A significant problem in demonstrating neighborhood effects relates to important unobserved biases in empirical estimates, particularly those due to selection. Residents in specific neighborhoods differ in important ways before they arrive in those neighborhoods, yet those who choose to live in (or leave) particular neighborhoods are also likely similar in important ways. Depending on these dynamics, neighborhood effects may be overestimated or underestimated. Effects might also be small because the degree

of variation naturally found in a neighborhood is small. But because most research has been conducted at the level of census tracts, the degree of variation may instead be too great, making it equally difficult to ascertain neighborhood effects.

This point also draws attention to the fact that neighborhood phenomena must be understood in dynamic rather than static ways. Changes in neighborhoods, changes in individuals, and the connections between them must be mapped simultaneously. However, temporal multilevel models pose significant challenges for theory and research (for a discussion of these challenges, see Settersten 1999). Where neighborhoods are concerned, longitudinal frameworks are particularly challenging because the geographic mobility of individuals and families dramatically increases the number of neighborhoods that must be managed as a sample is tracked over time.

Research on neighborhood effects must also begin to consider both short- and long-term effects and the forms of these effects. It is important to explore the possibility of non-linear effects, including threshold models (i.e., points after which neighborhoods may become especially relevant or irrelevant to individual development). It is also important to examine connections between neighborhoods and individuals that are not only top-down, but also bottom-up or reciprocal in nature.

Neighborhoods must also be considered in combination with other contexts, and family and school settings are especially likely to moderate neighborhood effects. Because social contexts are complexly interwoven, scholarship must specify how various contexts are interrelated and how these interrelationships impact development during different periods of life. Scholarship on this topic must, therefore, produce a more differentiated view of how neighborhoods affect human development. It must address how specific aspects (or specific combinations) of neighborhood composition, structure and process might be tied to specific kinds of developmental outcomes (whether physical, psychological, or social). And it must address whether specific subsets of residents (e.g., by age, race, gender, social class, or their intersections) are more or less affected by neighborhood factors, whether they are affected in different ways, and why.

Local policies and initiatives aimed at building the social capital of communities ultimately improve the welfare and development of neighborhood residents. These should include efforts to foster or better economic security, housing, safety, schools and other institutions, services, social interaction and support, community service and leadership, or a sense of belonging and pride (Brown and Richman 1997). However, intensive community organizing is required for most community-based initiatives and must reflect a broad array of strategies to mobilize residents and to teach them how to plan and take action. State and federal policies also affect the welfare and development of neighborhood residents, especially via policies related to employment and its correlates (e.g., training, health insurance, transportation, childcare), public safety, drugs, and education (Lehman and Smeeding 1997). Together, policies and initiatives at each of these levels shape the experience of everyday life and the options, flexibility, and control that individuals have as they grow up and older.

Community Power Structure

Two issues have been central to the study of urban politics and policymaking in the United States and, to a lesser extent, in Western Europe: Who holds power within the community? And how much autonomy do urban policy makers have to make meaningful decisions within national and global systems. Although the phrase 'community power structure' is commonly used to describe these discussions, the use of the term 'community' is somewhat misleading, since the jurisdictional level analyzed is usually that of the city.

1. *Origins of the Debate*

Consideration of the question of who has power within cities began with the debate between elitists and pluralists that developed after the publication of Robert Dahl's *Who Governs?* in 1961. Dahl examined the question of power in New Haven, Connecticut, by counting the participants in a series of important decisions. He focused on the issue areas of urban redevelopment, education, and political nominations and found that, while elites dominated in each area, only public officials subject to electoral sanctions had influence in all three. The system was therefore one of 'dispersed inequalities.' He further concluded that all social groupings had the potential to mobilize power resources. This finding was further elaborated by Nelson Polsby, who argued that urban society was 'fractured into congeries of hundreds of small special interest groups, with incompletely overlapping memberships, widely diffused power bases, and a multitude of techniques for exercising influence on decisions salient to them' (Polsby 1970, p. 118).

Polsby, in particular, contrasted the pluralist interpretation of urban power structure with elite theory, which contended that business leaders controlled public decision making. Hunter's (1953) study of Atlanta, Georgia, was seen to epitomize the elitist viewpoint. Hunter had asked informants who they thought made the important decisions in Atlanta. Each person interviewed was required to name those with power and to provide the names of additional informants. Hunter found that a small group of people was named in relation to a number of decisional areas and that the nominal participants in decision making were only the agents of those holding real power. According to Polsby , Hunter's use of this reputational method inevitably led to the result he found. Thus, the allegedly powerful had a reputation for power but did not necessarily really exercise power. In contrast, he claimed that the pluralists recorded actual behavior.

The pluralist contention of superior methodology, however, was challenged by Bachrach and Baratz (1970), who asserted that observing manifest behavior failed to capture 'the hidden face of power.' By exerting their authority behind the scenes or simply by shaping a set of expectations, truly powerful people structured the decisional agenda, insuring the exclusion of issues that could undermine their position. Community power, in this formulation, shifted from a set of overt actions involving the costly exercise of control to a more subtle manipulation of the context in which decision making took place.

2. *Shifting Terms of the Debate*

During the 1970s the analysis of community power evolved in two directions, both in response to events 'on the ground.' The initial community power debate took place against the backdrop of quiescent cities seemingly governed by a broad consensus over the contours of policy. Then suddenly cities in both the United States and Europe became arenas of social conflict. Within the United States divisions occurred primarily along racial and ethnic lines, with minority groups protesting their disadvantaged status as bureaucratic clients, as losers under urban renewal programs, and as the objects of discrimination (Fainstein and Fainstein 1974). In Europe urban social movements, based in both working class and student-radical strata, rebelled against sclerotic bureaucracies and rule by notables. They aimed at increasing collective consumption—that is, at improving the level and quality of state-sponsored benefits, especially housing. On both sides of the Atlantic demands for greater citizen participation challenged pluralist conclusions that, within democratic polities, previous low levels of mobilization indicated broad satisfaction with governance (see *Citizen Participation*).

Within the USA, heightened demands for state services, mobilizations around symbolic issues, and blocking of public programs by negatively affected groups led some observers to ask whether cities could be governed at all. Whereas earlier pluralists had regarded competition among groups as a benign exercise, this later group of 'hyperpluralists' regarded group conflict as counterproductive (Yates 1977, Wirt 1974, Judge 1995) (see *Locational Conflict (NIMBY)*).

In contrast, many other urbanists responded to urban unrest by sympathizing with the protestors. In Europe, the rise of urban social movements stimulated the application of Marxist theory to urban spaces, as part of a more general incorporation of spatial relations into Marxist structuralism (see Harvey 1973, Castells 1977). As a consequence, the question of power in cities shifted from the issue of who makes decisions to what were the forces that determined who benefited from urban change (Harloe 1977, Pickvance 1976). Pluralists and elitists had debated over who had power within cities. Now the question became whether local policy makers could actually control the destiny of a place. Instead cities were seen as the outcome of the impersonal operations of capital using space to maximize profits. Thus, cities experienced the benefits of capital investment or the depredations of capital withdrawal depending on factors mainly beyond the control of local decision makers (Harvey 1985). Moreover, capitalists benefited from the very volatility and competitiveness that jeopardized the wellbeing of urban residents.

Within the Marxist framework, the structural dependence of the local state on capital meant that politicians had little choice but to defer to the wishes of capitalists in making policy decisions (Foglesong 1986). In other words, the reliance by public officials on private investors for jobs for their constituents and, especially in America, for support of their tax base meant they had to conform to the wishes of capitalists. Only if they insured a 'good business climate' could they entice business leaders to invest in their locality.

The Marxist critique prompted the rise of the political economy approach to studying community power; within the US this mode of analysis branched into right and left forks. On the right, Paul Peterson (1981) argued that city governments needed to compete for business investment and were powerless to carry out redistributional policies, since the latter would create a intolerable burden on business. Unlike those on the left who considered cities as hostage to capital, however, Peterson regarded the pursuit of economic development as in the interest of all city residents. Thus, like the pluralists he maintained that public policy was made within a general agreement on the merits of economic development programs.

On the left, political economists ran a spectrum from neo-Marxist to neo-Weberian to eclectic. The neo-Marxists were particularly concerned with the contradictory demands on the local state to, on the one hand, provide the basis for capital accumulation through construction of infrastructure and subsidies to business, and on the other, to legitimate capitalist domination through social welfare expenditures. The outcome of this balancing act was a fiscal crisis of the state (Alcaly and Mermelstein 1977, Tabb and Sawers 1984). Capitalist domination of local decision making also manifested itself in land use planning, where urban redevelopment programs provided the basis for land grabs and gentrification (Dear and Scott 1981, Smith 1991).

Other critical approaches to urban political economy focused on local decision makers rather than the more abstract logic of capital. While partly Marxist-inspired, these works resembled the earlier pluralist and elite analyses in using case studies to locate the actors and processes that produced unequal results within particular cities. Influential works identified urban 'growth machines' or 'pro-growth coalitions' as the dominant agent in urban decision making (Logan and Molotch 1987, Mollenkopf 1983); property developers were central figures in these groupings. Comparative analysis of American cities indicated that the character of urban regimes changed historically and that the period of urban conflict in the 1960s and 1970s was marked in many cities by 'concessionary regimes' that responded to previously excluded population groups. With the decline of overt protest, however, 'conserving regimes,' while not totally eliminating redistributional programs from the earlier period, increasingly responded to business interests (Fainstein et al. 1986). Thus, the nature of community power did not remain stable and could not be captured in an ahistorical analysis (see *Urban Planning: Central City Revitalization*).

Attempts to apply the growth machine analysis to European cities found the concept less useful there (Harding 1994, 1995, Molotch and Vicari 1988). Because localities depended less on their own resources and government was considerably more centralized, the stakes of local politics were lower than in the United States. Nevertheless, some convergence toward the US model was found by Saunders (1979) in his study of development in Croydon (an outer borough of London).

As the US federal government withdrew from urban programs, city governments redefined their mission as promoting economic development rather than addressing social problems (Judd and Swanstrom 1998). The competition for footloose capital intensified, and public officials devised a variety of programmatic mechanisms to assist business development, primarily relying on off-budget tax subsidies. A number of analyses examined the 'public-private partnerships' supporting economic development efforts and concluded that the private side dominated the partnerships (Squires 1989, Beauregard 1989). Ultimately, however, the theoretical issue switched almost entirely

from the question of who governed to the extent of local agency (Harloe et al. 1990)—that is, what difference could local actors make, especially those who were not members of the business elite.

3. Urban Regimes and Local Autonomy

Political economic analysis seemed to make moot the issue of community power by attributing urban transformations to the effects of global economic restructuring. The implication was that human agency could not affect the most important factors determining people's lives (Goldsmith 1995). Critics, however, attacked the political economy approach as overly deterministic and pessimistic (Swanstrom 1993). They argued that local politics remained a meaningful endeavor and, like the early pluralists, that resources were available to be mobilized even by marginal groups. At the same time, however, analyses of the effects of African–American mayors on public policy indicated that changes in elected administrations did not change the basic contours of policy (Reed 1988). In particular, Clarence Stone's (1989) study of Atlanta demonstrated the persistence of a stable regime favoring business interests even as control of city hall passed from the white elite to rhetorically militant African Americans.

Stone (1993) laid out a theory of urban regimes that became the prevalent approach to urban power structure at the end of the century. According to regime theory, local politics mattered, and who dominated at the local level affected the welfare of urban citizens. Stone outlined a typology of possible regimes that included low-income opportunity regimes as well as business-dominated and progressive middle class ones. A regime consisted of both public and private actors, and it cut across a broad range of issues rather than, as the pluralists argued, being an issue-specific coalition. Although regime theory shared with pluralist theory a focus on the interaction of local political groupings, it differed in that Stone attributed a 'systemic bias' to urban power networks. Business interests, because of their control over investment allocations, usually dominated, and it took extraordinary effort on the part of other groups to overcome this natural tendency.

Regime theory thus fused political economy and pluralism. Like political economy it did not separate politics and economics, and it was concerned with who benefited from policy decisions, not simply who made them. Like pluralist theory it stressed the importance of building political coalitions and assumed that local decision-making could change people's lives. Stone (1993) also stressed that regime theory differed from pluralist theory in that it had a social production model of power—that is, power had to be created, was not simply a matter of control, and consisted of the ability to get things done. A careful reading of *Who Governs?* however, indicates that Dahl likewise emphasized the importance of coalition building; the mayor of New Haven was only able to achieve his urban renewal program through a process of social production similar to that described by Stone.

To date the application of regime theory has largely been restricted to American cities. Increasingly, however, the study of urban politics has taken on a comparative dimension, and analysis of local regimes offers a promising framework for comparison (Stoker 1995). Rational choice theory is its principal competitor as a theoretical basis for urban analysis. But while rational choice offers a method of analyzing the content and effects of public policy decisions, it does not lend itself to the scrutiny of power relationships.

The evolution of theory always reflects the development of an initial set of ideas and then a response. At the same time, it responds to actual events and real political conflicts. Perhaps in no area of political science has the social basis of different theoretical formulations been more apparent. The political quietude of the 1950s and the hegemony of anticommunism within the West underlay the pluralist rejoinder to the radical implications of elite theory. The social movements of the sixties and seventies stimulated both the neo-Marxist argument and the hyperpluralists' fears. The economic restructuring of the 1980s and the subsequent prevalence of neo-liberal ideology have framed the turn-of-the-century division of labor between political economists, who continue to focus on issues of class, race, and power in cities, and rational choice theorists, who focus on questions of strategies and their results.

Community, Social Contexts of

1. *From Rural Decline to Globalization*

Community denotes first a local government (village, town, city). Second it conveys social integration—actual, or desired by the speaker—as in 'the global community.' Community sociology was shaped by Toennies, Weber, and Durkheim in the late nineteenth century over concerns for rural decline, industrialization, and urbanization. They held that small communities generated more social integration. These concerns continue today, but in the post-industrial word, globalization is reshaping the basic contours of social life, via global capitalism, worldwide migration, mass communication, and the Internet (Sassen 1991). For Weber and Durkheim the community was a strategic research site for refuting theories of pure individualism. Today as then, localities are strategic research sites for huge processes and forces—strategic first since one can observe global dynamics on a scale manageable for research. Second, because there are so many communities, they encourage comparison and thus scientific generalization.

The massive community research by sociologists in the twentieth century was shaped more by nineteenth century concerns than by new global concerns, which emerged only near 2000. This article considers three major themes from past community research still vital today:

(a) individual citizens and the nation;
(b) intermediary groups, like civic associations, and;
(c) new public agendas like environment issues.

All three illustrate transformations of community processes by global forces that shift power among participants and redefine the rules of the game.

Weber's and Durkheim's concerns continued for decades across much of the world, sparked by rapid urbanization and industrialization, which often brought explosive numbers of migrants to large cities, escalating crime, and political and social conflicts between new and old residents.

More abstractly, Weber and Durkheim used local communities to illustrate collective processes like shared values, migration, and the division of labor. They discussed these interrelated processes to articulate a focus for sociology, complementing the methodological individualism of Adam Smith's economics and the political contract theory of Hobbes, Locke, Bentham, and J. S. Mill.

Durkheim, Toennies, and many others contrasted a rising and seemingly unbridled individualism of the city against the socially-integrated (if perhaps idealized) small town, the Gemeinschaft. In this traditional community, they suggested, the individual was integrated via deep personal relations with family, neighbors, and strong institutions, especially churches. Such ties were broken when people migrated to cities

for new jobs. For George Simmel and Louis Wirth the city could thus offer 'Freie Luft': freedom and cosmopolitanism in the sophisticated diversity of urban life, liberating individuals from local provincialisms. Many contemporaries, from Baudelaire's poetry of alienation to Dreisen's novels of despair, projected individualism to radical extremes. Durkheim wrote of anomie and suicide, and Weber of harshly ascetic Protestant individualism.

Yet these big hypotheses, which seemed almost patently obvious when first stated, were surprizingly often not supported on careful investigation. The main surprize was discovering tight and powerful social relations among families and (selected) friends and new institutions in large cities. Close ties were not necessarily nearby; they might be miles or a phone call away; but they were often found when sociologists looked closely. This 'rediscovery of the primary group' emerged in ethnographic studies and later systematic surveys. Further, many rural residents reported considerable isolation and distrust, when studied closely. We are still unclear how much has changed, since more precise research emerged only at the end of the twentieth century (e.g. Fischer 1982). Thus it may be that some past small towns demonstrated greater interconnectedness and value consensus. Still as the range and depth of studies expand to include rural persons in Asia, Africa, and Latin America, reports are common of deep social conflicts and manipulations paralleling those in large urban areas. I have recently analyzed citizen reported trust in 34 countries, and found almost no differences by city size for towns from 2000 up to millions of residents. In just three countries do residents in the smallest towns report more trust. (In towns under 2000 inhabitants in the UK and China and under 10,000 in India, using the World Values Survey of 80,000 respondents. Item:

'Would you say that most people can be trusted or you can't be too careful in dealing with people.'

Most countries, like the US in Fisher's results, are more homogeneous. Still locations vary drastically in trust and social relations. Why, if not by community size?

Weak support for earlier hypotheses prompted new investigations. Most differ from the past by elaborating more precise intervening connections, like civic groups, but still use the community as a strategic research site to detail impacts of 'community context' like residents' educational level. Stressing context, as Abbott (1999) suggests, was a key element of Chicago urban sociology that continues today. We consider three illustrations of contextual variation in the next three sections. Transition from the first to the third illustrates the principle of hierarchy leveling.

2. *Citizenship and the Nation State*

T. H. Marshall identified 'citizenship' as a core concept linking citizens to the nation. He traced shifts in its meaning over two centuries. Every citizen of a nation has 'rights' which rose from minimal to extensive along with egalitarianism. The national welfare state is the agency largely responsible for implementing these rights, which extended employment guarantees, health care, retirement, and later, children and animal rights. As they grew, dependence on the locality paled.

Still national centralization varies substantially across countries. Napoleon declared it illegal for French citizens to meet publicly or to organize civic groups; Soviet Russia and Nazi Germany went further by making everyone a potential police informant, thus seeking to destroy social ties among all individuals. Some national leaders pursue such centralization to control dissent. But centralization springs from other sources: building on the social contract tradition, the philosopher John Rawls held that no thorough egalitarianism is possible unless all social ties are eliminated, including those in families.

This is an extreme form of the common criticism that community institutions preserve tradition, and should thus be weakened. In societies with authoritarian leaders and institutions, opposition groups often seek to level hierarchies through radical egalitarian programs. Many left, social democratic-type parties thus favored national control to level hierarchy and implement egalitarian citizenship in much of the twentieth century. Parallel arguments led most northern and eastern European countries to consolidate their small towns into 'metropolitan governments,' consciously eliminating traditional 'parish-based' loyalties. Following these and other centralizing policies, nation states generally rose in power, social responsibility, and budgets for the past two centuries, undermining local communities.

The strong nation legacy came under criticism in the last decades of the twentieth century, as people grew more affluent, educated, and sophisticated: they criticized national agencies for high costs, inefficiency, and non-responsiveness to citizens. Support for local autonomy thus rose. Globalization presses in the same direction: with more cross-national travel, communication, investment, and trade, the nation declines in its abilities to deliver 'egalitarian' welfare benefits, since ideal standards are less national and increasingly international 'Human rights' rises as a new standard. Yet the world is too large, as are regional entities like the European Union, to implement specifics. The net effect is thus to bolster regional and local entities. Still, why should they work?

3. *Searching for Democracy and Trust In Active Civic Groups*

An early critic of Napoleonic state centralization was Alexis de Tocqueville, whose *Democracy in America* in

the 1830s contrasted the French state-dependency of citizens with the rich array of American community associations. Local civic groups, linked to small and autonomous local governments, gave (ideally) all citizens the ability to participate meaningfully in decisions affecting them. Such experiences built networks of social relations and taught the values of participation, democracy, and trust in fellow citizens. Parallel ideas have been advanced in research on organizations, small groups, families, and socialization: more participation by all generates more social interaction among peers, and more social skills and trust. This is achieved better in small units, encouraging more focused exchange and meaningful social contacts. This has similarly led to analyzing specific types of intermediary groupings, from social classes to political parties, churches, and business groups.

Large literatures document these basic ideas in studies of different types of associations, causes and consequences of greater participation, citizen trust, and confidence in leaders. Over the twentieth century, many organizations shifted from the hierarchical and centralized to the smaller and more participatory. The community power literature from Floyd Hunter (1953) to Robert Dahl (1961) and beyond suggests a decline in the 'monolithic' city governance pattern which Hunter described in Atlanta. In contrast, Dahl documented a more participatory, 'pluralistic' decision-making process, where multiple participants combine and 'pyramid' their 'resources' which affects decisions in different 'issue areas' Dahl's quoted concepts highlighted freedom of choice and openness of leadership to popular initiatives. Some 160 studies were completed seeking to explore implications for Hunter vs. Dahl's concepts. Peter Rossi, Robert Crain and Terry Clark started national comparative research in 1967 with the Permanent Community Sample at the National Opinion Research Center, University of Chicago. The same US municipalities were resurveyed periodically to monitor change. These studies continue in the Fiscal Austerity and Urban Innovation (FAUI) Project, which by 2000 included surveys of over 10,000 communities in some 30 countries.

These comparative studies document support among citizens and leaders for more decentralized, egalitarian, participation by citizens the world over. *The New Political Culture* (Clark and Hoffmann-Martinot 1998) uses the FAUI data to chart the rise of new rules of the game for public decisions and building more active citizen-leader contacts via mechanisms like focused groups, block clubs, cable-TV coverage of local associations, and Internet groups. Putnam's (1993) related work documents clear differences across Italian communities, from hierarchical, state control in the South to Tocquevillian participation in the North. Fukukyama shows national differences in citizen trust to follow the pattern Tocqueville proposed: least in counties with national states that destroyed civic groups (France, Italy, former Soviet areas), more in countries with active civic groups (USA, Scandinavia).

Globalization forces have opened more hierarchically-organized societies to permit civic and political associations to emerge even if they oppose the national government. Ethnic separatist groups in Mexico, Yugoslavia, and former Soviet areas grew more active via intervention from international human rights associations, global media coverage of scandals, and international organizations like the UN and NATO. The global trend is toward the more decentralized, participatory patterns of culture, which rekindle local democracy and civic life.

4. *New Movements, Agendas, and Policies: Greening the World*

New Social Movements (NSMs) emerged in the 1970s to push new agendas: they championed ecology, feminism, peace, gay rights and other issues that 'old' groups and political parties ignored. The NSMs were initially less formally organized and often used confrontational tactics, sometimes even terrorism, generating the findings that those more organized and ready to use violence had more impact (Gamson 1975, 1990). More recent work stresses the 'political opportunity structure' accessible to social movements (McAdam D, McCarthy J D, Zald M N 1996) or the more general 'hierarchical leveling' propositions in Clark and Hoffmann-Martinot (1998). For instance in the 1970s in Italy even Communist and Socialist parties rejected the new issues; this encouraged radical tactics including marches and street violence. But as political parties and governments embraced many new social issues, the opportunity structure drastically shifted. Movement leaders then shifted from 'urban guerilla warfare' to participating in elections, lobbying, and advising governments. This expanded participation process encourages moderating demands.

In Europe, the national state and parties were the hierarchical 'establishment' opposed by NSMs. In the US, local business and political elites were more often targeted. The NSMs demanded more responsiveness to the environment and to more diverse lifestyles and ethnic concerns. From the 1970s to 2000, support grew for the new issues, but explaining why remains controversial. One interpretation in the US literature is that business elites redirect agendas toward growth (Logan and Molotch 1987). Similarly Stone (1989) held that leadership 'regimes' were slanted toward business. For Peterson (1981) competitive market capitalism forced all communities to pursue growth by lowering taxes and welfare-like benefits—or lose residents and jobs. Business dominance driving a 'pro-growth agenda' was commonly reported in the 1970s and 1980s, but by the 1990s the rise of new issues led to questioning past interpretations. Clark and Goetz

(1994) showed that 26 percent of US municipalities had anti-growth movements in the 1980s, which often had major impacts: on zoning, limits on size and number of new building, environmental impact hearings, historic preservation, and sensitivity to amenities like lakes. If green NSMs won, did business lose? Logan et al. (1997) reviewed 20 years of studies and found much less business impact than the growth machine hypothesis suggested. Similarly, Clark and Goetz found zero relations between business dominance and environmental policy, although business leaders did rank as powerful in many US cities. The resolution of this apparent paradox is that many business leaders do not promote growth, but support public agendas which vary across communities, reflecting local concerns.

Behind pressures from NSMs and organized groups lies the question of why such groups emerge? They are more common in localities with citizens more highly educated, reasonable affluent, who work in professional and technical occupations, where the media are powerful, and traditional parties, unions, and ethnic groups are weak (Clark and Hoffmann-Martinot 1998). Individuals with such characteristics similarly support new agendas, termed a new political culture or post-industrial politics, in more than 20 countries where detailed surveys are available (Clark and Rempel 1997). Inglehart (1997) has argued that such 'post-modern' values emerge more powerfully as income rises, since after material needs are met, then 'post-materialist' or post-modern concerns can be pursued, like democracy, a nicer environment, gay marriages, or abortion rights.

Note that most of these new agenda issues concern consumption and leisure more than work and jobs. Aesthetic and amenity concerns rise—like suburban sprawl, sports stadiums, and parks. These issues do not divide people into rich versus poor as did class politics and party politics for much of the twentieth century. Rather than national issues like Keynesian spending or income redistribution championed by past left versus right (national) political parties, the new agenda issues are led more by community civic groups. Indeed the largest US environmental organization, the Sierra Club, reported that its average member belonged to seven other environmental organizations, many local. Even in Japan, where NSMs and local communities are less salient, local ecology groups were nevertheless the driving force generating national air and water standards, reversing the normal centralization (Michio 1997). The agendas of community civic groups (including block clubs and neighborhood associations) are set more locally through more general participation, consciously contrasting with more hierarchical parties and unions—which alienate many younger activists. Voter turnout for elections organized by the classical national parties (which still control local candidate selection in most of the world) thus declined, while new issue-specific community associations mushroomed in the late twentieth century.

What about poor and minority groups? Some have shifted from the classic welfare/redistribution issues to embrace more civic and individual initiative, albeit more in the US than traditionally hierarchical societies (consistent with the leveling proposition). By 2000, Jesse Jackson, heir of Martin Luther King's movement, continued civil rights issues through classic marches and protests, but he added more speeches advocating self-help and hard work to rise economically and socially—even publishing a book in 2000 with his politically active son entitled *It's About the Money: How You Can Get Out of Debt, Build Wealth, and Achieve Your Financial Dreams*. Broadly analogous, some observers hold, are the dramatic spread of Protestant evangelism in Latin America and Asia, even China, based often on a strong self-help message.

Globalization heightens these trends, weakening traditional agendas and promoting the new issues in countries that might change slower without international contact. Local affiliates of NSMs like ecology groups drew tactics and policies from their international counterparts, via congresses, newsletters, and the Internet. Tourism and the media lead citizens to aspire to consumption standards based more on global than national standards. With the Cold War over, global markets increasingly replaced national states. Left political party leaders the world over often shifted from class and national issues to these new agendas. Presidents and Prime Ministers in the US, the UK, and Germany, illustrated this shift, as did many in Latin America and Asia, plus countless mayors. The new agenda thus spread globally, with slogans like 'think globally but act locally,' helping local communities re-emerge.

Community/Society: History of the Concept

Community and society are key concepts in sociology and political and historical philosophy. In antique Greece, community and society were kept together in one concept *χοινωνι'α*. The antique Greek political philosophy did not distinguish between the institutions of community and society. *χοινωνι'α* was translated into Latin as sometimes *societas*, sometimes *communitas* without clear distinction. The synonymity—and the ambiguity—continued with the oldest Christianity and the scholastic philosophy. In the eighteenth century the complexity of the conceptual field around the equivalent terms of community and society had increased and included communion, participation, joining, taking part, sharing, liaison, union, corporation, co-operative, friendship, brotherhood, fellowship, etc. During the nineteenth century community and society split up and became counterconcepts expressing social and institutional alternatives. The roots of this separation were already in the eighteenth century. Together with another, closely connected, couple of counterconcepts, state and society, they played a crucial role in the reflection and the theory building in social sciences with clear ideological and political implications.

With Thomas Hobbes and Baroch Spinoza in the seventeenth century nature disappears as explanation of human collectivity. With the exception of the family all forms of socialization and communalization (collegium, corporation, craft, parish, municipality, partnership, trading company, etc.) were secondary formations within a state federation (*civitas*, *res publica*) constituted through a social convention. Hobbes talked about 'systems of people, numbers of men joined in one interest, one business.' Instead of the concept of society understood as synonymous with community a new concept of society emerged based on a conventional meaning identical to that of the state in the modern sense of the word.

From the middle of the eighteenth century and increasingly from the 1850s society and the social were seen as taking shape between individuals or households and the political order. Almost all social thought during this period was preoccupied with conceptualizing the collective entities that emerged within the 'social' in order to describe and analyze their nature, stability, and ties of cohesion. Besides community and society, concepts like nation, class, and culture were suggested. Societies were seen as organized by division of labor and social interests, by class struggle, or by cultural-linguistic identity. This was the more general framework of the debate on community and society.

John Locke emphasized the transformation from the traditional view on social relationships, based on natural right, to the modern thought based on rationalism and positive law, and replacing Aristotle's teleological view with the functional idea of collective security. The emphasis on collective security should be seen in the context of the growing role of private property. This development, where in political philosophy society became the preferred concept, did not mean that community disappeared. With the exception for political economy, where 'community' was narrowed down to trade company, the definition of society as community remained in everyday language until the end of the eighteenth century. Immanuel Kant viewed society, in its context of being based on reason and conventions among individuals, as a dynamic totality, the elements of which acted with and against one another. The 'unsocial sociality' (*ungesellige Geselligkeit*) of humans drove them to form societies. However, this drive towards convention-based collectivity provoked resistance, and the threat of the dissolution of the society was permanent. Kant's view was in this respect close to the school of English-Scottish moral philosophers (Adam Smith, David Hume, and Adam Ferguson).

Kant's question about a perfect society based on the free interaction among individuals was taken up by Johann Gottlieb Fichte at the beginning of the nineteenth century and put into a historical and linguistic-critical context. Although Fichte often used society and community as synonymous terms, he exposed the two concepts, and that of state, to linguistical-critical scrutiny observing the prevailing conceptual confusion.

As far as the German-speaking area is concerned, around 1800 Johann Gottfried Herder suggested a distinction between community and society. His point

of departure was the state-society connection, where 'state' emphasized the unity and closure of the collectivity, while 'society' had a focus on the multiple and open forms of collectivity including those based on the individual rights. In order to describe the relationship between state and church, Herder used society, based on Enlightenment reflection on the contextuality and historicity of religious forms. In order to emancipate the spirit and the mind, the *Geist*, from its entanglement with the state, and to rediscover the suprahistorical core of Christianity, Herder required the separation of society and community, *Gesellschaft* and *Gemeinschaft*, where the latter term was used to describe the community of spirits independent of the state. Herder's distinction, which again took up the old Greek and Biblical-Christian *χοινωνί'α* concept and infused it with new meaning, failed however to go beyond a specific religious vocabulary.

Kant's moral philosophy provoked criticism from G. W. F. Hegel, who rejected the idea of the autonomous individual. In Hegel's view the individual is certainly rational, although rationality is historical and trans-individual. The normative and legal order of a society could not have its point of departure in the idea of its individuals as *a priori* free, equal, and rational. Humans are free only within a strong moral community. Society is not based on convention but on moral. Such is Hegel's view. The human effort to be recognized as an individual results in the emergence of various communities, which are kept together by strong moral virtues, *Sittlichkeit*. The social community was linked to an ethical dimension, which, according to Hegel, appeared in various shapes through history, which was nothing but the development towards higher forms of ethical realization. The highest stage in this historical development was the state, which gave all its citizens true freedom through the confirmation and recognition of them in a meaningful totality. The individual is emancipated through subordination in the collective realization of *Sittlichkeit*.

From this condensed rational-romantic version of community, inspiration could a century later be picked up in Germany for extreme versions of the concept, where it was linked to the *Volk* ('people') concept and political action orientation. The difference between the individualistically oriented Kant and the collectivistic view of Hegel is not restricted to German history but is however more general and has been discernible in two alternative world views on community and society ever since. In the years around 2000 these alternatives are expressed in the debate between liberals and communitarians.

Emile Durkheim (1933 [1893]) developed Hegel's key question about the moral basis of modern societies in new directions. 'Modern society' is henceforth understood in terms of industrialization, division of labor, and democratization, processes that only had just begun when Hegel reflected on society, but were much more evident for Durkheim. His key question dealt with social solidarity, and how to bridge the distance between the state and the individual. The point of departure for Durkheim when he posed this question was the debate about the nature of the moral and political sciences. He was unsatisfied with the speculative character of political philosophy. He was convinced neither by the individualistic and utilitaristic approach developed by Kant or in the classical political economy, nor by Hegel's holistic enlightenment-romantic and mystical view on community, where the societies had goals, which were above and beyond those of the individuals. Durkheim looked in his positivist and empiricist approach for a position between Kant and Hegel for a society that was rather different than theirs. This debate was the very foundational moment of the social sciences in the contemporary sense.

Durkheim emphasizes the role of religion in premodern societies, in which, beyond the family, no other functionally cohesive institution other than religion existed. Religion provided 'mechanical solidarity,' which functioned as a social cement. This mechanical solidarity can be related to Hobbes's understanding of society (and nature) as clockwork. Post-Renaissance rationalism in the shape of Hobbes and others takes on new meaning when in the second half of the nineteenth century it was faced with a truly mechanical universe, i.e., the advances of physics, the division of labor, automized production, etc. In modern societies the division of labor changed the preconditions for social cohesion. A need for coordination of functional relationships emerged. The societies became ever more complex with growing divergence among individuals in their social orientation. Their interpretations of the world did not necessarily converge towards one collective will. The state was the only instrument for collective action when societies had developed a certain degree of complexity. Through the state organism reflexive thinking emerged. The 'stratification' of the ethnic nation was the modern beginning of this reflexivity, tearing the individual between instrumental-rational forms of belonging, and the organic, cultural, and social bonds. With this kind of reflection in the wake of the growing social division of labor organic solidarity arose alongside mechanical solidarity.

Durkheim problematizes the mediation between the individual and the society. The political philosophy of Enlightenment focused on concepts like people's sovereignty and political representation and on the issue of the institutional distribution of power. With intensified industrialization, capital concentration, the rise of the labor movement, and ideas of universal suffrage, the theoretical framework provided by the Enlightenment philosophers became insufficient. New forms of relationships between the individual and the state levels had to be developed. In this context

Durkheim evokes the notion of secondary institutions and develops ideas about what kind of organizational forms would fit an industrial society.

Taking his theoretical point of departure in his idea of division of labor as the basic principle of modern societies, he suggests interest-based representation through corporations rather than territory-based political representation. The corporations would reflect modern professions rather than traditional crafts and estates. In his functionalist approach Durkheim developed a moral theory in which he paid relatively little attention to questions of power and authority structures and social inequality. However his view on moral based on corporate representation and related to his idea of solidarity indicated the social question. The political function of the secondary institutions was both to keep the state sufficiently free from influences from the masses, so that the state could fulfil its role as the shaper of the society, and to protect the individuals from oppression by the state.

Hegel's problematization of the leading idea in moral philosophy and political economy, that society was based on the individuals and their agreement on conventions, constituted in the German-speaking area a step in the development from the traditional to the critical theory of society. The critical social theory, which emerged in particular in Germany around 1850, introduced new basic concepts and distinguished between society and community, between society and state, and between *bürgerliche* (the German term connotes in English translation both 'bourgeois' and 'civil') society and society. This critical social theory must be seen in the context of the social revolutionary movement, which emerged in the nineteenth century. This movement could be seen as a response to the crisis, which since the French Revolution, and with the industrial revolution, marked the everyday experiences in Europe and gradually also beyond Europe. Critical theory was an alternative reflection on society and community with respect to Durkheim's, based on ideas of functional differentiation and division of labor.

Politically the most long-term important element of critical theory was the conceptualization of a social history, or history of society, *Gesellschaftsgeschichte*, inscribed in the framework of the social sciences, by Karl Marx and Friedrich Engels. In their historical materialism, and in their emphasis on the political role of the proletariat, they depreciated the concept of society ('bourgeois'). They re-evaluated the community concept with its derivative communism, where socialism, with the same etymological origin as society, was seen as a transitional phase towards communism, the final stage, where history ceased. Marx and Engels criticized the view of society in earlier French and British social history, where society was seen as a set of mutual interactions. They criticized this view of society as being a society of exchange in which every member was a merchant. The society Marx and Engels discerned was societies in plural, where each of them was determined by the specific ways in which the production was organized. In each type of society specific power relationships prevailed. They followed one another in historical phases: the original society ('*Urgesellschaft*'), slave society, feudal society, bourgeois or capitalist society, socialist society, and communist community, where the merger into the old Greek *χοινωνι'α* was fulfilled in a new action- and future-oriented utopia.

A few years after the death of Karl Marx and after ever stronger experiences of industrial change and economic concentration, Ferdinand Tönnies (1887), analyzed quite differently, but still with a utopian embedding of the community concept, the connection between *Gemeinschaft* and *Gesellschaft*. In his view community took on a social romantic meaning connoting an archaic past based on the family and providing feelings of holism. His utopia was projected towards the past instead of the future. Society was the term used to describe the breaking-up of this past through industrialization, social disintegration, and experiences of atomism. Tönnies saw communism as a cultural system of community and socialism as the cultural system of society, i.e., communism was rather referred to as a historical or even archaic category, a kind of prototype, while socialism reflected the industrial society.

Tönnies' subordination of society to community had long-term political impact. Community was, in his view, in all sociological conceptualizations the superior and in all historical analyses the anterior concept. Community was the dialectical womb from which society arose in historical processes. The concept of society described the law-bound normal process of the decline of all community. The same process that Marx and Engels—in accordance with Hegel's idealistic philosophy and their critical-normative prognosis, where society became community—described as emancipation and a development towards higher stages of social organization, Tönnies analyzed as decay, as inexorable as the coming communism in the view of Marx and Engels. The only future hope that Tönnies could discern was weak: that the force of the community also within the era of society would remain although it was declining. The community could be promoted through the cooperative movement and through the union and solidarity idea in the labor movement.

Although Tönnies' concept of society includes the totality of the relationships among the individuals mediated through exchange, and in this respect can be historically situated, this historical location involves conceptual distinctions which cannot be justified either in genetic or in linguistic-critical terms. Both Max Weber and Georg Simmel observed this inconsistency and tried to solve it through a paradigmatic change of the sociological terminology. To consider social institutions like state, church, cooperative (*Genos-*

senschaft) as independent entities preceding the individual and attach them to a general society concept was in Weber's view a metaphysic residual, which needed to be overcome. He replaced society as a basic sociological concept with the term *Vergesellschaftung*, 'societalization,' an extremely general concept containing all forms of rationally motivated interest relationships under one umbrella concept. The generalization of the sociological conceptual framework around the term *Vergesellschaftung* certainly described processes and social change, but was basically a historical, where the analysis of the development was deprived of historical contextualization. Historical contexts were understood as 'cultural tragedy' (Simmel) or 'destiny of the rationalization of society through science' (Weber). The process of dehistorization of the concept of society that Tönnies began and Weber continued with his criticism of Tönnies had the effect of drawing growing attention to the community concept. *Gemeinschaft*, which can be seen as a kind of pseudo-historization, became topical. With the introduction of the concept of community in this way the sociological theory in Germany unintentionally opened up for the reactionary opposition against the industrial society. While in other European languages society and community remained synonymous concepts, *Gemeinschaft* became in Germany an ideological key concept connected to another highly ideologized crucial concept: the *Volk*. The ideological entanglement of the two concepts became a national-conservative instrument to mobilize the *völkische* movement after World War I against socialism, capitalism, and industrialism.

The cult and the dogmatization of the *Gemeinschaft* concept were also confirmed in German philosophy at this time. Max Scheler identified community as a person *sui generis*, 'a person of persons' as opposed to society, which was nothing but the sum of its individuals. He thus reinforced Tönnies' distinction. Community was based on blood, tradition, and historicity, while society was the waste product of internal disintegrative processes in the community. Society was synonymous with public, which continuously removed—Marx would have said alienated—the individual. Community was synonymous with personal solidarity, which reintegrated the individual.

Already before World War II, Talcott Parsons (1937) developed a view where community and society were seen as key concepts in structural-functional alternatives of value orientation, 'pattern variables': affectivity vs. affective neutrality, particularity vs. universalism, ascription vs. achievement, diffuseness vs. specificity. His approach was one, where, like in the German debate, the two concepts were separated, but for the rest his contribution was very different from the German debate.

In the 1950s René König (1955) was one of the leading figures in the reconstruction of the German sociology. He argued vehemently against Tönnies' dichotomy and use of the *Gemeinschaft* concept. He argued for an empirically oriented sociology with the American functionalism, where Talcott Parsons was a leading figure, as a source of inspiration, and warned against any attempt to conceptualize society as a totality, which only lead to speculation and dogmatism. Community in the German form of *Gemeinschaft* was in the 1950s rejected from the political and sociological vocabulary and society emerged instead in the 1960s as the key concept to describe and analyze the social organization.

At the same time as König in Germany warned against the *Gemeinschaft* concept community became the name of the European integration project in the 1950s. One of the key problems when this project was formulated was how to make Germany a strong ally in the Cold War and at the same time guarantee that the strength was controllable for its allies. The main architects of this design came from France, where the concern about the key problem for historical reasons was particularly great. There, *communauté*, for historical reasons, in the 1950s had a much more positive value charge than *Gemeinschaft* in Germany. In the form of the European Community in German translation, *Gemeinschaft* came back in as a political concept, which guaranteed the German incorporation in the West European Alliance in the Cold War, and which, therefore, was disconnected from its historical heritage in the German speech-area. When the European integration in the 1970s was exposed to strains, the idea of a European identity emerged connected to ideas of a supranational Europe. This intensification of the European Community concept was emphasized in the 1990s when community was changed for union. This European development can be understood as part of a modernization theory which is resurfacing with a communitarian twist, where culture is constructed around the idea of a community as a homogeneous discourse that somehow provides the glue to bind societies together. Such a theory of social integration, which takes for granted that cultural cohesion exists for national societies, and then simply transfers the idea of state-formation onto a supranational European level, built around the concept of European identity, echoes somehow Ferdinand Tönnies' idea of a sociopsychological community. After the Cold War the European Union is searching for new meaning and legitimization replacing the original rationale behind its foundation. This search is reflected on the conceptual level, where established concepts like community lose meaning and/or are charged with new content. Society seems in this respect to have become more stable and less ideologized.

The general theoretical framework of this discourse on European unity is the debate between libertarians and communitarians in social sciences since the 1970s, which debate, in turn, in a long historical view could be seen as continuity under transformation of the

bicentenary debate between Kantians and Hegelians. A point of departure for this theoretical debate was John Rawls's *A Theory of Justice* (1971). Erected in the tradition of contract theories and Kantian liberalism his theory bypassed the questions of political obligation and the welfare state through the idea of distributive rights in individualist terms. Utilitarian philosophers objected but in the long term the most substantive opposition to the neo-Kantian approach emerged from the 'communitarians.' The debate between the liberals and the communitarians became one of the most important issues in political philosophy in the 1980s. Methodologically the communitarians argued that the premise of individualism such as the idea of free and rational choice is wrong or biased and neglects the social, cultural, and historical contexts in which individuals act. In order to understand individuals one must look at their communities and communal relationships. In normative sense the communitarians argued that the premises of individualism give rise to morally unsatisfactory consequences. A. MacIntyre in *After Virtue* (1984) questioned the fundamental philosophical assumptions of liberalism. He and others questioned the claim of the priority of the right over the good and the image of the freely choosing individual. Political arrangements can not be justified without reference to common purposes. Freedom flourished within social interdependence not among free-floating individuals. However, the kind of community the communitarians drafted was one that often focused on the family, the tribe, or the neighborhood rather than on the nation, the state, or the class. The communitarian community is more than a mere association; it is a unity in which the individuals are members not in artificial or instrumental terms, but within its own intrinsic value. This is a view with similarities to Hegel's *Sittlichkeit* idea.

In the debate communitarianism has been dismissed both as little more than a corrective to the excesses of liberalism and as a form of old-fashioned collectivism. In the framework of the former view approaches have emerged, which can be described as a merger between liberalism and communitarianism. Michael Walzer sees communitarian thought as a permanently recurring corrective to liberalism (1983). Charles Taylor (1989) is another leading name in this approach. The trend at the end of the 1990s was that the divide that once seemed to separate communitarian and liberal theories began to close. Taylor and Walzer are often referred to as liberal communitarians. The theoretical debate has moved from the thick communitarian critique of thin liberalism to positions that combine elements of both. This trend has been nurtured not least from legal theory where a strong recent 'republican' turn aspires to hold both communitarian ideals and democratic participation together. The law is seen as sustaining community and promoting the common good to be negotiated through participation in a polity where liberal rights guarantee that the bargaining is uncoerced. Also the globalization discourse on the emergence of a globally rather than nationally organized economic order promoted the trend of closure between liberalism and communitarianism. The attempts to re-establish community, experienced as being lost to transnational globally operating forces, resulted in liberal politics of recognition of cultural alternatives in the name of multiculturalism.

Community has in this merger with liberal ideas been linked to the concept of citizenship, which borne in the French Revolution became a political key concept in the 1980s and 1990s. This linkage of community and citizenship is a dominant element not only of political and legal theory but of much current political debate as well, where both the Left and the Right try to establish positions of strength through various views, which emphasize both community and citizenship. This development is embedded in a broader theoretical and political reflection in the same direction around concepts like collective identity, network, trust, and social capital since the 1970s where the emphasis is on the historical emergence of reciprocal reliance among citizens. This trend around 2000 can be seen as attempts to establish a new merger between community and society from points of departure, which emphasize the role of the individual and plays down that of the state. Society is emphasized as civil society (in opposition to the state). The individual rather than the state has become the counter concept of society resulting in a migration of the society concept in the direction of the community concept, although this community concept is linked not only to the nation state but increasingly also to trans- and subnational levels of social and political organization.

Community Sociology

1. The Term Community

There are many meanings and uses of the term 'community.' Some have explored the implications of creating a 'global community' with governance based on human tolerance and understanding (The Commission on Global Governance 1995). Others have viewed economic 'communities' that promote national and corporate interests. A growing body of literature on rural communities, along with the International Rural Sociology Association, reflects the interests of researchers covering a range of educational, environmental, and social themes in developed and developing nations. However, this entry covers urban research concerning 'community' because such a selective approach enables a sharper thematic focus than would otherwise be possible with an all-encompassing survey of the wider research.

Today, contending theoretical perspectives complicate the task of arriving at a clear understanding of communities. Because the concept of 'community' is open to wide interpretation, it is frequently used as a term connected to urban citizenship (Lowndes 1995) or as a reference point in complex discourses about identity, place, and social meaning. For example, ethnic, racial, and gender affinities between groups may be regarded as aspects of 'community identity,' but these take on complex forms within the context of a wider range of cultural and social class affinities (Solomos 1993). Similarly, reference to geographic or 'place-based communities' implies the existence of groups with territorial interests or associations or communities based on formal local government boundaries, but place often plays only a small or even nonexistent part in locating 'community identity'. It is possible for individuals or groups to identify with others with whom they share particular attributes even though only vague geographical markers refer to a perceived 'community.'

Therefore, the diverse relationships between place and identity make theoretical conceptions of community highly contingent, especially when account is taken of global capital operating across national and local boundaries. Multifaceted economic and social change has challenged the basis of traditional social arrangements and attitudes (Soja 1996) and undermined old theoretical certainties and disciplinary boundaries in the discussion of place and identity (Allen et al. 1998) and in broader urban theory (Fainstein and Campbell 1996). The relationship between 'the local' and 'the global' is also more problematic as transnational corporations 'embed' their operations in localities and regions (Amin and Thrift 1994, Amin 1994) making it possible to define influential networks of corporations (Friedland 1982) and partnerships involving public and private sector groups. Elite groups are often seen as representing social class interests (Scott 1997) rather than more narrowly defined community interests. The question remains however, that despite profound social and economic changes is it still plausible to assume, as Etzioni (1993) does, that local communities can represent an alternative to radical individualism by providing individuals with a sense of purpose and a moral framework within which citizens can prosper?

2. Diverse Perspectives

This question is not new, and it relates to the basis of communities and social cooperation within them. Urban sociologists of the Chicago School in the 1920s and 1930s concentrated on the 'human ecology' of urban life and the social relationships and forms of organization in the metropolis. Robert Park, influenced by Georg Simmel and Émile Durkheim, presented a complex view of neighborhood organization where co-operation and competition underlay relationships between groups. The resulting tensions undermined social control, but communities achieved order through social specialization and interdependence. Later, Park (1952) emphasized the inherent 'biotic' competitiveness of urban life and the struggle to control scarce resources. Other Chicago School sociologists referred to human struggle within cities and the consequent adaptation of social organization to external environmental change. For example, Louis Wirth (1938) argued that cities represented the agglomeration of human activity, and that the social specialization of cities led to complex patterns of social segregation. Despite recognizing the coming together of groups with shared identities, Wirth stressed the superficiality of social relations and the resulting social psychology of urban life where class and ethnic affinities were less important than social heterogeneity. For Wirth, cities were large and impersonal, and divisions arose between people producing different ways of life that made true consensus and stable community life difficult to achieve (see Reiss 1964).

Wirth remained influential after World War II, but sociologists outside the human ecology tradition argued that the urban experience could be socially defined better by reference to the forces transforming traditional social class and community relationships. In the UK, Young and Willmot (1957) discovered strong working class community and family identities in the East End of London that contrasted with new housing projects where relationships were less intimate and not so cohesive. In the USA, Gans (1962) studied Boston's West End where a multiethnic 'urban village' had developed with a rich variety of social and political institutions.

Political scientist Robert Dahl (1961) provided the classic pluralist interpretation of local politics in a study of New Haven, CT, USA. There, 'polyarchy' represented the rule of the many where power was unequally distributed, but where groups could influence crucial local political decisions. However, elite theorists, disagreeing with pluralism, engaged in the 'community power debate' by arguing that local power-holders dominated the policy process by excluding many local community groups. The pluralist perspective was further questioned as social unrest affected big American cities and class conflicts and social exclusion defined the condition of large, disadvantaged cities. Urban riots in the 1960s, the expansion of militant community politics, and the rise of the black power movement highlighted an urban crisis while public policy shifted to favor public spending on aid programs for run-down communities. But, political scientist Edward Banfield (1970) provided a classic critique of government urban policies through controversial research that highlighted cultural trends in *The Unheavenly City* that undermined stable and cohesive urban communities.

Against the backdrop of the 'urban crisis,' research increasingly focused on race, social disadvantage, and the inaccessibility of local bureaucracies. Rex and Moore (1967) adopted a neo-Weberian approach viewing ethnic minority access to housing in the city of Nottingham, UK, where peoples' goals were influenced by the interaction of social and spatial conditions. Pahl (1975), also from a neo-Weberian perspective, regarded urban state bureaucracy as a mechanism restricting the access of local people to urban services.

There was also attention to broader urban processes. Gottdiener (1994a, 1994b) refers to the 'New Urban Sociology' in the 1970s and 1980s that integrated the analysis of social class, gender, cultural, economic and political change by building upon the work of neo-Marxist writers such as Castells (1977) and Harvey (1973). Castells studied the functions of cities and the role of social classes in the reproduction of capitalism. His early work was conducted at a time when the welfare state had expanded under capitalism. For Castells, local communities economically contributed to capitalist reproduction, so cities and regions were spaces supporting economic production as well as social organization.

Despite such contributions, the opposition to extensive state involvement in community development from the new right was echoed in research focused on the social problems of cities allegedly caused by government failure. Charles Murray's (1984) controversial notion of the 'underclass' identified the long-term plight of a growing 'underclass' of permanently welfare-dependent people in deprived urban communities. Community empowerment came high on the new right political agenda in the USA as an alternative to welfare dependency and government-funded solutions to urban problems. Conservatives argued that empowered communities could become more self-sufficient and better able to increase their capacities to make changes for themselves through free enterprise and local initiative.

3. Contested Boundaries

During the 1980s and 1990s, urban sociologists continued to draw on different paradigms and develop cross-disciplinary themes. The diversity of papers presented to panels organized for the Community Research Committee at the 1998 World Congress of Sociology illustrates the interdisciplinary interests of

urban and community researchers. The panels displayed the varied perspectives of sociologists, political scientists, policy analysts, geographers, and others. Contributions reflected the contested boundaries between disciplines and the broad horizons of researchers variously concerned with the relationships between social groups, local communities, post industrialism, post modernity, and globalization. Contemporary research has thus generated new insights into the spatial dimensions of urban change and the complexities of the issues confronting local communities.

Many sociologists, geographers, and political scientists argued that global social and economic change, multinational corporations, and financial institutions substantially influenced the urban agenda and the fate of local communities. Innovative research provided fresh and controversial perspectives on the changes affecting the global, regional, and local communities (e.g., Castells 1996, Soja 1996). Tensions arising from the expansion of local global capital and the defense by groups of local interests underscore the profound changes affecting communities. Local communities confront major changes as corporations pursue new strategies, regional economies restructure, and traditional social relations breakdown. In the new information economy, old certainties no longer hold. With economic reordering, there are social and political changes. Some see communities linking to governing corporate-dominated 'urban regimes' (Stone 1989). Others identify 'growth machines' (Logan and Molotch 1987, Ferman 1996). There have also been social dislocation, increased ethnic and racial competition, and discrimination against minorities. The notion of stable and harmonious neighborhoods is questioned as economic and social change fractures traditional communities and generates new urban problems and patterns of social intercourse. Studies of social disorder and urban riots, as in Los Angeles in 1992 (Baladassare 1994), illustrate the racial and ethnic cleavages that can result from rapid urban restructuring. Communal divisions often eclipse class solidarity, especially when groups compete for scarce resources and attempt to access urban services. Indeed, the 'community' is threatened as social change undermines consensus and stability. Political scientist, Robert Putnam (2000) argues that there is a decline in social capital in modern communities in the USA. Putnam argues that social capital, represented as the networks, norms, and trust in communities that help people to work for shared objectives, is in decline despite the efforts of governments and community leaders to increase the active participation of people in civic affairs.

4. *The New Political Culture*

An important theme in recent Community Research panels at the World Congress of Sociology has been the emergence of a new political culture (NPC). The NPC views political fragmentation against a background of fundamental social change affecting urban communities worldwide. According to sociologist Terry Nichols Clark and political scientist Vincent Hoffmann-Martinot (1998), the NPC increases the salience of issues such as the environment, citizen democracy, gay rights, abortion, and lifestyle politics. The politics of post industrialism places less emphasis on class and workplace politics and greater stress on single issues championed by diverse groups within a complex and changing sociopolitical environment. The NPC challenges traditional political parties and old state hierarchies and undermines the assumptions of the post war welfare state. People are more skeptical about large public bureaucracies and likely to support human-focused policies, smaller and more localized government units, and more responsive forms of local democracy. The NPC emerges 'more fully and forcefully in cities and countries with more highly educated citizens, higher incomes, and high-tech service occupations' (Clark and Hoffmann-Martinot 1998, p. 3). This marks a change in the ways local communities articulate social and political demands. Local groups are more likely to organize across social class lines as they adopt new methods of social and political action. Information technology opens new horizons and provides opportunities for more effective networking and communication.

5. *Networked Communities*

Technological change therefore produces new patterns of social life. In his later work, Castells combines an analysis of the global and local effects of information technology through the rise of a 'network society.' Castells, acknowledging Howard Rheingold (1993), argues that new information technologies integrate the world through global networks and a 'vast array of virtual communities' (Castells 1996, p. 22) that network groups and individuals by way of 'politics and religion to sex and research.' The Internet and 'electronics grass-roots culture' (Castells 1996, p. 354) enables individuals to interact globally and interactively, but also privately. For Castells, a new globalized and customized mass media permeates all levels of society directly affecting the local community and the individual.

Together with technological networks, social and inter-organizational policy networks influence local life and community organization. Social network analysis originated in social psychology and extended to sociology. White (1963) and Fischer (1982) developed social interaction models showing how networking influenced local social organization. Sustained sociological interest in the influence of complex networks in local communities (Scott 1991) accompanied interest in the role of networks in political

systems (Dowding 1995). Political scientists have argued that the collaboration of various well-organized corporate groups in local networks, together with public–private partnerships, help to bring about government policies favorable to those groups, sometimes with little local community involvement. Influential groups gain access to decision-makers and thereby manage to raise crucial issues up the political agendas of local governments.

6. *Communitarianism*

Studies of technological change, globalization, political networking, social capital, and the NPC all imply discontinuity and uncertainty in the development of local communities despite the different theoretical approaches adopted. Etzioni (1993), and a group of like-minded communiterians, have responded to the impersonal forces of globalization, social dislocation, and the undermining of community and family values by calling for a new 'moral, social, public order.' They seek a stronger sense of community to counter what they regard as a threat to the moral underpinnings of community life. Etzioni argues for a reassertion of community values by creating a new 'spirit of community' through rights and responsibilities that strengthen the moral foundations of society. Following the publication of the journal *The Responsive Community: Rights and Responsibilities*, the group advocated an alternative to market individualism by fostering values favoring mutual support and the family.

Community Studies: Anthropological

The terms community and community studies in anthropology have two main denotations. One is generic, echoing the interest anthropology and anthropologists have always had in ordinary, stable, small-scale localized collectives. The other pertains to studies of rural populations (e.g., villages, parishes, counties) and urban enclaves (e.g., neighborhoods and quarters) within industrialized, developed Western countries.

1. *The Concept of Community in the Social Sciences*

Community, one of the most ubiquitous and imprecise terms in the social sciences, is usually associated with an array of positive connotations such as solidarity, familiarity, unity of purpose, interest, and identity. Earlier sociological debates of communities and their social significance stressed either a territorial base, i.e., groups whose members share a well-defined location (see Hawley 1950), or, later, community as state of mind—a collective sharing of an underlying feeling of sameness and belonging regardless of geographical dispersion (see Bell and Newby 1974). The latter option, while analytically promising and intellectually suggestive, produces a perplexing category. Since affiliation and identification with nonterritorial communities can be unclear even to the actors themselves—let alone to social scientists attempting to characterize and study them—the concept can often be used and interpreted as an omnibus for a variety of intended and unintended meanings.

Not surprisingly, some sociological attention was given to the distinctions between the informal nature of communities and the more rigid structure of organizations (Gottshalk 1975, Azarya 1984) as well as to the problem of indeterminacy of community boundaries (Hillery 1955). These notwithstanding, community studies emerged since the 1920s and well into the 1980s as a solid branch of sociological inquiry, not least through the consistent preoccupation of the Chicago school with modernization and its impacts on urban culture, subcultures, and urban society.

2. *Community (Re)Enters Anthropology*

Anthropology, with its early emphasis on intensive field study focusing on small-scale groups, whereby culture and society were assumed to be unproblematically linked to bounded space, had an inherent affinity with the view of communities as bounded territorial units. This may explain why the concept of community was not explored by anthropologists in earnest, receiving little explicit analytical and theoretical attention prior to the 1980s. Habitually working with bounded communities, anthropologists tended to develop context-specific tools for their analysis. Early emphasis on customs and manners, the subsequent emergence of the concept of culture, the paradigms of structural functionalism, transactionalism, symbolic interaction and structuralism *à la* Lévi-Strauss all offered, in their respective heydays, rich and convincing frameworks for studies of small-scale bounded groups.

Thus, while the term community was always present in the anthropological lexicon, its syntactic status tended to be relegated to noun or synonym. It remained a finite, noninterpretative idiom and was arrested from becoming a dynamic theoretical tenet. In short, engulfed in 'native' ways of explaining solidarity and social relations, and taken by the concept of an immutable culture occupying an ethnographic present, anthropologists had little use for the community. And while Lynd and Lynd's classic study of Muncie (eternalized as *Middletown* in Lynd and Lynd 1929), Lloyd Warner's Yankee City volumes (Warner and Lunt 1941, Warner and Low 1947) and Arensberg's work on the relationship between community and culture (see Arensberg and Kimball 1965) undoubtedly inspired ethnographically oriented studies such as Robert Redfield's *The Little Community* (1955), Marriott's edited volume on villages in India (Marriott 1955) or Frankenberg's *Communities in Britain* (1965), a strong and clear anthropological tradition of community studies was slow to materialize.

Two factors may have contributed to the emerging interest of anthropologists in the 1980s in the community as an analytical and theoretical category. One was the aforementioned emergence in the 1960s and 1970s within sociology of the view of the community as a more abstract entity, whereby meaning and a sense of solidarity became more salient than tangible physical contact. The other was a growing need amongst anthropologists, by then more willing than ever before to study societies and cultures in the core and on the margins of Europe, to develop a theoretical toolbox for this new challenge.

An edited volume and an ethnography by Anthony Cohen (1982, 1985) indicated the efficacy of the concept of community for a more sophisticated understanding of the relationship between local rural and urban communities and wider affiliations and identity,

not least the ones connected to the nation state. The edited volume (Cohen 1982) had six anthropologists writing two essays each about rural communities in Britain. One essay was incorporated into a section of the book entitled 'Belonging to the Part: Social Association within the Locality,' while the other was included in a section called 'Belonging to the Whole: The Community in Context.' The sections corresponded to the dual theme of the inquiry: how people develop a sense of belonging in a small community; and how they develop an identification and a set of practices that reflect their sense of place in the broader realm that lies beyond the local. The first theme naturally focuses on kinship, sect, regional histories, and affiliations. The second theme, pursued in Cohen's subsequent work, leads to a growing preoccupation with cultural boundaries and borders.

In terms of theory and analysis, the ethnographic attention paid by Cohen and his contributors to (mainly Celtic) rural Britain owes much to Clifford Geertz's emphasis on meaning and cultural interpretation. The community, according to Cohen's introduction to the volume, must be studied and interpreted not so much as a structured social organization but as an arena where experience is ordered, partly through a 'local' culture. This in turn produces a distinct local identity which is engaged in constant interplay with broader cultural formations, processes, and signals. Cohen's volume thus signposted a new field of inquiry, the form and theoretical approach of which were different from those of the adjoining anthropological arena of peasant studies, the latter focusing mainly on rural communities in semiperipheral areas, including the margins of Europe and Latin America.

The importance attributed by Cohen to meaning and imagination, and the Wittgensteinian supremacy he advocates of context of use over lexical occurrence, becomes even clearer in *The Symbolic Construction of Community* (Cohen 1985). Simple people too, he shows, are preoccupied with symbols, constantly using them to make comparisons (and sense) of appearance and reality, likeness and diversity, similiarity and difference. Once more, social structure collapses at the feet of culture, subverting the monopoly of sociology over the concept of community. Significantly, more emphasis than ever before was now directed at the borders. Writers came to recognize that it is near boundaries, and across them, that community culture and identity were being determined.

Community studies reduce methodological, analytical, and theoretical differences between anthropology and sociology. Conrad Arensberg's works of the 1950s and 1960s are by no means wholly sociological, and the same is true for Maurice Stein's *The Eclipse of Community* (Stein 1960). By the same token, the strongly ethnographic turn of Warner's *Yankee City* volumes, West's *Plainville* (West 1961) or the Lynds' *Middletown* (Lynd and Lynd 1929) probably warrant counting them as anthropological, while the preoccupation displayed by Cohen (1982, 1985), Frankenberg (1965) and Hannerz (1980) with broad sociological issues merit labeling their works at least partly sociological.

Some writers have alluded to an obvious shortcoming of anthropological (and, for that matter, sociological) studies of communities—their propensity to be a-political. Rich in analyses of inherent traits and characteristics, such studies lend themselves willingly to elaborate treatments of culture, cultural identity, and demarcation. This, however, can often serve as a cover for shying away from and even blindfolding themselves to issues of internal and external power disparities, political economy, and historicity (cf. Aronoff 1984, Cox 1987).

A strength that anthropological studies of communities have had, at least since the 1980s, has been their emphasis on abstract experiences, not least imagination, as idioms shaping human identity and agency. Major inspiration for this project undoubtedly came from Benedict Anderson's work, not least from his creative employment of this notion in his seminal work on nationalism, *Imagined Communities* (Anderson 1983). The focus on imagination resurfaced later in attempts to explore new ways in which anthropology could tackle the paradoxes and complexities of transnational experience and culture.

3. *Critical Anthropology and the Concept of Community*

Like 'ethnography,' 'the ethnographic present,' 'fieldwork,' 'informants,' and other key anthropological idioms, 'community' became, in the 1990s, a construct. Idealized as a composite, unproblematized pillar of old guard anthropology, it could now serve as a hammering block against which critical ideas could be articulated.

Malkki (1997) looks at the connection between the concept of community and anthropology's propensity to look for the ordinary, durable, 'everyday' routines and practices. This approach, which gained anthropology justified rewards and insights, gradually bred an expectation that all people studied by ethnographers are not just haphazard collections of humans somehow thrown together into the same location. Rather, they were expected to have always been part of a stable, permanent and—in particular—localized 'community.' But while such groups do of course exist, the emphasis on communities pushed anthropologists to overlook other possibilities, including those where life does create transient collections of humans randomly united. Such, Malkki (1997, p. 91) indicates, are what Barbara Myerhoff called *accidental communities*—Woodstock 1968 being a dramatic instance—and what Malkki herself found in refugee camps in Rwanda, where displaced people from a

variety of places of origin huddled together, reinventing a sense of communal rootedness they may or may not have had in the lives they had before their dislocation.

Arjun Appadurai (1996), in his seminal work on the relationship between bounded place and culture in a world that is rapidly becoming dislocated, transnational, and diasporic, likewise uses an idealized icon of the term community in anthropology to develop a more sophisticated concept of culture. Localities and communities, he asserts, must be historicized and contextualized, identified as processes of growth and shrinkage. Not least, anthropology should—and can—become more sensitive to what he calls the global production of locality.

Traditional concepts of community in the social sciences, as they had been applied to studies of rural Mexico, give Roger Rouse's (1991) study of migration into the USA a much needed structure against which to prop his concept of transnational migration. Earlier migration studies, he aptly indicates, had a bipolar picture, with culturally and demographically stable and homogeneous collectives on both ends. Immigrants, within this framework of analysis, simply moved—more or less successfully—between two 'communities.' His own ethnography, however, convinced him that what was taking place in fact was a more complex phenomenon, a translocal movement backward and forward. This productively subverts the wholesome view of the community—be it in rural Mexico or in the migrants' quarters of western USA—offering new tools for understanding of these complex and uneasy situations.

D. Rabinowitz

Comorbidity

The term 'comorbidity' was coined by Feinstein (1970) to refer to the situation in which an individual has two or more physical and/or mental illnesses. Comorbidity is clinically important for three reasons. First, some types of comorbidity complicate diagnosis because presenting complaints are a mix of symptoms of different comorbid conditions. Second, some types of comorbidity complicate treatment because standard therapies for one disorder in a comorbid set are contra-indicated for patients with another disorder in the set. Third, some types of comorbid disorders can magnify the functional impairment and adversely influence the course of other conditions.

1. The Causes of Comorbidity

Some comorbidities occur purely by chance. For example, given that approximately 15 percent of the

adult population in the United States suffers from seasonal allergies and that approximately 20 percent suffers from arthritis, one would expect to find 3 percent of adults who suffer from both disorders merely on the basis of chance association (i.e., 15 percent of 20 percent is 3 percent). There are also situations, though, in which certain comorbid disorder clusters occur at higher than chance levels.

Nonrandom comorbidity can be brought about by at least three broad classes of processes. The first is when one disorder directly effects the onset of a second disorder. For example, persistent alcohol abuse can lead to cirrhosis of the liver. A second class of processes involves indirect effects of one disorder on the onset of a second disorder. The stresses associated with the threat and lifestyle changes that follow from receiving a diagnosis of heart disease, for example, can predispose to the onset of an anxiety disorder. A third class of processes that can lead to comorbidity involves common causes. Traumatic life events, for example, can predispose to a wide range of comorbid anxiety and mood disorders. Biological factors can also be common causes. Twin studies, for example, show that there are common genetic factors that play an important part in bringing about the strong comorbidities found among many commonly occurring mental disorders (Kendler et al. 1995).

2. *Basic Patterns of Comorbidity*

Three types of comorbidity have been of particular interest to clinical psychologists: comorbidity between different mental disorders; comorbidity between mental disorders and substance use disorders; and comorbidity between mental disorders and physical disorders. All three types of comorbidity are quite common in the general population. Nearly half of all people with a mental disorder in the general population meet criteria for two or more such disorders, while more than half of people with a substance use disorder and as many as three out of four patients in treatment for substance abuse or dependence also meet criteria for a mental disorder (Kessler et al. 1996). Mental disorders, especially anxiety and depression, are also found in a substantial minority of people in treatment for physical illness and especially among high utilizers of primary care (Miranda et al. 1994).

2.1 *Mental–Mental Comorbidities*

Bivariate associations between pairs of hierarchy-free *DSM-III-R* disorders in general population epidemiological surveys reveal three general patterns (Kessler 1997). First, there is a generally positive pattern of associations among the vast majority of commonly occurring anxiety, mood, personality, and substance disorders. Second, associations are generally stronger within than between broad classes of disorders (e.g., anxiety disorders are generally more strongly related to each other than to mood disorders). Third, extremely strong comorbidities are found among disorders in clinically recognized syndrome clusters, such as panic and agoraphobia, double depression (major depression and dysthymia), and bipolar disorder (major depression and mania).

Some mental–mental comorbidities appear to be brought about by indirect causal processes, as in the case of panic predisposing to agoraphobia. Others appear to be due to common underlying causes, as in the case of the cycling episodes of depression and mania characteristic of bipolar disorder. Causes are less clear in other types of mental–mental comorbidity. There is currently a great deal of interest in using longitudinal twin and family research designs to investigate some of the more poorly understood of these comorbidities in an effort to refine nosological distinctions.

Many of the strongest comorbidities involve combinations of anxiety and depression—panic, generalized anxiety disorder and social phobia with depression. The anxiety disorder usually starts at an earlier age than the depression in all these cases. Whether this is true because anxiety is the primary disorder or because some types of comorbid anxiety depression are a single disorder in which anxiety is the earliest manifestation is not clear. The fact that certain antidepressant medications have been found to be effective in treating some anxiety disorders but not others, and the fact that the types of anxiety disorders that are affected vary from one antidepressant to another, strongly suggest that complex common neurobiological pathways are involved in these comorbidities. Although good progress is being made in tracing out these pathways, having enough knowledge to develop pharmacologic agents to treat specific types of comorbid anxiety depression is still a long way in the future (Boyer 2000).

2.2 *Mental–Substance Comorbidities*

Substance use disorders have strong comorbidities with a number of mental disorders (Kessler et al. 1996). These comorbidities are thought to come about largely because of a combination of indirect effects of mental disorders on substance use disorders (e.g., self-medication) and common causes (e.g., exposure to predisposing environmental experiences). There are also some cases in which substance use disorders bring about mental disorders either directly (e.g., brain kindling caused by heavy use of psychostimulants leading to panic) or indirectly (e.g., alcoholism leading to adverse environmental consequences that predispose to depression). However, these processes are

thought to be less common than those involving effects of mental disorders on subsequent substance use disorders.

The patterns and processes involved in mental–substance comorbidity differ by gender. Among women, anxiety and depression are the mental disorders most strongly related to substance use disorders (Kessler et al. 1996). These mental disorders typically occur prior to the onset of substance problems among women. Self-medication is thought to be the main process leading to the secondary substance problems. Among men, in comparison, acting out disorders such as oppositional-defiant disorder, conduct disorder, and pathological gambling are the mental disorders most strongly related to substance use disorders. Both sets of disorders are generally thought to be joint consequences of other influences involving such things as impulsivity, risk taking predisposition, and peer influences.

There is a good deal of evidence showing that patients with certain combinations of substance use disorders and comorbid mental disorders are more difficult to treat and have a more severe and chronic course than patients with pure disorders. This is true, in part, because continued use of substances can interfere with psychotherapy for mental disorders as well as because the existence of abuse potential limits the range of pharmacologic therapies available to the clinician to treat the mental disorder. In addition, treatment compliance is often lower and functional impairment is often higher among patients with mental–substance comorbidities than patients with pure disorders. These factors all predispose to a poor prognosis.

There is considerable interest among treatment researchers in using information about these processes to develop targeted interventions for patients with particular types of mental–substance comorbidity (Carroll et al. 1997). These processes are often quite complex. In the case of comorbid substance dependence and antisocial personality disorder, for example, there appear to be reciprocal effects in which antisocial behavior adversely affects the course of substance dependence as well as substance dependence adversely affecting the course of antisocial personality disorder. In addition, people with this type of comorbidity report earlier ages of first use of drugs, more rapid progression from initial drug use to dependence, and greater drug-related problems in daily living than other people with comparable drug problems. This type of comorbidity is also associated with high rates of relapse after treatment.

There has been some success at developing targeted treatment strategies linked to comorbidity. Relapse prevention programs, for example, have had success treating patients with primary anxiety disorders who use drugs to self-medicate their fears by helping these patients recognize that their relapses of substance problems are often triggered by stress reactions. Refinements of this approach have shown that drug abusers who use drugs as a form of self-medication of a mental disorder respond differently to treatment depending on the type of primary mental disorder they have. Large-scale mental–substance patient–program matching efforts that go beyond these cases, though, have had only mixed success so far (Project MATCH Research Group 1998).

Another treatment matching issue of considerable policy importance concerns the distinction between integrated treatment and parallel–sequential treatment. The evidence is clear that both mental and substance use disorders need to be treated in order to successfully reduce the persistence of mental–substance comorbidity. This being the case, integration of the treatment of the two types of disorders in a single setting makes sense both in terms of benefit to the patient and cost-effectiveness. However, integrated treatment remains the exception rather than the rule in the US today due to disciplinary controversies among the professionals who provide treatment for substance disorders and mental disorders. Differences in philosophy of treatment and concerns about control of resources have kept the two systems apart to the detriment of patients.

This is especially true in the public sector, where most states have separate departments of mental health and substance abuse services and where federal block grants to fund the two types of services are often given to separate organizations that refuse to collaborate. This separation has led in many states to a system characterized by parallel and sequential treatment in which the mental health treatment provider refuses to see the patient unless they are free of drugs and the substance abuse counselor ignores mental health treatment issues. Innovative strategies have been developed both to increase integration of these systems and to help patients negotiate these systems with the aid of a single case manager (Miller 1994). These strategies can be effective both in improving the quality of life of patients and in saving money by reducing inefficient duplication of effort across uncoordinated systems of care. However, entrenched systems move slowly and formidable barriers exist to system change.

2.3 Mental–Physical Comorbidities

It has long been known that high utilizers of primary medical care have high rates of anxiety and mood disorders (Katon et al. 1990). Although some of these patients suffer from physical disorders that indirectly predispose to their comorbid mental disorders, others have untreated primary mental disorders that lead to high medical care costs due to unnecessary medical tests and visits (Miranda et al. 1994). Primary care doctors who are aggressive in detecting and treating mental disorders among their patients generate signifi-

cantly lower overall per panel member health care expenditures than other physicians with comparable case mixes. Furthermore, treatment effectiveness trials designed to help primary care doctors improve their detection and treatment of mental disorders have documented significant reductions both in somatic complaints and in overall treatment costs for somatic complaints (Campbell et al. 2000).

Epidemiological studies have also documented significant comorbidities between particular mental–physical disorder pairs such as panic disorder with asthma and depression with diabetes (Ciechanowski et al. 2000). Prospective epidemiological studies of predisposing personality characteristics provide some evidence that early-onset mental disorders might be risk factors for some chronic physical disorders such as cancer and coronary heart disease. In other cases, such as comorbidity between asthma and panic disorder, the evidence suggests that the physical illness is causally primary.

The evidence is even stronger in showing that comorbid mental disorders, whether causally primary or secondary, adversely affect the course of chronic physical disorders. A variety of reasons have been proposed for this, including effects of mental illness on sensitivity to somatic symptoms, lack of adherence to medical regimens, reduction in immune competence, and increase in sympathetic nervous system reactivity (Rozanski et al. 1999). This evidence is strong enough in the case of some comorbidities to justify experimental trials aimed at evaluating the impact of treating comorbid mental disorders on the course of chronic conditions. For example, the government is currently sponsoring the Recovery in Coronary Heart Disease trial, in which heart patients with comorbid depression are being randomized either to usual care or to an enhanced program of care that includes cognitive-behavioral therapy for their depression.

3. *Implications of Comorbidity for Prevention of Secondary Disorders*

Many strong comorbidities begin with early-onset mental disorders that occur during the school years. One important implication of this fact that has not yet been exploited involves the possibility that temporally secondary disorders could be prevented by aggressive outreach and treatment of these prior mental disorders in school-based screening and intervention programs. This possibility would appear to be especially promising for comorbidities involving early-onset anxiety and mood disorders that predispose to secondary substance use disorders through self-medication. Epidemiological studies show that the time lag between the first onset of these primary mental disorders and subsequent substance abuse averages between six and 10 years (Kessler et al. 1996). This interval of time represents the window of opportunity during which detection and treatment of mental disorders can be used to help prevent or delay the onset of substance use disorders. Little is known about the likely success of these early treatment efforts due to the fact that most people who obtain treatment for anxiety or mood disorders do not receive early intervention. Efforts are currently underway to refine understanding of the transition from primary anxiety and mood disorders to secondary substance use disorders in epidemiological data and to carry out evaluations of early treatment programs in order to determine whether early outreach and treatment of these mental disorders can help prevent later substance abuse. Long-term follow-up of such programs might also provide important insights into the effects of such interventions on the later development of chronic physical disorders.

4. *Future Directions*

As knowledge about the neurobiology of mental disorders increases, some of the syndrome clusters presently considered mental–mental comorbidities will likely turn out to be single disorders. As this happens, a probable concurrent realization will be that some of the syndromes now considered single disorders are in fact heterogeneous. For example, several different types of depression might be identified, each characterized not only by a somewhat different set of depressive symptoms, but also by a characteristic profile of comorbid anxiety symptoms. The ultimate goal of this subtyping will be to refine treatment. As a result, advances in treatment, especially pharmacologic treatment, will spur on these refinements. Indeed, complex treatment trials evaluating the effects of patient–treatment matching will likely be the core research design used to validate subtypes. Initial trials of this sort already have shown the heterogeneity in newer pharmacologic treatments by their ability to treat various comorbid depression and anxiety disorders. Epidemiological twin and family aggregation studies will be useful to provide hypotheses about potentially important subtypes. Similar refinements will occur in studies of mental–substance comorbidities.

Research on mental–physical comorbidities is likely to proceed in a somewhat different way. Although research eventually may show that there are some common neurobiological pathways that predispose to certain closely related comorbidities of this sort, such as early-onset anxiety and later ulcers, most research on mental–physical comorbidities will probably continue to focus on mental disorders as complicating factors in the course of physical disorders. Chronic disease doctors increasingly are recognizing that anxiety and mood disorders are highly prevalent among their patients and strongly related to illness

course. The next logical stage is the development of programs for adjunctive treatment of mental disorders among the physically ill. A great increase in such programs in the future is anticipated. More widespread screening for mental disorders in primary care will likely occur in conjunction with these programs. Closer integration of mental health with physical medicine is an inevitable consequence, although the structure of this integration doubtlessly will be shaped by future developments in the organization and financing of services.

Comparable Worth in Gender Studies

Until recently, it was accepted practice to pay men more than women even for the same work. Men's wages reflected not only what their jobs were worth but also their status as breadwinners for their families. A woman's wage, when she worked for pay, was regarded as a supplement to those earned by the man she depended on and not the basis of her economic autonomy (Kessler-Harris 1990). In the 1940s, several US states enacted equal pay laws to ensure that men and women who performed the same jobs would receive the same pay. In 1963, the US Congress amended the Fair Labor Standards Act to include the right for equal pay for equal or essentially similar work. These laws proved severely limited in scope. Rarely did men and women do the same or essentially the same work. Occupational segregation is pervasive. And, it is a major factor accounting for the gender-based wage gap.

The National Research Council has concluded, 'not only do women do different work than men, but the work women do is paid less, and the more an occupation is dominated by women, the less it pays' (Treiman and Hartmann 1981). Using national US Census data, they found that each additional percentage point female in an occupation is associated with a $42 penalty in median annual earnings. Paula England's (1992) summary of many studies concludes that as much as 30 to 37 percent of the wage gap is a result of gender segregation at work combined with the tendency to pay women's jobs less, net of their requirements for education, skill, and difficult working conditions. According to a recent study done by the Institute for Women's Policy Research, a typical 29-year-old woman with a college degree stands to lose approximately $990,000 in wages over her working life as a result of the wage gap. Comparable worth, also known as pay equity, emerged in the US in the late 1970s and 1980s to correct for the gender-based gap in wages that is a by-product of occupational segregation.

Comparable worth broadens the scope of equal pay for equal work legislation. It requires that dissimilar

jobs of equivalent worth to the employer be paid the same wages. Comparable worth examines the extent to which work done primarily by women is systematically undervalued because that work has been and continues to be done primarily by women. Systematic undervaluation means that the wages paid to those who perform historically female work are lower than they would be if these jobs had been and were being performed by white males. Comparable worth involves correcting the widespread practice of paying women less than white men for work that requires equivalent skills, effort, responsibilities, and working conditions (Steinberg 1984). It seeks to remove 'femaleness' as a factor depressing the wage rate for historically female work. It attempts to base wages solely on the productive contribution of the work performed to the overall objectives of a work organization, removing the effect on wages of the sex of the typical incumbent.

1. Historical Background

Assumptions about gender that pervade the structure of compensation have their origins in nineteenth-century assumptions about the gender division of labor and the cult of domesticity. (For a fuller document see Steinberg and Figart 2000.) Specifically, by the end of the nineteenth century, occupational segregation had intensified, allowing for the development of a two-tiered wage structure by the gender of the typical job incumbent. Not only was the two-tiered wage structure taken for granted, it was also a legal workplace practice.

Several decades later, these breadwinner–homemaker ideologies were institutionalized into the wage structure through job evaluation procedures. Job evaluation systematically orders jobs as more or less complex and more or less valuable to the organization's mission for the purpose of paying wages. Jobs are described and assessed in terms of relevant job content characteristics. Wage rates are based on these assessments of job content. Individuals performing the jobs are assumed to have the required knowledge, skills, and character to perform the job competently.

Job evaluation systems can be traced back over 100 years, although their use in the private sector became widespread in the 1950s (Treiman 1979). Job evaluation systems in use today have their roots in systems first developed in the 1940s and 1950s (Steinberg 1992). Early evaluation systems and even most current systems use existing wage rates for jobs as the basis for determining what types of job content were complex. For example, if responsibility for supervising a work unit was found to be positively correlated to wages, then supervising a work unit was treated as complex work. At the other extreme, if a low-paying job involved working with the public, then working with the public was defined as simple work. Once a hierarchy of complexity had been established based on existing wages, all references to the derivation of the hierarchy were dropped (Schwab 1980). The fact that job content measures were a proxy for existing wages was lost.

Contemporary job evaluation systems appear to be scientific and objective in their assessment of job content, but actually have built into them gendered cultural assumptions from the 1940s and 1950s including the two-tiered wage structure. Modifications of these systems since the 1950s have been largely cosmetic. Kim (1989) found, for example, that 1986 salaries in California State public employment were affected by explicit assumptions about gender embedded in a compensation system established in 1931. These assumptions pervade the wage structure because over two-thirds of all employers use some form of job evaluation as the basis for their compensation policies.

Comparable worth first emerged as a policy objective during World War II, when the War Labor Board required that employers abide by equal pay for equal worth (Milkman 1987). This policy was honored in the breach. Several states did, however, enact equal pay for equal work laws, primarily in response to union pressure to protect male wages from being lowered when women replaced them during the War. Early drafts of the federal equal pay legislation, endorsed by the Kennedy administration, included language that required equal pay for 'work of comparable character on jobs the performance of which requires comparable skills. Final legislation substituted the word 'equal' for 'comparable' (Steinberg 1984, Hutner 1986).

The contemporary comparable worth movement in the US crystallized in the late 1970s. In 1974, the State of Washington conducted the first comparable pay study. In 1979, the newly constituted National Committee on Pay Equity (NCPE) convened a national conference. In 1981, the Supreme Court of Washington State in *County of Washington v. Gunther* found illegal differential pay between women prison guards and male prison guards, based on the content of their work. Also in 1981, the NAS report, *Women, Work and Wages: Equal Pay for Work of Equal Value*, was published (Treiman and Hartmann 1981). It found strong evidence for gender-based discrimination and legitimated the claims of comparable worth advocates.

The pace of activity on comparable worth accelerated in the US in the 1980s. By the end of that decade, all but five states had at least investigated gender differentials in their civil service pay scales. Over 50 municipalities, 25 counties, 60 school districts, and nearly 250 colleges and universities had investigated comparable worth inequities. Many enacted wage adjustments for historically female occupations.

In 1978, the federal government of Canada enacted the Canadian Human Rights Act, which established equal pay for worth of equal value. By 1990, 9 of the 12 Canadian provinces had adopted pay equity legis-

lation. The 1987 Ontario Pay Equity Act, the most far reaching pay equity legislation to date, requires that comparable worth be proactively established in all private firms with 10 or more incumbents, as well as in the public sector. It requires as well that job evaluation systems be gender-neutral in their assessment of work complexity (Cuneo 1990).

The pace of initial comparable worth efforts began to slow considerably in the late 1980s in the US and in the mid-1990s in Canada. In the US, this was due to a disappointing turnaround in legal decisions, to President Reagan's landslide victory in 1984, to President Clinton's reluctance to support labor policies that intervene directly in the labor contract, to the lessening fear among politicians at the state level of the gender gap at the polls, to the decline in membership and power of organized labor, and to the successful containment of reform implementation by employers (Steinberg 1991). Nonetheless, according to an IWPR study, in the US, $527 million in pay equity adjustments have been disbursed by 20 state governments.

2. *Job Evaluation and Gender Bias*

Job evaluation is the institutional mechanism that perpetuates wage discrimination, especially in medium-sized and large organizations. Approximately two-thirds of all employers use some form of job evaluation. A minority of work organizations set wages without using these formal processes. They rely instead on local market wages, employer biases, and institutional inertia in setting wages. However, if large employers modified job evaluation practices to pay women fairly, smaller employers who do not use such procedures would be affected by these outcomes. There are many aspects of gender bias that remain in virtually every traditional job evaluation system currently available to employers (Steinberg and Haignere 1987, Acker 1989, Steinberg 1990). Four of the most common forms of bias are discussed below.

First, the prerequisites, tasks, and work context of jobs historically performed by women have been ignored or taken-for-granted. Working with mentally ill or dying patients or reporting to multiple supervisors are not considered to be stressful working conditions. Working with noisy machinery, however, is considered stressful. University secretaries who protect the confidentiality of the records they work with do not receive compensation for that responsibility. When examining the skills associated with clerical work, most job evaluation system's treat as invisible requirements for knowledge of spelling and grammar, ability to compose straightforward correspondence, knowledge of the substantive work of the office, and knowledge of the organizational shortcuts within a bureaucracy. The ability of a public health nurse to break down complex and technical material to present to nontechnical audiences is also not acknowledged as a communication skill in traditional job evaluation. If job content remains unacknowledged in the process of describing and evaluating jobs, it is not taken into account when determining a wage rate.

Second, evaluation systems confuse the content of the job with stereotypic ideas about the characteristics of the typical jobholder. Since authority is associated with masculinity, managers are perceived as running offices and departments. The work of the secretary in the actual daily running of an office remains invisible, especially if she performs her work competently. The technical skills and life-and-death responsibilities required of a Registered Nurse are often subordinated to her perceived responsibility for the emotional comfort of her patients. Social psychological experiments confirm that the value of an activity is lowered simply by its association with women (Shepala and Viviano 1984).

Third, the content of work historically performed by women is recognized in the evaluation hierarchy of complexity, but, by definition, is assumed to be less complex than the content of work historically performed by men. For example, both women's and men's jobs require perceptual skills. Male jobs are more likely to require spatial perceptual skills, female jobs visual skills (England 1992). In traditional job evaluation systems spatial skills are treated as more complex than visual skills. Similarly, women's and men's work both require human relations skills, but the human relations skills associated with men's work often involve power and control, while the human relations skills in women's work often involve taking care of others. Job evaluation systems define power and control over others as involving more complex skills than emotional labor. Virtually every off-the-shelf system of job evaluation defines skill, effort, responsibility, and working conditions in way's that treat the job content of male work as more complex than that of female work.

Fourth, some job evaluation systems negatively value job content associated with female jobs in a way that actually lowers wages. One study of a major university found that staff whose jobs involved working with students on a regular basis actually 'lost' pay for that aspect of their job net of other aspects of their job content. Another study found that working with difficult clients and dying patients actually lowered pay independent of other job content. The ironic logic of this evaluation outcome is that the more an incumbent is required to perform the undervalued content, the less the incumbent earns.

3. *Gender Neutral Job Evaluation for Comparable Worth*

To achieve comparable worth, it is necessary to cleanse traditional compensation practices of those gender biases of which we are aware. Achieving this goal

requires recognition that systems of job evaluation have been socially constructed. Thus, they can be *socially reconstructed* to achieve gender neutrality. Early comparable worth initiatives attempted to modify traditional job evaluation systems. In Oregon, for example, a major compensation consulting firm, Hay Associates, agreed in principle to modify its own job evaluation system (Acker 1989). Yet, in practice, the consultants fought against all but minor changes proposed by the Task Force directing the project. When Hay modified its system, the changes had little bearing on the evaluations of the actual jobs being assessed. Some of the lower paid historically female jobs received wage adjustments, but the original hierarchy of job complexity was left intact. More recently, technical pay equity proponents have begun to design gender-neutral evaluation systems to measure job content. The new systems measure more accurately and positively value the invisible skills associated with historically female jobs. One way in which gender neutral job evaluation minimizes gender bias is by developing new dimensions of job complexity or new job factors to capture work differentially found in historically female work. An example is the construction of a factor for Emotional Effort. This factor measures the intensity of effort required to deal directly with the needs of patients, customers, clients, citizens, and coworkers in assisting, instructing, caring for, or comforting them. Hierarchies of complexity are built: dealing with clients who are unpredictably hostile or confused, or discussing death with the terminally ill and their families, is assessed as requiring more emotional effort than dealing with coworkers who are seeking information. The emotional effort of both female and male jobs is assessed in relation to a consistent metric.

A second way in which gender-neutral job evaluation reforms traditional job evaluation is by including and revaluing previously unacknowledged or undervalued characteristics of historically female work in measures of job content already included. For example, in a gender-neutral system, the measurement of Human Relations Skills would not only encompass the skills necessary to supervise subordinates and the skills necessary to speak with top-level executives of organizations. It would also include the skills required to deal effectively with or care for others or to shape, affect, or influence others' feelings, actions, or decisions. Similarly, a job factor on Communication Skills would not only recognize and positively value writing complexity, it would also recognize that presenting technical information to an audience where the level of understanding varies involves more complex communications skills than presenting technical information to a technical audience (Steinberg 1999).

Gender neutral job evaluation is almost never used in pay equity initiatives in the US and only rarely used in Canada. It remains a technical solution in search of a political base with sufficient power to implement it.

4. *Containment of Pay Equity*

Comparable worth advocates have not fared well in their efforts to reform the systems of job evaluation that are used in pay equity initiatives. Public sector employers that enacted pay equity early, such as Minnesota, Washington State, and San Jose, California, did so using unmodified traditional job evaluation. While political expediency in these jurisdictions did result in raising wages for those who work in historically female jobs, it did not remove most of the sources of gender bias from compensation systems. During the second phase of pay equity initiatives, advocates were well aware of the biases of traditional job evaluation, but political resistance to the modification of traditional job evaluation was formidable. Pay equity was not openly opposed. Instead, it was effectively contained, as illustrated by the Oregon example. Most strategies of containment involved manipulation of the process and results of traditional job evaluation. Employers gave the appearance of full cooperation with advocates, but structured decision making around the study in a way that would minimize advocate input and thus minimize both the economic costs of the reform and the changes in compensation practices (Steinberg 1991).

How did these containment tactics work? One strategy involved turning political decisions, such as what constitutes a female-dominated job, into technical decisions and making them nonnegotiable. How much should educational job requirements be valued relative to supervisory responsibilities? Determining the relative importance to overall job value of different dimensions of job content is one of the most important decisions involved in a job evaluation exercise. It is a political decision requiring debate and consensus. It is typically obscured, however, as a technical decision. A second strategy involves withholding information from political advocates until it is too late for them to do anything about it. In Oregon, by the time the pay equity advocates on the Task Force understood the implications of the actions of the consultants, their choice was to abandon the project entirely or accept the flawed results. They accepted the results.

A third strategy, perhaps the one most frequently used by employers, involves placing proponents in a minority position on a Task Force or dividing them among themselves. Most often, trade union advocates are initially placed in a privileged position and representatives of women's groups are marginalized. When they must unite in opposing employer efforts to undercut the reform, their distrust of each other makes common action difficult, if not impossible.

With the availability of Gender Neutral Job Evaluation, achieving pay equity becomes less a technical than a political challenge. But it is a formidable political challenge. Comparable worth is a political goal well worth fighting for. Cleansing compensation systems of gender bias would put an extra $1,500–

5,000 per year in the paychecks of those performing historically female work. Even flawed studies with gender biased evaluation systems have resulted in important wage increases for hundreds of thousands of women. For many women, it represents the difference between poverty and economic autonomy. It would empower women as decision makers in their families. It would make visible and positively reward the productive contribution of women's labor market work.

Comparative History

Comparative history differs from other historical methods in that it takes an explicit line of questioning to compare two or more cases stemming from different contexts. The aim of this operation is either to bring out the similarities and differences of the different cases, or to determine the scope of social scientific theories or theoretical approaches. Seldom does comparison itself lead to the formulation of theories. These characteristics distinguish historical comparison monographic work concentrating on case studies, from historical syntheses with an international scope and from implicit comparison, which indeed belongs among the analytical instruments of all historical work.

1. The Story of 'Comparative History'

Although the comparative perspective has appeared repeatedly in the history of historiography, it has only presented itself as a methodical instrument of explicit theoretical comparison since the 1930s. Of course, the historiography of the Enlightenment made use of comparison in its endeavor to grasp the specific characteristics of the historical process by means of universal historical types; in this context, Montesquieu, Adam Smith, and the Cameralist J. H. G. Justi should be mentioned. In Scottish, English, French, and German Enlightenment literature as well, cultural areas and development stages were compared. Thus, just as the demarcation of the European model against non-European civilizations in the eighteenth century belonged to the arsenal of universal history, so did the belief that developed societies can trace their own history in that of less-

developed societies (e.g., Karl Marx). In this attempt, development thinking became closely intertwined with a Eurocentric perspective. This universal historical tradition persisted, carried on in the twentieth century by such diverse authors as Oswald Spengler and Arnold Toynbee, Karl Polanyi, and Schlomo Eisenstadt.

Modern comparative history, however, is not rooted in this tradition. Profoundly affected by the experience of World War I and the traumas suffered by parts of academia under nationalistic exclusionism, comparative history established its argument for comparison as a fruitful enterprise particularly based on the results produced in neighboring sciences. Henri Pirenne, a Belgian historian and one of the pioneers of internationally comparative historiography, did admittedly make reference to universal history in his opening speech at the fifth international conference of historians in Brussels in 1923, but with the intention of combating the narrowness of purely national perspectives and the subjection of historical research to functional ends. However, Marc Bloch and Otto Hinzte, two of the most influential forerunners in the field of comparative study, were even more active in taking up approaches from neighboring disciplines where comparison had long been a commonly practiced method. Historiography, as a historically comparative discipline, was a latecomer compared with other sciences. In fact, as early as the late eighteenth and early nineteenth centuries, various sciences had practiced comparative study successfully. Such works were produced not only in anatomy and physiognomy, but also in religious studies, jurisprudence, geography, and philosophy. Among them was that of F. Max Müller, the first *Introduction to the Science of Religion*, published in 1873. Thus it was no coincidence that Marc Bloch, in his 1928 essay advocating the practice of comparative history, does not cite historians, but rather Antoine Meillet and the broad range of scholars who had been carrying out internationally comparative linguistic research since as early as the nineteenth century.

In the development of modern comparative history, contact with the social sciences played the central defining role. Marc Bloch, whose works on the 'royal touch,' on the agrarian history of England and France, and on the different forms of feudal society in Europe up to 1940 provided important examples of comparative study, had received theoretical stimuli, above all from Emile Durkheim. Durkheim saw comparison as the sociological method *par excellence*, enabling the delineation of the fundamental characteristics of social types. Bloch used this method, for example, in his analysis of feudal society when he concentrated on its dominant dependency relationships. Otto Hintze, who was among the pioneers of historical comparison, also took the work done in the social sciences as his model. He adopted the concept of the ideal type from Max Weber and went on to construct an ideal-type concept of feudalism. He then applied this to the various manifestations of feudal domination, which he found to be particularly pronounced in Russia, Japan, and the Islamic countries.

In the period following World War II in particular, the number of theoretically based works with an internationally comparative perspective increased. The science of history bore a complex interrelationship to historical sociology. On the one hand, it profited from the broad scope of sociology's macro comparisons, which were limited neither to a specific epoch nor to a specific continent. These comparisons studied different national cases, using stringent argumentation to examine theoretical questions. Thus Barrington Moore inquired as to the role of agrarian development in the emergence of either democracy or dictatorial fascistic regimes in a broad comparison of six national cases, while Jack Goldstone compared revolutionary crises of the early modern age in Europe and Asia. On the other hand, however, it was only the historical research in monographic form that made available to historical sociologists the theses and research results that would enable them to carry out extensive comparisons. The stimuli obtained from historical sociology were also accompanied by critique of its generalizations and its handling of the historical state of research, which it did not always improve upon extensively. Nevertheless, historical sociology provided an important stimulus to comparative history. Its works elicited an increasingly favorable response in the 1960s to the extent that history was open to theoretical questions, and gradually after 1970, these works were also emulated.

The theory of modernization, which originated mainly in the United States in the 1950s, provided a powerful comparative impetus as well, and elaborated parameters of development against which it measured individual societies. The successful combination of market economy and political democracy was its criterion for modernity. In this sense, the vague but positively cast concept of 'modernity' was used widely in historiography on the nineteenth and twentieth centuries; it emphasized structures, functions, and interdependencies among the different parts of systems more strongly than their historical individuality. In individual historiographies—particularly in those countries catching up in industrial and political development—the comparison to the Anglo-Saxon 'leader' countries soon became one of the standard lines of argumentation. In the West German debate about the long-term and medium-term causes of National Socialism, structural deficits were identified in comparison to Anglo-Saxon development, which itself was admittedly highly typological and idealized: these included the feudalization of the German middle classes, a general deficit in the middle-class way of life, the exceptional proximity of middle-class life to the state, and the persistence of privilege-based social orders in the old and new middle class. Especially in

this debate about Germany's *Sonderweg* ('unique path')—but in Italian historiography as well—it was no longer just the linear and unceasing advance toward modernity that was at issue, but the ruptures, contradictions, and deficits in the development.

Within the science of history, comparative methods by no means penetrated all disciplines to the same degree or simultaneously. They emerged earlier in economic history, population history, and political history than in social history, gender history, or cultural history. As early as 1957, the Economic History Association dedicated one day of its annual conference to comparative economic history, and it was no coincidence that one year later, economic historian Sylvia Trupp founded the journal *Comparative Studies in Society and History* with the expressed goal of publishing studies of an interdisciplinary and comparative nature. In Europe, the English model of industrialization and its spread was the central topic of the comparative studies that appeared even before 1960. The most broad-based and influential comparative analysis was produced by Alexander Gerschenkron, who studied the basic similarities and differences within the European process of industrialization, inquiring into not just the different answers to similar challenges, but also the functional equivalents among European societies. He explains the differences in development on the basis of both the specific position of the individual economy in the system as a whole ('relative backwardness') and the influences generated by developed societies. Walt Rostow's 'stage theory' of economic growth also provided an impetus to comparative economic history after 1960, as did Simon Kuznets's quantitative studies. Rostow's thesis that every society has to go through similar phases of economic growth and that therefore each society's position can be identified against this background was almost a direct invitation for checking by historical comparison. Kuznets, in contrast, instead emphasized the uniformity of modern economic growth, although without ignoring its national diversity. His three-sector thesis also led to comparative studies.

In historical demography, in 1963 at Princeton, Ansley Coale began comparing 600 European regions to answer the question of whether and why the birth rate was declining in Europe; this was called the European Fertility Project. Although the project did produce convincing demographic results, the explanation of demographic behavior on the basis of historical macro processes came under criticism. The reasons for the early comparative studies of political movements and institutions can be found not only in the field of 'comparative politics,' which gained importance in the USA in the 1960s, but also—according to Klaus von Beyme—in a unique approach to research within political science. This approach applies to institutions that can be classified under the general type of democratic systems, but that nevertheless take on specific forms. Research on resistance movements and on social systems or constitutions paved the way for the advancement of comparison in social history .

Nevertheless, since the mid-1960s, sociohistorical comparison has taken on a leading role, showing a remarkable breadth of research and differentiation in approaches. In Europe, at least a handful of papers have been published every year since 1970 on comparative social history, none limited to a specialized area, but including the history of the family and social classes, and the development of the social state, the city and education. These studies have been focused mainly on three central issues. First, they deal with the explanation of national peculiarities, which often—because of political events—are seen as characteristic of the social development of the last few centuries. In the debate about the German *Sonderweg*, this orientation of comparative sociohistorical research has taken its most comprehensive and probably also most fruitful form as a scientific heuristic device. Second, they focus on the different pathways of individual European societies into the modern age: their distinctive features are identified above all in comparisons between different societies, and between European and non-European cultures. A third focal point has been the European model and its social characteristics. All these studies have demonstrated methodical diversity in both quantity and in quality; have integrated social, political, and economic factors; and have focused attention on both linear and cyclical developments. Furthermore, they have compared societies as well as parts of societies.

European historiographies have not all made use of the comparative method to the same degree. Surprisingly, Marc Bloch's appeal in France went unheard for many years, as French historiography was and continues to be strongly oriented toward monographic work and highly skeptical of theory. In Great Britain as well, historical comparison did not catch on because of the dominance of national history and the distance from the social sciences. In Italy, comparative history remained on the periphery—despite the proximity of many historians to debates in the social sciences—because of the strong regional orientation. In West Germany, Scandinavia, Switzerland, and Austria comparative work remained rather limited within total historical production, even though the number of comparative works was significantly higher than the number of other European historiographies. Although sociohistorical comparison was particularly strong in Germany, this was a result of both debate on the theory of the German *Sonderweg*, which was dealt with in many comparative historical essays, and the explicit discussions of social-scientific theories and proposed explanations that characterized modern German social history. In general, one may assume that internationally comparative history had a difficult time gaining a foothold wherever the relation to theory

was weak, and wherever attempts to explain national patterns of development in the philosophy of science remained only peripheral. Before 1989, this was the case in Iberian societies as well as in Eastern Europe.

The study of history in the United States, where, according to Raymond Grew, comparison is a weak point rather than a strong one, has not only brought forth a series of excellent comparative studies on European history, but also practices transepochal and transatlantic comparison more intensively than does European historiography. Among the comparative works on Europe, those of Charles Tilly, Peter Baldwin, and Susan Pederson are particularly worthy of mention. The study by Arno Mayer on the Holocaust, which he sees in the tradition of the Crusades and the Thirty-Years' War, takes a transepochal and internationally comparative approach and presents a comparative tableau of the situation of Jewish people in Eastern European societies in the 1930s. Transatlantic perspectives are opened up by those studies that place slavery in the South, the frontier problem, and the situation of migrants in a larger, multinational context.

In gender history, the comparison of male and female roles was for a long time the constitutive element of analysis, and only recently have theoretical, internationally comparative studies been produced. These have concentrated on institutions or sub-areas which, like social laws, have attained a special meaning for gender roles. Modern cultural history as well, which discusses the creation and relevance of stems of meaning, rituals, and symbols, has concentrated thus far on national configurations and ascribed little importance to international comparison.

In historiography on classical antiquity, the Middle Ages, and the early modern age, comparative studies were carried out, comparing rulers, regimes, and individual institutions. Because of the international character of political systems, the national aspect decreased in importance as a unit of comparison. However, theoretically oriented comparisons remained scarcer in this area than in the historiography on modernity.

2. *Functions of Historical Comparison*

The comparative method pursues two goals alternately. On the one hand, it seeks to accentuate the distinctive feature of each individual case, and on the other, attempts to derive evidence on general developments from case studies. While historians tend toward the first approach, the second is more prevalent among social scientists. Comparative historical studies do, however, also deal with the question of commonalities. Four functions are granted to comparison in these studies: a heuristic function, a contrastive function, an analytical function, and a distancing function.

Comparison plays a heuristic role when it alone can offer explanations and reveal phenomena that had been unknown or inadequately known up to that point. This function was already referred to by Marc Bloch, who, based on his knowledge of the English enclosure movement, sought an equivalent in French agrarian history. Founding his thesis on research in regional history, he dates the disappearance of collective rights in Provence as early as the fifteenth century, and concludes from this that similar movements took place in France not only earlier, but also under other conditions. Thanks to the comparative method, Bloch was able to discover a characteristic of French agrarian development through his studies of the agrarian history of other countries.

Historical comparison can be called contrastive when it serves to define more precisely the special features of a specific case. Above all in German–French comparison, this method was used to bring into bold relief the particularly xenophobic character of German nationalism in the early nineteenth century, the insurance character of Germany's social security system, and its unique characteristic of having a highly educated middle class. Comparison of Italian and Anglo-Saxon developments brought out the regressive state of Italian industrial development, its lack of a modern party system, and its unique feature of having a patrician, noble class. Depending on the country selected for comparison and the logic behind this comparison, specific characteristics of the mostly isolated national case but also of regional patterns of development are illuminated and brought into clear contrast against the totality. At least two problems emerge in this endeavor: the further the development stage in the reference country or region deviates from the individual case in question, the less suitable it is for defining the specifics of the case beyond mere identification of general deficits. If one measures the economic development in Italy in the nineteenth century using as a yardstick the conditions that promoted industrialization in England, one can only determine that these conditions were lacking in Italy, but cannot identify the specific conditions for the economic growth that took place there. The more that the comparative reality is used merely as a foil to highlight the contours of a specific case, the more typological and reductive the resulting picture. International case studies written in comparison to the German case with the aim of presenting a general view of the livelihood and benefits of German white-collar employees have only rarely provided convincing analyses of the individual national developments in the employee milieu. This inherent bias of comparison should be borne in mind in each case.

Comparison has an analytical character when it either tests a scientific hypothesis or identifies constellations of causes in a specific situation. The thesis that a causal relationship exists between capitalism and feudalism is relativized by the fact that strong fascist

movements did not emerge in all capitalist societies; they were able to develop only under specific conditions. Jürgen Kocka qualified this assumption in his comparison of American and German society between the two World Wars. In a study of the French, Russian, and Chinese revolutions, Theda Skocpol inquired as to the results of collapsed administrative apparatuses, broad peasant rebellions, and movements among political elites, thereby demonstrating the extreme diversity in the constellations of causes which explain the outbreak of modern revolutions.

In this analytical approach, comparison can also serve as an indirect experiment. When phenomenon *a* is ascribed to cause *b*, the historian can test their hypothetical connection by looking for constellations in other societies in which *a* appears without *b*, or where *b* exists without leading to *a*. This heuristically useful procedure is distinguished from experiments in the natural sciences in that here, the *ceteris paribus* conditions are seldom given.

Comparison has a distancing effect when it offers another perspective to observation and analysis. It can produce surprising discoveries as well as relativizing the tradition-based context of national historiographies. Especially for those historiographies that are deeply embedded in a national context, comparison can open up new and often broader vistas. When confronting comparisons with other reference cases—especially those from other cultures—not only does one gain experience with different types of question and method, but also fundamental assumptions of one's own historiography can be revealed and their problems expounded. The comparative view can also contribute new insights: Skocpol, for example, uses the comparative method to shed new light on the similarities between the French Revolution of the eighteenth century and the Chinese revolution of the twentieth century in her comparison of revolutions, and between the cities of France and Japan in the eighteenth century. Taking into consideration the variety of alternative pathways into the modern age prevents exclusive concentration on the European development path, and offers insight into those conditions of European development which cannot be generalized.

3. *Methodology of Comparison*

Although comparative history does not possess its own methodology, it does present particular methodological problems in bold relief.

Historians have used the proximity of their work to original sources as a special proof of its scientific nature. The goal of reconstructing history via a multitude of sources in as comprehensive a manner as possible is one of the fraternity of historians' standards. This fundamental methodological principle to a certain degree evades historical comparison. In so far as it compares more than two cases, it depends more heavily on secondary literature than on the evaluation of a consistent body of sources. Thus, it also faces the problem of having to assess adequately the historiographic context, where each individual work of secondary literature interprets the original sources in its own specific way.

Another of the principles of historical study is that individual aspects of reality cannot be understood separately from their place within a totality or within a historical development. The full meaning of details comes into focus only when looked at in synchronic and diachronic perspective. The method of isolating variables—a common one in empirical social research and political economy—can and should be used within the framework of research projects, but is inadequate for representing the results of research. Comparisons can trace diachronic development processes in their similarities or differences, but they can also examine trans-epochal cases along one specific line of questioning. For example, Raymond W. Goldsmith studies the premodern financial systems in ancient Mesopotamia, the Indian Mogul empire, and England under the rule of Elizabeth I. For him, what is of interest is not how an epoch can be characterized, but the contribution of different states and ages to a central line of questioning. Comparison can also evade both chronology and the total context in question: one separates out the individual cases, subjects them to examination from a specific perspective, reduces their complexity, and studies them as exemplary cases belonging to a 'universal,' the *tertium comparationis*.

Because of this isolation and reduction, the methodology of comparison enters into a relationship of unresolvable tension with fundamental principles of historical study. What has proven to be a rule of thumb is that the loss of context in comparative study is less severe the smaller the number of reference cases. By choosing medium-range theories and argumentation on a moderate level of abstraction, one limits as far as possible both the loss of concreteness and the distance from the object of study. To do justice to the diverse kinds of relationship affecting a particular case, comparative historical studies include processes rather than constellations, and link the analysis of individual situations with questions derived from the historical study of relationships. The integration of individual cases into the total social context can be intensified through close attention to the linguistic and conceptual specifics that define and influence these contexts.

Despite all of these methodical problems, historical comparison also has a positive impact on historical research by raising its consciousness about the extent and limits of different approaches, the implicit premises of scientific study, and the coherence of the total context. It opens up historical study to theoretical reflection.

The unit of comparison changes according to the line of questioning and the information being sought. For a long time, a national framework of study was dominant in the science of history, both because this framework influenced the problems being studied, and also because answers to questions of national history were sought in comparison. Research on nationalism and welfare states, democracy and religious denominations have been given a privileged place in the national framework. This national approach has been called into question by two developments: microhistory and intercultural history.

Microhistory has brought increased interest to local, often unique sources and problems which give a privileged role to the viewpoints of the people involved, and which—because of the emphasis on individuality—had been excluded previously from methodical comparison. In addition, this shows the importance of another area which calls into question the self-assuredness of past research on national historical developments. For the study of family constellations and famine unrest, local frameworks present themselves as the most appropriate, while for the analysis of linguistic dialects or industrialization, the regional level is preferable. As the study of history becomes increasingly global, the national level will decrease continuously in significance. This does not just apply to colonialism, the migration movements of the nineteenth and twentieth centuries, or the global economy that has been developing since 1880. Marc Bloch pointed out as early as 1928 that the development of manorial rule in the Middle Ages and early modern age in individual localities and regions cannot be understood independently of the decline of money rent throughout Europe.

In so far, then, as one seeks to identify the special features of Europe's development, it is necessary to include non-European cultures, which, however, should no longer serve merely as a foil as they did for Max Weber, but rather be examined with a differentiated view to their independence and specificity. In order to obtain a new perspective, Jürgen Osterhammel proposes a new approach: instead of analyzing non-European cultures from a European standpoint, one should take the opposite point of view and determine European specifics from the standpoint of non-European cultures. The methodical problems of such a perspective are as obvious as its advantages: these include on the one hand problems of languages, the knowledge of often very different historiographies, and aggregation of data that decrease in meaningfulness and are often statistically antiquated, and on the other, a new view of known developments, and the opening of a wider sphere of activity and relationships.

In particular, the history of transfer processes brought attention to Galton's problem of ethnologies when it questioned whether two or more cases can really exist independently alongside one another, or if they are enmeshed in a visible or invisible web of relationships that influence them decisively. The question of how specific constellations develop through direct influence, appropriation or imitation of foreign models does indeed increase the complexity of comparison, but in no way replaces it. As is well known, Marc Bloch extolled the study of societies in the same epoch which are neighboring, mutually influential, and subjected to the same macro changes as one of the ideal methods of historical comparison.

4. *Comparative History's Agenda and Unsolved Problems*

Comparison poses methodical and theoretical problems for the science of history, but at the same time challenges it, and can even work as a factor to increase method-consciousness and support theoretical reflection. Currently, an expansion of previous approaches and fields of comparison in the following directions could be considered:

Until now, comparative studies have limited themselves to defining the range and meaningfulness of theories. Such problems as whether Weber's class theory is appropriate for the history of the European middle class, whether Pierre Bourdieu's concept of cultural capital is useful for an analysis of intellectuals, or whether Marx's theory can be applied to modern revolutions—and whether all of these can explain more than just national cases—have been the focus of interest thus far. However, the question of what changes must be made in theoretical concepts if they are to explain more than one national development and encompass a multitude of empirical cases has seldom been asked. Therefore, comparative history has contributed little to the development of theory thus far, and has seldom taken the step to formulate theoretical alternatives by relativizing existing approaches.

In historical comparison, progressive types and structures—rather than the constitutive processes of historical facts and materials—were, for a long time, at the center of attention. With the increasing importance of constructivist approaches, individual sources such as reports and statistics are being interpreted to be more a representation of individual administrations or rulers than an account of social or political reality. Comparisons that strengthen this point of view would involve representations and strategies of representation, and prevent the naive use of sources and statistics. In this area, new fields of research are opening up.

In numerous comparative studies, the process of modernization is built in as the *tertium comparationis*. This enables that the trajectory of development of each particular case be identified and defined. The more that temporally staggered comparisons are used

in these studies, however, the less importance they ascribe to synchronic observation and the more they ascribe to the content of the line of questioning. In this way, comparison concentrates less on the characterization of phases of historical development, and more on different contexts—such as collectives' self-descriptions, social placement strategies, ascription of religious meaning—which it analyzes for several collectives.

Contemporary processes of globalization have left their mark above all on the capital and labor markets, but have also called into question the national contexts of thinking prevalent in the sciences. On the one hand, historiography in the European framework reacts to this relativization of the national: it can give a privileged role both to comparison between individual societies as well as to the homogeneity of powerful forces and processes. Transcultural comparison with non-European cultures also presents a promising means of isolating and identifying the factors of Europe's development. On the other hand, the individual societies themselves have become complex 'melting-pots,' as reception and diffusion of cultural models, social modernization, and social and cultural coding have merged in them, accompanied by national-historical and global-social influences. With the increasing demand for an adequate survey of contemporary society, the demands placed on a theoretically based, methodically differentiated comparative history will increase as well, expanding the spectrum of questions with which history will be interpreted.

Comparative Method, in Evolutionary Studies

Comparative methods seek evidence for adaptive evolution by investigating how the characteristics of organisms, such as their size, shape, life histories, and behavior, evolve together across species. They are one of evolutionary biology's most enduring approaches for testing hypotheses of adaptation. This article discusses the application and interpretation of comparative studies, reviews their historical development, then describes new methodologies for analysing comparative data.

One of the classic comparative relationships is that between the size of an organism's body and the size of its brain (Fig. 1): brain size increases steadily and predictably with body size in mammals, and this relationship also holds within most other animal groups. Much of the interest that comparative rela-

Figure 1
Plot of brain mass versus body mass in mammals. Selected points are labeled. Note the logarithmic scales. The correlation between the two variables is 0.96 and the slope of the line relating brain mass to body mass is 0.61 (see text and Table 1 for further discussion.

tionships such as this one generate derives from their ability to reveal broad or general evolutionary trends. Table 1 lists a small number of such trends and the species in which they have been found.

Comparative trends, in addition to describing the 'end-points' of evolution across contemporary species, can also be shown to have an historical interpretation: the relationship observed across a group of contemporary or extant species reflects the correlation that would have held in the ancestral species as they evolved over time up to the present (Pagel 1993). Thus, the relationships reported in Table 1 tell us that as organisms evolve and grow larger, their lifespan, ages at maturity, brain size, and basal metabolic rates increase, but their heart rates slow down.

The natural interpretation of comparative relationships is that they reveal adaptive trends. This is to say that the organisms that individually evolved to produce the trend were somehow more fit or suited for survival than those that did not. Thus, as animals evolve to become larger, a larger brain is required for 'housekeeping' functions as well as simply to monitor the increased number of neuronal signals coming from the organism's body and internal organs. Larger animals also tend to roam over wider areas and a larger brain may be advantageous for taking advantage of what the terrain has to offer. Small animals could have larger brains, but if the adaptive argument is correct, a relatively large brain in a small animal

Table 1
Selected comparative relationships

Trait	Slope or relationship to body size	Species in which measured
Brain mass	0.67–0.75	Mammals
Age at maturity	0.25	Birds, mammals
Lifespan	0.25	Birds, mammals
Heart rate	−0.25	Birds, mammals
Basal metabolic rate	0.75	Wide range

Note: the slope records how much the 'Trait' variable changes in response to a unit increase in body weight, when both variables are plotted on logarithmically transformed axes

might be a disadvantage. Brains are costly to produce and maintain (they must be supplied with blood and nutrients) and so animals are unlikely to evolve 'spare capacity.'

Some comparative trends reveal a relationship that is mediated by some other set of factors. It is not obvious why a longer lifespan is only advantageous to larger animals. Would not a small organism benefit from living a long time and thereby having more opportunity to reproduce? One possibility is that smaller organisms suffer higher rates of mortality, from natural variation in the environment to higher rates of predation. If this is true, it may not pay smaller organisms to evolve to have a long lifespan. Rather, natural selection may favour adaptations in small organisms that allow them to grow, mature, and reproduce rapidly: there is little point in a 'slow and steady' lifestyle if one is likely to be dead before reaching maturity. Conversely, a slow and steady lifestyle may be advantageous to longer-lived species. By putting resources into producing a large and healthy body, an individual may be able to produce a larger number of offspring over a long period of time.

When such additional factors are thought either to mediate a relationship or to offer an alternative explanation, comparative methods can still be applied. The relationship between two variables can be investigated, having statistically removed the effects of a third. Rates of mortality, for example, remain correlated with lifespan even after controlling for body size: thus, one can say that decreasing mortality rates, for a given body size, will be associated with a longer lifespan. These examples show that comparative studies can both test adaptive hypotheses and reveal trends whose precise causes can often be discovered by further investigation. Alternatively, a comparative trend might be regarded as evidence, not of adaptation, but rather of some form of constraint. Animals with larger bodies may have larger brains because the genes that make larger bodies also make larger brains. Similarly, larger animals may have a longer lifespan simply because it takes longer to grow a larger body than a small one. This tension between adaptive and nonadaptive explanations for observed comparative trends is what drives investigators to make ever more precise tests of their hypotheses. So-called nonadaptive hypotheses can often be tested by controlling for suitable 'third' variables.

1. *The Problem of Independence*

One of the strongest pieces of evidence that a comparative relationship represents an adaptive trend is to show that it has arisen independently on more than one occasion. Were this simply a matter of collecting information on a wide range of species and plotting a trend, the 'comparative method' would be little more than a commonsense set of rules for displaying information. However, the hierarchical nature of biological evolution means that individual species can seldom be considered independent instances of the adaptive relationship.

Over evolutionary time species evolve and give rise to daughter species which in turn give rise to more species. At each branching point in evolution, the ancestral species may live on independently of its daughter species, or it and its daughter species may evolve into something slightly different from the ancestral form. The collection of such ancestral-descendant relationships among a set of species is described by a phylogenetic tree. Phylogenetic trees are characterized by a series of branching points leading from the 'root' or common ancestor of the species up to the tips or contemporary organisms.

The phylogenetic tree diagram also makes clear why species cannot typically be considered independent instances of an adaptive trend. Consider the example of Fig. 2(a). Eight species, all descendant from a common ancestor take the values {A, B} on two traits. Eight other species, all descendant from a different common ancestor, take the values {a, b} on the same traits. The relationship counted across the sixteen species is perfect: 'A' always goes with 'B' and 'a' always goes with 'b.' But the phylogeny of these sixteen species reveals that the pairing {A, B} and {a, b} probably arose only once. For sake of argument, assume that the ancestor at the root of the tree was {A, B} and that the traits 'a' and 'b' evolved along the branch leading to the ancestor to the eight species on the right of the diagram. These traits were then retained in the eight descendants.

The phylogenetic perspective forces us to realize that what might have appeared to be a broad adaptive trend linking two traits could be little more than a chance pairing. For some reason 'a' and 'b' each evolved in the same branch, but quite possibly independently of each other. Their retention in the eight contemporary species is no evidence at all that they coevolve: each may be adaptive in its own right, but their joint presence is not evidence that they evolved together for some adaptive reason.

If the phylogenetic tree looked like that of Fig. 2(b), however, then there would be evidence that the relationship {a, b} had evolved repeatedly: that is, on a number of independent occasions, when 'a' evolved, so did 'b.' The summary of the number of species with traits {A, B} and {a, b} would be identical to that of Fig. 2(a). But, the result in Fig. 2(b) would compel us to seek evidence for a link between 'a' and 'b' in a way that was missing from Fig. 2(a).

These considerations lead to the following important conclusion: the strength of evidence for an adaptive relationship in a comparative study derives, not from knowing how many species come to inherit some set of traits, but in how many times the relationship between two traits has arisen independently. Nearly all of the effort among researchers who design methods

Figure 2
A phylogeny of sixteen species showing (a) two sets of eight species which have retained their ancestral values on each of two traits; (b) the evolution on eight separate occasions of the pair of traits {a, b}. Figure 2(b) provides the greater evidence for correlated evolution between the two traits, despite both figures having the same overall number of species with trait combinations {A, B} and {a, b}.

for comparative studies has been directed at this problem of independence and how to exploit phylogenies to reveal independent events of evolution.

2. *Phylogenies and Independent Evolution: A Brief History*

Three broad classes of method have been developed to identify independent events of evolution in phylogenies: so-called *higher-nodes* approaches, *phylogenetic-subtraction* techniques, and methods that partition the phylogeny into independent subsets of information. Of these three classes, those that partition the phylogeny came to be dominant. Very recently new statistical approaches have begun to replace these partitioning methods.

The *higher-nodes* approach seeks to identify a level of taxonomic classification that can be considered independent for statistical purposes and then restricts analysis to that level. For example, it is well established that in mammals, most of the diversity in brain and body size observed across species, is evident in differences among taxonomic 'orders' and 'families.' The Carnivora are an example of a Mammalian order and within the Carnivora the family *felidae* comprises the cats. The Artiodactyls and the *bovidae* (the cows) are another example of an order and family. Orders and families are commonly referred to as 'higher' taxonomic levels. In this instance, the higher nodes approach would proceed by analyzing differences among family means and counting families—not species—as the independent units of analysis. This would be analogous in Fig. 2(a) to comparing only the two nodes of the phylogeny. Here the procedure works by suggesting that there are only two independent data points in the phylogenetic tree, properly recognizing that the differences represented among the sixteen species arose independently perhaps only once.

Phylogenetic-subtraction methods proceed in a manner directly opposite to the higher-nodes in their attempts to identify independent evolution. These approaches seek to identify variation among species that is independent of their phylogenetic relationships to each other. Thus, taking again the example of brain and body size, the phylogenetic subtraction methods would subtract the appropriate taxonomic family-mean from each species data point. The resulting 'residual' value is taken to represent evolution that is independent of that species phylogenetic position. Applied to Fig. 2(a), the phylogenetic-subtraction methods would calculate the mean values at each of the two nodes, then subtract the appropriate mean from each species. Here the phylogenetic-subtraction methods would identify that none of the variability among species was independent of the immediately ancestral nodes.

Both the higher-nodes and phylogenetic-subtraction methods remove some portion of the variability among the species in an attempt to identify independent examples of evolutionary change among species. The successor to both of these classes of approach, *partitioning methods*, was based upon the recognition that the phylogeny itself provides a way of partitioning all of the variability amongst species into a set of, in principle, independent units of evolution. That is, none of the variability is discarded.

The best known partitioning method is that of *independent-contrasts*. A contrast is defined as a difference between two species, a species and a node of

the phylogeny, or between two nodes. Careful choice of the contrasts yields a set of difference scores such that each member of the set is independent of each other member and which collectively account for all of the observed variability amongst species.

Figure 2(b) shows how the independent-contrast methods work. The phylogeny shows that species 1 and 2 share an immediate common ancestor. Thus, the simple numerical difference between these two species on the trait of interest identifies some amount of evolution that occurred since they branched from their common ancestor. Similarly, differences among other pairs of species identify amounts of evolution that arose since they diverged from their common ancestor and which are independent of the other pairs of species in the phylogeny. The phylogeny identifies eight such differences among the tips of the tree. Moving back one level on the tree, four additional differences can be calculated, corresponding to pairs of nodes that immediately precede the tips of the tree. Each of these differences also measures a unique portion of the evolutionary change on the tree. Here, the comparisons reveal that no evolution has taken place on the traits between pairs of these more ancestral nodes. Moving back another level there are two more comparisons, and finally the last comparison, that between the nodes that represent the two descendants of the root or common ancestor of the whole tree.

In this manner, fifteen comparisons have been identified for the sixteen species. These fifteen comparisons, each one in principle independent of the others, exhaust the variability in the phylogeny, treating all of it as relevant to the hypothesis test. By comparison the phylogenetic-subtraction methods and the higher-nodes approaches always exclude some portion of the variability among the species' traits. In general, with a bifurcating tree (each node gives rise to two descendants) such as seen in Fig. 2(b), there will always be $n-1$ independent contrasts, given n species.

A set of contrasts can be calculated separately for each of two or more traits, then the correlation of the two sets of contrasts is used to test the hypothesis of coevolution. Importantly, each pair of contrasts provides an independent test of the hypothesis of coevolution: if, for example, brain size and body size covary, then each positive difference in body size between a pair of species (or nodes) should be accompanied by a positive difference in brain size. Further, larger differences in body size should be accompanied by larger differences in brain size.

3. *New Statistical Methods and the Analysis of Comparative Data*

The capability of independent-contrasts methods to use all of the variability in the phylogeny made them the favored technique of comparative analysis throughout the 1990s. A new set of statistical methods based upon the statistical approach known as *maximum likelihood* has since replaced these techniques. The new methods, like their predecessors, identify independent instances of evolution in the phylogeny. They do so without the mechanical procedure of forming contrasts or of calculating means at higher nodes and they have greater flexibility for manipulating the phylogeny and the species data. They also retain information that is lost in the independent-contrast approach. For example, contrast methods cannot estimate the ancestral state at the root of the phylogeny.

In words, the new methods use the phylogeny to specify the expected lack of independence among species. They then use that information to adjust the statistical analysis internally to reflect the lack of independence. The new methods have been developed for two broad classes of data: *discrete* or *categorical-variable* methods are applied to data that fall into a small number (typically two) of discrete classes or categories. Diet type, mating system, and the presence or absence of some feature or behavior are examples of this kind of data. The statistical Markov-model provides a natural framework for discrete traits (Pagel 1994). *Continuous-variable* methods are applied to traits that are measured on a continuous scale. Most traits relating to size, shape, timings, frequency, or concentrations are measured on continuous scales. For this kind of data a statistical technique known as *generalized least squares* or *GLS* is well suited to analyze trait evolution on a phylogeny (Garland 2000, Schluter et al. 1997, Martins and Hansen 1997, Pagel 1997, 1999)

3.1 *Correlated Evolution of Continuously Evolving Traits: The GLS Approach*

The most commonly used model for continuously evolving traits is the constant-variance random-walk process (sometimes called Brownian-motion). In the conventional random-walk model, traits evolve each short instant of time dt by some random amount that might be positive (for example, the trait gets larger) or negative. The successive random changes to a trait are independent of each other, they have a mean or average of zero, and some unknown and constant variance, denoted σ^2.

The random-walk is presumed to unfold independently at each instant of time and along each of the branches of the phylogeny. Given this, the phylogeny specifies how much a given species' trait value is expected to vary were evolution to be rerun as a random walk many times (this is the variance, σ^2), and how similar any pair of species are expected to be. These are the quantities that are needed to adjust the statistical analysis for nonindependence amongst species.

Variance-Covariance matrix

$$V = \begin{bmatrix} \sigma^2(t_1 + t_4) & \sigma^2 t_4 & 0 \\ \sigma^2 t_4 & \sigma^2(t_2 + t_4) & 0 \\ 0 & 0 & \sigma^2 t_3 \end{bmatrix}$$

Figure 3
The variances and covariances among species (matrix V) implied by the phylogeny (left), under the assumption of a constant-variance (Brownian motion) model of evolution. The symbols 'Y' represent some trait that is measured on the three species. The value Y_0 corresponds to the ancestral value at the root of the tree.

The variance of any species' trait value turns out to be given by $t\sigma^2$, where t is the total path length from the root of the phylogeny to the species (the summation of all the small dts); t might be measured in units of time or in units of 'operational time' such as genetic divergence. Closely-related species will tend to have similar trait values, even under a random-walk, owing to sharing most of their evolutionary history. The expected covariance (like a correlation) between two species in their trait values is given by $t_s\sigma^2$, where the subscript s denotes the shared path length from the root up to the point at which the two species separate.

The generalized least squares model represents the information about the expected variances and covariances of species in a matrix, usually denoted V. Figure 3 shows the matrix V that is implied by the simple phylogeny depicted there. GLS statistical methods use V to adjust internally for the expected lack of independence among species. This means that one can simply analyze the species data points as if they were independent, the nonindependence having been controlled for automatically by V. It also means that one can specify transformations of V that effectively change the underlying model of evolution (Pagel 1999).

3.2 Mammalian Brain-size Evolution

The evolution of mammalian brain size provides a good example of the use of the GLS approach to analyze comparative data. Theories of the evolution of mammalian brain size link brain volume to body mass either through body surface area or through basal metabolic rate. The surface area hypothesis requires that the slope of the line relating brain volume to body mass is 2/3; the metabolic rate hypothesis predicts that the slope of brain volume against body mass will be 3/4, owing to the relationships of basal metabolic rate to body and brain size. Empirically derived brain-body slopes generally lie somewhere in the 2/3 to 3/4 range.

Applied to the data of Fig. 1 and using a suitable phylogeny of the mammals, the GLS model returns a slope relating brain mass to body mass of 0.61. This is lower than the expected 2/3 to 3/4, despite a very strong correlation between the two traits (Table 2). Even in these comparatively small samples, the 95% confidence intervals exclude 3/4, and nearly exclude 2/3. The GLS model also estimates the ancestral mammalian brain and body sizes, here found to be a brain mass of 20 grams and a body mass of about 5 kilograms. By comparison to the brain and body size relationship, the slope of basal metabolic rate to body mass (Table 2) is near to the expected value of 0.75 (Table 1).

The GLS model returns unfavorable support for the surface-area and metabolic rate theories of mammalian brain size. Theories linking brain-adaptations to specific environmental demands may offer new ways of thinking about brain evolution.

3.3 Testing the Adequacy of the Model of Evolution

The GLS approach makes it possible to test the adequacy of the underlying constant-variance (Brownian motion) model and to test hypotheses about trait evolution (Pagel 1999; see also Table 3). This is done by transforming the elements of V. A parameter κ scales individual phylogenetic branch lengths and can be used to test for a punctuational mode of evolution; a parameter δ scales overall path lengths in the phylogeny—the distance from the root

Table 2
Slope of the regressions of brain-volume and basal metabolic rate against body size in mammals. Derived from directional GLS model. Ninety-five percent confidence intervals in brackets.

Variable	Number of species	correlation	GLS regression slope, 95% CI	Theoretical expectation
Brain volume	23	0.96	0.59 (0.52–0.67)	0.67–0.75
Basal metabolic rate	15	0.95	0.72 (0.60–0.84)	0.75

Table 3
Three scaling parameters available to the GLS model and their interpretation when applied to trait evolution on a phylogeny

Parameter	Action	0	< 1	1	> 1
λ (lambda)	Assess contribution of phylogeny	Star phylogeny (species independent)	Phylogenetic history has minimal effect	Default phylogeny	Not defined
κ (kappa)	Scale branch lengths in tree	Punctuational evolution	Stasis in longer branches	Default gradualism	Longer branches more change
δ (delta)	Scale total path (root to tip) in tree	Not defined	Temporally early change important (adaptive radiation)	Default gradualism	Temporally later change (species-specific adaptation)

to the species—and can detect adaptive radiations; and a parameter λ asks whether the phylogeny correctly predicts the patterns of variance and covariance. If species are evolving as if they are independent, this parameter will indicate that phylogenetic correction can be dispensed with, and will automatically do so.

For the brain and body size data, the 95 percent confidence intervals of all three parameters overlap 1.0, the default values under the constant-variance model: $\kappa = 1.06$ (0.42–1.63); $\hat{\delta} = 0.96$ (0.078–2.79); and $\hat{\lambda} = 1.0$ (0.94–1.0). These values justify using the phylogeny to correct for nonindependence, and indicate that trait evolution is proportional to the branch lengths.

3.4 Correlated Evolution of Discrete Traits: The Markov Model

The Markov-transition process is the statistical model widely used to describe the evolution of traits that adopt only a finite number of states. The Markov approach estimates the rates at which a trait or character makes transitions amongst its possible states as it evolves over time. A trait is assumed to begin some epoch of time in one of its possible states and then at each short epoch of time dt it can jump to one of its other states. The Markov transition rates are the rates at which these jumps are made. These rates are sufficient to calculate the most probable states at any node or tip of a phylogeny, given some starting point at the root. Similar to the situation with continuously evolving characters, closely related species will typically have similar trait values under a Markov model, whereas more distantly related species are not expected to be as similar.

To test for correlated evolution between two binary discrete characters the Markov model compares the fit of two models to the data. In one the two traits are allowed to evolve independently; in the other they evolve in a correlated fashion. Evidence for a correlation is found if the model of correlated evolution fits the data significantly better than the model of independent evolution (Pagel 1994).

For a trait that can take only two values (e.g., 0,1), two rates must be estimated, one for transition from '0' to '1,' and the other for transitions from '1' to '0.' Four parameters are required for two traits evolving independently. The model of correlated evolution considers the four possible states that two binary characters can jointly adopt (0,0; 0,1; 1,0; 1,1). It then allows one of the variables to change state in any branch of the tree, yielding eight possible transitions to be estimated (Fig. 4). These can be shown to be sufficient to calculate the probability of any kind of change in any branch of the tree, and they can be used to chart the most probable course of evolution from the ancestral state to the contemporary derived state.

Figure 4
Independent transitions between two binary states in two traits (upper); Linked or correlated transitions in two binary traits (lower). Dashed lines are not calculated.

3.5 The Evolution of Lactose-tolerance

The evolution of lactose tolerance in human societies illustrates how to test for correlated evolution using two discrete traits. The lactase enzyme confers an ability to digest milk. Human infants can digest it, but most adults cannot (widespread tolerance to lactose amongst some European groups is exceptional). A dominant view is that adult lactose-tolerance in humans is an adaptation to reduced exposure to the sun: both the sun and the lactase enzyme promote calcium absorption. The hypothesis accounts for the lactose-tolerance of some northerly-dwelling cultural groups such as the reindeer-herding Lapps, and the prevalence in some European groups. An alternative to the latitude theory is that adult tolerance to lactose is advantageous in cultures that keep animals for milk. If milk forms a significant portion of the diet, selection pressures on adults to develop the ability to digest it could be strong. Thus, two binary traits are available (lactose tolerant/intolerant and dairy/nondairy subsistence) and the adaptive hypothesis is that they coevolve.

The Markov-process model applied to a phylogeny of human cultural groups shows that adult lactose-tolerance has arisen independently in humans up to three times in cultures that keep animals for milk, but never in nondairying cultures (Holden and Mace 1997). This association is sufficiently strong to reject the model that the two traits have evolved independently in human groups, in favor of the view that they have coevolved. The Markov approach also reveals the probable course of the evolution of lactose-tolerance: the ancestral condition of nondairying and no adult lactose-tolerance was first replaced by dairying, perhaps as early as 6,000–8,000 years ago, which then favored the evolution of tolerance to lactose. The data do not support the alternative scenario that human groups with adult lactose-tolerance were more likely to adopt dairying subsistence practices.

4. General Discussion

Comparative methods remain a popular set of techniques for investigating adaptation. New statistical approaches are easy to use and make use of more of the information in the data than previous methods. Coupled with increasingly accurate and informative phylogenies based upon gene-sequence information, comparative methods can be used to test new hypotheses and to re-examine old ones. The availability of statistical parameters for scaling branch lengths, and the phylogeny itself usher in a new range of hypothesis tests for comparative data.

Comparative Neuroscience

Ever since the brain was recognized as responsible in some way for behavior, awareness, and mental activity, the question has been alive: how do our brains compare with others, from apes to flat worms?

This question has frequently been investigated solely by comparing brain sizes. Specialists in comparative anatomy have also pointed out differences between major taxa, such as mammals and reptiles, in the layering of the cerebral cortex and the development of a corpus callosum, among other gross features. With the invention of a battery of new methods in experimental microanatomy that make possible the tracing of first order neuronal connections (those not interrupted by synapses), an extensive body of knowledge has accumulated on comparative hodology—the projections into and out of identified brain regions, nuclei, and laminae. There is, in addition, a more limited literature on the comparison of neurally active compounds, such as transmitters and modulators, among the major taxa, including phyla.

Still less advanced is knowledge of mesoscopic and microscopic organization, including physiological as well as anatomical features that differ among animals, especially those relevant to behavior. Examples are: (a) cell types, especially those defined by response properties; (b) local circuits intrinsic to a nucleus or laminated structure; (c) the degree of reciprocity of connections between structures at the same level—such as cortico–cortical—and at different levels—such as thalamo–cortical; (d) dynamical interactions (potentiation, induced rhythms, event-related potentials, brain waves); (e) kinds of information processing (command cells, head-position compensating cells, pattern-sensitive cells, face-selective cells); and (f) emergent properties (kindling, seizures, learning of each of several kinds). Virtually unknown and awaiting future study are the neural substrates of behaviorally defined traits such as (g) the number and resolution of discriminable stimuli like individual voices, smells, and places within the environments experienced—roughly knowledge; (h) the number and qualia of emotions, sets, moods, and status symbols that an individual can manifest and can discriminate in others; and (i) the variety, specificity, and longevity of memories of past events.

This list, obviously, is not exhaustive and serves simply as a framework upon which to review the state of comparative neuroscience today.

1. *Evolution of the Nervous System*

The nervous system and its sense organs and effectors have evolved through a greater span of complexity than any other system within living organisms, if we consider the animals with the simplest nerve nets and those with the most complex brains. It has not evolved linearly, steadily, or inevitably but with repeated instances of retrograde loss of complexity. But, overall and roughly, the more primitive taxa represented among surviving species have very simple nervous systems as well as behavior, relative to certain branches of the most derived taxa, which have extremely advanced (i.e., complex) brains and behavior.

This difference was already strong long before hominids or primates or mammals or vertebrates appeared. Even if we consider only gross anatomy and crude histology of the nervous tissue, a comparison of cnidarian medusae to polyclad flatworms, or of pulmonate snails to octopods, of agnathan hagfish to mormyrid teleosts, or of reptiles to mammals, dramatically underlines a diversity of grades of organization differing, above all, in complexity.

By complexity, in this context, we mean the sum of the kinds of elements and operations. This includes kinds of structural elements (distinguishable cell types on all possible criteria, plus groupings of cells, and structural parts with subdivisions at all levels), the kinds of functional connections and interactions, of physiological properties and influences, and of discriminable stimuli and behavioral actions. Each of these would be difficult to count but is concrete and not vague. On this tangible scale, one approachable by degrees, we can recognize higher and lower species, purely with respect to complexity.

We can thus estimate the degree of independence of evolution of traits and systems of traits, for example vision and movements, or vision and olfaction. We can approximate a distinction between major steps in grade (gastropods and cephalopods; reptiles and mammals), on the one hand, and on the other, adaptive specialization within roughly the same grade of overall complexity (e.g., life styles and adaptations among rodents or among bats). We can estimate that most evolution has been adaptation within grade, at the level of species, genera and families, whereas saltations in the major grades of complexity have been relatively few and clearest at the levels of (some) classes and (some) phyla. To see the big picture we should eschew arguable questions at the level of families and even higher taxa of roughly equivalent advancement, such as whether bats are a higher grade than rodents, or lobsters a higher grade than cock-

roaches. It is best to compare phyla and classes, sometimes orders, choosing the most advanced species in each and avoiding taxa that might be secondarily simplified.

With these caveats, made to dispel charges of anthropocentric or moralistic, value-laden reasoning or a simplistic, linear animal scale, we can look at the grand sweep. Most of the time we scrutinize evolution with respect to how it happens, or how it is adaptive or what phylogenetic branching is most likely. We tend to overlook the perspective of consequences in terms of major grades of complexity. A grand fact of animal evolution is the development of more and more complex brains and, probably, also behavior—slowly and erratically, without a clear and self-evident increase in survival value but spanning an overall series of levels of advancement almost impossible to overstate.

The main thesis of this essay is that modern biology has neglected to study the details of the differences between grades of complexity. Beyond the gross and macroscopic anatomical differences in classical textbooks, such as the mammalian hippocampus, corpus callosum, corticospinal tract, and six-layered isocortex, we lack an accumulated body of comparisons—at each of the relevant integrative levels from molecule to cognitive system. This is surely a rich vein of ore for future investigators to mine.

2. *Macroanatomy and Connectivity*

The state of knowledge of the gross and microscopic anatomy of the nervous systems of invertebrates (Bullock and Horridge 1965) and vertebrates (Butler and Hodos 1996, Nieuwenhuys et al. 1998) can be found in text and reference books, richly illustrated. Four levels of inquiry may be distinguished.

2.1 *Brain Size*

Brain size is the crudest, usually plotted against body size, since a regression of these two measures is general. Both measures have large uncertainties, including how much of the normal cerebrospinal fluid, blood, blood vessels and plexuses, meninges, and nerve roots should be included, how the brain was removed and preserved, how body weight is taken and how exoskeleton, horn, shell, gastrointestinal contents, fat, preservative, and other variables are treated. The regression is characteristically very low for plots of individuals of the same species, substantially higher for species of the same family, and still higher for higher taxa. This makes compensating for size, sex, age, nutritive state, and cutaneous appendages only an approximation. The general result is clear—that brains considered more advanced on other criteria tend to be larger in proportion to the body. To an unknown extent the larger brains are considered to reflect greater sensory input and a larger variety of discriminable stimuli plus a greater efference and larger variety of responses. These, however, are essentially untested hypotheses and it can be seriously doubted that these factors adequately account for the size differences.

2.2 *Brain Lobes and Nuclei*

Brain lobes, clumps of nerve cells (nuclei), and gross subdivisions of these are potentially more meaningful than sheer size to compare across taxa, life style, and behavioral adaptations. Many examples are known where prominence of optic lobes, auditory nuclei, areas of the cortex representing snout or whiskers, bird-song centers, or hippocampal place-memory enlargements correlate with behavioral adaptations. Yet many other features of comparisons between species are not obviously explicable in terms of the known habits of life—as for extreme differences in cerebellar size among families of elasmobranchs, size diversity in the habenula and corpus striatum, or diversity of layering in visual cortex among primates and in the dorsal cochlear nucleus among rodents. This level of analysis might be expected to be more sensitive than others to behavioral complexity, especially in the degree of differentiation of the relevant brain parts. It seems likely that enumeration by equivalent standards of the number of distinguishable subdivisions of the thalamus or hypothalamus, or of the cortex as between reptiles and mammals—taxa at quite distinct grades of complexity—would show a greater variety in the mammals. But we have, so far, very few attempts to make such comparisons. This would quantify the strong impression from qualitative histology that the brains in the most advanced teleosts are more complex than those in the most advanced amphibians, as well as elasmobranchs.

2.3 *Connections, Afferent and Efferent, into and out of Each Nucleus or Lamina*

Connections, afferent and efferent, into and out of each nucleus or lamina, indeed each cell type, are now extensively worked out in both invertebrates and vertebrates, thanks to an ever expanding battery of methods that reveal origins and destinations of axons, and even to some extent of dendrites, cell by cell. Hodology offers a multitude of comparisons, often complicated by a problem peculiarly serious at this level. That is the problem of what criteria are adequate for establishing which cell group in one family or order is equivalent—preferably homologous—to a cell group in another taxon. Besides the simple list of connections in and out of every structure, some significant general features of comparison are op-

portune. How do two taxa compare in the number of connections between higher and lower brain levels, ascending and descending, between regions at the same level (e.g., corticocortical), between cells of the same local region (often called interneurons or intrinsic neurons), and how localized are the terminations?

2.4 Identifiable Neurons

Widespread among invertebrate phyla and present to a limited extent in anamniote vertebrates is the phenomenon of identifiable neurons. These are neurons that can be recognized and named as the equivalent cell in each individual examined, hence one-of-a-kind cells, most often duplicated on left and right sides. Defined by a combination of anatomical and physiological features, especially their afferent and efferent connectivities, the cells with the same name in different individuals typically belong unequivocally to their unique class but are not identical. Identified neurons are conspicuous and common in leeches, probably in some polychaetes, insects, crustaceans, some gastropods, and a few other taxa. Some workers believe that most of the neurons in certain animals, such as the tectibranch gastropod, *Aplysia*, are potentially identifiable. A small number of identified neurons are known in lampreys and a pair in many teleosts. It is not clear what factors of phylogeny, or life style correlate with their occurrence. The question of intermediate classes of cells has been raised—those cells which belong, not to a class of 1 but 2 or 10 or 100. It is quite plausible that smallish equivalence classes are abundant even in mammals, taking account of all distinguishing features—immunological, dendrological, and especially functionally relevant connectivity. The significance of this notion is that the equivalence classes: (a) are in fact the biologically important kinds of cells in the nervous system; (b) may run into very large numbers—probably far beyond any other organ in the body; and (c) may represent, in principle, one of the best measures of evolutionary advancement, defined as complexity.

3. Cellular Processes and Messengers

The breakthrough of Hodgkin and Huxley gave us two specific ion channels with distinct roles. Simplifying history, Hagiwara added calcium channels in some tissues of some species. Today we have scores of distinct channels (see *Ion Channels and Molecular Events in Neuronal Activity*) and no clear picture of their distribution among cell types or animal species. It appears not to be the case that a wide array of different channels was evolved only in later, more derived or more complex animals. Studies on relatively primitive living groups show a high diversity of channels. It is still possible that general principles will emerge relating the relative abundance of different kinds of channels—their sensitivities, dynamics, and interplay—in different kinds of excitable cells and then among the taxa.

Much the same seems to be true for transmitters, modulators, and intracellular messengers. The half dozen or so transmitters, a rather stable list (see *Neurons and Dendrites: Integration of Information*; *Neurotransmitters*), are each quite widespread among phyla and differences in distribution are mainly between functional systems within a given brain. Modulators are increasing in number; currently there are scores. Several are known to be widespread but no simple picture is yet tenable as to evolution or distribution, particularly if we ask for evidence of what the compounds do neurally.

4. Mesoscopic Traits and Organization

If the vast differences between brains of simpler invertebrates and complex mammals are not obviously correlated with vast differences in the membrane and cellular machinery, could sheer numbers of cells and connections explain complexity? Multiple sources of evidence argue against this as adequate, even though mere numerosity doubtless contributes largely. Already mentioned is the domain of the increase, probably many orders of magnitude, in the number of kinds of neurons. Among the differences are permutations of neuronal personality traits that determine the output of a neuron as an integration of its weightings assigned to inputs and their spatiotemporal patterns and its own proclivities (see *Long-term Potentiation* (*Hippocampus*); *Long-term Depression* (*Cerebellum*); *Neurons and Dendrites: Integration of Information*; *Long-term Depression* (*Hippocampus*); *Long-term Potentiation and Depression* (*Cortex*)). Lists of integrative variables, each with a spectrum of possible states, run to well over 50 and new items continue to be discovered, such as the recently documented supralinear summation of multiple synaptic inputs upon dendritic gain mediated by an 'inward-rectifier' potassium current in leech pagoda cells (Wessel et al. 1999). Differentiation not only of kinds of cells but of assemblies, columns, and circuits appears to have resulted in emergent systems, and these in higher levels of systems. Between the microscopic, cellular, and subcellular levels of many components and interactions and the realm of human achievements, such as recognizing a national political opportunity, there are layers of mesoscopic organization that embody the main variety of evolutionary novelties in the grades of brains and behavior.

This mesoscopic level is where our knowledge of comparative neuroscience is weakest. We lack the

advantages of lower, cellular levels where the component elements, structures, and interactions are extensively known in well-studied species. The higher behavioral levels are more difficult to compare but at least provide many measurable variables, just because of their familiarity. The mesoscopic levels that hide the first-order explanations lack both of these advantages and lack even a recognized list of relevant measurable variables. As examples, to suggest the wealth of potential discoveries as well as their slipperiness, one thinks of electrical signs of assembly activity—brain waves, evoked and event-related potentials, sleep stages, seizure stages, patterns of cortical coherence during several kinds of thinking, localized increase in blood flow or oxygen consumption during subtle cognitive states, clinical observations of blindness to animate objects or denial of one's own left side after local lesions, and 'magic bullets' represented by neuroactive molecules that ameliorate clinical depression or obsessive-compulsive disorder. The comparative dimension will surely yield valuable perspectives to this level of analysis.

5. *Discriminable Stimuli, Responses, and States*

Any overall comparison or estimate of the degree of complexity of the nervous system as a whole, including special adaptations to a particular life style, must take the whole ethogram into account, particularly the range and variety of discriminable social situations, sign stimuli, food, enemy, habitat, and microclimatic signals, plus the range and variety of behavioral responses and internal states. The last named stand for the conative states of readiness, biases, changes of weightings, drives, and moods. The obvious difficulty of enumerating, even of discerning all of these—each representing a theoretically distinguishable spatio-temporal neural pattern—is no reason to neglect their recognition.

Even this list may allow us to forget a major measure of the capacity of the nervous system—one which is hardly touched in the bulk of the literature on comparative behavior and cognition. That is, the extent and depth and detail of the knowledge that an organism can acquire, retrieve, and use in its lifetime. This, like most of the foregoing list, may not be the task of the neuroscientist but comparative neuroscience should be based on the most complete ethology. In other words, it embraces neuroethology at every level up to the most subtle behavioral and cognitive abilities.

T. H. Bullock

Comparative Psychology

Comparative psychology is a diverse field, one which is characterized by at least four different approaches to its subject matter. The most venerable of these approaches is to describe similarities and differences in the behavioral and psychological abilities or capacities of various species, irrespective of their evolutionary lineage (relationship) (see Sect. 1). A variant of this first approach is to study the behavior or learning abilities of various species with a view toward describing the advancement or progression of psychological functioning going from the more simple to the more complex, in lines that are not necessarily closely related in an evolutionary sense; this approach is called anagenesis (or the *levels* approach) and typically shows improvements in developmental plasticity, learning ability, etc. in more recently evolved forms. The point of this approach is to discern broad trends in evolution, especially psychological evolution, and it is based on a hierarchical conception of learning abilities, going from the simple to the complex.

A more recent variant of that approach is to describe similarities and differences in species that are closely related in an evolutionary sense, and to try to interpret these results with respect to the evolution of particular behavior (see Sect. 2). Another approach practiced by comparative psychologists is to study the species-typical behavior of animals in the field throughout their life cycle (see Sect. 3). That approach was made more popular by the zoologically-trained animal behaviorists in Europe, who called themselves etho-

logists to distinguish themselves from psychologically-trained animal behaviorists in the United States, many but not all of whom confined their studies to the laboratory. Finally, there is the animal model approach, which tries to find nonhuman species with behavioral or psychological repertoires that are similar to humans so that the results of experiments with the model may throw light on seemingly related behavior in human beings (see Sect. 4).

As stated by T. C. Schneirla (1962, p. 690R), 'Comparative psychology is studied because the behaviour of animals is in itself interesting, because of important applications in fields such as medicine and animal training, and also because of significant bearings on human psychology.' The remainder of this article gives examples of each of these approaches.

1. *Similarities and Differences in Distantly Related Species*

One of the most fundamental similarities in animals of all species is their ability to stop responding to a repeated stimulus in the absence of reward. This phenomenon is called habituation and it is, along with sensitization (described next), the lowest form of learning. It is of course adaptive for animals to cease responding to a stimulus event that poses no threat and offers no reward. In snails, for example, when the substrate upon which they are walking is given a mechanical shock, they withdraw their tentacles for a brief period. When the shock is repeated in exactly the same way at regular intervals, the extent and duration of tentacle withdrawal steadily decreases until finally the animal becomes completely indifferent to the stimulus. Sensitization is the obverse of habituation in that animals will orient to abruptly presented sights, sounds, smell, etc., and their orientation reaction will be quicker and longer if the stimulus changes somewhat from trial to trial. Both habituation and sensitization are nicely demonstrated in an experiment using the wiping reflex of frogs. When the frogs are touched with a hair on precisely the same zone of skin from trial to trial, their wiping reflex declines (fewer wipes per 100 stimuli). However, when the same hair is used to stimulate the frog's skin at somewhat different places each time, the wiping reflex is enhanced (more wipes per 100 stimuli). The next higher form of learning is called associative (stimulus–response or S–R) learning or conditioning, and was made popular by Ivan Pavlov's experiments with the salivary response of dogs. In these experiments, a bell or tone was sounded followed by the sight of meat powder. The hungry dog salivated at the sight and smell of the meat powder (unconditioned response). After numerous pairings of the to-be-conditioned stimulus (tone) with the unconditioned stimulus (meat powder), the dog began to salivate at the sound of the tone (conditioned response) in advance of the presence of the meat powder. Associative learning of this kind—called classical conditioning—has been demonstrated in all vertebrates from fish ('lowest' vertebrate) to humans ('highest' vertebrate). It has also been demonstrated in some invertebrate species, but not in all, so this must be considered a higher level of learning than habituation and sensitization. There is another form of conditioning—operant learning—that strengthens existing responses through reward (food for a hungry animal, e.g.) or reduces existing responses through punishment (electrical shock, e.g.). This form of conditioning is widely practiced among animal trainers and all vertebrates and some invertebrates are capable of it. The next psychological level as far as learning is concerned is trial-and-error or selective learning, in which there is a significant perceptual, perhaps cognitive, component, in the sense that the animal must discover a specific relationship between its activities and a goal object. As first studied by E. L. Thorndike in the late 1890s in connection with his doctoral dissertation, a variety of vertebrate species were placed in a puzzle box or a maze, from which they had to escape in order to get food or join companions. Thorndike's idea was that the animal had to learn to associate making certain movements (R) in a problem situation(s) (pulling a cord or unlatching a lock) with a subsequent 'satisfying' state of affairs (getting to food or joining companions). So the S–R association in this context is the situation and the successful movement leading to the satisfying state of affairs. While some invertebrate species can do trial and error learning, this class of learning reaches its peak in mammals. The highest category of learning ability, considered by some the true criterion of intelligent behavior, is reasoning or, in other terms, insightful problem-solving. This is seen in nonhuman animals when an organism solves a problem by using as a tool (means) some object(s) that never previously in that animal's experience had been used in that way. The most famous instance of this kind was Wolfgang Köhler's chimpanzee Sultan, who, in order to reach a banana high in his cage, stacked boxes one upon another to make a ladder enabling him to reach the banana. While no doubt occurring in humans and chimpanzees, comparative psychologists have been sparing in applying this appelation to other mammalian species.

There is a form of learning that takes place through mere exposure to physical and social objects; the exposure leads to subsequent attachment, preference, or acceptance of these objects (i.e., animals and humans not exposed to these objects do not show attachment, preferences, or acceptance of these objects). This familiarity mechanism is pervasive; it is found in many invertebrate species as well as vertebrates (Szentesi and Jermy 1989), and it is often referred to as imprinting, although, technically speaking, imprinting involves a sensitive period early in life

Figure 1
Six-blind maze problem used for testing both ants and rats. Solid line indicates total errors for eight ants; broken line indicates total errors of eight rats. Ants and rats learned maze by going in the direction 1 to 13*e*; rats to food at X, ants to their nest at X (from Schneirla 1953. Reproduced with permission of John Wiley & Sons, Inc.).

and is usually defined as inducing an enduring preference not merely acceptance (nonavoidance) of an object. While particularly striking in young animals (Sluckin 1965), exposure learning operates throughout life in some species such as our own (Hebb 1946, Zajonc 1971). Exposure learning is difficult to classify with certainty in the hierarchical scheme adopted here. Since it is so pervasive and is brought to bear by mere exposure, it probably fits in above the level of habituation and sensitization because of its requirement for a higher degree of perceptual differentiation and longer term memory. It would almost always be adaptive to form attachments, preferences, and acceptance of familiar physical and social objects.

There are two approaches to classification: lumping and splitting. The hierarchical classification of adap-

Table 1
Results of tests with displacement of food.

		Walks around the screen on the side					
		With food		Empty		Total	
Species	Total trials	Trials	Percentage	Trials	Percentage	Trials	Percentage

Dogs	18	14	77.8	2	11.1	16	88.9

Data from Krushinsky, 1965, p. 283.

tive or adjustive learning abilities into habituation, sensitization, exposure learning, conditioning, trial-and-error learning, and reasoning is an example of lumping. In 1971, Gregory Razran published a book, *Mind in Evolution: An East–West Synthesis of Learned Behavior and Cognition*, in which he described 11 forms or levels of learning. He included the ones described here (except exposure learning) and further broke down the various forms of conditioning and also added 'symboling' to include the role of language in what Razran called 'the learning of thinking, planning, and willing.' Razran's treatise is without equal in the literature concerning the comparative analysis of learning ability in a large number of species, as well as introducing Western scientists to the large literature that appears only in the Russian language.

A striking example of behavioral anagenesis is provided by an experiment in which the progression in learning a maze is observed in ants and rats (Schneirla 1962). As shown in Fig. 1, the ants took more than twice the number of trials to get their error rate down to near zero, as compared with the rats. Not only do the rats learn the maze much more quickly than the ants, they do it in a different fashion. Note the large reductions in errors from trial to trial in the rats' learning curve compared with the ants', in which there is slow and gradual progress.

Schneirla observed not only a quantitative difference in the behavior of the rats and ants but also a qualitative difference:

> Not only do the rats make fewer errors and require fewer runs than the ants to master this maze problem, but their learning process in it differs markedly in several respects from that of the ants. The three stages so clearly marked in the ants cannot be distinguished reliably in the rats. The rats, in fact, progress from the very first run in shortening and eliminating their entrances into the blind alleys; moreover they drop out some of the blinds quickly and almost as units and others 'by jumps' although less rapidly. The ant's pattern of eliminating blind-alley entrances gradually by small degrees is very unlike the rat's response to this problem (Schneirla 1962, p. 513).

Anagenic trends in learning (improvements over the course of evolution) have always been considered in light of evolutionary changes in brain structure and function. In an instructive experiment with three species of birds and three species of mammals, L. V. Krushinsky and colleagues (1965) examined what he considered the ability of these different species to solve an 'elementary logical problem' by what he called 'extrapolation' without any specific training. The task involved the animals facing a screen with a gap in its center. A bowl of food passed the gap moving either in the right or left direction, remaining out of sight behind the screen once having passed the gap. The animal was free to move behind either end of the screen during one minute after the bowl passed the gap. The question was whether the animal would walk around the screen on the side of the food bowl. The number of trials each animal responded and the side to which they responded was recorded. Each animal was tested two times within one week and were given 4–8 trials during each test, with the food bowl moving alternately in both directions from trial to trial.

As can be seen in Table 1, among the three bird species, the pigeons responded only twice in 27 trials, the chickens (hens) responded in slightly over one-half of the trials but their choice of sides was at a chance level, and the crows responded at a high rate (85.7 percent) and chose the correct side 71.4 percent of the time. Among the three mammalian species, the rabbits responded on only 27 percent of the trials (9) but they were correct on eight of the nine trials. The cats showed a high level of response but their choice was at a chance level (21 times to the side with food and 15 times to the empty side). The dogs responded on almost 90 percent of the trials and their correct performance (77.8 percent) was somewhat better than the crows (71.4 percent).

Psychologically speaking, Krushinsky's task involves at least three components: object permanence (the animal must be aware that an object still exists even though it has passed from view), logical inference

Figure 2
Brain–body ratios of birds and mammals ('higher vertebrates') vs. fish, amphibians, reptiles ('lower vertebrates') (from Jerison 1969. Reproduced with permission of University of Chicago Press).

(it must be on this side rather than that side, depending on the bowl's direction of movement), and detour learning (the animal must be able to move around an obstacle without being able to see the food). There is a great deal of variation among avian species in a structure of the brain called the wulst. The high level of performance of the birds in the crow family was attributed by Krushinsky to the high level of differentiation of their wulst in comparison to chickens and pigeons, the latter having the least developed wulst. The wulst is believed to be homologous (i.e., it is the 'same' organ in a different species) to the neocortex in mammals. Given the poor performance of the rabbits, if Krushinsky's reasoning is correct, one would predict a low level of neocortical development in rabbits compared with cats and dogs, and, to carry the comparison one step further, a difference between cats and dogs in favor of dogs. It is not known whether these predictions are correct or not.

The anagenesis of the brain that does not have precise parallels in psychological function and behavior is the increase in the ratio of brain size to body size that has occurred in the vertebrate phylum (fish, amphibians, reptiles, birds, and mammals). As shown in Fig. 2, the size of the brain of birds and mammals exceeds that of all other vertebrates at all body sizes. This rather gross statistic would suggest important psychological differences between birds and mammals and the other three classes of vertebrates, and has given some validity to the division of the phylum into 'higher' (birds, mammals) and 'lower' (reptiles, amphibians, fish) vertebrates. In the terms already developed in this article, one should expect to see, by and large, greater behavioral plasticity in birds and mammals than in lower vertebrates. As it happens, that prediction does accord rather well with learning ability, especially of a species' ability to show forms of learning above the level of conditioning: sensory preconditioning and learned stimulus configuring are possible only in birds and mammals, according to Razran's (1971) extensive review of the literature. In terms of exploratory behavior in the face of novel objects, in a study of over 300 animals in over 100 different species, there was a consistent finding of mammalian superiority over the other vertebrate species (Glickman and Sroges 1966). Finally, given the presumptive relationship between large brains and behavioral plasticity, species with large brains showing a greater degree of exploratory behavior, may be evidence of a faster evolutionary pace in these species than in species with smaller brains. That expectation accords rather well with the findings of Wyles et al. (1983) of an

Table 2
Brain size in relation to rate of anatomical evolution.

Taxonomic group	Relative brain size	Anatomical rate
Homo	114	> 10
Hominoids	26	2.5
Songbirds	23	1.6
Other mammals	12	0.7
Other birds	4.3	0.7
Lizards	1.2	0.25
Frogs	0.9	0.23
Salamanders	0.8	0.26

From Wyles et al. (1983). (Reproduced by permission of Professor J. G. Kunkel.)

almost perfect correlation between relative brain size and rate of anatomical evolution for a large number of vertebrate species.

As shown in Table 2, humans, the group with the largest relative brain size (Fig. 2), show the fastest rate of anatomical evolution, with the larger and older hominoid groups (human-like forms) ranking second in brain size and rate of evolution. What is perhaps most interesting is that the relatively recently evolved songbirds rank just below hominoids and well above other mammals and other birds on both relative brain size and rate of anatomical evolution. Finally, the classifications of 'other mammals' and 'other birds' show a relatively larger brain size than the lower vertebrates (lizards, frogs, salamanders) and a corresponding faster tempo of evolutionary change. Variations in early experience during the course of individual development also contribute in an essential way to exploratory behavior and learning ability in adulthood (Gottlieb 1992), so it is not solely the possession of a large brain that is responsible for these outcomes.

2. *Similarities and Differences in Closely Related Species: Importance of Early Experience and Context*

Humans share psychological and social characteristics with other primates. Language has always been considered the greatest difference between humans and other primates. Nonhuman primates do not share our vocal apparatus and thus cannot speak, so, in order to study linguistic competence in our relatives, manual sign language or tokens have been used. There are three components to language: syntax (grammar), semantics (meaning), and pragmatics (using language to attain goals). There is little doubt that chimpanzees in particular show evidence of the latter two and some primitive understanding of grammar (e.g., changing word order to alter the meaning of a phrase or sentence). What has hampered a genuine testing of the limits of chimpanzees' and other nonhuman primates' linguistic competence has been the age of the subjects when language instruction was started. Adults are inferior in language learning to juveniles, and it is only quite recently that a bonobo (pygmy chimpanzee) has been started in infancy and the as yet unpublished results are said to represent quite an improvement over previous attempts (Savage-Rumbaugh et al. 1998).

The importance of the presence and absence of early learning or experiential opportunities has not always been appreciated in comparative psychology, although the otherwise influential scientist T. C. Schneirla advocated the study of individual development as 'the backbone of comparative psychology.' An example of the influence of different developmental opportunities for learning is the use of pointing in chimpanzees as a communicative gesture to indicate an object of interest to a conspecific partner or human caretaker. Language-trained chimpanzees point with their index finger, as do humans aged 13–18 months. Language-naive chimpanzees point with their whole hand, as do humans aged 8–12 months (Leavens and Hopkins 1999). So developmental experience with linguistic training fosters pointing with the index finger in nonhuman primates and it parallels the beginning use of words in the older human infant (pointing frequently accompanies naming in human infants and their primary caretakers).

The importance of development and rearing context in comparing closely related species is shown in studies of domesticated animals compared with their wild (free-living) ancestors. Such studies uniformly show a reduction of aggressiveness, an increase in social tolerance, and a decrease in the domestic organism's physiological stress axes (Kunzl and Sachser 1999). These are inevitable accommodations to human-made housing and living conditions. The importance of environmental context is shown in a study by D. B. Miller (1977) in which he compared the courtship patterns of domestic and wild mallard ducks. In the barnyard situation, domestic mallards do not show courtship patterns and it was believed that these patterns were lost due to 'degenerate' genetic changes presumed to be inherent in the domestication process. Miller discovered that, when placed on a farm pond, domestic mallard not only showed all the courtship patterns of their wild progenitors but also showed them in the same order: the courtship and mating patterns were undistinguishable between the wild and domestic birds when the more natural species-typical context was provided.

3. *The Importance of Field Studies of Animals Living in their Usual Habitat*

While some comparative psychologists have done (and do) field studies, most comparative psychology was (and is) studied in the laboratory. Laboratory analysis

is more precisely controllable than fieldwork, and so it is a necessary adjunct to field observations. For a period of time in the mid-twentieth century, much of comparative psychology lost touch with natural ecological settings and, consequently, the relevance of the laboratory findings to a species' adaptation in its usual abode became dubious. (There was also an increased tendency to study a narrow range of readily available domesticated species on a narrow range of problems dictated by general theories of behavior that held sway for too many years in experimental psychology.) It is largely to the credit of the zoologically trained European ethologists that ecological relevance and the study of animals as they exist in nature became focal points. The observations in naturalistic settings provide the problems (questions) to be answered by experiments in the laboratory, so the results of the laboratory experiments are ecologically valid.

The study of imprinting in waterfowl and other precocial bird species is a case in point. Imprinting was believed to be the process whereby a young bird learned its species identification. It was thought that the young birds' perceptual system was wide open (like a blank slate), so all sorts of nonspecies-typical artifacts were used in the laboratory as imprinting objects, because it was convenient and the young incubator-hatched birds would indeed approach, follow, and become attached to these visual objects. Field observations (by a comparative psychologist!) indicated that, in a number of species, the mother uttered a special call to which the young were highly attracted. As subsequently shown in laboratory experiments, even incubator-hatched ducklings and chicks were attracted to the maternal call of their species, even though they had not previously heard it, having been hatched in an incubator (Gottlieb 1971). Those field observations, and the subsequent laboratory experiments, cast serious doubt on the ecological validity of the prior experiments on visual imprinting, especially when it was shown in the laboratory that the incubator-hatched birds were more attracted to the maternal call than to the visual aspect of a hen of their species. Because of their attraction to the maternal call, in nature young birds would always follow a hen of their own species, not just any object that happened to be passing by as implied by laboratory studies of visual imprinting.

4. *Animal Models*

The question of the utility of animal models for understanding human psychological and behavioral development does not seem tenable, if by animal model we mean we are modeling identical or even highly similar human psychological, social, and behavioral phenomena. On the other hand, the validity of animal models of human genetic, physiological, and anatomical outcomes seems much more likely because the analytic techniques are available to specify the identity of the genes, physiology, and anatomy in question. In that case, it is much easier to know whether one is right or wrong about the model. The certainty that animal models are faithfully mimicking their presumed human counterparts in the arena of psychological, social, and behavioral functions is always open to question. On the other hand, the outcome of programmatic developmental experiments with animals can sometimes provide interesting and significant food for thought—hypotheses not facts—about human development. Also, insofar as they do that they can also provide food for thought about development in other animal species. So, it is at the level of generalities, not specifics, that animal experiments are useful for thinking about human development.

Animal models may not do justice to human development when they emphasize (or seem to implicate) single developmental pathways to psychological or behavioral outcomes. Human development involves equifinality (more than one pathway to a given outcome), a principle of extreme importance, especially when dealing with problem populations (psychological disorders): there is likely not only one way to intervene (or develop the disorder in the first place).

An excellent example of how comparisons of animal models and human psychological functioning can mutually enrich each other is provided by experimental studies of prenatal and early postnatal experience in the development of intersensory perception in human and animal infants (Lickliter and Bahrick 2000). By taking a comparative approach, these authors were able to show how prenatal factors, brain–behavior relations, and context and experience contribute to infants' intersensory responsiveness. Another area in which human and animal comparisons has been mutually rewarding is the study of the role of early auditory experience in vocal development in young songbirds and human infants (Heaton and Brauth 1999).

Comparative Research in Education: IEA Studies

Comparative research in education relates to the field of comparative education and the subfield of international education, but differs from them in so far as it is not concerned directly with teaching and training or the advancement of programs in developing countries. It has been strengthened by the movements that have occurred during the second half of the twentieth century for Westernization and modernization and more recently for globalization and it feeds back information to support these movements, but is independent both historically and structurally from them. This entry considers the formation of the field of comparative education, the place of comparative research in education with respect to that field, the theories and methods of comparative research in education, and the types of research studies that have been undertaken with a comparative and cross-national perspective. As an example of this body of research and scholarly inquiry, the studies conducted under the auspices of the International Association for the Evaluation of Educational Achievement (IEA) are considered from both theoretical and methodological perspectives and the key findings of these studies are listed and briefly discussed. The concluding section of this article addresses the issues arising in the future development of comparative research in education.

1. *The Field of Comparative Education*

The field of comparative education has identified as its founding father, Marc-Antoine Jullien, whose seminal study *l'Esquisse et vue préliminaire d'un ouvrage sur l'éducation comparée*, which was published in 1817, emphasized the collection of documents, objective observation, thoroughness in recording, and systematic analysis. This study established a strong research perspective in comparative education that has been maintained over time. Nevertheless, the ease of travel during the latter half of the twentieth century, together with greatly increased opportunities for communication, has led sometimes to superficiality rather than scholarly work in which comparisons are systematically examined, with sound theoretical foundations.

Leadership in comparative research in education has come traditionally from outside the USA, although the World Bank which is based in the USA has more recently supported the collection of information on the provision of education across developed and developing countries. Moreover, nongovernmental foundations as well as governmental agencies in the USA have supported financially the conduct of cross-national research studies. UNESCO, as a central organization, has sought directly to collect information on the provision of educational services across the world and its institutes, the International Institute for Educational Planning (IIEP) in Paris, the International Bureau of Education (IBE) in Geneva, and the UNESCO Institute for Education (UIE) in Hamburg have maintained for over half a century a research orientation in their studies of education across both the developed and developing world. Likewise, the

Centre for Educational Research and Innovation (CERI), which is established within the Organization for Economic Cooperation and Development (OECD) in Paris, has examined educational issues within and between the developed countries that are members of OECD. In the closing decade of the twentieth century, OECD sought to provide a stronger database through the calculation of educational indicators for use in its member countries and its publications 'Education at a Glance': OECD indicators have provided a valuable start in the provision of soundly based information.

Two publications from UNESCO, *Learning To Be: The World of Education Today and Tomorrow* (Faure et al. 1972) and *Learning: The Treasure Within* (Delors et al. 1996) have provided and are providing a basis for debate both within and between nations on the future of education from a world perspective. These publications emphasize the idea of lifelong learning in a world context that includes both developed and developing countries in which the seven tensions:

(a) between the global and the local,
(b) between the universal and the individual,
(c) between tradition and modernity,
(d) between long-term and short-term considerations,
(e) between the need for competition and concern for equality of opportunity,
(f) between the extraordinary expansion of knowledge and human beings' capacity to assimilate it,
(g) between the spiritual and the material

are very conspicuous in a world in which globalization is taking place rapidly (Delors et al. 1996). The monitoring of change in education across the world during the critical years of the first half of the twenty-first century is a major challenge for comparative research in education. Only with soundly based information on the magnitude and direction of change that could be provided through strong and well-recognized indicators can policy making and planning be carried out in all corners of the world to avoid the major catastrophies that could be caused by nuclear war, a population explosion, degradation of the biosphere, and widespread death from disease and famine.

2. *Comparative Methods in Research*

Research and scholarly inquiry in education uses two different strategies of investigation. One strategy is a holistic or systemic approach in which the characteristics or the parts are viewed with respect to the whole to which they belong. Within this strategy the pattern of relationships between the parts and the processes operating within the whole are examined. The issues involved in inquiry are whether an elementary part or characteristic can be considered to exist and whether a model of the whole built from the parts is an adequate representation of reality. The second strategy is a comparative approach in which the characteristics or the parts are compared across two or more research situations. If a difference is found between the two situations, with an adequate degree of likelihood or probability, then the origin or cause of the difference is sought. Moreover, if a difference is not found, then the reasons for the similarity may be of interest to the researcher. The comparative method is primarily concerned with the second strategy. However, the establishment of the existence of a characteristic, a part, or a relationship must precede the making of a comparison, although it might be argued that the detection of a difference through comparison can be considered to be evidence for the existence of an entity, a characteristic, or relationship.

Comparative research in education may be undertaken from either a scientific or humanistic perspective, where the former involves measurement and statistical analysis and the latter is largely descriptive or ethnographic. Furthermore, comparative research in education may draw on one or more of the major disciplinary fields, such as history, philosophy, sociology, and social psychology. There are, however, four specific ideas regarding the methods and nature of comparative education that must be considered to be fallacious.

First, there is the fallacy advanced by Holmes (1965) in his study, *Problems in Education: A Comparative Approach*, that there is a single scientific method for comparative research in education. He drew on the writings of John Dewey and advanced a sequence of eight major steps as a method of investigation that led to the production of new knowledge in education. While such systematic inquiry may be desirable in certain problem-solving studies, research in comparative education draws on more than one disciplinary field and their methods of investigation and cannot be constrained to a particular sequence of steps in inquiry.

Second, there is the fallacy that investigation in comparative research in education involves a choice between a quantitative or a qualitative approach or even a combination of the two approaches (Rust et al. 1999). The distinction between quantities and qualities is misconceived, when they are taken to be clear alternatives. Complex statistical procedures are now available for the rigorous examination of categorical or qualitative data, where information is recorded in terms of two or more categories that does not involve any attempt to measure, but merely employs classification. The advantage of measurement is that the improved precision increases the likelihood of detecting or rejecting a hypothesised relationship.

Third, there is the fallacy of making a clear-cut distinction between policy-oriented research and discipline-oriented research, or between decision-based research and conclusion-based research in comparative education. Holmes (1965) recognized that comparative education provided a strategy of inquiry that

led to a greater understanding of educational systems as well as providing information for the planned development of an educational system. However, the undue emphasis shown by politicians and administrators on the 'horse race' aspects of international studies of educational achievement, to the neglect of developing a greater understanding of the operation of the systems through comparative research, would seem to involve a serious misunderstanding of the nature of social action and the power of ideas. It assumes that research findings in the social and behavioral sciences, including education, are applied in the same way as the findings of research in the physical and biological sciences through technology and applied science. Consequently, there is a need for the UNESCO Institutes, The World Bank, and for the Centre for Educational Research and Innovation of the Organization for Economic Cooperation and Development to provide international forums for the discussion and debate of the findings of comparative research in education in terms that policy makers can understand and subsequently apply in both policy and practice.

Finally, there is the fallacy that comparative research in education is not concerned with the outcomes and products of education but only with the processes that are in operation. Nevertheless naive input–output models of education provide little of value for the making of policy or the improvement of practice, as does undue emphases in simplistic terms on achievement outcomes that are evident in the media presentations of the findings of some international studies of educational achievement.

3. *Paradigms and Theories in Comparative Research in Education*

Altbach (1991) has argued that in the late 1980s the theoretical frameworks employed in comparative research in education shifted away from a central role for sociology and from structural–functional and statistical paradigms towards greater heterogeneity. Paulston (1994) has more recently identified four world views in a taxonomy of knowledge perspectives in scholarly writings on comparative and international education. These four world views are (a) functionalist, (b) radical functionalist, (c) radical humanist, and (d) humanist perspectives. These four perspectives have been mapped by Paulston in a two-dimensional space with the many general theories involved in comparative and international education located within this two-dimensional map. The macromapping of paradigms and theories makes clear the multiplicity of general perspectives that, at the end of the 1990s, were present in the field of comparative and international education. Through the use of this map the broader movements that influence scholarly work in the field of comparative education are presented in a way that indicates the dynamic but adventitious nature of the field at a time when issues of globalization and the cross-national transfer of ideas and knowledge are being greatly facilitated by the new information technology. The challenge for comparative social theory is to make sense of the rapid changes that are occurring in the late 1990s and early 2000s.

4. *The Many Methods and Approaches of Comparative Research in Education*

There can be no argument about the fact that there are many different tactics and strategies being employed in comparative studies in education. Each of these different approaches has considerable utility in a field of inquiry that is actively pursued around the world, particularly along economic, social, and political dimensions. Of particular importance are the contributions that comparative research in education can make to the economic development, social development, and political development of a particular country, especially in those countries that are classified as developing countries.

In addition to those studies that might be classified as theory building and that address issues related to the structure of both knowledge and inquiry in the field and are sometimes described as theoretical or conceptual studies, there are studies that employ methods of inquiry derived from particular disciplines. These disciplinary studies involve historical, demographic, linguistic, economic, political, or other perspectives as they relate to education. There are, however, comparative research studies in education that extend across disciplines and that would seem to fall into one of three types: (a) descriptive studies, (b) developmental studies, and (c) analytical, relationship, and process studies.

4.1 *Descriptive Studies*

An important task in comparative education is to provide a descriptive account of how education is conducted in different countries, with generally only one country under survey in each study. However, the national systems of education of more than 130 countries are presented in the *International Encyclopedia of Education* (Husén and Postlethwaite 1994) and the derived *Encyclopedia of National Systems of Education* (Postlethwaite 1996) in a way in which education in each of the different countries is described within a common framework. Such descriptive studies serve an important purpose since they provide relatively concise accounts of educational policies and practices in each particular country and thus assist in

the building up of an understanding both within that country and elsewhere of the different systems of education that have been developed in different contexts across the world.

The comparative value of these descriptive statements is limited by the existence of many problems. The major problems involve: (a) the lack of a list of key educational indicators which have been agreed on by scholars and administrators in all countries, so that accurate and consistent data are collected; (b) the cost and practical difficulties of assembling data from many sources; (c) the lack of comparability of the data collected, in spite of efforts to maintain uniformity; (d) the tendency of ministry officials in each country to present the conditions of education within their country in the best possible light and as a consequence to withold data that are unfavorable; and (e) insufficient analysis and presentation of context without which the data recorded have only limited meaning.

4.2 Developmental Studies

The influence of the social and behavioral sciences is effected not through technology and direct application, but through the power of the ideas and relationships that arise from research, which are disseminated and debated and which give rise to collective social action. The contribution of education to this process of promulgation and discussion of ideas and relationships is greatly underestimated, and the nature of social action in democratic societies across the world is only gradually being understood. As a consequence, many of the societal developments that have occurred in different countries of the world and that have their origins in education still remain to be examined and reported.

Some attempts have been made to account for both changes in education and social life. Hans (1949), for instance, argued for a level of generality with the identification of factors influencing educational development: namely, (a) religious factors (Anglican, Catholic, and Puritan); (b) natural factors (racial, geographic, linguistic, and economic); and (c) secular factors (socialism, humanism, nationalism, and democratic ideals). Nevertheless, these factors do not provide an explanation in terms of the common or universal factors that have influenced the spread of educational provision across the world, and would seem to involve the unique factors which might explain why countries now differ with respect to educational provision in particular ways. Mallinson (1957) suggested that educational development within a country was influenced by a national mental constitution that had formed over time within the country. While this might help to account for particular features of German and Japanese education it would not seem to explain the marked growth in education that has taken place in so many countries since the latter half of the nineteenth century.

Meyer and Hannan (1979) have contended that the thrust for universal primary education must be seen in a cross-national context, and that the powerful ideas are to be found in the Darwinian theory of evolution, and the impact of Marx's ideas, particularly in China and the USSR. There is much more work to be done to explain the common developments in education that have occurred cross-nationally during the twentieth century.

4.3 Studies of Relationships and Processes

The systematic study of relationships and processes in comparative research in education has emerged only during the second half of the twentieth century. These studies seek to increase understanding of how variables relate to one another, to explain better the dynamics of teaching and learning and educational change, and to investigate how such relationships and processes vary across countries. Nevertheless, cross-national studies of educational achievement are difficult and costly to conduct because extensive cross-national consultation is required. The International Association for the Evaluation of Educational Achievement (IEA) has been the major pioneer of this type of investigation into the factors influencing achievement outcomes across the countries of the world.

5. The Research Program of IEA

In the late 1950s a group of educational research workers meeting at the UNESCO Institute for Education in Hamburg saw the need for comparative studies of the relationships and processes operating to influence the educational outcomes of achievement and attitudes. They recognized that there was generally insufficient variability within a particular country to detect the effects of specific factors on the outcomes of learning, using existing methods of statistical analysis. They argued that if research studies could be undertaken between countries, as well as within countries, then the greater variation that existed across countries and the different school systems within countries would permit the identification of common factors of importance which influenced learning outcomes.

The feasibility of conducting research studies across countries into factors influencing educational achievement was tested in a pilot study. The success of this study led to the establishment of the IEA. Over a period of nearly 40 years IEA has carried out a sustained program of research studies, which have in the main been survey and cross-national investiga-

tions, into factors that have an effect on educational achievement, participation rates, and attitudes towards school and school learning. The data collected have been examined across countries, between schools within countries, and between students within countries, and where possible relationships have been tested after controlling for other factors that might affect the educational outcomes under consideration. The specific relationships that have been tested fall into one of several types, namely: (a) relationships between predictor and criterion variables across countries; (b) similar common relationships between predictor and criterion variables at the levels of between students and schools within countries; (c) relationships between predictor and criterion variables at the levels of between students and between schools that are unique to a particular country or a small group of countries; and (d) the absence of an observable relationship where current opinion has hypothesized that such a relationship should exist.

Before the systematic examination of processes between students, between schools, and between countries can take place advances must be made along three fronts. First, it is necessary for theory to be developed and models formulated of specific processes of school learning. Second, it is necessary for data to be collected that are sufficiently comparable across countries, so that the testing of models in a comparative manner is worthwhile. Third, statistical procedures for the testing of models must be developed in order to provide strong estimates of effects and efficient estimates of error for the examination of statistical significance and effect size.

Several theoretical frameworks have guided the development of models in IEA research studies. From the Gränna Workshop conducted in Sweden by IEA in 1971, which examined in detail the seminal work *Handbook on Formative and Summative Evaluation of Student Learning* (Bloom et al. 1971) came the theoretical view of curriculum implementation that has been tested in several IEA studies. In this model the curriculum can be considered to exist at three levels: (a) the intended curriculum, (b) the implemented curriculum, and (c) the achieved curriculum, which are influenced by the antecedent and contextual factors as well as the learning conditions in the schools and teaching practices. A second highly influential model in IEA research has been Carroll's (1963) model of school learning, which was tested empirically with respect to the study of learning French as a foreign language, and has formed the basis for causal models in several IEA studies. A third model that has guided IEA research has been a cross-national model of educational achievement in a national economy advanced by Dahllöf (1967). Of particular interest for policy making are the frame or structural variables. Moreover, their dependence on (a) the environment and the economy, (b) demand for personnel, (c) curriculum content, and (d) the objectives of the school system, is argued on theoretical grounds by Dahllöf. However, only limited aspects of this theoretical model have been tested in either primary or secondary analyses.

IEA studies have consistently recorded the marked differences in levels of achievement between developed and developing countries, with much lesser variation between the countries within each group. Furthermore, it has been shown that a causal model, which explained well the influence of individual student factors on reading achievement at the 14-year-old level in developed countries, was less than adequate in two developing countries, India and Iran. These findings suggest that there are different processes in operation influencing educational outcomes in developed and developing countries.

As statistical procedures for the testing of models of causal processes have been developed, IEA has remained at the forefront of statistical analysis and has advanced and tested complex models to generate an understanding of the processes that operate to influence educational outcomes. It is noteworthy that such analytical procedures as blockwise regression analysis, partial least squares path analysis, and linear structural relations analysis were developed in collaboration with scholars at the Institute of International Education in Stockholm, who were working on the analysis of IEA data. Likewise, the advancement of procedures for the improvement of the measurement of educational outcomes in large-scale surveys, with equating across levels of test administration and over time owes much to the work of IEA.

6. *The Key Findings of the IEA Studies*

The IEA studies taken together have involved millions of students in testing programs, hundreds of thousands of schools, and thousands of research workers in the field of education from a very wide range of countries. In 1999, over 50 countries were members of IEA and its headquarters remained firmly established in Europe, although substantial financial support has been received from time to time but not exclusively from agencies and foundations in the USA. The school subjects involved in IEA testing programs have included mathematics, science, civic education, reading, French as a foreign language, English as a foreign language, computing, literature, and writing. In addition, there have been studies in preschool education.

There are marked differences in average levels of achievement between the students in school in the more developed countries (MDCs) and those in the less developed countries (LDCs). This occurs in spite of the fact that in the LDCs less than 100 per cent of the relevant age groups are enrolled in school.

The average level of achievement within a country at the terminal secondary school stage is inversely related to the proportion of the age group enrolled at

school or participating in the study of the subject under survey.

At the terminal secondary school stage, when equal proportions of the age groups are compared, there are only small differences in levels of achievement, irrespective of the proportions of the age groups retained at school. The best students do not suffer with increased retention rates.

Student achievement in mathematics, French as a foreign language, and science is positively related to the time given to the study of the subject at school, both in comparisons across countries and between students within countries.

The achievement of students is related to the time spent on homework after other factors influencing achievement have been taken into account.

The average level of student achievement across countries is positively related to the opportunity that the students have to learn the content of the items tested.

In LDCs the use of a textbook has an effect on student learning. However, the same effects have not been reported from studies in MDCs.

The level of reading resources of the home is positively related to student achievement, as are other indicators of language usage in the home, such as the use of a dictionary in the home, and whether or not the language of the home is the language of instruction.

Measures of the socioeconomic status of the home are positively related to student achievement in all countries, at all age levels, and for all subjects.

Although the effects of home background variables are similar across subject areas, the effects of the learning conditions in the schools differ between subject areas, and in some subject areas are equivalent to or greater in the size of their influence than the effects of the home.

For more detailed accounts of these 10 key findings from IEA studies and the more specific findings from particular studies, the report by Keeves (1995) should be consulted. Nevertheless, it is important that the vision of those who founded IEA for the advancement of research in a cross-national context is sustained at a time when the increased visibility of international educational achievement studies gives rise to serious misunderstandings, disputable conclusions for policy and practice, and undue emphasis on the rank ordering of national achievement (Beaton et al. 1999).

7. *Research in Comparative Education in the Future*

From an examination of the Delors report (Delors 1996), seven critical world issues emerge for which education would seem to provide the major contribution to their resolution. These problems involve:

(a) the feeding of the growing population of the world;

(b) the containment of population growth;

(c) the sharing of the world's wealth between the developed and the developing countries;

(d) the advancement of technological development in the poorer countries in order to raise standards of living;

(e) the building of schools and the training of teachers to achieve universal primary schooling;

(f) the establishment of greater equity between the sexes; and

(g) the establishment of greater equity between different social and racial groups.

Not only must comparative education help to monitor change with respect to these problems, but it must also play an active part in their resolution through the spread of knowledge. The rapid expansion of knowledge during the twentieth century demands the worldwide development of the learning society. The new information technology opens up new ways in which the learning society might operate. The field of comparative education provides the links across the countries of the world, but the exact manner in which comparative education through research might contribute is unclear. Nevertheless, it is necessary to recognize that the world's problems involve not just the wealthy and more highly developed nations, but all nations irrespective of size and wealth.

Comparative Studies: Method and Design

1. *Definition*

Comparisons are essential in any science to establish systematic similarities and differences between observed phenomena and, possibly, to develop and test hypotheses and theories about their causal relationships. Whereas this broad definition of comparative inquiry comprises several distinct methods, including case studies, statistical analysis, and experimental research, the comparative method in the narrower sense of the term characteristically involves a limited number of cases ('small *N*'), but usually very complex phenomena and relationships often at the 'macro'-level of entire societies or political systems. In this latter sense this method and its respective designs will be discussed here.

2. *Intellectual Context*

Comparative procedures in the historical and political sciences date back to antiquity, but their methodological backgrounds have only been developed systematically in the natural sciences in the eighteenth and nineteenth centuries based on studies, for example, by Linné in botany, Cuvier in anatomy, or Bernard in experimental medicine. The logical foundations for this method have been laid by Hume and, in particular, J. S. Mill's (1843) 'canons.' The first of these refers to the 'Method of Agreement' eliminating all similarities but one: 'If two or more instances of the phenomenon under investigation have only one circumstance in common, the circumstance in which alone all the instances agree is the cause (or effect) of the given phenomenon' (p. 390). By contrast, the 'Method of Difference' establishes the absence of a common cause or effect, even if all other circumstances are identical: 'If an instance in which the phenomenon under investigation occurs, and an instance in which it does not occur, have every circumstance in common save one, that one occurring only in the former; the circumstance in which alone the two instances differ, is the effect, or the cause, or an indispensable part of the cause, of the phenomenon' (p. 391).

Both methods thus are concerned with the systematic matching and contrasting of cases in order to establish common causal relationships by eliminating all other possibilities. Both procedures are, however, somewhat extreme in the sense that they attempt to establish a single common cause, or its absence, by controlling all other possibilities and the entire environment. The method of difference can, to some extent, be approximated in 'pure' laboratory situations where such experiments may be conducted. The method of agreement is more applicable in 'field research' situations, but then the question of how to control the 'environment' becomes crucial (see *Field Observational Research in Anthropology and Sociology*).

Mill, therefore, devised a combination of the two which he called the 'Joint Method of Agreement and Difference' or the 'Indirect Method of Difference' which consists of a double employment of the Method of Agreement, once before and once after a certain event: 'If two or more instances in which the phenomenon occurs have only one circumstance in common, while two or more instances in which it does not occur have nothing in common save the absence of that circumstance, the circumstance in which alone the two sets of instances differ, is the effect, or the cause, or an indispensable part of the cause, of the phenomenon' (Mill 1974, p. 396). This 'quasi-experimental' design is, however, as Mill himself realized, less cogent than the pure Method of Difference.

A fourth method, which is a derivation of the Method of Difference, is the 'Method of Residues'. When cause and effect of other factors have been established by previous experiments, remaining variation in the outcome can be attributed to the 'residues' in the original experiments: 'Subduct from any phenomenon such part as is known by previous inductions to be the effect of certain antecedents, and the residue of the phenomenon is the effect of the remaining antecedents' (Mill 1974, p. 398).

Finally, for instances where a certain common external factor cannot be entirely eliminated by any of these procedures, its impact may at least be systematically varied from one situation to another (e.g., altitude above sea level, or heat or air pressure in certain experiments in physics) and then its varying influence assessed. This is the 'Method of Concomitant Variation': 'Whatever phenomenon varies in any manner whenever another phenomenon varies in some

particular manner, is either a cause or an effect of that phenomenon, or is connected with it through some fact of causation' (Mill 1974, p. 401).

3. Changes in Emphasis

Mill's 'canons' imply rather rigid 'positivist' assumptions about the relationships of cause and effect and the state of valid theory in any given area of research. These are: (a) contiguity between the presumed cause and effect; (b) temporal precedence, in that the cause had to precede the effect in time; and (c) constant conjunction, in that the cause had to be present whenever the effect was obtained (cf. Cook and Campbell 1979, p. 10). On the whole, such relatively mechanical and deterministic relationships can only rarely be established even in the 'hard' sciences.

By themselves, therefore, these methods do not produce any new *discoveries* unless some truly relevant factors have been included. Similarly, they may not *prove* any causal relationship unless a clear and complete (preconceived) model of such links has been tested and other factors were sufficiently 'controlled.' But even such a model may eventually be falsified and be integrated in a more comprehensive theory. So these methods may not produce any 'positive' results. They constitute, however, a valuable step to eliminate many irrelevant factors and to approximate the causal conditions in the 'real' world. In this sense they correspond to Popper's (1934) famous principle of 'falsification.' Or as it was expressed in another 'classic' of this period, Mill's methods are nevertheless '… of undoubted value in the process of attaining truth. For in eliminating false hypotheses they narrow the field in which true ones may be found. And even where these methods may fail to eliminate all irrelevant circumstances, they enable us with some degree of approximation to so establish the conditions for the occurrence of a phenomenon, that we can say one hypothesis is logically preferable to its rivals' (Cohen and Nagel 1934, p. 267).

If these qualifications have to be made from a general epistemological point of view, they apply even more to the social and behavioral sciences where 'objective' facts and their 'subjective' perceptions are closely interlinked and may change in the course of time. Mill himself was aware of the much higher complexity in the social sciences and the inapplicability of his methods in a very strict sense: in 'politics and history … Plurality of Causes exists in almost boundless excess, and effects are, for the most part, inextricably interwoven with one another. To add to the embarrassment, most of the inquiries in political science relate to the production of effects of a most comprehensive description, such as the public wealth, public security, public morality, and the like; results liable to be affected directly or indirectly either in *plus* or in *minus* by nearly every fact which exists, or event which occurs, in human society' (Mill 1974, p. 452, emphases in the original). He, therefore, found the Method of Difference inapplicable and the Methods of Agreement and Concomitant Variation inconclusive in the social sciences (pp. 881 ff.). Similarly, the Method of Residues requires a much more developed state of theory than is usually available in the social sciences (p. 884 ff.).

However, in the realm of the human and social sciences, Mill was willing to adopt a less deterministic and more probabilistic perspective:

> Inasmuch as many of those effects which it is of most importance to render amenable to human foresight and control are determined, like the tides, in an incomparably greater degree by general causes, than by all partial causes taken together; depending in the main on those circumstances and qualities which are common to all mankind, or at least to large bodies of them, and only in a small degree on the idiosyncracies of organisation or the peculiar History of individuals; it is evidently possible with regard to all such effects, to make predictions which will *almost* always be verified, and general propositions which are almost true. And whenever it is sufficient to know how the great majority of the human race, or of some nation or class of persons, will think, feel, and act, these propositions are equivalent to universal ones. For the purpose of political and social science this *is* sufficient (Mill 1974, p. 847, emphases in the original).

4. Emphases in Current Theory and Research

Two basic problems remain in any research of this kind, namely the questions as to what have been called the 'internal' and 'external' validity of any scientific findings (see also *Internal Validity; Causal Counterfactuals in Social Science Research*). The first refers to the 'approximate validity with which we infer a relationship between two variables is causal,' the second to the 'approximate validity with which we can infer that the presumed causal relationship can be generalised to and across alternate measures of the cause and effect as well as across different types of persons, settings and times' (Cook and Campbell 1979, p. 37). Even though both kinds of validity can only be approximated and remain subject to the possibility of further falsification, they can be established with some kind of certainty with the help of procedures of randomization.

As far as internal validity is concerned, Mill's original procedures can be enhanced by first randomly selecting two groups of subjects and then administering a certain stimulus or treatment to one of them. If a significant effect can be observed in this group, then the stimulus may be considered to have been the 'cause.' This corresponds to Mill's method of difference, but where all kinds of external influences can now be controlled, within certain limits, by the 'equalizing' procedure of random selection. This is the

realm of 'experimental research' proper (see *Laboratory Experiment: Methodology*). Similarly, if a random sample has been drawn from a larger universe of persons, as for example in survey research, the relationships which can be observed in the sample may be generalized to the larger universe from which it was drawn. This is the realm of 'statistical' analysis (see *External Validity*).

Unfortunately, however, both procedures of randomization are not feasible when we deal with the characteristic 'many variables–small *N*' situation of many kinds of current social research apart from the fact that many 'real' experiments with groups of human beings are not possible for practical, political, or ethical reasons either. We are thus left with Mill's original predicaments and have to attempt to cope with them in some other ways. This also depends, of course, on the kinds of cases and problems we are dealing with and the state of theory in any given area of investigation. In social research, 'cases' often refer to larger distinct groups of people, e.g., certain ethnic groups or entire societies and states, which have a proper name and in which we are interested because of their intrinsic relevance and not just as an anonymously selected unit out of a multitude of cases.

The kinds of problems we are dealing with vary according to the respective emphasis of the different social and behavioral sciences. What they have in common is the 'multidimensionality' (i.e., comprising 'objective,' 'subjective,' and often also normative dimensions) and the 'malleability' (i.e., possible changes over time and probabilistic internal relationships) of their subject matter (Almond and Genco 1977). The ways such relationships are perceived depend on the 'social,' i.e., also theoretical constructions of this reality. These, by necessity, can only be certain approximations as to their 'real' (and changing!) nature, but they have concrete referents and are not, in our view, entirely arbitrary whims of imagination as some of the more extreme 'postmodern' authors pretend (see *Postmodernism: Methodology*). *What* to compare thus differs from one discipline to the other and depends on the respective state of theory.

By contrast, here we are concerned with *how* to compare under particularly difficult conditions concerning problems of internal and external validity in the social sciences. From this perspective, a number of ways can be conceived to cope with the prevailing 'small *N*–complex cases' dilemma. First of all, the number of cases may be increased, including for example historical cases or investigating them at some lower level of analysis, e.g. certain districts rather than entire nation-states. But even then neither randomly selected control groups nor random sampling for statistical purposes are possible. In any case, we usually are interested in concrete societies and their problems and not just in any 'anonymous' units of investigation. A second strategy concerns the purposeful selection of cases and a third, the reduction of complexity by means of combining several variables or employing better theory.

At the outset of any investigation an area of homogeneity must be defined which establishes boundaries for the selection of cases. Cases must 'parallel each other sufficiently' and be comparable along certain specified dimensions. This is meant by the common saying that 'apples and oranges' should not be compared. In this regard, the subject matter and the problem we are interested in must first be specified in order to make any sense. Thus, these fruits may well be compared concerning their sugar or water contents, their nutritional value, etc. when these dimensions as the *tertium comparationis* have been made explicit. The specification of relevant cases at the start of an investigation thus amounts to an explicit or implicit hypothesis that the cases selected are in fact alike enough to permit comparisons. The primary consideration in delimiting cases for a small *N* comparative study is the dependent variable. For example, the breakdown or survival of democratic regimes in interwar Europe presupposes the prior existence of some form of democracy in the selected cases. In addition, some limitations in time and space can also enhance the homogeneity and thus the comparability of the cases examined. For example, certain kinds of colonial or other forms of external domination or religious-cultural influences may be useful criteria for selecting a specific group of cases.

A second consideration concerns the extent of diversity within the selected universe. In this regard, a maximum of heterogeneity for a minimum number of cases should be achieved. Taking the above example again, both survivors and breakdowns of democracy can be considered, and among the latter perhaps some more specific variants such as fascist vs. more generally authoritarian outcomes.

Within this universe two opposite strategies now become possible. One is the 'most similar,' the other the 'most different' systems design. These have been explicitly formulated and discussed by Przeworski and Teune: 'The most similar systems design is based on a belief that a number of theoretically significant differences will be found among similar systems and that these differences can be used in explanation' (1970, p. 39). By matching these similar cases as much as possible, most of the variables can be 'controlled.' Mill's 'indirect method of difference' where different outcomes may be attributed to the remaining factors which differentiate these cases now becomes applicable. Even though only rarely just a single factor will remain to which the effect can be attributed, at least many others can be excluded, and the remaining ones can be examined more closely in a theoretically guided qualitative manner. The 'internal validity' of the observed relationships can thus be greatly enhanced.

The opposite strategy is the 'most different' systems design: this design, '… which seeks maximal het-

erogeneity in the sample of systems, is based on a belief that in spite of intersystemic differentiation, the populations will differ with regard to only a limited number of variables or relationships' (Przeworski and Teune 1970, p. 39). This 'contrasting' of cases thus eliminates all factors across the observed range which are not linked to an identical outcome. In this way, more 'universal' explanations are sought as far as the selected area of homogeneity is concerned. To some extent, thus, the 'external validity' of some hypothesized causal relationship can be extended and the range of its applicability including certain limitations in time and space can be established.

Until recently, these designs had not, however, been fully operationalized. Several problems must be addressed which follow from the necessity of measuring the proximity or remoteness of pairs of cases in the heterogeneous, multidimensional space defined by the independent variables. These distance measures provide the basis for determining the 'most different' and 'most similar' pairs or groups of cases with regard to the respective outcome. The two main issues are: (a) choosing from among a variety of different ways of measuring the distance between pairs of cases in a multidimensional space; and (b) assigning relative weights to the variables that define this space. In this way the complexity of the data can be retained as much as possible in the complexity of the proximity measure. These procedures then make it possible to identify 'most different cases with the same outcome' (MDSO) and the 'most similar cases with different outcomes' (MSDO). The causes of different outcomes may now be assumed to lie in the commonalities that remain among MDSO cases and the differences that distinguish MSDO cases (for such operationalizations see, e.g., De Meur and Berg-Schlosser 1996).

Another strategy for dealing with the 'many variables—few cases' dilemma concerns the variables side. Here, for reasons concerning the 'internal validity' of Mill's methods, one should take a rather comprehensive approach in order not to leave out any possibly relevant variables. This, of course, depends on the state of theory in any given area of investigation, but usually in the social sciences there are several contending or supplementary hypotheses which should all be considered. Furthermore, not only bivariate relationships with an independent variable and the respective outcome, but also the possibility of more complex causal problems, e.g., 'multiple' (several variables combined have a certain effect) or 'conjunctural' ones (alternative combinations of different variables may lead to the same outcome) must be taken into account.

One technique is to look for 'constants' across the observed cases. If one variable turns out to be consistently linked to a particular outcome, it becomes a strong candidate for inclusion in any explanation as a necessary but perhaps not sufficient condition. A related approach focuses on correlations between the independent variables and the dependent variable. Like the search for constants, the examination of correlations may provide strong hints. More sophisticated techniques include discriminant analysis and logistic regression (applied to dichotomous outcome variables). A relatively large number of variables can be simultaneously treated in this way. These techniques are typically used to assess the net, additive contribution of each independent variable to some outcome. Variables that are uncorrelated with other variables but strongly correlated with the outcome are favored by these methods. Thus, these techniques are biased toward causal factors that act independently, not conjuncturally.

These statistical approaches are useful for identifying broad patterns, but they are of limited utility in situations of causal complexity. Most complex causal combinations are hidden from analyses based on correlations. For example, if a variable must be present in some conjunctures for an outcome but absent in others, the correlation between this cause and the outcome may be 0. 'Qualitative Comparative Analysis' (QCA), a recent comparative technique based on Boolean algebra (cf. Ragin 1987), can be used in situations of causal complexity. In contrast to the linear techniques just described, QCA focuses on configurations of variables. In QCA, an independent variable can be eliminated from an analysis if it does not uniquely distinguish any case that manifests an outcome from at least one case lacking the outcome.

Other techniques for reducing the number of variables focus on patterns among the variables. In the light of relevant theoretical and empirical knowledge, investigators may select a more limited number of major variables or reconstruct them in different ways. Such reductions may proceed statistically. For example, researchers often use factor analysis to combine correlated variables into single indices.

Qualitative techniques for constructing more encompassing causal variables are also possible. For example, in the interwar study the existence of a rural proletariat and large-scale landlords has been combined into the more encompassing concept of 'feudalism.' Similarly, a Boolean 'addition' of factors, constituting alternative constellations in combination with another variable, may be possible. For example, the presence of ethnic, religious, *or* regional social cleavages in the absence of any overarching ('*verzuiling*') structures was combined to the variable of 'social heterogeneity' in the study of democratic breakdowns and survivals (see also Berg-Schlosser and De Meur 1997). Use of ideal typic constructs can also be conceived of as reductions of complexity emphasizing some characteristics and de-emphasizing others. In this way, the overall number of variables may be reduced considerably while still retaining much of the original information. With the help of such strategies, both from the cases and the variables sides, the relationship between their respective numbers may

be reduced to manageable proportions, thus avoiding the problem of 'overdetermination' when the latter exceed the former.

QCA can also be employed for other purposes. It is based on dichotomized variables (which, however, can be constructed as 'dummies' from multichotomous or interval ones) and reduces, by employing certain algorithms, the observed complexity of possible independent factors with regard to a particular outcome to a minimal logical formula (or several alternative ones) taking account of the possible interactions of these factors. In this way it can: (a) examine a universe of cases with regard to a given output in an exhaustive manner; this description will be the most concise, including all possible alternate minimal expressions which allow for the most parsimonious interpretations. (b) test hypotheses by showing whether they are consistent with the combinations described; if many contradictions occur, the hypothesis fails. (c) deduce the shortest possible formulas, describing the simplest subset of actual, potential, or counterfactual cases not contradicting the respective outcome; in this way, more general expressions can be deduced by using 'simplifying assumptions.' QCA thus serves some of the most important aims of any science, namely systematic description and the falsification and construction of theories.

QCA shares some of the problems and limitations concerning the loss of information and a certain amount of arbitrariness in setting cutting-points for dichotomized variables. In contrast with common statistical procedures, however, it retains the full complexity of all cases and all variables considered. Nonunique formulas may emerge, but this must be considered a strength and not a weakness. It deals explicitly with 'outliers' and covers them fully. It can arrive at several 'conjunctural' constellations which explain the same outcome. When several different formulas cover a single case, the technique forces the researcher (as the MSDO technique) to take a closer look at the results and to *interpret* them in light of the historical knowledge of the case. In comparative inquiry, this approach is preferred to a purely mechanical procedure which, in many statistical analyses, entirely obscures the fate of particular cases. Here, in fact, begins the real *qualitative* work, depending very much on the training and quality of researchers, their in-depth knowledge of cases, but also their sensitivity and understanding.

5. *Methodological Issues and Problems*

Even though the 'small *N*' comparative and the statistical methods have their own realm of possible applications, each with its own advantages and problems, different 'schools' have formed around these approaches fraught with controversies. In part, these reflect certain biases; to some extent they are based, however, on real problems which cannot easily be resolved. Some of these issues have been stated as quantitative vs. qualitative, and 'case-oriented' vs. 'variable-oriented,' holistic vs. analytic, or deterministic vs. probabilistic research.

These distinctions pose some false alternatives and represent differences in emphasis rather than in kind. Thus, statistical procedures are, by their very nature, based on larger quantities, but 'small *N*' analyses similarly may deal with numbers and certain quantitative data. 'Qualitative' aspects here refer to the presence or the absence of a factor, as in QCA, but should not be confounded with 'qualitative' methods as, for example, hermeneutics or participant observation (see *Interpretive Methods: Micromethods*; *Participant Observation*) in a different sense of the word.

In the same way, 'case-oriented' means that emphasis is laid on a number of known and theoretically or historically particularly interesting and relevant cases, as opposed to, for example, the anonymous ones in random sampling, but all scientific inquiry is, of course, based on distinct units (cases) *and* variables and a number of relevant observations (King et al. 1994). 'Holistic' is also a misleading term referring to the usual higher complexity of case-oriented research but it does not mean in this context that cases can only meaningfully be understood in their 'entirety' (as for example in Confucian philosophy) as opposed to 'critical-rational' analysis.

Finally, 'deterministic' is a misnomer for procedures based on Millian methods or logical distinctions as in Boolean algebra. Here, only the presence or absence of a factor is referred to and not its 'probabilistic' nature with respect to its effect on the internal or external validity of any particular finding. 'Logically minimized' relationships found by Boolean procedures may be as 'spurious' as correlational analysis. The revealed patterns indicate different more complex 'qualitative' constellations, but they are not based on their relative frequency or 'probabilistic' inferences.

As to the 'real' problems, however, these persist and only certain approximations or tradeoffs between certain emphases are possible. Millian methods and similar ones can only serve to eliminate false hypotheses and to delineate the 'conditions for the occurrence' of a phenomenon (Cohen and Nagel 1934). Within this realm the truly 'qualitative' and interpretative skills of knowledgeable experts etc. are called for to provide meaningful assessments of the factors involved. These may be more tedious and less universalistic, but they are often more meaningful and less superficial than many of the 'macroquantitative' studies.

Most 'small-*N*' comparative studies, but also the majority of statistical analyses, have been 'cross-sectional' and 'static.' There have been some advances in the statistical field in recent years as far as 'pooled time series' and 'event history' modeling are concerned

(see also *Event Sequence Analysis: Methods*), but these share some of the limitations and the relative 'superficiality' of macroquantitative procedures. There are, as yet, no truly 'dynamic' procedures comparable to the MSDO or QCA techniques combining both cross-sectional and longitudinal aspects in a 'macro-qualitative' way. These still rely more on well-informed 'thick narratives' (see *Thick Description: Methodology*), but some specific 'path-dependent' techniques have been developed more recently (see *Structural Equation Modeling*).

A further limitation refers to the 'structure' ('macro'-) and 'actor' ('micro'-) dimensions of any social and, by implication, comparative analysis. Most comparative studies are concerned with the broader and presumably more enduring 'structures' of social processes both in time and space. The final outcome, nevertheless, may very well depend on any particular (group or individual) actor in the analyzed chain of events. Again, only certain approximations can be arrived at in this regard and certain tradeoffs between more 'universalizing' and more 'individualizing' approaches (Tilly 1984) have to be made. No 'macro'–'macro' shortcuts should be made in sociological explanations because always concrete subjects with their respective perceptions and preferences are involved, which only in a later step may be aggregated at a 'meso-' or 'macro'-level. Whether these actors should always be conceived of as 'rational' or as 'Resourceful, Restricted, Expecting, Evaluating, Maximizing Men' (RREEMM) or women (Esser 1993, Chaps. 6 and 14) need not concern us here. But at least the 'expecting' and 'evaluating' aspects point to the possibility that different things may be perceived, valued, and maximized in different cultures. In any case, the broader structural (and also larger contingent) aspects can be conceived as the 'opportunity set' within the boundaries of which actual actors operate and respective choices are made. In this regard, the 'scale' and detail of any particular analysis may vary as with maps for different purposes. Thus, a hiker's map may serve for a close orientation on the ground, whereas a pilot's map may only include the more important contours and 'structural' features, and even a global and 'universal' one may be devised, but it is important that all scales and features remain consistent with each other!

A final point must again be mentioned, the problem of inference. Another important and relatively recent work has stressed, once more, the 'unified logic of inference' of both quantitative and qualitative research (King et al. 1994). In spite of many important issues which are raised and clarified in this book, the experiences and recommendations of the authors lean somewhat too strongly on the 'quantitative' side of research. This relates both to the 'internal' and 'external' validity of the inferences to be drawn. In terms of the 'internal' causal chains which should be established, King et al. look at them, as has also been noted by Scharpf (1997, 22 ff.), from the side of the independent variables in a 'forward' sense towards their eventual effect on the outcome.

Much of small-*N* comparative research, as for example in policy studies, is, however, concerned with disentangling the different influences on an outcome from a 'backward' perspective in order to identify the different factors in their complex interactions over time involving the major 'structures' and 'actors,' but also many contingent and unique aspects. This resembles more a detective's investigation of a crime or an accident than any more 'nomothetic' generalizing scientific efforts and remains 'idiographic.'

The more complex pattern of causality which has been established in this way in terms of its internal validity, can then, however, serve to devise new more complex hypotheses which can be tested across more similar (comparable!) cases and, possibly, establish a certain range of their external validity through 'process tracing' and similar procedures. A much stronger theory may thus emerge. We concur, therefore, with Goldstone's conclusion that the comparative case study method does '… not stand on flimsy methodological foundations, but on a stronger combination of skill and insight in framing and testing hypotheses than many large-*N* statistical studies' (Goldstone 1997, p. 119).

6. *Probable Future Directions of Theory and Research*

The strength of the comparative method lies, therefore, in its critical applications to theory testing and development. The state of affairs of theory building in the social sciences remains relatively weak and is subject to specific problems and restrictions and to the general 'malleability' of its substance. Even if only certain approximations can be reached, the relevance of many macrosocial and political problems, for example in policy research, institution-building, 'constitutional engineering', etc., for potentially millions of people make it worth every effort. Better theory, in the longer run, then may also contribute to a better practice.

It is difficult, if not impossible, to predict any more distinct developments in this regard, but at least some of the *desiderata* which reflect some of the existing deficiencies can be outlined. First of all, many more existing propositions across the various fields of social inquiry based on other methods of data collection and theory building should be subjected to systematic testing by comparative methods as far as they refer to 'small-*N*' environments. Counterfactual examples and 'most different' cases should be sought to establish their respective range of external validity. Second, from this body of research, more coherent propositions may emerge delineating their respective range of application, both in space and time.

It seems likely that such 'medium range theories' will increasingly be based on regional and historical commonalities of certain countries and cultures. Some 'deep structures,' such as the social cleavages in Western Europe, and 'deep cultures,' such as certain characteristic submilieus in Germany or Italy, have persisted over centuries and can be linked to present developments (see also Flora 1999). What is needed are still better qualitative and quantitative methods to assess their continuities and changes over time and dynamic concepts and tools to establish their 'self-referential' nature, not just in abstract theory, but also in empirical reality. Such a combination of theoretical and historical concerns may also employ better 'analytic narratives' and lead to a new focus on the interactions between structures and actors.

Competencies and Key Competencies: Educational Perspective

In accordance with mainstream thought, we understand 'competence' as referring to combinations of those cognitive, motivational, moral, and social skills available to (or potentially learnable by) a person or a social group that underlie the successful mastery through appropriate understanding and actions of a range of demands, tasks, problems, and goals.

Because everyday schooling, work, and social life present countless tasks and goals, it is possible to postulate any number of competencies as necessary personal and/or social preconditions for successfully meeting task demands. Competence generally implies complex action systems with cognitive, motivational, social, and behavioral components, rather than basic cognitive abilities or simple skills. Because the psychological structure of such systems is frequently unclear, and the possibilities for substituting, compensating, and/or combining single components of competencies are unexplored, the psychological relations between external demands and personal competencies are often regarded as tautological. It seems as if the concept of competence reveals a negative correlation between its popularity and its precision.

What are the consequences of this state of affairs? One clear solution might be to avoid using the term competence and, of course, key competencies in scientific discourse, and to seek more appropriate concepts or terms for the intended construct. Would this constitute progress? Alternative concepts such as skill, ability, aptitude, or proficiency are not used in ways that are any more coherent or consistent. Moreover, the disadvantages of using the concept of competence are compensated somewhat by the semantic advantages. There have been many attempts to constrain and sharpen the concept of competence on phenomenological, definitional, or theoretical grounds. However, these attempts have failed to gain broad conceptual acceptance in the social sciences. This entry starts with a brief description of the concepts of 'competence' and 'key competence' in terms of their rather vague scientific meaning and their variable practical use. It then goes on to discuss both the psychological and the educational problems so often associated with the concept of key competencies

(key qualifications, core skills). The final section draws a few conclusions for educational practice, education processes, and instruction processes.

1. Definitions of the Concept of 'Competence'

In general, we know what the terms 'competence,' 'competencies,' 'competent behavior,' or 'competent person' mean, without being able to define them precisely or differentiate them clearly. The same can be said for terms such as 'ability,' 'qualification,' 'skill,' or 'effectiveness.' The use of these terms as synonyms is reflected in dictionary entries as well. For example, Webster's dictionary defines 'competence' as 'fitness or ability.' 'Capability,' 'capacity,' 'efficiency,' 'proficiency,' and 'skill' are given as synonyms or related terms.

An inspection of the Latin roots and historical variations in meanings reveals that competence is also understood to mean 'cognizance' or 'responsibility.' This concept of competence has been, and continues to be, used in very specific and arbitrary manners in biology, immunology, jurisprudence, and in several other scientific disciplines. However, this will not be elaborated further in this entry. Restricting our focus to the use of the term 'competence' in psychology and education still leaves a wide variety of definitions. Nonetheless, in many disciplines, competence is interpreted as a roughly specialized system of abilities, proficiencies, or skills that are necessary or sufficient to reach a specific goal. This can be applied to individual dispositions or to the distribution of such dispositions within a social group or an institution (such as a business company).

In recent decades, 'competence' has become a fashionable (and sometimes even modernistic) term with a vague meaning not only in lay usage, but also in many social sciences. One could even talk about a conceptual 'inflation' with the lack of a precise definition being accompanied by considerable surplus meanings. A typical illustration of this can be found in a report published in 1998 by an advisory committee for technology and innovation appointed by the German Chancellor. The report states:

> Competence can generally be understood as knowledge times experience times power of judgment. Knowledge is the necessary foundation of competence, and experience is the habitual way one deals with acquired and continuously changing knowledge. Power of judgment is a criterion for the independence of knowledge and its use. Thus, competence is always more than just knowledge or just experience (BMBF 1998, p.10).

Specific competencies mentioned in this report include: economic, technological, technical, and methodological competencies; social competencies; creativity and innovation skills; mobility and flexibility, combined with persistence, reliability, and precision.

In some respects, this report is typical of many current publications: although the term 'competence' is used to refer to both high-achieving individuals and successful social groups that master specific tasks and reach important goals, it is, at the same time, always concerned with the necessary learning dispositions that are available to individuals and/or the members of social groups and have to be used to solve demanding problems. The variety of meanings given to the concept of competence is seen not only in its many uses but also in the construction of compound words to express competence, such as: media competence, business competence, traffic competence, age competence, and also cognitive, social, motivational, personal, and many other competencies. It is not possible to discern or infer any coherent theory from these many uses. There is no basis for a theoretically grounded definition or classification from the seemingly endless inventory of ways in which the term 'competence' is used.

2. Key Competencies

In recent times, similar concepts such as key competencies, core competencies, key qualifications, and core skills have become popular in the social sciences and in educational policy. The concept of key competence is, however, no less vague or ambiguous than that of competence. Clear and well-reasoned distinctions between the two concepts are either arbitrary or nonexistent. Towards the end of the twentieth century, at least 654 different key competencies have been suggested in German literature on occupational training alone. These range from such constructs as creativity, logical thinking, problem-solving skills, achievement readiness, independence, and concentration abilities to foreign language skills, communication skills, and media competencies.

The search for key competencies is motivated by two notions: (a) the well-founded assumption that competencies acquired in school and vocational settings are learned and used in context-specific ways (e.g., within a discipline, within a vocation, within a company), and (b) that most activities over the life course take place in a variety of social and vocational contexts. This has led to the search for context-independent key competencies that are equivalent in their use and effectiveness across different institutions, different tasks, and under varying demand conditions.

Why is the concept of key competence so attractive? The term generally refers to multifunctional and transdisciplinary competencies that are useful for achieving many important goals, mastering different tasks, and acting in unfamiliar situations. For many teachers and politicians, there is also the hope that a curriculum bursting at the seams with the many

competencies necessary for modern life could be reduced if it were only necessary to transmit a limited number of key competencies.

Regardless of how much scientists and practitioners agree on the formal criteria for defining key competencies, there are major disagreements about which competencies should be classified as key competencies. If one considers the tasks and demands that most people have to master in order to achieve personal success in modern societies, the following key competencies can be identified as being mentioned frequently in the available literature: oral and written mastery of the mother tongue; mathematical knowledge; reading competence for rapid acquisition and correct processing of written information; mastery of at least one foreign language; media competence; independent learning strategies; social competencies; and divergent thinking, critical judgments, and self-criticism.

When key competencies are identified and defined within a normative-philosophical and socially critical frame of reference, one derives, for instance, those key competencies characterized by Canto-Sperber and Dupuy (in press), who sketch the conditions for the possibility of a good life in modern, complex democratic societies. The authors derive some personal competencies and five key competencies from an analysis of the features and characteristics of the general idea of good living. They are not concerned with particular basic skills, but with the dimensions that define an abstract, multidimensional space in which specific skills, abilities, and capacities can be localized.

The primary personal prerequisite for a good life is conceptual competence—defined either as general conceptual competency (conceived as a context- and content-free ability) or as special cognitive competency (conceived of as a special cluster of cognitive prerequisites and context-dependent capabilities). Conceptual competency is supplemented by procedural competency, motivational competency, and action competency. These competencies are not understood as cognitive goals; they are not curricular bounded knowledge or skills, but cross-curricular competencies.

In addition to these person-oriented competencies for a good life, Canto-Sperber and Dupuy (in press) identify five key competencies that are defined and characterized on a very high level of abstraction. These are competencies for coping with complexity, perceptive competencies, normative competencies, cooperative competencies, and narrative competencies.

3. *Psychological and Educational Problems With the Scientific Concept and the Practical Application of Key Competencies*

Regardless of whether one chooses a reality-based or a philosophical-normative perspective to identify important key competencies, there are always some questions and problems requiring principal or pragmatic answers. Competencies and key competencies follow no strict formal definitional constraints but are defined at very different levels of universality, generality, and abstraction. It is often noted that very abstractly formulated key competencies need to be further divided into subcompetencies. Such scientific plans have often failed in psychology, however. The underlying multilevel models can be reconstructed logically, but not validated psychologically. The different degrees of abstraction therefore mean a fundamental asymmetry in competence research: high abstraction: intellectually brilliant, pragmatically hopeless; low abstraction: pragmatically useful, intellectually unsatisfactory.

A related but independent issue is the frame of reference within which key competencies are defined. Competencies and key competencies may be identified from philosophical ideas about the nature of humankind, ideas about the good life and a desirable society, or even expectancies about present human life and social demands. There is a strong danger that the necessary skills for successful everyday life, for social and personal effectiveness, or for professional success will be trivialized when compared with normatively anchored universal competencies. Nonetheless, if one wants to go beyond an individual's adaptation level to the world of today with its limited possibilities of further development, and change the world by equipping people with the appropriate competencies, it is necessary to choose a normative starting point when defining key competencies rather than an empirical one.

Key competencies are always complex systems of knowledge, beliefs, and action tendencies, that are constructed from well-organized, domain-specific expertise; basic skills; generalized attitudes; and converging cognitive styles. Without a minimal hypothetical structure and process analyses, key competencies can easily deteriorate into catchwords that refer only to desired states. Frequently, cognitive abilities, cognitive styles, and emotional qualities are viewed as constituent components of key competencies. There are large individual differences in these psychological features, and it is doubtful whether and to what degree they can be modified through learning; whether deficits can be compensated; and whether people can indeed change in the required direction. If this question remains unasked or unanswered, there is a danger that an academic discussion of key competencies may trivialize the already enormous interindividual differences and thus lead to an upsurge in individual discrimination.

Frequently dangerous illusions regarding the possibilities and limitations of socialization and education are tied to the concept of key competencies. Many scientists suggest to an amazed public that it will no longer be necessary to acquire a large amount of world knowledge, expertise, and competencies or to work

hard to learn a lot. In the future it will be sufficient, so the story goes, to possess some key competencies, to have learned how to learn, and to have acquired enough media competence to obtain the necessary information at any time in an electronic form. This will create an attitude of personal self-confidence that one can always react appropriately and creatively in response to any difficult situations in life. Modern cognitive psychology would tell us that such an educational model is not only utopian but mostly just nonsense.

The more general a competence or strategy (i.e., the range of different types of situations to which it applies), the smaller its contribution to the solution of demanding problems. Over the last decades, the cognitive sciences have demonstrated convincingly that content-specific skills and knowledge play a crucial role in solving difficult tasks. Generally, key competencies cannot compensate adequately for a lack of content-specific competencies (Weinert 1998).

The lively discussions on the meaning of systematic vs. situated cognitions have demonstrated that general competencies have virtually no practical utility by themselves. Instead, specific knowledge, embedded in experience, is required to implement available competencies successfully when solving specific practical problems. For many key competencies, the question is whether and how they can be acquired through planned instructional programs. A typical example is critical thinking. Although there are special training programs for this key competence (Halpern 1998), their construction and efficiency remain controversial in scientific terms.

4. Concluding Remarks

Putting aside the philosophically and normatively derived key qualifications and concentrating on the methodologically functional key qualifications that can be used in the greatest possible range of different and important situations, one can name four essential criteria for their acquisition from an educational perspective. First, key qualifications should be capable of being learned by as many people as possible. This holds just as much for the oral and written forms of one's mother tongue and foreign languages as for basic mathematical and statistical skills or for media competence. However, not everything that can be learned can be taught; even though key qualifications have proved to be, in principle, both teachable and learnable. Things become problematic with key qualifications such as critical or logical thinking, because these abilities depend very strongly on the individual endowment with intelligence along with interindividual differences in intelligence. As a result, it cannot be assumed that the majority of people can acquire this key competency in a corresponding way. Second, key competencies have to be highly automatized if they are to be applied in very different situations. In other words, they have to be available in the behavioral repertoire and relatively easy to access. Third, key qualifications need to possess reserve capacities for acquiring the context knowledge that each case demands, building up new experiences, and acquiring additional skills. Fourth, key competencies not only have to be acquired in a way that makes them a domain-specific expertise, but they also have to be trained through forms of situational learning to make them adaptable to fit different occasions. Viewed from the standpoint of the psychology of learning, this can be attained only when methodological key competencies are acquired systematically, but their application is subject to permanent training in variable contexts.

Competitive Strategies: Organizational

A firm's competitive strategy concerns how to compete in the business areas the firm operates. In other words, competitive strategy means to define how the firm intends to create and maintain a competitive advantage with respect to competitors. A business area identifies: (a) a distinct set of products or services sold

to a uniform set of customers; and (b) a well defined set of competitors to be faced. Holding a competitive advantage over competitors means to be more profitable than competitors over the long term. Superior profitability over competitors can be achieved in different ways: (a) a company sustains lower costs than competitors and this can lead to either selling the same volume as competitors (if the selling price is the same) with larger margins (because of lower costs) or selling a larger volume of products, obtained as a consequence of the reduction of the selling price (the selling price can be reduced as far as the difference between price and cost is that of competitors and therefore the company has the same margins as competitors); or (b) a company is able to commercialize a differentiated product from that of competitors: this advantage can be exploited either by increasing the selling price and therefore exploiting higher margins at the same volume or attracting a larger number of customers (which means larger volume) keeping the same price as competitors.

The definition of competitive strategy itself addresses the underlying dynamic character of the issue. Competitive advantages are created as the result of direct actions of the firm (proactive strategies) or as the result of the reaction of the firm to external changes (reactive strategies). As a consequence of the creation of a competitive advantage, competitors react trying to erode the advantage. This can be done either by imitating the holder of the advantage or doing actions that create a new advantage. Therefore, the protection of the advantage is also part of a competitive strategy. This leads to the key concept of the sustainability of the competitive advantage. The stronger the protection of the advantage, the longer the window of time in which the advantage can be exploited by the holder and the higher profitability for the holder. Moreover, an advantage can be maintained exploiting the time factor. Once an advantage has been created, the holder of the advantage can exploit the time competitors spend to close the gap to generate another advantage. The strategy in this case is staying ahead of competitors.

Therefore, a competitive strategy within a given business area is examined looking at two factors: the creation of the competitive advantage and the protection of the competitive advantage. As it can be argued from the discussion below, whatever type of competitive strategy, the ultimate source of competitive advantage and the potential of protection of such advantage reside in the resources of the firm. Resources may be tangible (such as physical or financial assets), intangible (such as technology, reputation, culture), human (specialized knowledge and competencies, communication and inter-relational capabilities, motivation), or organizational (organizational routines and business processes, organizational architecture, interrelations with suppliers and customers).

1. *Creating the Competitive Advantage*

The creation of competitive advantage within a given business area is examined looking at the two categories of competitive strategies as mentioned above: proactive and reactive competitive strategies.

1.1 *Proactive Competitive Strategies*

In proactive competitive strategies, the creation of competitive advantages is the result of the direct actions of the firm. Therefore, in this case, the sources of such advantages are internal to the business: the creation of competitive advantage is the result of the actions such as the introduction of a new product, or the use of a new production process. Such change is successful if it generates higher profitability for the firm than competitors (under one of the forms seen above): this means that the firm has created a competitive advantage over competitors (which is different from saying that 'the firm holds a competitive advantage' which means to maintain the advantage and have higher profitability than competitors in the long term). The competitive advantage is therefore the result of a competitive strategy deliberately meant to introduce changes in the business area in order to make the firm more profitable than competitors. It should be noted that such a form of competitive advantage creation not only generates advantages to the holder of the advantage, but may also destroy existing advantages, as the basis of competition may radically change.

The types of competitive advantages and the underlying competitive strategies can be of two types.

1.1.1 Improvement of performance (same game competitive strategy). If the business area is considered at a certain time, the competition among firms is played around some key performance factors such as cost, time, quality, variety, etc. (see below in this section). These are the performance factors by which customers measure their satisfaction.

A first type of competitive advantage creation concerns the improvement of product/service along one or more of the existing performance factors. The basis of competition is still the same as the performance factors are still the same. This form of competitive advantage creation is the most frequent in mature and established business areas, where the basis of competition tends to be more stable.

In more detail, major performance factors and therefore sources of advantage are the following:

Superior functional performance. Each product/service is related to specific functional performance. Products with superior functional performance with respect to competitors are sources of advantage.

Complementary services. A performance factor can concern the services added to products. Such services can be embodied into the product or separated from

the product. The ability to add services can be a source of advantage.

Quality (compliance). Another performance factor is the compliance of all products produced to the level of quality claimed by the firm. Firms able to commercialize products all of the same quality may create an advantage (it is also referred to as zero defect production).

Variety (mix). Another performance factor concerns the range of products the firm is able to offer within the business area considered. A wider mix of products can be a source of advantage.

Delivery time. A further performance factor is the ability to deliver products when customers want. The most desired time for customers is not always the earliest: if a firm produces industrial goods the required performance (and source of advantage) is to bring products to customers exactly when the customers use them in their production process.

Time-to-market. Time-to-market is the time spent to have a new product idea brought onto the market. Reducing time-to-market enables the firm to introduce new products earlier than competitors.

Environmental compatibility. In certain businesses the environmental compatibility can represent a source of advantage. Helping customers to comply with norms and legislation can be a form to differentiate products from those of competitors.

Cost. Cost is often a key performance factor in established businesses and reducing costs, a major competitive weapon. Major sources of cost advantage are here reported.

(a) Scale economies. Scale economies occur when an increase in the production scale determines a reduction of the cost per product unit. It means that an increase of the resources used determines a more than proportional increase of the output. The production scale at which the economies of scale are completely exploited is the minimum optimal scale (which is the minimum scale to obtain the minimum cost). This means that firms operating the minimum optimal scale have cost advantages with respect to firms operating lower scales.

(b) Learning curve. The learning curve shows the relation existing between cumulated production and cost per product unit. There is a reduction of 20–30 percent of the cost when the cumulated production doubles. Learning curve advantages mainly refer to savings in production, because of fewer scraps, shorter idle times, and incremental innovations. This means that firms which start producing a product before competitors can benefit from cost advantages because of learning effects.

(c) Process technologies. A certain production process using a defined process technology may be technically superior and more efficient than other process technologies.

(d) Input costs. There may be cost advantages related to the cost of input factors (materials or labor). Firms that directly own sources of raw materials or have access to input factors at lower cost have cost advantages.

(e) Localization. Cost advantages can also be based on the geographical location. The proximity to raw material sources or the localization of labor-intensive activities in low labor cost countries is a typical example.

(f) Production capacity utilization. If market demand fluctuates a major problem is the adaptation of production capacity. Firms with more flexible production systems benefit from cost advantages.

Finally, within a certain business area, a firm's competitive strategy can be based on a niche strategy. This means that competitive advantages are based on the ability to offer products/services tailored to the specific needs of a limited number of customers within the business area.

1.1.2 Change of the rules of the game (new game competitive strategy). Competitive advantages can be reated introducing a new performance factor in the business area. In such cases, the 'rules of the game' in the business area change as the basis of competition changes. It should be noted that there is a difference between cost and the other performance factor. The introduction of cost as a performance factor gives an advantage to the firm in absolute terms, whereas the introduction of another performance factor gives an advantage if that factor is perceived by the customers as critical.

1.2 Reactive Competitive Strategies

The creation of competitive advantages in proactive competitive strategies is the result of the actions of the firm. Competitive advantages can also be the result of the reaction to external changes.

External factors, which may determine profitability differences among firms, may be: changes in the consumer demand, price changes (for example, changes of the price of a raw material, price changes due to changes of the exchange rates), and technology changes. All these changes affect firms' profitability. The impact of such changes on firms operating the same business may strongly differ according to the responses of the firm to such changes, which in turn depend on the resource profile of the firms themselves. The quickness and the effectiveness of response to changes affect the profitability. The capability to respond quickly and effectively is based on a key resource (information) and a key competence (flexibility). Firms able to grasp information quickly are able to analyze weak signals through early warning systems. The ability to respond effectively depends on a firm's flexibility, which is in turn strongly linked to

characteristics such as organization, decision systems, culture, values. Such competitive advantages are purely the result of reactive strategies, i.e., strategies taking place as reaction to external changes.

2. Protecting the Competitive Advantage

The company that holds the advantage tends to maintain this position (in certain cases it can exploit a monopolistic position), whereas competitors tend to erode (destroy) the advantage. The erosion of the advantage can take place either through imitation or creation of a new advantage.

Therefore, whereas the holder of the advantage has to defend its competitive advantage, the competitors have to erode (destroy) this advantage. The time window in which the competitive advantage can be held over competitors brings to the concept of the sustainability of the advantage: the larger time window, the more sustainable advantage. The sustainability is related to the capability/opportunity to protect the firm's source of advantage. Factors of protection are the following.

Secrecy. It is a form of protection especially if the source of competitive advantage is the production process. Although information can be obtained from products and there is an inevitable leakage of know-how through a variety of channels (technical community, suppliers, etc.), firms can keep secrecy over that. Firms that do not open their plants to anyone external to the firm may succeed in keeping their own process innovations secret.

Accumulated tacit knowledge. If the knowledge at the basis of the advantage is strongly embodied into people and technical systems, and relies upon people's experience, it is difficult to make the knowledge explicit, and the related advantage can be highly protected. The well-known case of Italian small firms, often world leaders in niche markets and traditional manufacturing industries, is largely based on the accumulation of tacit knowledge. In very concentrated geographical areas (districts), there are networks of small firms that are strongly specialized in highly specific manufactures. Knowledge is, to a large extent, embedded in people living in that area.

Lead times. The ability to generate and quickly put new products on the market is a major source of advantage and is itself a major source of protection against imitation. It helps establish brand loyalty and credibility, accelerate feedback from customer use, accelerate learning effects, and consequently increase cost of entry for imitators. The market leadership is based on the ability to provide new generations of products frequently and stay ahead of competitors.

Complementary assets. The ability to make profits from the commercialization of a new product or service often depends on the availability of assets or competencies, such as production capabilities, marketing, distribution, after-sale service, which are complementary to the product and its technology. These complementary assets determine who exploits the new product introduction and the appropriation of the related benefits and to what extent. As a matter of fact, they are often the reason for failures of firms, that, having once generated the new product do not have the required complementary assets to exploit it or have to invest largely to acquire them. Both these conditions may cause the firm not to create a competitive advantage from the new product introduction. On the other hand, the availability of complementary assets for the firm may represent not only the means which ensure that profits are made from new product introduction but also a barrier against imitation by competitors especially when such assets may be difficult to acquire, access, or imitate.

Product complexity. In some sectors, product complexity is a major barrier against imitators. The large electromechanical equipment industry or the aircraft industry is a typical example.

Standards. In certain industries, making the firm's own product accepted as a standard opens and develops the market and raises barriers against competitors. This is especially true in network markets, where the compatibility of a product with related products (for example a software package with the related hardware) is a prerequisite for the product's success. Once the product is diffused throughout the market as a standard, it is difficult for competitors to erode the advantage. In fact, new products marketed by competitors should replace the existing product but may also involve the replacement of the other related products. This represents a major barrier. Computing, telecommunication, consumer electronics industries show examples in which standard setting is a key factor to appropriate the benefits of new product introduction and create a sustainable competitive advantage.

Pioneering radical new products. If a product is radically new, i.e., represents a strong discontinuity with the existing products/processes/services and lies upon a base of knowledge that is completely different from that behind traditional products, the firm is more protected against imitation. Potential imitators cannot rely on the existing knowledge base to replicate the product.

Strength of patent protection. Patenting is also a major means of protection. This is especially true in some sectors, chemical and pharmaceutical for example, where products can be clearly and rigorously described (often with a structural formula) and imitation by small differences is not easy as in most industries.

3. Other Competitive Strategies

Finally, it should observed that so far competitive strategies have been examined considering a given business area and that the actions or the reactions

involve only the firms operating in such business areas. In reality, higher profitability can be pursued implementing other strategies that are here mentioned but not treated in depth.

3.1 Creation of a Completely New Business Area (New Business Competitive Strategy)

A competitive strategy may be meant to create a completely new business area. If the business area is profitable for the firm, the firm creates a competitive advantage. The firm holds a monopolistic position as far as new firms enter the business area. This case especially occurs in highly innovative and emerging industries.

3.2 Enlarging the Geographical Scope or the Business Scope (Cross-market or Cross-business Competitive Strategy)

There are other two types of competitive strategies that can generate competitive advantage. They do not concern the specific business area considered but, in one case, the fact the firm operates that business in different geographical markets and, in the other, the fact that the firm operates different business areas.

In the first case, it is the geographical scope of the strategy that may represent the source of advantage. A firm can pursue a global strategy being present in different geographical markets. The global market is seen as one. The sources of advantage over competitors who compete on a local basis are mainly twofold: the homogeneity of market demand in different countries and the exploitation of economies of scale in different activities (R&D, production).

In the second case, the source of advantage resides in the range of business areas operated. The advantages are based on the interrelationships across distinct business areas. Interrelationships may concern the following: infrastructure (accounting, legal department, government relations, human resource management, finance); technology; purchased inputs; manufacturing (location of raw materials, production process, assembly, quality control, factory support activities); marketing (buyer, distribution channel, geographic market).

Compliance and Obedience: Legal

The law specifies what is acceptable behavior within a given society. A society enacts laws, and creates legal authorities, to regulate the conduct of its members by inhibiting the occurrence of those behaviors that are damaging to society, to the individuals within society, or to both. For the law to be effective in fulfilling its role of minimizing the occurrence of socially damaging behaviors, people must comply with the dictates of the law—i.e. the law must be obeyed.

If the law does not shape the behavior of most citizens most of the time, bringing those people's actions into conformity with legal rules, then the legal system is not effectively fulfilling its social regulatory function. In fact, the ability to secure widespread

compliance with the law is often viewed as a central characteristic of effective legal authorities. 'The lawgiver must be able to anticipate that the citizenry as a whole will … generally observe the body of rules he has promulgated' (Fuller 1971, p. 201), since the effective exercise of legal and political authority requires compliance from 'the bulk of (citizens) most of the time' (Easton 1965, p. 185). Hence, 'a judge's ruling means little if the parties to the dispute feel they can ignore it. Similarly, passing a law prohibiting some behavior is not useful it if does not affect how often the behavior occurs' (Tyler 1990, p. 19).

Recognizing the importance of gaining widespread compliance with the law, most discussions of compliance focus on the issue of why people obey or disobey laws. One straightforward and widely noted perspective on this issue is the deterrence, sanctioning, or social control perspective. That perspective argues that law gains its influence over people's behaviors because people are concerned about being caught and punished for wrongdoing. It is based upon the rational choice model of personal motivation, which views people as motivated by the desire to maximize their gains and to minimize their costs in social interactions.

From the deterrence perspective, two issues are relevant to decisions about whether or not to comply with the law. These issues are the expectation of gain, and the expectation of loss. The expectation of gain involves the person's estimate of the likely gains from engaging in law-breaking behavior. That estimate is a multiplicative combination of the estimated likelihood of gain and the expected amount to be gained. For example, a person contemplating robbing a bank has an estimated gain that reflects his sense of the likelihood that he will gain a particular sum of money from robbing a bank.

The expectation of loss involves the possibility of being caught and punished for engaging in rule-breaking behavior. This expectation can be broken down into two components: estimates of the likelihood of being caught and punished for law-breaking (the probability of punishment), and estimates of the expected magnitude of such punishment (the severity of punishment). These two estimates are typically multiplied to produce the subjective estimated risk associated with law-breaking behavior.

One way to reduce the amount of law-breaking behavior is to minimize the possibility of gain that is associated with such behavior. So, to minimize the risk of robbery, taxi drivers put their profits in a floor safe and people carry little pocket money when they go out at night. However, since the amount to be gained by law-breaking is typically beyond the control of legal authorities, studies of deterrence usually focus on the ways in which changing either the estimated probability of punishment or the estimated severity of punishment affect the occurrence of criminal behavior.

The likelihood of being caught and punished for breaking the law can be changed in many ways, such as by increasing the number of police officers seeking to solve crimes, by raising the likelihood that charges will not be dismissed, and by altering legal procedures to change the likelihood of conviction. The move toward a nonunanimous jury decision rule or the use of smaller jury, for example, increase the likelihood of being found guilty for a crime.

The severity of punishment can be altered by increasing the penalties for various crimes or by limiting or eliminating parole. The recent increase in the number of crimes for which criminals in the USA might receive the death penalty is one highly salient example of heightening the potential severity of punishment.

When legal authorities heighten either the actual likelihood of being caught and punished for wrongdoing or the severity of punishment, they are increasing the objective risks of rule-breaking. The authorities assume that these changes alter people's subjective estimates of the likelihood and severity of punishment for wrongdoing, and, as a consequence, lead to lower levels or rule-breaking behavior. Studies on the deterrent effect of estimated risk suggest that such deterrence effects do occur (see Nagin, 1998). While studies often find evidence of deterrence effects of rule-breaking behavior, the magnitude of those effects is typically small. For example, MacCoun (1993) examines deterrence studies in the area of drug use and estimates that approximately five percent of the variance in drug use behavior can be explained by variations in the expected likelihood and/or severity of punishment. Other studies using panel designs fail to find evidence of any significant independent deterrence effects (Paternoster et al. 1983, Tyler 1990). Hence, when deterrence effects occur, their magnitude is low.

The deterrence effects identified are more strongly associated with people's estimates of the probability of punishment than they are with the anticipated severity of punishment (Nagin and Paternoster 1991, Paternoster 1987, 1989, Paternoster and Iovanni 1986). This suggests that efforts to increase compliance with the law need to focus on increasing the presence of the police, on encouraging apprehension, and/or on raising the likelihood of conviction in the courts. Efforts to lower the crime rate by intensifying penalties—such as the proliferation of death penalty offenses—will be relatively less successful.

Why are risk judgments not more strongly related to law-breaking behavior? One reason is that judgments of risk have to be reasonably high to influence people's behavior—i.e., they have to exceed some threshold level to be psychologically meaningful (Ross 1982). However, in most actual situations, the objective risks of being caught and punished are quite low. For example, the objective risk of being caught, convicted and imprisoned for rape is 12 percent, for robbery 4 percent, for assault, burglary, larceny and motor vehicle theft, around one percent (Robinson and

Darley 1995). Of course, the psychological or subjective estimate of risk is the key to people's behavior—not the objective risk. Research suggests, however, that subjective risks are, if anything, lower than objective risks. As a consequence, subjective estimates of risk are quite low.

Ross (1982) applies the psychology of deterrence to the problem of drunk driving. He suggests that raising risk estimates enough to lower the rate of behavior, while not impossible, involves prohibitively high costs in terms of police manpower and citizens' willingness to accept state intrusions into their personal lives. He argues that it is difficult to implement deterrence approaches within democratic societies. Interestingly, Ross argues that even the intensive efforts of Scandinavian authorities, including random road blocks and other similar expensive and intrusive law enforcement measures, are insufficient to create and maintain subjective risk estimates that are high enough to deter drunk driving. Many of the problems associated with deterrence-based strategies are structural; they concern our general inability to monitor people's opportunities to break laws.

This argument suggests that there are situations in which deterrence strategies will be more or less effective in deterring law-breaking behavior. The two key variables that determine how conducive a situation is to a deterrence approach are the ease of behavioral surveillance and the level of resources that society is willing to devote to the task of surveillance. The effects of behavioral surveillance on the rate of law-breaking behavior can be illustrated by tax payments. If people are wage earners, their income is recorded, the possibility of hiding cheating is low, and the opportunities for effective deterrence of law-breaking behavior are high. The societal resource variable is illustrated by the case of murder. The objective risk of being caught and punished for murder is high (around 45 percent; Robinson and Darley 1997) because society has committed considerable resources to resolving this type of crime. Because society is willing to devote sufficient resources to investigating murders, the likelihood of being caught for committing a murder is high enough for deterrence to be effective in lowering the murder rate.

However, the case of deterring murder illustrates an important limit to deterrence strategies. They are more effective in shaping the crime rate for crimes that are committed for instrumental reasons. For example, car theft, burglary, and crimes of this type are typically motivated by calculations about the costs and benefits expected from law-breaking. However, other crimes are expressive; they are more strongly shaped by one's emotional state and events of the moment. Crimes of this type, such as rape and many murders, occur on the 'spur of the moment' and in the 'heat of passion.' Such crimes are not influenced by deterrence considerations, irrespective of the possibility of being caught and punished for wrongdoing. Deterrence approaches work most effectively in shaping the occurrence of instrumentally motivated crimes.

The problem faced by those responsible for the everyday enforcement of law in democratic societies is that, for most crimes, the resources devoted to law enforcement are low and the opportunities for cheating are high. As a consequence, deterrence strategies are unlikely to be a sufficient basis for an effective system of social regulation. Deterrence can form the foundation of efforts to maintain the legal order, but they cannot be a complete strategy for gaining compliance. To ensure sufficient public compliance, citizens must have other reasons for obeying the law.

Social psychologists typically divide the motivation for social behavior into two basic components. The first are people's assessments of the potential gains and risks associated with engaging in various types of behavior. The influence of these judgments has already been examined. The second are the internal values that shape people's feelings about what behavior is appropriate. Behavior based upon internal values is especially important to the legal system, since the desire to be consistent with internal values leads people to obey the law voluntarily. As a consequence, to the extent that people are following laws because of their internal values, society need not put its resources into supporting agents of social control. Further, such voluntary compliance is more reliable because it does not vary as a function of the person's circumstances. When one drives up to a stop sign on a deserted road at night, one's internal values lead one to stop, even when the possibility of punishment for ignoring the law is essentially nonexistent. It has been widely suggested that the ability of legal systems to function in democratic societies depends upon the system's ability to gain such voluntary compliance with the law (Easton 1975, Engstrom and Giles 1972, Parsons 1967, Sarat 1977, Scheingold 1974).

What type of internal values might lead people to obey the law? Two types of values have been recognized as central. The first value concerns how people view the morality of engaging in illegal behaviors. Morality is concerned with personal feelings about what is right or wrong. For example, murder would still be viewed by most people as immoral, even if it were not illegal; drug use, in contrast, is regarded by many people as moral, even though it is illegal. The second value concerns how people view the legitimacy of law and legal authorities. Legitimacy denotes people's sense of the degree to which they have a personal obligation to obey social rules.

1. *Morality*

Studies generally suggest that people's views about the morality of engaging in rule-breaking behaviors shape their willingness to engage in those behaviors. Further,

the influence of morality is typically found to be greater than that of the probability of punishment for rule-breaking. A classic study illustrating this point is that of Schwartz and Orleans (1967), which evaluated the effects of a persuasive appeal to pay taxes on taxpayers' behavior. Citizens received either no appeal, an appeal based on the risk of being punished, or an appeal based on the immorality of cheating. The influence of the appeal was established by examining the level of taxes paid before and after the appeal. In the control group which received no appeal, the average change in taxes paid was -$13 dollars. In the sanction-based punishment group, the average amount paid increased $181. In the appeal to moral conscience group, the average payment increased $804.

Other studies support the argument that moral values influence law-related behavior, and that they have a greater influence than do variations in the threat of punishment. Tyler (1990) compared the influence of sanction threats and moral judgments about law-breaking on people's everyday obedience to the law. He found that moral values significantly influenced law-related behavior and were more influential than were variations in the perceived risk of being caught and punished for wrongdoing. Paternoster (1989) also examined the influence of sanction threats and moral values on everyday law-related behavior and found that moral values were the primary factor shaping people's behavior. And Grasmick and Green (1980) and Grasmick and Bursik (1990) found that moral values were more central to people's law-related behavior than were their concerns about sanctions.

Paternoster and Simpson (1996) also found that moral values had an important influence on whether or not people committed corporate crimes. Their study involved interviews with business students and executives who were given hypothetical situations in which they might break laws. They found that moral considerations exerted a 'powerful and independent source of social control' (p. 579). They also found that moral judgments constrained the operation of risk judgments. If people felt that law-breaking was immoral, considerations of the gains and losses associated with law-breaking became 'virtually superfluous' (p. 549) to their decisions about whether or not to follow the law. On the other hand, if people did not feel that law-breaking was immoral, their law-breaking behavior was linked to their risk judgments.

The degree to which moral values support the law depends upon the degree to which the behaviors that the law defines as illegal correspond to public views about what is right and wrong. When these two elements coincide, people's motivation to obey the law should be especially strong, since law-breaking is then not only illegal, but also immoral. Robinson and Darley (1995) systematically examine the relationship between formal law and public views about what is right or wrong and demonstrate that there are a number of discrepancies. Such discrepancies, to the degree that people are aware of them, should lessen people's motivation to comply with the law.

Studies of public opinion about the law suggest that the most persistent sources of public discontent with law involve public perceptions that: (a) too many criminals go unpunished due to legal 'technicalities' such as the insanity defense and the exclusionary rule, and (b) the sentences given for crimes are too lenient. In both cases, studies suggest that public views exaggerate the discrepancy between public conceptions of what is morally appropriate and what actually occurs.

One compliance-enhancing strategy available to the legal system is public education about what the law actually says and what the courts actually do. Such a strategy may be beneficial in increasing public compliance with the law by showing people that the law is more consistent with their moral values than they think. However, the work of Robinson and Darley (1995) makes it clear that if the public accurately understood the totality of the criminal and civil law, they would recognize a number of discrepancies between public morality and the formal law. Hence, any long-term effort to bring law and public morality together must involve some efforts to reconcile true discrepancies between the law and public morality.

2. *Legitimacy*

The second internal value that shapes behavior toward the law is the legitimacy of the law and of legal authorities. A law has legitimacy when others feel obligated to obey it. A legitimate authority is one which is entitled to have its decisions and rules accepted and followed by others. In the case of law, people feel a personal responsibility to comply voluntarily with those laws that are created and enforced by legitimate legal authorities. In contrast to morality, legitimacy is a general acceptance of the right of the law to dictate appropriate public behavior. When authorities possess legitimacy, they are better able to regulate effectively the behavior of citizens.

Tyler (1990) examined the influence of views about the legitimacy of the law on citizens' everyday compliance with the law. He found that legitimacy had a significant influence on the degree to which people obeyed the law. Further, that influence was greater than were the effects of variations in the estimated probability of punishment. He has already asserted that legitmacy is a key value.

Studies suggest that the key to developing and to maintaining the legitimacy of law and of legal authorities lies in citizens' evaluations of the procedures through which legal rules are created and implemented. Studies of local legal authorities, such as the police and local courts, make it clear that the

central element that shapes public evaluations of their legitimacy are evaluations of the fairness of their procedures (Tyler 1990; Tyler et al. 1989). This is also true of citizens' evaluations of national level authorities, including the Supreme Court (Murphy and Tanenhaus 1969, Tyler 1993, Tyler and Mitchell 1994) and Congress.

The key to effective social regulation is recognizing that people's experiences with legal authorities not only shape their immediate compliance behavior, but also change their views about law and legal authorities in ways that lead to lasting compliance with the law. Studies indicate that experiencing fair procedures both leads to greater adherence to third-party decisions over time (Pruitt et al. 1993) and encourages long-term obedience to the law (Paternoster et al. 1997, Sparks et al. 1996). When legal authorities act in fair ways, they encourage the immediate acceptance of their decisions and enhance the values that lead to longterm compliance with the law.

3. *The Law-abiding Society*

The distinction between risk/gain estimates and internal values highlights the possibility of two types of legal culture. The first is a culture that builds public compliance on the basis of people's concerns about the possibility of being caught and punished for wrongdoing. Such a deterrence-based society depends upon the ability of legal authorities to create and maintain a credible threat of punishment for wrongdoing. The studies outlined demonstrate that, while deterrence influences law-related behavior, the social context of democratic societies makes it difficult for authorities to engage in the levels of surveillance needed to sustain a viable legal system.

To be viable, a legal system requires that citizens' behavior be influenced by internal values that promote compliance most of the time. Democratic societies depend heavily on people's self-regulatory motivations. Both public views about the morality of engaging in illegal behaviors and widespread feelings of obligation to obey legitimate legal authorities are central to such voluntary compliance with the law. Internal values, then, are critical in creating a society based upon the willing consent and cooperation of citizens. That cooperation develops from people's own feelings about appropriate social behavior, and is not linked to the risks of apprehension and punishment that people estimate to exist in their social environment.

A law-abiding society cannot be created overnight through changes in the allocation of resources within government agencies, because such changes only alter the expected gains and/or risks associated with compliance. It depends upon the socialization of appropriate social and moral values among children and the maintenance of those values among adults. Evidence suggests that the core elements in the creation and maintenance of such social values are: (a) the belief that law is consistent with public views about morality, and (b) the judgment that legal authorities follow fair procedures in exercising their authority.

T. R. Tyler

Comprehension, Cognitive Psychology of

1. Definitions and Forms of Comprehension

'Comprehension,' often used interchangeably with 'understanding,' can generally be defined as the solution of the problem of 'the "how" and "why" of the connections observed and applied in action' (Piaget 1978), but like many other psychological terms, it is used differently by different authors. The term means both the process (act of comprehending) and the product (an achieved state of comprehension) with more emphasis on one or the other. More importantly, comprehension is characterized as either high-cost or low-cost cognition. In other words, the core process of comprehension is regarded either as controlled-effortful or automatic-effortless, and is contrasted to other terms in different ways accordingly. For instance, according to Collins et al. (1980), understanding is a process of progressive refinement of models, and involves a variety of problem-solving strategies (e.g., rebinding variables, questioning a default assumption), as in solving a crossword puzzle. In contrast, Kintsch (1998) assumes comprehension to be a process in which 'the majority of elements are meaningfully related to one another' through automatic and effortless spreading activation. Thus, to comprehend means to adopt a coherent and plausible interpretation of pieces of information obtained from both outside and inside the mind (i.e., to satisfy multiple constraints), but it may or may not be cognitively demanding.

It is sometimes useful or even necessary to distinguish a few forms or levels of comprehension. The depth of understanding may be expressed only in relative terms ('deeper' vs. 'shallower'), but a frequent qualitative distinction is whether comprehension is explicit or implicit (Greeno 1983). For instance, finding a coherent and plausible interpretation for a target object or phenomenon produces differentiated and appropriate predictions about the target but may not always lead to explanations for it. Such forms are called implicit understanding. Another dimension differentiating levels of comprehension is whether the interpretation involves a causal device or only an empirical generalization. For example, a patient's recovery from beriberi by consuming barley instead of rice can be explained either by referring to the well-known effectiveness of the altered diet or by referring to the causal device, that is, that barley contains considerable Vitamin B1, the lack of which causes beriberi. Moreover, even among causal explanations, some are considered to reveal a deeper understanding than others. As indicated by Miyake (1986), an explanation at one level is what needs to be explained at the next deeper level. We can ask further, for instance, why the lack of Vitamin B1 causes beriberi.

2. Processes of Comprehension

Comprehension is more complex and interactive than schema application, in which a relevant schema is triggered by one of its key words or headers and imposed on the given pieces of information. However, much of comprehension can be induced within a short period of time and often with little effort. Kintsch (1988, 1998) proposes the two-stage Construction–Integration (CI) model of comprehension to capture these features. The first stage of construction is for the generation of a variety of inferences (activation of related ideas through association). The second stage of integration is multiple constraint–satisfaction through spreading activation. As we will discuss below, this model fits especially nicely with the comprehension of ordinary (not experimentally deformed) discourse, because readers or listeners spontaneously and readily generate inferences as the discourse proceeds, and integrate inferred as well as presented pieces of information very rapidly.

However, both inference-generating and coherence-seeking processes may be time-consuming and effort-intensive for other tasks of comprehension, such as scientific inquiry. Those tasks induce what Hatano (1998) calls comprehension activity. Comprehension activity often offers multiple interpretations at one time, and compares their plausibility carefully by deriving and testing predictions from each of the interpretations being considered. It is not a process in which one holds onto the first idea that comes to mind or one waits for a single interpretation to emerge

through spreading activation. A comprehender may feel uncertainty or puzzlement during this enterprise.

Plausible interpretations that are to be examined can be induced in a variety of ways both in low-cost and high-cost comprehension. Sometimes they are derived directly from prior knowledge including schemas. Other times a comprehender relies on interpretation-generation heuristics, such as modifying a parameter and observing what occurs. Still other times, candidate interpretations are brought about by analogies.

When people encounter a novel object or phenomenon, they may try to understand it by likening it to a highly familiar object or phenomenon. For example, at the time of Iraq's invasion into Kuwait, many Americans (partly through the campaign by the government) likened Saddam Hussein to Hitler, and thus justified their bombing of Iraq. Interestingly, some objected to the military action by analogizing the Persian Gulf War to the Vietnam War. This illustrates how people try to understand a novel phenomenon by referring to the instances in their past experience that they think are most similar, and how their reactions to the phenomenon are mediated by their analogy (Holyoak and Thagard 1995).

The analogies people make may involve structurally inaccurate mapping, and induce biased reasoning. Even a highly productive scientist like Kepler was misled by analogies at the beginning of his career (Gentner et al. 1997). However, analogy-based interpretations are often highly useful in comprehension activity, both in science (Dunbar 1995) and everyday cognition (Hatano 1998).

3. *Experimental Studies on Comprehension*

In this section we review three categories of phenomena of comprehension that have been studied extensively. They are grouped in terms of inputs: a set of observations, a set of connected sentences, and patterns of actions and their consequences.

3.1 *Understanding as Identification Based on Observations*

Recognizing something that is ambiguous as an instance of a concept or schema constitutes understanding, because it is adopting a coherent and plausible interpretation of a set of observed features of the target based on relevant concepts or schemas. Once we understand the target object or phenomenon, we can make sense of the observations and can remember them much more easily (e.g., Bransford and Johnson 1972). Moreover, we can recognize the target's essence or underlying process, and decide reasonably how to treat it.

The diagnosis of disease by reading X-ray films is a good example of such tasks of categorization or identification. The same disease does not always produce the same appearance on the film, and there can be several diseases that have similar appearances. Therefore reading X-ray films involves many inferences and requires a constraint–satisfaction process to reach a diagnosis. This is undoubtedly a process heavily dependent on prior knowledge, in which experts and novices would be expected to differ.

Lesgold et al. (1988) compared the abilities of expert and novice radiologists to make accurate diagnoses by reading x-ray films. The participants were asked to report a diagnosis after being shown chest X-ray films just briefly, and their protocols were analyzed. It was found that compared with the novices, the experts reported more varied findings (i.e., attributed specific properties to the film or the patient), their reasoning chains were longer, and a greater number of their findings were connected to at least another finding.

However, experts and novices do not make the same observations and then interpret them differently based on their different amounts of knowledge in natural settings. In a further study, the participants were required to examine the film as long as desired, while thinking aloud, and to dictate their formal diagnostic reports. Qualitative analysis of the protocols revealed that the experts exhibited more flexibility and were able to better tune their schemas to the perception of features in the film that were relevant to the specific case with which they were working. They could discount most of the obvious film features that the novices were likely to be misled to judge as evidence of disease symptoms, by using a mixture of technical knowledge about how the films were made and a better developed perception of the features.

Diagnosing films requires apparently simple outputs, that is, whether there are pathological changes, and what kind of disease the changes are due to. However, the process of understanding is more dynamic and interactive than the top-down process of applying the relevant schema stored in memory or the bottom-up process of summarizing and abstracting collected pieces of information. Perception, inference, and memory retrieval are inextricably connected. This is probably true for the understanding of other targets.

3.2 *Discourse Comprehension*

Comprehension of discourse (including both narrative and expository text) is one of the most popular topics in the study of understanding. Here, the input information is in the form of a set of spoken or written sentences, and the comprehender's job is to form a coherent whole from individual sentences. Versions of schema theory (e.g., Schank and Abelson 1977) were predominant in earlier studies. However, as pointed

out by Kintsch (1998), such top-down views have limitations: Discourse comprehension is interactive if not bottom-up, and it is much more flexible and context-sensitive than predicted from the schema theory.

Most contemporary investigators assume that to understand a story (i.e., a narrative text) is to build a microworld in which the described events are likely to occur. Kintsch (1998) calls this microworld the 'situation model.' In addition to the textbase that consists of those elements and relations that are explicitly described in the text itself, the situation model involves pieces of information that make the textbase coherent, complete, and interpretable in relation to prior knowledge. These pieces of information are inferred from both the text and prior knowledge. Multiple situation models may be constructed from the same text (e.g., differing in the coverage or the mode of representation).

When people understand a story, they make inferences that are not given in the text. They sometimes infer that an event occurred, even though it is not written explicitly (e.g., from the sentence, 'He took a subway downtown,' the reader infers that the subject bought a ticket); other times, the reader infers how an event occurred, although the text does not give any concrete details. (From the sentence, 'He bought a ticket with coins,' one infers, 'He used a vending machine.') In other situations, readers connect two adjacent propositions. (From the two sentences, 'Taro wanted to buy some tuna for sashimi at a discounted price. He went to the fish-market,' one infers, 'Taro went to the fish-market to buy tuna there.') How many inferences are generated spontaneously may depend on the readers, texts, and modes of reading. Graesser et al. (1994) claim that the inferences that are needed to explain why given events occur and to establish the coherence of the text tend to be induced spontaneously as the text is being processed. How many inferences are based on conscious and deliberate attempts to build consistent and detailed situation models also depends on several factors. Kintsch (1998) proposes that a coherent situation model is built based on these presented and inferred propositions through spreading activation. However, studies using experimentally designed defective texts (e.g., in Collins et al. 1980) have revealed that text comprehension may require a number of effortful attempts to instantiate, coordinate, and even insert pieces of information.

Almost everyone is very experienced in discourse comprehension, because it is a major medium of human communication. However, knowledge about the topic of the discourse still makes a difference, especially in the generation of inferences. As a result, more knowledgeable people can build a richer situation model than less knowledgeable ones. They learn more, especially when the text is less coherent and thus requires comprehension activity on the part of the comprehenders. Schneider et al. (1989) demonstrated that students who knew a lot about soccer not only remembered the details of a given story about soccer better, but also made more inferences and recognized contradictions in the text more often than their agemates who knew little about soccer.

3.3 Comprehension of Procedures and their Target Entities

Just knowing the procedures required to achieve goals differs from knowing how and why they work. By possessing knowledge to build mental models of the procedure-target combination (what the target is like and how it is changed by various procedures), we can grasp how and why these procedures work, modify the procedures flexibly, and even invent new procedures. Building such models is usually accomplished through a process of comprehension.

Kieras and Bovair (1986) showed that having a 'device model' (a mechanical version of the procedure-target model) that describes the internal mechanism of a piece of equipment enhances not only the participants' learning of how to operate the equipment but also their inventing of more efficient procedures than the ones they have been taught. Their experiments compared two groups, that is, a model group and a rote group. The participants in the model group were presented with the device model in a fantasy context before being given procedural instruction, whereas those of the rote group learned the identical operating procedures of the equipment by rote. It was observed that the model group learned the procedures faster, retained them more accurately, and executed them more efficiently than the rote group. More interestingly, the model group could simplify inefficient procedures and infer new procedures much more often than the rote group, indicating the benefit of their deeper understanding. An additional experiment showed that what was critical was the knowledge about the internal structures of the components of the equipment, not the context of fantasy.

In the experiments by Kieras and Bovair (1986) described above, an externalized form of the standard device model was presented and explained. Active human minds often ask the questions 'how' and 'why,' even when they know that a given procedure works, and may construct a procedure-target model through comprehension activity. For example, the recipe for bonito sashimi sometimes induces comprehension activity, because it is not just the slicing of raw fish, but involves the steps of roasting the skin-covered surface quickly at a high temperature and putting the roasted side into ice-water (Hatano 1998). People may wonder why such a recipe is required, and if they comprehend it, they can modify it flexibly when they have to meet a different set of constraints, for example, when there is no ice or no source of searing heat. To understand a given procedure is, as in this example, to find a

plausible interpretation for how and why it works. In other words, it permits the comprehender to infer what kind of effect each step of the procedure has on the target entity of the procedure. Thus, trying to generate to oneself an explanation for how a procedure is applied tends to enhance its understanding (Chi et al. 1989).

We sometimes engage in an even more ambitious attempt to reconstruct a procedure from its product in our daily lives, which is similar to the scientific inquiry that tries to model a process from its observed outcomes. For example, we may want to reproduce an unfamiliar but tasty dish (Hatano 1998). In an experiment, college students who were given a slice of perch mousse and asked to find how it had been made by tasting it (more specifically, to indicate its recipe) seemed to engage in comprehension activity. They often proposed ideas that they eventually discarded themselves. For example, they offered a number of possible ingredients, but rejected some of them both from their taste and knowledge about cooking. They expressed their feelings of uncertainty or puzzlement, as well as insight.

Although there have been few studies, prior knowledge seems critical for the understanding of procedures. First, prior knowledge enables comprehenders to think of hypotheses. Second, it serves as constraints in the pursuit of coherence and plausibility.

4. *Comprehension Monitoring and Repair*

To understand something deeply, it is necessary to assess one's extent of understanding, and to take appropriate action based on that assessment. However, whether one understands is not obvious (whereas whether one has solved a problem can be recognized more clearly). To put it differently, every task of comprehension is inevitably ill defined. Therefore how well people can monitor their own understanding and how this monitoring ability develops are interesting questions in the study of comprehension.

Research on comprehension monitoring, following the pioneering work by Markman (1977), has shown that younger children tend to miss the insufficiency or inconsistency of a given message more often than older children or adults, but another line of research on metacomprehension has revealed that even college students tend to have this 'illusion of comprehension' (e.g., Glenberg and Epstein 1985). College students often believe that they understand a given text, though in fact they do not, at least as assessed by a multiple-choice test. This suggests that people have a general tendency to overestimate the adequacy of their own comprehension. People must be selective in directing prolonged comprehension activity, because it requires considerable time and effort. The illusion of comprehension guards them from engaging in the activity too often or in too diverse domains.

This tendency to overestimate the extent of comprehension may be due to the human ability to readily repair comprehension by supplementing pieces of missing information. Ackerman et al. (1991) observed that recovering coherence by adding a piece of new information by inference is frequent among both children and adults. People seldom suffer from the lack of comprehension for an extended period of time. This seems adaptive in the 'wild environment' in which quick decision-making and prompt action are required (Toda 2000).

As suggested by Schneider et al. (1989), it is likely that the more and less knowledgeable people differ in their ability to estimate accurately the degree of coherence among pieces of information and the adequacy of their comprehension. Humans seem to have a general tendency to make sense of their observations and actions, in other words, to derive coherent and plausible interpretations. However, judging whether the achieved understanding is adequate is a totally different issue. The criterion of adequacy may vary from context to context. Therefore only those who have performed many similar ill-defined tasks of understanding in the target domain can assess it accurately.

5. *Comprehension as a Paradigm of Cognition*

As Kintsch (1998) aptly points out, many forms of cognition can be regarded as a process of constraint–satisfaction, and thus a process of understanding. Comprehension as a process thus represents cognition in diverse areas, as does problem-solving through searching a problem space. However, as we have seen, the process of constraint–satisfaction is not necessarily executed through spreading activation, nor is it automatic–effortless. The process of understanding is in a sense to solve an ill-defined problem, that is, to find a 'reasonable' solution to a problem for which only an incomplete set of information is given, using a variety of constraints. A set of constraints is provided by prior knowledge, but, in addition, interpretations of many related observations can be used as mutual constraints, as in solving a crossword puzzle. It is a process of maximizing coherence among the pieces of information, whether they are presented, stored, or inferred.

In terms of the function, understanding is primarily to make a best guess about what the external world is like, based on observations, and constitutes a core function of the mind, more specifically, of central systems (Fodor 1983). Understanding enables us to build enriched, stable, coherent, and usable representations of the world, which often serve as the basis for solving problems, that is, for changing the world as we desire. In this sense, understanding is an investment in an unknown future, and the human tendency to seek deep understanding, spending much time and effort,

can be considered adaptive, even though it seems to be just intellectual luxury.

Compression of Morbidity

The compression of morbidity paradigm (Fries 1980) envisions reduction in cumulative lifetime morbidity principally through primary prevention, by postponing the age of onset of morbidity to a greater amount than life expectancy is increased, largely by reducing the health risks which cause subsequent morbidity and disability. Recent data document slowly improving age-specific health status for seniors, indicate that postponement of the onset of disability by at least 10 years is feasible, and prove the effectiveness of some specific lifestyle modification interventions by randomized controlled trials.

The health of senior persons is the largest of all health problems in the developed nations. Over 80 percent of all illness, morbidity, mortality, and medical costs are concentrated in the years after age 65. The illness burden is mostly made up of chronic illness, complicated by the frailty of increasing age. In the twentieth century we saw a transfer of the illness burden from the acute infectious diseases prevalent in 1900 to ascendancy of chronic disease by mid-century, to a decline in major chronic illnesses, led by car-

diovascular disease, and now to the slow transition from chronic disease *per se* to the associated problems of aging (Fries 1980).

1. An Overview of the Aging Process

1.1 Mortality Changes over Time

Changes in survival curves in developed nations over the twentieth century are instructive, since they lead us beyond a simplistic, if popular, notion of ever-increasing life expectancy. Life expectancy from birth is affected most strongly by changes in infant mortality rates and in deaths in early and middle life. Successive survival curves (Fig. 1) have become more rectangular, as marked reduction in deaths at early ages flatten the initial part of the curve. There are now few deaths prior to age 50 or 60. At the same time, the downslope of the curves has become steeper, and the insertion point has changed little (Fries and Crapo 1981). A natural barrier to biologic longevity may be visualized through these successive curves. In the USA, life expectancy from birth increased from 47 to 76 years in the twentieth century. However, life expectancy from advanced ages has changed relatively little. From 1980 to 1998, life expectancy for females from age 65 increased only by 0.7 years in contrast to more rapid rises in prior decades. Life expectancy for both sexes from age 85 remained stable at 6.1 to 6.3 years in the USA in the 18 years from 1981 (Kranczer 1999). Projections for future increases vary widely from high (Manton et al. 1991) to low (Olshansky et al. 1990). Nevertheless, with increasing size of successive birth cohorts and with increased survival to age 65 or age 85 the absolute numbers of senior citizens will increase very substantially in coming years.

Figure 1
The rectangularization of survival curves. Successive curves, at 20 year intervals, illustrate (a) the flattening of the early part of the curves from decreases in premature deaths, (b) the steepening of the downslope as natural life limits are approached, and (c) the nearly constant insertion site of the curves

1.2 Declines in Organ Reserve Function with Age

Data from longitudinal studies of aging show a consistent decline in the maximum function of the various organs with age, the decline being essentially linear at a rate of 1.5 percent per year after age 30. Data on maximal performance, such as world record marathon times, similarly show a nearly linear decline with age at the same rate (Fries and Crapo 1981).

Physiologic normal values, however, remain constant with increasing age. Normal pH, blood chemistry, white count, and other homeostatic values do not vary over the lifespan, representing the internal physiologic environment essential for cellular function. However, with the linear decrease in organ reserve in multiple organs, the ability to respond physiologically to a perturbation decreases exponentially. As a result, mortality rates increase exponentially, with a doubling of mortality rates each seven or eight years after age 30 (Fries and Crapo 1981).

With these realities of human aging comes a paradox: the decline in organ reserve is inevitable, yet organ reserve can be increased quite readily, at almost any age (Rowe 1999). For example, an increase in exercise levels can increase cardiopulmonary reserve very substantially, even at advanced ages (Stewart et al. 1993, Fries et al. 1996).

1.3 Enhanced Personal Autonomy and Modifiable Determinism

In philosophic writings, a classical conflict has been between the advocates of free will and those of determinism, and this conflict now exists in modern dress. Determinism is represented by molecular genetics, with the sometime notion that your health over the lifespan is ultimately determined only 'by your genes.' Free will is represented by the advocates of health promotion, seeking voluntary changes in behavioral risk factors, such as lack of exercise, cigarette smoking, obesity, and excessive dietary fat; changes which can enhance organ reserve, preserve function, and extend life. In this view, health requires that you 'take care of yourself.' The tension between these two paradigms is complex and sometimes uneasy.

2. The Compression of Morbidity

2.1 The Hypothesis and the Paradigm

The compression of morbidity hypothesis was introduced in 1980 (Fries 1980) and has become a major paradigm underlying health improvement programs and health improvement policies directed at more successful aging (Fries et al. 1998). Most morbidity results from chronic processes of disease and frailty and is concentrated in the years prior to death. The

Figure 2
Compression of morbidity. The top line provides a graphic estimate of current lifetime morbidity, disability, or cost, expressed as a shaded area between onset of disability at an average age of 55 years and an average age of death of 75 years. Possible future scenarios are shown below. The second line represents the extension of morbidity if life expectancy is increased but the onset age of morbidity is not. The third shows a 'shift to the right'

goal is compression of morbidity between its time of onset, currently averaging 55 years, and the age of death, currently averaging 76 years, as diagrammed in Fig. 2. A crescendo of increasing morbidity occurs, on average, over this period.

With social and scientific progress it is likely that both the age of onset of infirmity and the age at death will increase over time. At issue is the relative movement of the two points. If mortality decreases predominate there may be more morbidity in the typical life, the so-called 'failure of success' (Gruenberg 1977, Verbrugge 1984, Scheider and Brody 1983), as shown in the second line of the figure. If postponement of the age of onset of morbidity predominates, then morbidity is compressed and the average illness burden is less, the period of adult vigor is prolonged, life quality is improved, and the need for medical care and associated costs may be reduced.

For many, the ideal life is one vigorous and vital over the lifespan, with a terminal collapse of physical and mental function limited to a few months or years immediately preceding death (Fries and Crapo 1981). A central issue, when considering the eventual impact of new scientific discoveries or behavioral changes, is whether they may add years of health or add years of illness to the average life. If morbidity is compressed by a new advance then the advantage is clear; if the process of dying is prolonged then major ethical issues arise (Verbrugge 1984).

2.2 *Trends in Morbidity Compression*

Since the early 1980s there has been some compression of morbidity in the elderly, as documented by a number of recent studies (Manton et al. 1997, Nusselder and Mackenbach 1996, Allaire et al. 1999). The major chronic illnesses, including heart disease, cancer, and stroke, are about 70 percent preventable. The true causes of death are not the chronic diseases themselves but the underlying causes of these diseases, which are led by cigarette smoking, sedentary living, obesity, and diets high in saturated fat and low in complex carbohydrates (McGinnis and Foege 1993). The potential for postponement of morbidity is now much better understood.

Freedman and Martin (1998), among others, have shown significant age-specific functional improvement in seniors over a recent seven-year period. Cross-sectional studies have suggested compression of morbidity in favored groups, such as those with higher levels of education (Leigh and Fries 1994), higher socioeconomic status (House et al. 1990), and those with fewer lifestyle health risks (Vita et al. 1998). Daviglus and colleagues (1998) showed substantial decreases in Medicare costs for those with few health risk factors in midlife. Reed and colleagues (1998) related healthy aging to prospectively determined health risks. Allaire et al. (1999) showed a reduction of disability of 25 percent across successive generations in the Framingham study. Clearly, social and behavioral health risks make a very major contribution to both morbidity and mortality. Selected medical advances also evidently contribute to compression of morbidity, from established therapies such as total joint replacement and cataract extraction to any other treatment which makes a major contribution to life quality. The central measure of success at compression of morbidity is reduction in average cumulative lifetime morbidity (Vita et al. 1998, Wang et al. 1999, Hazzard 1997). Hitt et al. (1999) analyzed morbidity in centenarians and found it to be mild, with a rapid terminal decline.

3. *How Long May the Onset of Morbidity be Postponed?*

Substantial numbers of aging seniors in two cohorts have been followed longitudinally to identify the factors which postpone onset of morbidity, the magnitude of the postponement, and the effects of lifestyle health risks, using disability as a definable and measurable surrogate for morbidity and cumulative

disability as a surrogate for cumulative lifetime disability.

The University of Pennsylvania Study followed 1,741 university attendees studied in 1939 and 1940, surveyed again in 1962, and followed annually since 1986. Health risk strata were developed for persons at high, moderate, or low risk, based upon cigarette smoking, body mass index, and lack of exercise, and assigned by risk status in 1962 (average age 43 years). Persons with high health risks in 1962 or in 1986 had twice the cumulative disability of those in the low risk strata. This 100 percent decrease in disability rates was offset only partially by a 50 percent decrease in mortality rates in the high risk strata, documenting compression of morbidity. Onset of disability was postponed by about seven years in the low risk stratum as compared with the high stratum (Vita et al. 1998).

In the Precursors of Arthritis Study 537 senior runners and vigorous exercisers and 423 age-matched community controls were studied over 13 years with careful controls for self-selection bias. The exercising group has had less than one-half the cumulative disability of the sedentary controls and differences between groups has actually increased over time. The proportion of those disabled was also reduced by more than one-half in the exercise groups. The postponement of disability for the exercising group was 8.7 years for minimum disability and approximately 12 years for higher levels of disability (Wang et al. 1999).

While these two studies are the only ones to directly assess the magnitude of morbidity progression they are entirely consistent with the larger literature (Stewart et al. 1993, Daviglus et al. 1998, Freedman and Martin 1998, Campion 1998, Allaire et al. 1999, Reed et al. 1998).

4. *Randomized Controlled Trials of Behavioral Interventions*

Epidemiologic studies of associations, no matter how strong and consistent, ultimately require randomized study of interventions for proof of causality, and a number of these are now available (Fries et al. 1998). Health promotion programs in senior populations directed at risk prevention, health improvement, and medical cost reduction have been studied in a number of large and well-performed randomized trials, with positive results. The Bank of America randomized study of 4,500 retired subjects reduced risks by 12 percent in the intervention groups in the first year compared with controls and reduced medical care requirements by even more, confirmed by study of medical claims (Fries et al. 1993). The California Public Employment Retirement System study (Fries et al. 1994), involved 57,000 subjects in a one-year randomized trial with similarly dramatic results confirmed by claims data endpoints. Over 42 carefully designed high quality health improvement programs have now been proven effective and cost-effective at preventing illness and at reducing medical need (Fries et al. 1998).

5. *Issues for Contemplation*

The human aging process, when not prematurely stopped by trauma or disease, moves toward multiple organ system frailty (Fries et al. 1998). The immediate cause of death shifts from external toward intrinsic factors. The formally assigned 'cause of death' becomes increasingly irrelevant compared with the underlying frailty, the inability of the aging organism to withstand even a minor perturbation. With frailty, an analogy is an old curtain, rotted by the sun, where an attempt to repair a tear in one place is followed by a tear in another.

William Osler considered pneumonia to be the 'old mans' friend,' terminating the infirmities of frailty. Influenza epidemics result in an increase in death rates, but they are followed by a six-month period of death rates which are actually below expected baselines. Pneumovax and influenza vaccines can prevent a number of specific perturbations and associated attributable deaths, but only in the context of multiorgan frailty. The ultimate health benefits of successful interventions in the terminally frail may prove in substantial part illusory when so many competing risks remain.

Health policies directed at healthy aging may now be visualized quite clearly. An underlying paradigm is the compression of morbidity. Prospective longitudinal studies now link health outcomes firmly with antecedent health risk factors, providing proof of concept. Randomized controlled trials of interventions in seniors document the ability to reduce health risks, to improve outcomes, and to reduce costs, providing proof of causality. National and international initiatives are now needed to provide these benefits to populations.

Computational Approaches to Model Evaluation

A measure of scientific advancement in a discipline is the discovery of general laws and principles that govern the phenomenon of interest. As the underlying principles are typically not directly observable, they are formulated in terms of hypotheses. Models are formal expressions of such hypotheses, whose viability must be evaluated against data generated by the phenomenon. In this article we review computational approaches to model evaluation, with a special emphasis on the inductive inference perspective. A more in-depth treatment of the topic can be found in Cherkassky and Mulier (1998) and Haykin (1999). For a discussion of some of the issues presented here from the statistical perspective (see *Model Testing and Selection*, *Theory of*, which complements the present article).

1. *Modeling as Inductive Inference*

The goal of modeling is straightforward: given observed data, identify the underlying system that generated the data. Realistically, modeling is viewed as a learning problem in which we estimate an unknown function from observed data and then use the estimated function to predict the statistics of future data. When modeling, we reconstruct an unknown function based on several sample points in the data space (local subspace) and then apply it globally, throughout the data space. This process of generalizing from a particular instance to *all* instances is referred to as inductive inference, or predictive inference given the predictive nature of the process and the goals of the modeler. It is at the heart of the scientific enterprise in modern science as well as in engineering.

1.1 Ill-posedness of the Modeling Problem

Identifying an unknown function from data samples is an ill-posed problem, meaning that obtaining a unique solution is not in general possible. The reason stems from the reality that there is rarely enough data available (or information in the data) to discriminate between models. Multiple functions may provide equally good descriptions of the data in hand. This problem is known as the *curse of dimensionality*, which states that for a function defined in high-dimensional space, it becomes increasingly difficult to estimate accurately the function as dimensionality increases, with required sample sizes increasing exponentially with dimensionality (Cherkassky and Mulier 1998). This problem of ill-posedness can be overcome only by introducing external constraints on, and/or prior information about, the data-generating function.

1.2 Model Evaluation: Finding Best Approximation to Truth

An implication of the ill-posedness problem is that the 'true' model, the one that generated the data, can never be found in practice. Accordingly, the previously defined goal of finding the true function underlying observations must be modified. A more realistic goal is to find the best possible approximation to the truth, in which the best approximation is defined as the one that generalizes (i.e., infers) best in some defined sense.

2. Bias-variance Dilemma

Formally, a model is defined as a parametric family of probability distributions defined on random variables Y, representing data. An observed sample of size n denoted by a lower case vector $y = (y_1, \ldots, y_n)$ represent realizations (measurements) of Y, which are presumed to be generated from some true distribution $g(y)$ that the scientist seeks to unravel. The scientist, using a family of distributions $f(y|\theta)$'s where θ is a parameter vector on the parameter space Θ, seeks to construct the best approximation to g within the family f.

Let $t = E(y)$ denote the population mean vector of the true distribution $g(y)$, and let $z(\theta) = (z_1, \ldots, z_n)$ denote the vector predicted by the model atθ. Also, let the quadratic function

$$L(x, z(\theta_x)) = \min_{\theta} \left(\frac{1}{n} \sum_{i=1}^{n} (x_i - z_i(\theta))^2 \right) \quad (1)$$

denote a measure of the discrepancy or error between a vector x and the prediction vector $z(\theta)$. Note that θ_x denotes the value of the parameter that minimizes the discrepancy measure given a vector x. This function is used to measure the effectiveness or risk of the model family f in approximating the truth g. For example, $L(y, z(\theta_y))$ represents the minimized mean squared error between observed and predicted data, that is, the best possible fit the model provides given data y. Because this quantity changes from sample to sample, a better measure of model effectiveness (or risk) is the expected value of $L(y, z(\theta_y))$, which can be expressed as the sum of two terms:

$$E[L(y, z(\theta_y))] = L(t, z(\theta_t)) + E\left[\frac{1}{n} \sum_{i=1}^{n} (z(\theta_y) - z(\theta_t))^2 \right] \quad (2)$$

In the above equation E denotes the expectation (i.e., average) taken over all data samples of size n which could be realized under the true distribution g, and t is the mean vector of the true distribution $g(y)$ that has generated the data. Note that the value of the prediction vector $z(\theta_y)$ varies across samples whereas $z(\theta_t)$ is a fixed constant vector, which can be replaced by $E[z(\theta_y)]$.

The left-hand side of the above equation is the expected risk in predicting all data samples given the model family f, and thus it measures the model's generalizability. The first term of the right-hand side of the equation is the discrepancy between the true mean vector t and the model's best approximation to t, $z(\theta_t)$. Accordingly, this term captures the model's inability to accurately approximate the truth g, and is called the *bias* or approximation error. If the model family f includes g as a special case, the bias term becomes zero, and takes on a positive value otherwise. The second term is the expected variability of the prediction vector $z(\theta_y)$ around its mean $z(\theta_t)$, and is called the *variance* or estimation error. It captures the lack of information in the sample of finite size about the truth g. As such, this term decreases to zero as sample size n goes to infinity.

To achieve good generalization performance, both the bias and variance of the model family f would have to be minimized at the same time. It turns out, however, that this is not possible because the bias can be minimized by increasing model complexity, whereas increasing complexity will have the detrimental effect of increasing the variance by capturing random error in the data, thereby reducing generalization performance. Complexity refers to the flexibility inherent in a model that enables it to fit diverse patterns of data. In general, a simple model with few parameters has a large bias but a small variance, whereas a complex model (one with more parameters) has the opposite. We thus have a *bias-variance dilemma* (Geman et al. 1992), with model complexity as the intervening variable that mediates between the two.

The bias-variance dilemma is a useful conceptual framework for understanding the trade-off between approximation error and estimation error, both of which contribute to a model's generalizability. How-

ever, the generalizability measure represented by the sum of bias and variance is not directly observable, because the truth g is unknown, and therefore it must be inferred from observed data.

3. Computational Approaches to Model Evaluation

In order to make the ill-posed problem of modeling into a well-posed one, additional constraints and prior information must be incorporated into the model evaluation process. Computational approaches to the problem differ from one another in how this is accomplished. *Structural risk minimization* (Vapnik 1992), *regularization theory* (Tikhonov 1963) and *minimum description length* (Rissanen 1989) are three major inductive methods of model evaluation.

Briefly, the structural risk minimization method imposes a constraint requiring that, among a set of candidate models, the one that minimizes an expected risk functional should be chosen. Regularization theory chooses among models based on the prior assumption that the unknown function underlying the data is smooth, in the sense that similar inputs map onto similar outputs. The minimum description length method prescribes the constraint that the description length of data should be minimized. Formalizations of these ideas are described in the following sections.

3.1 Structural Risk Minimization

The basic idea of structural risk minimization is to estimate an upper bound of the expected risk, $E[L(y, z(\theta_y)]$, in terms of the observable empirical risk, $L_{\text{emp}}(y, z(\theta_y))$, given data sample y and a confidence interval, the value of which depends on a measure of model complexity and sample size, n. For binary classification problems for which $y_i = 0$ or 1, the following inequality holds

$$E[L(y, z(\theta_y))] \leqslant L_{\text{emp}}(y, z(\theta_y)) + I_\alpha(h, n) \qquad (3)$$

where I is the confidence interval, α is the alpha level of inferential statistics, and h is a quantity known as the Vapnik–Chervonenkis (VC) dimension (Vapnik and Chervonenkis 1971). The model that provides the lowest value of the upper bound for the expected risk should be chosen.

The VC dimension for a given model family of classification functions is defined as the maximum number of distinct binary samples that the model can fit perfectly without error for all possible labelings of the samples. Thus the VC dimension may be viewed as a measure of the complexity or flexibility of a model. Interestingly, the VC dimension depends not only on the number of parameters of a model but also, importantly, on the functional form of the model equation. A model with only one parameter can have infinite VC dimension while a model with a billion parameters can have a low VC dimension. For linear models, the VC dimension is equal to the number of parameters.

Given and n, the empirical risk $L_{\text{emp}}(y, z(\theta_y))$ is a monotonically decreasing function of the VC dimension whereas the confidence interval $I(h, n)$ is a monotonically increasing function of the VC dimension. These relationships along with the above equation reveal how structural risk minimization works. Among a set of competing models, the method chooses the model that describes the data sufficiently well (i.e., smallest empirical risk) with the least complex structure (i.e., narrowest confidence interval), thereby formalizing the principle of Occam's razor. In practice, structural risk minimization is implemented by first creating a set of k nested models with successively increasing VC dimensions, $h_1 < h_2 < \ldots, < h_k$, and then calculating the empirical risk for each model given sample data. The model with the smallest expected risk is then selected.

3.2 Regularization Theory

Regularization theory's solution for solving the ill-posed problem is to secure the uniqueness of the solution by requiring it to satisfy some secondary condition that embeds prior information or assumptions about the solution. The form of prior information most often used is the condition that the unknown function being sought is sufficiently smooth. Formally, the regularization risk for a model is defined as

$$R(\theta) = \frac{1}{n}\sum_{i=1}^{n}(y_i - z_i(\theta))^2 + \lambda S(z(\theta)) \qquad (4)$$

where the vector $z(\theta)$ is the model's prediction at θ, is known as the regularization parameter, and $S(z)$ is a functional that measures smoothness of the solution. The quantity often used for $S(z)$ is the integral of the squared second derivatives with respect to an independent variable x on which smoothness of the solution is assessed, i.e.,

$$S(z) = \int \left\| \frac{\partial^2 z(\theta, x)}{\partial x^2} \right\|^2 \mathrm{d}x \qquad (5)$$

The regularization theory prescribes that the model with the smallest $R(\theta)$ should be chosen.

The first term of the above equation is a measure of the discrepancy between the data and the model's prediction, that is, the empirical risk of the model. The second term, $S(z)$, is a measure of complexity of the model. The larger the value of $S(z)$, the less smooth the prediction, and thus the more complex the model. The

regularization parameter λ represents the relative importance of the complexity of the model with respect to its empirical risk. With λ_0, the solution is primarily determined by observed data and thus tends to be highly complex in structure. On the other hand, with $\lambda \to \infty$, the smoothness condition entirely dictates the form of the solution, which tends to be simple in structure. In practice, a value between these two extremes is chosen based on some principled approach (Haykin 1999). In short, the regularization method, like the structural minimization method, uses complexity to steer the solution toward improved generalization. As such, it is another implementation of the principle of Occam's razor.

3.3 Minimum Description Length

Minimum description length (MDL), which originated from algorithmic coding theory in computer science, regards both model and data as codes. The idea is that any data set can be appropriately encoded with the help of a model, and that the more we compress the data by extracting redundancy from it, the more we uncover underlying regularities in the data. Thus, code length is directly related to the generalization capability of the model, where the model that provides the shortest description of the data should be chosen. Formally, the total description length of a model is given by

$$MDL = L(\text{data}|\text{model}) + L(\text{model}) \tag{6}$$

where $L(\text{data}|\text{model})$ is the description length of the data given the model, measured in bits of information, and $L(\text{model})$ is the description length of the model itself.

The above definition of minimum description length is broad enough to be applied to any well-defined models, even verbally defined, qualitative models. For a statistical model defined as a parametrized family of probability distributions, the minimum description length for such a model takes the following form (Rissanen 1996):

$$MDL = -\ln f(y|\theta_y) + \frac{k}{2}\ln\left(\frac{n}{2\pi}\right) + \ln\int d\theta\sqrt{\det(I(\theta))} \tag{7}$$

In the equation θ_y is the parameter value that maximizes the likelihood function $f(y|\theta)$, k is the number of parameters, $I(\theta)$ is the Fisher information matrix and $\det(I)$ is the determinant of the matrix. The first term of the MDL can be interpreted as a measure of risk or lack of fit, and the second and third terms together are a measure of model complexity. Model evaluation is therefore carried out by trading off lack of fit for simplicity.

In summary, although the three approaches to model evaluation evolved from different conceptual frameworks and philosophies, they all share the common goal of achieving optimum generalizability by striking a balance between risk (or lack of fit) and complexity. Another commonality between these approaches is the aspect of a model that is captured by the complexity measure; they not only include the number of parameters in the model, but also, importantly, its functional form, which refers to the way in which the parameters are combined in the model equation.

4. Relations to Statistical Approaches

So far we have considered computational approaches that view model evaluation as an inductive inference problem, which is the predominant view in computer science and engineering. Model evaluation is also a topic of central interest for statisticians (statisticians prefer the term *model selection* to *model evaluation*). Approaches which have been developed within the statistical framework include the generalized likelihood ratio test (GLRT), cross-validation, the Akaike information criterion (AIC), the Bayesian information criterion (BIC) and Bayesian model selection (see *Model Testing and Selection*, *Theory of*). There are many important differences between these methods, but in essence, they all implement a means of finding, explicitly or implicitly, the best compromise between lack of fit and complexity by trading off one for the other. Statistical model selection methods are entirely consistent with the computational modeling approaches discussed above (see Sect. 3).

Here are a few notable differences and similarities between some of the statistical methods and computational methods. First, GLRT, AIC, and BIC differ from the computational methods such as structural risk minimization and minimum description length in that the two statistical selection criteria consider only the number of parameters as a complexity measure, and thus are insensitive to functional form, which can significantly influence generalizability. Second, application of the statistical methods requires that each model under investigation be a quantitative model defined as a parametric family of probability distributions. On the other hand, the computational methods can be applied to qualitative models as well as quantitative ones. For instance, the minimum description length method defined in Eqn. (4) is applicable to evaluating the effectiveness of decision tree models or even verbal models (Li and Vitanyi 1997). Finally, there exists a close connection between Bayesian model selection and the minimum description length criterion defined in Eqn. (5). The minimum description length criterion can be derived as an asymptotic approximation to the posterior probability in Bayesian model selection for a special form of the parameter prior density. An implication of this connection is that choosing the model that gives the shortest explanation for the observed data is essen-

tially equivalent to choosing the model that is most likely to be true in the sense of probability theory (Li and Vitanyi 1997), see *Algorithmic Complexity*.

5. Conclusion

The question of how one should decide among competing explanations (i.e., models) of data is at the core of the scientific endeavor. A number of criteria have been proposed for model evaluation (Jacobs and Grainger 1994). They include (a) *falsifiability*: are there potential outcomes inconsistent with the model? (b) *explanatory adequacy*: is the explanation compatible with established findings? (c) *interpretability*: does the model make sense? Is it understandable? (d) *descriptive adequacy*: does the model provide a good description of the observed data? (e) *simplicity*: does the model describe the phenomenon in the simplest possible manner? and (f) *generalizability*: does the model predict well the characteristics of new, as yet unseen, data?

Among these criteria, computational modeling approaches described in this article, as well as statistical approaches, consider the last three as they are easier to quantify than the other three. In particular, generalizability has been emphasized as the principal criterion by which the effectiveness of a model be judged. Obviously, this 'bias' toward the predictive inference aspect of modeling reflects the dominant thinking of the current scientific community. Clearly one could develop an alternative approach that stresses other criteria, and even incorporates some of the hard-to-quantify criteria. There are plenty of opportunities in this area for the emerging field of model evaluation to grow and mature in the decades to come.

Computational Imagery

Reasoning with diagrams (that is, image, pictorial, depictive, or analogical representations) has long been a topic of interest among psychologists and philosophers. Diagrammatic representations are important for both the storage and communication of information, whether they are stored externally, such as a pictorial representation on paper, or internally in the form of a mental image. Recently, researchers in Artificial Intelligence (AI) have also been considering how diagrams can be used in computational approaches to reasoning and problem solving.

This article considers diagrammatic or imagery-based reasoning primarily from the computational perspective. In particular, we consider the issues of how images or diagrams can be represented and used for automated reasoning. The applications of computational imagery in the context of problem solving is also considered. As this is a relatively new area of research in AI, there is not yet an agreed upon underlying theory or standard approach for problem solving with images. Therefore, this entry presents an overview of approaches to this form of reasoning along with a description of various applications. A more detailed discussion of some of the issues presented here can be found in the book *Diagrammatic Reasoning* (Glasgow et al. 1995).

1. Reasoning with Images

A primary characteristic of a good formalism for knowledge representation is that it makes relevant properties explicit. Traditional approaches to knowledge representation and reasoning were developed primarily for linguistic or sentential reasoning, whereas computational imagery is concerned with emulating the problem solving abilities associated with mental imagery. Larkin and Simon (1987) have suggested that diagrammatic representations allow for the explicit representation and direct retrieval of depictive information that is only implicit in the more traditional descriptive representations.

In the context of artificial intelligence, imagery can be considered as the ability to manipulate representations for the purpose of retrieving visual and spatial information that was implicitly, rather than explicitly, encoded in long-term memory. Marr (1982) has proposed three levels of analysis that are necessary to understand vision: computational theory, algorithmic and hardware (see *Marr, David (1945–80)*). Although all three levels of analysis can also contribute to the understanding of diagrammatic reasoning, this entry focuses on the algorithmic level, which is concerned with the underlying representations and computational processes involved in problem solving with images or diagrams. A thesis of much work in computational imagery is that some of the processes involved are facilitated by depictive knowledge rep resentation schemes that incorporate inferencing techniques based on direct inspection and transformation of the representation.

Computational imagery generally involves tools and techniques for visual and spatial reasoning, where depictive image representations are generated or recalled from longterm memory and then transformed, scanned, associated with similar forms (constructing spatial analogies), pattern matched, composed, and so on. Whereas visual reasoning is concerned with what an image looks like, spatial reasoning depends more on where an object is located relative to other objects in a diagram or a scene. This computational distinction is analogous to the distinction between visual and spatial models proposed in cognitive studies of imagery. Note that the representations generated to retrieve image information may correspond to real physical scenes or abstract concepts that are manipulated in ways similar to visual forms.

Funt (1980) proposed a computational approach to visual imagery that represents the state of the world as a diagram and actions in the world as corresponding to actions in the diagram. Similar to Kosslyn's computational theory (1980), Funt uses two-dimensional arrays to depict visual images. In a more recent study of imagery, Chandrasekaran and Narayanan (1990) describe how visual information can be represented within the computational framework of discrete symbolic representations in such a way that both mental images and symbolic thought processes can be explained. Visual knowledge in this model is structured as multilevel hierarchies consisting of imaginal (two-dimensional pixel arrays) and symbolic (shape primitives) descriptions of the image configuration.

Lindsay (1988) suggests that depictive representations possess properties that help avoid 'the combinatorial explosion of correct but trivial inferences that must be explicitly represented in a prepositional system.' Sloman's (1985) definition of analogical representations states that a representation is depictive if there is a correspondence between the structure of the representation and the structure of the image being denoted. More precisely, if D is a depictive representation of an image I, then (a) there must be a mapping of the parts in D (e.g., symbols or pixels) to parts in I, and (b) it must be possible to define a correspondence between properties or relations of parts of D and properties or relations of parts of I (e.g., shape, relative location, volume). In a *vivid* form of knowledge, there is also a one-to-one correspondence between symbols and objects in the world, and for every simple relationship of interest in the world there exists corresponding connections among symbols in the knowledge base. Levesque (1986) asserts that the main advantage of vivid knowledge bases is that they provide for efficient worst case reasoning behavior, since calculating what is logically implicit generally reduces to retrieving what is explicit.

Figure 1
Alternative representations for molecule

As a criteria for assessing alternative representations for shape description in vision, Marr (1982) introduced the concept of accessibility, which is defined as the ability to derive a representation from an image at reasonable computing costs. A similar criteria can also be applied to potential representations for imagery. Although formulating an image representation is often straightforward, constructing one that is efficient in terms of the amount of information stored, and also effective for problem solving, may be a complex process. For example, in the molecular domain it is possible to represent a structure in several different ways; our choice of representation depends on the questions we wish to ask. Take, for example, the multiple representations of a molecular structure illustrated in Fig. 1. If we wish to determine how many atoms of carbon are contained in a molecule, then the formula in Fig.1(a) is sufficient. However, if we need to derive connectivity, angle, distance or shape information, then a more complex image representation, such as one corresponding to the illustration in Fig. 1(b) or (c), may be more appropriate.

Hayes (1974) discusses the notion of direct representations in which there exist similarities between what is being represented and the medium of the representation. Sloman (1985) has also argued the pros and cons of analogical representations, and has concluded that a variety of representation formalisms—including those specialized for spatial reasoning—are important to AI problem solving. Other hybrid approaches have been suggested for visual-spatial and model-based reasoning. Habel et al. (1993) have developed a system consisting of a propositional

and depictorial partonomy (organization of parts) for reasoning, where the depictorial partonomy reflects the hierarchy proposed in representations for visual processes. They suggest that the advantage of the depictorial representation in the system is that it facilitates an efficient attention-driven method for reasoning. Myers and Konolige (1992) treat model-based manipulations as a form of inference within a classical logic system. More specifically, they store partially interpreted sensor data using an analogical representation that interacts with a general-purpose sentential language. A technique for qualitative spatial reasoning, based on the directional orientation information made available through perceptual processes, has been presented by Freksa and Zimmermann (1993). In this work, orientations in two-dimensional space are defined by the relation between a vector and a point.

Motivated by cognitive studies of mental imagery, Glasgow and Papadias (1992) have proposed a hybrid knowledge representation scheme for computational imagery consisting of three representations, each appropriate for a different kind of image processing: an image is stored in long-term memory as a hierarchically organized, descriptive representation; the spatial representation denotes image components symbolically and preserves relevant spatial and topological properties; and the visual representation depicts information such as shape, relative distance, and size. Imagery-based reasoning is carried out using primitive and high-level processes that construct, transform, and inspect visual or spatial representations.

2. *Applications to AI Problem Solving*

Visual-spatial reasoning techniques have also been considered in the context of specific application domains. Funt (1980) represents and manipulates a visual analog of a world in order to predict potential instabilities and collisions in a physical domain. Others have also used diagrammatic reasoning to simulate potential solutions for problem solving.

Epstein and Gelfand (1998) use spatial representations to generate potential moves in game playing. Barwise and Etchemendy (1993) have proposed a system called Hyperproof which integrates diagrammatic reasoning with sentence-based logics. Hyperproof uses both diagrams and logic notation to teach students how to reason logically. They have also presented a formal semantics for reasoning with Hyperproof diagrams.

Research in geographical information systems and spatial databases has long been concerned with the issue of representing spatial knowledge (see *Geographic Information Systems: Critical Approaches*; *Spatial Data*). Samet (1989) has proposed a method for storing geographic knowledge based on the recursive decomposition of space. In this work, the term *quadtree* is used to describe binary array data structures that iteratively subdivide regions into segments until blocks are obtained that consist entirely of 1s or entirely of 0s. These structures (and their three-dimensional counterpart, termed octrees) are efficiently stored and implemented as trees, where each node of the tree corresponds to a region in the decomposition hierarchy. Another approach to reasoning in geographic systems has been described by Papadias and Sellis (1993). In this work, a symbolic two-dimensional array structure is used to preserve a set of spatial relations among geographic entities.

Spatial representations have also been considered in a machine vision research. According to Biederman (1987), the representation of objects can be constructed as a spatial organization of simple primitive volumes, called geons. The process of image analysis, as defined by Marr et al. (1982), depends on a series of representations culminating in a three-dimensional model of the spatial relations among entities which makes explicit what is where. As in Marr's approach to computational vision, research in molecular scene analysis (1993) is concerned with discovering what is present in the world and where it is spatially located. The act of determining the structure of a molecule is an interactive process consisting of a state space search of partially interpreted scenes, which can be represented and evaluated using processes from computational imagery.

Other problem domains where diagrammatic reasoning has been applied include qualitative physics, route planning, biology, human/computer interaction, architecture, geometry, and theorem proving.

3. *Future Research*

Research in the area of diagrammatic and imagery based reasoning is still in its infancy. Most of the work to date has focused on individual applications where visual or spatial reasoning can provide a guide to problem solving. There are still many unanswered questions and areas to pursue that would lead us to a better understanding of how reasoning with images could improve problem solving in artificial intelligence. Some of the questions we might consider are:

(a) Are there general representation and reasoning techniques that cross application boundaries? Forbus (1993) has stated the Poverty Conjecture that claims: 'there is no problem-independent, purely qualitative representation of space or shape.' Whether this claim is true or not is clearly a topic for future research.

(b) How does diagrammatic reasoning interact with other reasoning paradigms in AI? Already, researchers have been investigating how image representations and reasoning techniques may interact with approaches such as rule-based reasoning or case-based reasoning. More work needs to be carried out to

understand how such hybrid systems can best be constructed and applied.

(c) What can we learn from human cognitive models? The topic of mental imagery has long been studied in areas such as psychology, philosophy, and linguistics. Researchers in AI have much to learn from the understanding of how the human information processing system reasons with image representations.

(d) What are other potential domains of application for diagrammatic reasoning? Although several application areas have been considered, there are certainly other areas that would benefit from the ability to incorporate diagrams or images for the purpose of problem solving.

The area of diagrammatic reasoning is relatively new in AI. Prior to 1990 there were only a handful of papers related to this topic. Although interest and activity has greatly increased during the 1990s, there are still many questions to be posed and answered in this emerging area.

Computational Neuroscience

The term 'computation' in computational neuroscience refers to the way that brains processes information. Many different types of physical systems can solve computational problems, including slide rules and optical analog analyzers as well as digital computers, which are analog at the level of transistors and must settle into a stable state on each clock cycle. What these have in common is an underlying correspondence between an abstract computational description of a problem, an algorithm that can solve it, and the states of the physical system that implement it (Fig. 1). This is a broader approach to computation than one that is based purely on symbol processing (Churchland and Sejnowski 1992, Arbib 1995).

There is an important distinction between general-purpose computers, which can be programmed to solve many different types of algorithms, and special-purpose computers, which are designed to solve only a

Figure 1
Levels of analysis. Marr (1982) advocated a top-down approach, starting with the computational level and proceeding down to the implementation level. The two-way arrows indicate that constraints between levels can be used to gain insights in both directions. Research in computational neuroscience often starts at the implementation level and proceeds up to the computational level

limited range of problems. Most neural systems are specialized for particular tasks; an example is the retina, which is dedicated to visual transduction and image processing. As a consequence of the close coupling between structure and function, the anatomy and physiology of a brain area can provide important clues to the algorithms that it implements and its computational function (Fig. 1); in contrast, the hardware of a general-purpose computer may not reveal its function, which also depends on software.

Another major difference between brains and general-purpose digital computers is that computers are hardwired, but the connectivity between neurons and their properties is shaped by the environment during development and remains plastic even in adulthood. Thus, as the brain processes information, it changes its own structure in response to the information that is being processed. Adaptation and learning are important mechanisms that allow brains to respond flexibly as the world changes—on a wide range of time scales, from milliseconds to years. The flexibility of the brain has survival advantage when the environment is nonstationary, and the evolution of some cognitive skills may depend deeply on genetic processes that have extended the time scales for brain plasticity.

Brains are complex, nonlinear dynamical systems with feedback loops, and brain models provide intuition about the possible behaviors of such systems. The predictions of a model make explicit the consequences of the underlying assumptions, and comparison with experimental results can lead to new insights and discoveries. Emergent properties of neural systems, such as oscillatory behaviors, depend on both the intrinsic properties of the neurons and the pattern of connectivity between them. For example, the large-scale coherent brain rhythms that accompany different states of alertness and sleep arise from intrinsic properties of thalamic and cortical neurons that are reciprocally connected (Destexhe and Sejnowski 2001).

1. *Models at Different Levels of Detail*

1.1 *Realistic Models*

Perhaps the most successful model at the level of the neuron has been the classic Hodgkin–Huxley model of the action potential in the giant axon of the squid (Koch and Segev 1998). Data were first collected under a variety of conditions, and a model was later constructed to integrate the data into a unified framework. This type of model requires that most of the variables in the model have been measured experimentally, and only a few unknown parameters need to be fitted to the data. Detailed models can be used to distinguish between different explanations of the data. In the classic model of a neuron, information flows from the dendrites, where synaptic signals are integrated, to the soma of the neuron, where action potentials are initiated and carried to other neurons through long axons. In these models, the dendrites are passive cables, but recently, voltage-dependent sodium, calcium, and potassium channels have been observed in the dendrites of cortical neurons, which greatly increase the complexity of synaptic integration (Stuart et al. 1999). Experiments and models have shown that these active currents can carry information in a retrograde direction from the cell body back to the distal synapses tree. Thus, it is possible for spikes in the soma to affect synaptic plasticity through the mechanisms discussed in Sect. 2.

Realistic models with several thousand cortical neurons can be explored on the current generation of workstation. The first model for the orientation specificity of neurons in the visual cortex was the 'feedforward' model proposed by Hubel and Wiesel, which assumed that the orientation preference of cortical cells was determined primarily by converging inputs from thalamic relay neurons. Although there is solid experimental evidence for this model, local

cortical circuits have been shown to be important in amplifying weak signals and suppressing noise, as well as performing gain control to extend the dynamic range. These models are governed by the type of attractor dynamics that was analyzed by John Hopfield (1982), who provided a conceptual framework for the dynamics of feedback networks.

Although the spike train of cortical neurons is highly irregular, and is typically treated statistically, information may be contained in the timing of the spikes in addition to the average firing rate. This has already been established for a variety of sensory systems in invertebrates and peripheral sensory systems in mammals (Rieke et al. 1996), but whether spike timing carries information in cortical neurons is an open research issue. In addition to representing information, spike timing could also be used to control synaptic plasticity through Hebbian mechanisms for synaptic plasticity, as discussed in Sect. 2.

1.2 Signal Processing Models

Other types of models have been used to analyze experimental data in order to determine whether they are consistent with a particular computational assumption. For example, a 'vector averaging' technique has been used to compute the direction of arm motion from the responses of cortical neurons (Georgopoulos et al. 1986), and signal detection theory was used to analyze the information from cortical neurons responding to visual motion stimuli (Movshon and Newsome 1996). Bayesian methods can effectively decode the position of a rat in a maze from place cell recorded in the hippocampus (Zhang et al. 1998). In these examples, the computational model was used to explore the information in the data but was not meant to be a model for the actual cortical mechanisms. Nonetheless, these models have been highly influential and have provided new ideas for how populations of neurons may represent sensory information and motor commands.

Neural network or 'connectionist' models that simplify the intrinsic properties of neurons can be helpful in understanding the computational consequences of information contained in large populations of neurons. An example of this approach is a recent model of parietal cortex based on the response properties of cortical neurons (Pouget and Sejnowski 2001). The parietal cortex is involved in representing the spatial location of objects in the environment and computing transformations from sensory to motor coordinates. The model examined the issue of which reference frames are used in the cortex for performing these transformations. The model predicted the outcomes of experiments performed on patients with spatial neglect following lesions of the parietal cortex.

Cognitive functions such as attention have also been modeled. Francis Crick (1994) proposed that the relay cells in the thalamus may be involved in attention, and has provided an explanation for how this could be accomplished based on the anatomy of the thalamus. Models of competition between neurons in cortical circuits can explain many properties of single cortical neurons in awake, behaving monkeys during attention tasks (Reynolds et al. 1999).

Finally, small neural systems have been analyzed with dynamical systems theory (Harris-Warrick et al. 1995). This approach is feasible when the numbers of parameters and variables are small. Most models of neural systems involve a large number of variables, such as membrane potentials, firing rates, and concentrations of ions, with an even greater number of unknown parameters such as synaptic strengths, rate constants, and ionic conductances. Where the number of neurons and parameters is very large, techniques from statistical physics become applicable in predicting the average behavior of large systems (Van Vreeswijk and Sompolinsky 1998). There is a midrange of system sizes where neither type of limiting analysis is possible, but where simulations can be performed (Bower and Beeman 1998). One danger of relying solely on computer simulations is that they may be as complex and difficult to interpret as the biological system itself.

2. Learning and Memory

One of the goals of computational neuroscience is to understand how long-term memories are formed through experience and learning. There is increasing experimental evidence that the strengths of interactions between neurons can be altered by activity, called synaptic plasticity. For example, high-frequency trains of stimuli at synapses in the hippocampus induce a form of long-term potentiation (LTP) that can last for days (Bliss and Lomo 1973). Moreover, these synapses require simultaneous presynaptic activity and postsynaptic depolarization (Kelso et al. 1986), as suggested by Hebb (1949). Models of associative memory that incorporate Hebbian synaptic plasticity have been widely explored (Anderson and Hinton 1981).

Hebbian synaptic plasticity can also be used to form maps and has been used to model the early development of the projection from the thalamus to the visual cortex. In particular, these models can explain why inputs from the right and left eyes form alternating stripes in primary visual cortex of cats and monkeys, called ocular dominance columns (Miller et al. 1989). Specific mappings arise in the cortex because temporal contiguity in axonal firing is translated into spatial contiguity of synaptic contacts.

The change in the strength of synapses in the hippocampus and neocortex depends on the relative timing of spikes in the presynaptic neuron and the postsynaptic neuron. Reliable LTP occurs when the presynaptic stimulus precedes the postsynaptic spike, but there is long-term depression (LTD) when the

presynaptic stimulus immediately follows the postsynaptic spike (Markram et al. 1997, Bi and Poo 1998). This temporal asymmetry in synaptic plasticity solves the problem of balancing LTD and LTP, since chance coincidences should occur about equally with positive and negative relative time delays. When sequences of inputs are repeated in a network of neurons with recurrent excitatory connections, temporally asymmetric synaptic plasticity will learn the sequence and the pattern of activity in the network will tend to predict future inputs. There is evidence for this in the hippocampus where place cells representing nearby locations in a maze may be linked together (Blum and Abbott 1996), and in visual cortex where simulations of cortical neurons can become directionally selective when exposed to moving visual stimuli (Rao and Sejnowski 2000).

The temporally asymmetric Hebbian learning rule can be used to implement the temporal difference learning algorithm in reinforcement learning and classical conditioning (Montague and Sejnowski 1994, Sutton and Barto 1998, Rao and Sejnowski 2000). The unconditioned stimulus in a classical conditioning experiment must occur before the reward for the stimulus–reward association to occur. This is reflected in the temporal difference learning algorithm by a postsynaptic term that depends on the time derivative of the postsynaptic activity level. The goal is for the synaptic input to predict future reward: if the reward is greater than predicted the postsynaptic neuron is depolarized and the synapse strengthens, but if the reward is less than predicted, the postsynaptic neuron is hyperpolarized and the synapse decreases in strength. There is evidence that in primates the transient output from dopamine neurons in the ventral tegmental area carries information about the reward predicted from a sensory stimulus (Schultz et al. 1997), and in bees, an octopaminergic neuron has a similar role (Hammer and Menzel 1995).

The temporal window for classical conditioning is several seconds—much longer than the window for LTP/LTD observed at cortical and hippocampal synapses. A circuit of neurons in the basal ganglia and frontal cortex may be needed to extend the computation of temporal differences to these long time intervals (Berns and Sejnowski 1998). It is surprising to find the same learning algorithm in different types of learning systems in different parts of the brain. This suggests that the temporal order of input stimuli is a useful source of information about causal dependence in many different learning contexts and over a range of time scales.

3. *Future Directions*

3.1 *Molecular/Synaptic*

Almost all of the proteins that make up synapses are now known, and the sequencing of the human genome will make it possible to complete that list within the next few years. Coupled with high-voltage electron microscopy and methods for labeling these proteins, it should be possible to develop a reasonably complete model for the neuromuscular junction and central synapses in a few more years. This will allow us to understand the synapses as a molecular machine and to understand the mechanisms that are involved in synaptic plasticity (building on a large existing body of research, for which the Nobel Prize in Medicine was given to Arvid Carlsson, Paul Greengard and Eric Kandel in 2000). It is highly likely that advances in modeling and computational theory at this level will have direct impact on the pharmaceutical industry through the design of new drugs and new approaches to mental disorders.

3.2 *Neuron/Network*

Progress in this area has been slower because experimental technique for recording from many neurons simultaneously still lags behind. However, the advent of large electrode arrays and optical recording techniques will make rapid progress possible so before long we should have a reasonable understanding of neural circuits in simple creatures and some parts of the vertebrate brain. Computer models are being used to understand how the intrinsic properties of neurons and the synapses that join them produce complex spatio-temporal patterns of activity and how these networks are used to encode, store and retrieve information in large neural systems such as cortical columns. Advances at this level could lead to a new generation of pattern recognition systems and sensorimotor control systems for robotic devices.

3.3 *Map/System*

The major breakthrough that has occurred recently in human brain imaging, primarily with the development of functional magnetic resonance imaging, is allowing rapid progress to be made in localizing cognitive functions within the human brain. Magnetic resonance technology is still at an early stage of development and new approaches, such as magnetic resonance spectroscopy, should make it possible to observe biochemical reactions occurring within the brain. However, until such time as resolution of these new techniques is improved, or they can be integrated with older techniques such as electroencephalography (EEG) and magnetoencephalography (MEG), it will not be possible to uncover the mechanisms that underlie the activity that is observed with functional imaging. It may take decades before techniques mature to the point where we can begin to understand the large-scale organization of primate brains. However, even before this, significant progress will be made using invasive techniques in nonhuman primates and other mammals. Understanding of brains at this level

will provide the ultimate insights into major philosophical questions about consciousness and autonomy (Crick 1994).

3.4 Technology for Brain Modeling

Do new properties emerge as the number of neurons in a neural system becomes large? This question can be explored with large simulations of millions of neurons. Parallel computers have become available that permit massively parallel simulations, but the difficulty of programming these computers has limited their usefulness. An approach to massively parallel models introduced by Carver Mead is based on subthreshold cMOS VLSI (Very Large Scale Integrated) circuits with components that directly mimic the analog computational operations in neurons. Several large silicon chips have been built that mimic the visual processing found in retinas. Analog VLSI cochleas have also been built that can analyze sound in real time. Analog VLSI chips have been built that mimic the detailed biophysical properties of neurons, including dendritic processing and synaptic conductances (Douglas et al. 1995). These chips use analog voltages and currents to represent the signals, and are extremely efficient in their use of power compared to digital VLSI chips. A new branch of engineering called *neuromorphic engineering* has arisen to exploit this technology.

4. Conclusions

Although brain models are now routinely used as tools for interpreting data and generating hypotheses, we are still a long way from coming up with explanatory theories of brain function. For example, despite the relatively stereotyped anatomical structure of the cerebellum, we still do not understand its computational functions. Recent evidence from functional imaging of the cerebellum suggests that the cerebellum is involved in higher cognitive functions and is not just a motor controller. Modeling studies may help in exploring these competing hypotheses. This has already occurred in the oculomotor system, which has a long tradition of using control theory models to guide experimental studies.

Digital computers have been increasing in power exponentially from around 1950 when the first machines, built from vacuum tubes and mercury delay lines, were introduced. The number of operations per second roughly doubles every three years. This vast increase in computer power, or, conversely, decrease in the cost of computing and data storage, has had a major impact on the study of the brain and on the development of brain models and theories. For example, functional magnetic resonance imaging, which has made it possible to study human brain activity non-invasively, would not have been feasible without fast digital computers that direct the pulse sequences, data acquisition and data analysis. The increasing power of computers is transforming our ability to analyze complex neural systems at many levels of investigation and will have far-reaching consequences on society.

It is very important to note that, at this stage in our understanding of the brain, a model should only be considered a provisional framework for organizing thinking. Many partial models need to be explored at many different levels of investigation, each model focusing on a different scientific question. As computers become faster, and as software tools become more flexible, computational models should proliferate. Close collaborations between modelers and experimentalists, facilitated by the internet, should lead to an increasingly better understanding of the brain as a computational system.

Computational Psycholinguistics

Psycholinguistics is the scientific discipline that studies how people acquire a language and how they comprehend and produce this language. The increasing complexity of the models of human language processing which have been evolved in this discipline makes the development and evaluation of computer implemented versions of these models more and more important to understand these models and to derive predictions from them. Computational psycholinguistics is the branch of psycholinguistics that develops and uses computational models of language processing to evaluate existing models with respect to consistency and adequacy as well as to generate new hypotheses.

1. Cognitive Modeling and Computational Psycholinguistics

Not every computer model mimicking linguistic behavior can be declared as being psychologically relevant. For example, the ELIZA question-answering system (Weizenbaum 1966) is able to imitate the role of a therapist very well, although the system's behavior is based solely on simple pattern matching mechanisms that do not say anything about the linguistic and nonlinguistic processes underlying a dialogue. In order to be a psycholinguistically relevant computer model, the model must simulate a specific human cognitive function. As a prerequisite for the construction of such a model, formal analyses of the linguistic domain and empirical studies are required to determine the complexity of that domain and of the parameter values of the respective cognitive function to be modeled.

This research methodology corresponds to the typical methodology in cognitive modeling (see *Cognitive Modeling: Research Logic in Cognitive Science*). In fact, there is only one difference between cognitive modeling and computational psycholinguistics: While cognitive modeling deals with all aspects of human cognition, computational psycholinguistics is confined to architectures and mechanisms for human language processing.

1.1 Computer Models in Psycholinguistics

In essence, psycholinguistics addresses the questions of how speakers put pre-linguistic concepts into words, and then combine these words to larger units in order to produce the oral or written output, and how a listener parses the auditory or visual input into meaningful units and arrives at an understanding of the input.

Although psycholinguistics as part of the interdisciplinary field of the cognitive sciences shares the view that cognition should essentially be regarded as computation, the research methodology in psycholinguistics is primarily oriented at experimental studies with the computer as a tool for the selection and presentation of appropriate stimulus material, and the exact measurements of reaction times, etc. Computer modeling itself does not play a major role in model development. Surveys of psycholinguistic research

(e.g., Gernsbacher 1994) dedicate only a minor part to computer modeling in psycholinguistic research, and the use of computer models to evaluate models of (sub)tasks of language comprehension or production. This means that, compared with approximately 100 years of psycholinguistic research and 25 years of institutionalized cognitive science, computational psycholinguistics can be glossed as a brand new area of psycholinguistic research. Computer modeling turns out to be advantageous in model development for at least two reasons.

First, specifying a model only verbally makes it more difficult to check its completeness and overall consistency, if the model is appropriately complex. If such a model has been realized as a computer program and produces the desired input-output effect, it is not just a specification of relations in the model domain, but also a fully specified and consistent theory of the investigated cognitive function.

Second, the implemented model may be used to generate hypotheses: the compulsion of being explicit in every detail while developing the computer model may result in predictions under conditions which have empirically not been investigated before. These predictions can then be tested by new experiments that will either support or not support the predictions made by the program.

1.2 Techniques for Modeling Human Language Processing

In general, a reconstruction of an empirical fact by a model can be done in each of two ways: a narrow one or a process-oriented one. The former means that the computer model realizes an input–output relation that is identical to that of human beings. However, whether the processes underlying this mapping from informational inputs to the desired outputs correspond to the processes of humans or not is irrelevant. The latter means that the computer system does not only realize a correct input-output relation, but it also accounts for the internal representations and operations which will be used and performed accordingly, within the human mind. Artificial Intelligence typically develops models of the first class (see *Artificial Intelligence: Connectionist and Symbolic Approaches*), while computational psycholinguistics strives for models of the second class. Evaluation criteria for the resulting computer models are the same as for every model: their descriptive and explanatory adequacy, simplicity, generality, and falsifiability. An important additional criterion is the possibility to match empirical results to the system's behavior. Computer models of the same task can also be evaluated in a model-to-model comparison.

Techniques used in computational psycholinguistics range from all kinds of symbolic processing mechanisms like graph unification, planning, or deductive reasoning to connectionist approaches. The advantage of symbolic mechanisms is the achievement of a high level of abstraction that makes it easier to check the adequacy of the system's behavior. One disadvantage of symbolic systems is the possible rigidity so that exceptions to the rule require additional treatments. This robustness problem is problematic for several aspects of human language processing, because often decisions for the production or recognition of a specific linguistic form or structure turn out to be highly context-dependent (e.g., the modeling of typical speech errors).

Connectionist approaches, especially activation spreading, are also quite popular in computational psycholinguistics. The connectionist paradigm bypasses the robustness problem and it accounts for learnability. Its disadvantage is the lack of modeling of rule-based structural relationships that is assumed to be an essential characteristic of many tasks in human language processing.

2. Stages in Human Language Processing

Although the various proposed architectures of the human language processing systems and the respective mechanisms differ considerably in detail, there is not much disagreement on the basic stages involved in transforming concepts into a linguistic utterance and *vice versa*.

2.1 Stages in Language Production

Most psychological models of language production agree on the division of the production process into three major stages that are called, following (Levelt 1989), conceptualization, formulation, and articulation. Differentiation with respect to the subcomponents, interrelations, and functions of these components takes very different directions.

Conceptualization for language production comprises the selection, preparation, and linearization of pre-linguistic information. These processes lead to a conceptual representation which functions as input to a formulator.

Formulation involves the conversion of the output from the conceptual level into linguistic structures. It includes the selection of appropriate lexical items, and the retrieval of syntactic structures and phonetic information. It is widely accepted that the selection of lexical items consists of a two-step process. The first step involves the selection of lemmas, i.e., semantically appropriate items together with syntactic features. The second selection process concerns lexeme retrieval where phonological information becomes available. The relationship between both retrieval processes is still controversial, which finds its expression in the different architectural bases and the directionality of activation flow in the corresponding computer models of this task. The result of the formulation process

is an articulatory plan. Finally, articulation can be described as the realization of that phonetic plan and its execution at the motoric level.

One fundamental difference between the various production models relates to how the flow of information between the various processing stages is designed. Sequential models assume a unidirectional flow from the conceptualizer to the formulator, and from the formulator to the articulator. The enormous rate of human speech production is explained in these models by incremental processing, i.e., the processing of information in a piecemeal way: All modules work in parallel, but not on the same piece of information. Increments will be handed down to subsequent modules although the whole informational unit has not been completed yet.

In contrast to sequential models, interactive models allow direct feedback from subordinate to superordinate modules. Sequential models have the advantage of being easier to check empirically and simulate via computer programs. However, they have a completeness problem concerning the relationship between language and conceptualization. Sequential models must assume intermediate representations that reflect the previous decisions and the momentary knowledge. For example, all relevant conceptual decisions must have been concluded at the point where a conceptual fragment is handed down to the formulator. Nothing can be left unspecified which is relevant for selection processes in the formulator since the formulator itself does not provide criteria for decisions relating to content.

Both types of information flow are often directly related to the symbolic and connectionist processing paradigm, although there is no cogent link between a specific type of information flow and propositional or connectionist models.

2.2 *Stages in Language Comprehension*

From a logical point of view, the basic stages in comprehending a linguistic utterance must be the same as in language production, although there is overwhelming evidence that production is not simply the reverse of comprehension. The visual (in the case of reading) or auditory (in the case of listening) input must be perceived, the single words must be recognized, and the syntactic structure of the respective utterance units must be determined. Based on this structure the meaning of the utterances will be determined. During the discourse comprehension the meaning will be embedded into the overall discourse situation. The same issues as in production models arise in models of language comprehension with respect to information flow and feedback. Disagreements exist about the architecture of the human language comprehension system, as well as about the underlying specific processes.

However, one characteristic feature that models of language comprehension should support is incrementality. There are many studies showing that as soon as a word has been recognized, it is immediately attached to the preceding information (Crocker et al. 2000). Perhaps the most convincing argument for incremental processing in sentence comprehension comes from the so-called garden-path effect. People starting to read a sentence like 'The horse raced past the barn fell' (Bever 1970) interpret the initial sequence (The horse) (raced) (past the barn) as 'subject,' 'predicate,' and 'direction.' Only after the last word has been recognized do they have a feeling of being stranded (in other words they are 'led up the garden path'), because the syntactic analysis made so far has turned out to be false. In actuality, the sentence must be interpreted as 'the horse that was raced past the barn fell.'

3. *Computer Models of Human Language Processing*

Although most computer models in production and comprehension simulate processes around the level of lexical items (cf. Norris 1999), there are also several models at the sentence level. Computer models of the mechanisms in sentence comprehension simulate how people obtain a particular syntactic and semantic analysis for a sentence (e.g., Crocker 1996, Crocker et al. 2000). Computer models of sentence production simulate how people construct, depending on retrieved lexical information, the syntactic structure of a sentence while simulating typical speech errors that occur on the sentence level (cf. de Smedt and Kempen 1987). Computer models that go beyond the sentence level to the production or comprehension of discourse turn out to be much harder to develop, since it is very difficult to determine all discourse-related parameters in experimental studies. From a broader perspective, the phenomena to be considered on the discourse level are all related to the notion of inference; they range from the interpretation of referring expressions to listener modeling.

The computer models that are presented in this section are models of various stages in language processing. The list is far from being exhaustive: It does not include all computer-implemented models that have been developed for one processing task, nor do the models completely cover all tasks in human language processing. The models presented should give an impression of the advantages of computer modeling in psycholinguistic research.

Differences in the architectural basis and the techniques used depend on the theoretical background and the system's task. Each of the computer models presented below will be characterized along the following dimensions: first, the task in human language processing, which the model simulates, will

be outlined. The architectural basis for the processing mechanisms will be characterized and the technique used for the simulation will be presented. Finally, relations between the system's behavior and empirical data will be outlined.

3.1 Computer Models of Language Production

Since models of human conceptualization are in the early stages of development, elaborated computer models of conceptualization are currently not on the market. Issues related to the topic of how people organize their pre-linguistic knowledge in order to put it into language have been addressed primarily in Artificial Intelligence research, especially in Natural Language Generation, but the models developed in these disciplines are not intended to simulate human processing. Conceptualization is still very under-developed in computational psycholinguistics.

Computer modeling starts at the interface between conceptualization and formulation, viz. the retrieval of lemmas from the lexicon, given pre-linguistic information that needs to be expressed. Models of lemma retrieval come in two forms, symbolic and connectionist approaches, but only two connectionist models shall be characterized that are based on spreading activation networks, because they show the merits of computational modeling in psycholinguistics very well.

The decompositional model of (Dell and O'Seaghdha 1992) aims at the selection of appropriate lemmas so that the relevant conceptual features can be linguistically expressed. The system's architecture is non-modular and interactive. Hence, direct feedback is possible. The system uses a network consisting *prima facie* of nodes for conceptual features and nodes for the lemmas. Bidirectionality of the links between these two layers allows this model also to be used for language comprehension. After activating the conceptual features, activation spreads towards the lemma nodes and back. Depending on the chosen parameter values for the spreading formula, the model makes several empirical predictions with respect to the activation of semantically related lemmas and the speed of activation. However, the model also incorrectly retrieves hyponyms because all features that activate a word will also activate the word's hyponyms. Hyponyms are the semantically subordinated lemmas of a given lemma. For example, if the conceptual features activate the word 'pet,' they will also activate the words 'dog,' 'cat,' etc. These hyponyms can receive a higher activation value than the target word 'pet.'

The nondecompositional model of (Roelofs 1992) also aims at the selection of lemmas, but in contrast to the previous model, concepts are represented as one node, not as conceptual features, i.e., the model assumes that concepts cannot be decomposed into conceptual primitives. In this model, activation spreads towards the lemma nodes. The lemma will be selected which receives an activation level exceeding that of other nodes by some critical amount. The model correctly describes the activation of lemmas given some activation of concepts, and it does not suffer from the hyponym problem. Furthermore, the model makes some predictions on activation speed, which have been tested empirically and turn out to be correct.

Since an evaluation of both models along all dimensions is almost impossible, only the hyponym problem is discussed further. The missing hyponym problem of the non-decompositional activation model, together with the resulting correct empirical predictions, are strong arguments for the assumption that concepts do not consist of conceptual primitives. Whether mental representations of conceptualized objects, events, times, etc. are built up from conceptual primitives or not, is a topic that has been intensively discussed for a long time in linguistics and the philosophy of mind. Since the successful implementation of a cognitive function is the proof of the theory's consistency, the results argue against conceptual decomposition.

Two systems simulating the next step in language production, namely the construction of syntactic structures of the sentences to be expressed, are now presented.

The incremental parallel formulator (IPF) (de Smedt 1990) simulates how syntactic structures are constructed in a piecemeal way, if conceptual increments are given as input at specific time points. These increments are mapped onto single words or thematic roles. The system is based on a modular architecture and uses graph unification as operation. Graph unification is the standard operation in computational grammar formalisms. It allows the combination of two informational units to a third one if the information is not contradictory. The IPF formulator simulates parallelism in formulation. By means of the time-point and accessibility of incoming conceptual fragments the system also explains specific word order variations.

The flexible incremental generator (FIG) (Ward 1992) is a connectionist model with an interactive architecture. The task of incremental sentence construction is realized on the basis of an associative network. The input for the formulation process is conceptual information that is provided with an activation value. Contrary to the previous model, this input will not be offered incrementally but as a whole. However, the sentence production process is incremental because sentences are uttered word by word. Activation spreading through the network results in the activation of words; those words with the highest activation will be uttered. The model accounts for speech errors, because non-intended concepts might receive an activation.

Although the architectural basis and processing strategies of the models are completely different, they show that incremental processing is psychologically plausible. In the first model the time span between incoming fragments corresponds directly to incrementality effects. The second model describes the incremental selection of words. However, no predictions can be derived directly from either model. They differ in their assumption about where incremental processing is involved, namely on the level of conceptualization and formulation or during formulation only. With respect to the processing mechanisms that are used, both models are equally simple, because each system uses only one operation.

It has been claimed that connectionist approaches are more robust than symbolic ones. However, for incrementality effects during sentence construction, this statement is too general. The IPF model shows that a symbolic processing strategy does not necessarily impose constraints on the data to be explained.

3.2 Computer Models of Language Comprehension

Since comprehension begins with the recognition of words, this section deals first with models of spoken word recognition. In spoken word recognition, the models proposed must answer two main questions. First, they must describe how the sensory input is mapped onto the lexicon, and second, what the processing units are in this process.

The TRACE model (McClelland and Elman 1986) is an interactive model that simulates how a word will be identified from a continuous speech signal. The problem with this task is that continuity of the signal does not provide clear hints about where a word begins and where it ends. By means of activation spreading through a network that consists of three layers (features, phonemes, and words), the system generates competitor forms, converging to the ultimately selected word. Competition is realized by inhibitory links between candidates.

The SHORTLIST model (Norris 1994) is based on a modular architecture with two distinct processing stages. It uses spreading activation as well, but in a strictly bottom-up way. Contrary to TRACE, it generates a restricted set of lexical candidates during the first stage. During the second stage, the best fitting words are linked via an activation network.

Both models account for experimental data on the time course of word recognition. Assumptions on the direction of activation flow and its nature lead to several differing predictions, but the main different prediction concerns lexical activation. While TRACE assumes that a very large number of items are activated, SHORTLIST assumes that a much smaller set of candidates is available so that the recognition of words beginning at different time points is explained differently.

The last model is a model of sentence processing. In sentence processing, one of the fundamental questions is why certain sentences receive a preferred syntactic structure and semantic interpretation.

The SAUSAGE MACHINE (Fodor and Frazier 1980) is a parsing model that assumes two stages in parsing with both stages having a limited working capacity. The original idea behind the model is to explain preferences in syntactic processing solely on the architectural basis by means of the limitations in the working memories.

The SAUSAGE MACHINE is a quasi-deterministic model, because one syntactic structure for each sentence is generated. Only if the analysis turns out to be wrong, is a reanalysis performed. Since reanalyzing a sentence is a time consuming process, the system tries to avoid this whenever possible. The model accounts for garden path effects and the difficulty in understanding multiple center embedded sentences (like 'the house the man sold burnt down'). Furthermore, the model explains interpretation preferences by means of the limitation in working memories. However, it is now understood that the architecture of a system cannot be the only factor that is responsible for processing preferences, but additional parsing principles must be assumed (Wanner 1980). Newer computational models of sentence processing show that an explanation of several phenomena in sentence processing requires the early check of partial syntactic structures with lexical and semantic knowledge (Hemforth 1993).

4. Conclusion

The outline of different computational models of human language processing shows that psycholinguistics benefits in several respects from the use of simulation models. The influence of several factors in language processing such as the directionality of activation or information flow, the link between prelinguistic and linguistic knowledge, layers of information in specific processing tasks, limitations in working memory, and many others, have been tested successfully by simulation models.

The dominant use of activation spreading as a processing mechanism for stages in language processing below the sentence level is probably due to the derivation of computational models from psycholinguistic models, which have been developed on the basis of statistical methods. Using symbolic operations is primarily inspired by linguistic investigations. Models of human language processing that originate from linguistic research do not explain the time course of the underlying mechanisms or statistically significant effects, but do explain the linguistic competence underlying the skill of speaking and comprehending. Hence, computer models aiming at various effects in sentence processing predominantly use symbolic operations to explain this competence.

This situation suggests that one future direction in computational psycholinguistics could be the development of models combining symbolic with connectionist methods to describe the interplay of various tasks in language production or comprehension.

An excellent introduction to various computer models of subtasks in human language processing is given by the contributions in Dijkstra and de Smedt (1996).

Computer Networking for Education

Computer networks such as the Internet and the World Wide Web (WWW) have an increasingly high impact in schools as well as in higher and further education. Teachers and researchers try to analyze both the current potential and future developments (e.g., Roschelle and Pea 1999) in computer networking in education. In this article we consider aspects of computer networking for education at the individual level, the group level, the level of the organization, and the societal level in turn. We report on important basic scenarios and developments as well as on approaches to improving learning and education.

1. Computer Networking and the Individual

1.1 Basic Scenarios

With the advent of the WWW, the learning individual has moved back into the focus of attention, especially in the context of teaching remote learners and using the WWW as a teaching resource.

1.1.1 Teaching remote learners. The internet is seen as an ideal medium for delivery and communication between teacher and learner. In this context teleteaching becomes increasingly more important. In teleteaching, a lecture is typically held in a university lecture-room and is synchronously transmitted through two-way interactive video to university students at another university. Another approach to teaching distant learners is that of online course delivery. In the tradition of distance learning, learners receive course material as computer files or on web pages. By e-mail or by videoconferencing they can ask their teachers for assistance.

1.1.2 Using the Internet as resource. The second major application of computer networks for individual learning is the use of existing Internet-based

material as resources to prepare and to elaborate on instruction. Students search the Internet in the sense of 'knowledge mining' (Roschelle and Pea 1999), trying to explore the knowledge of a certain expert community by analyzing web sites or newsgroup discussions. Teachers are using the Internet as resource as well. A large number of publications in education-related journals describe web-based teaching resources for use during classroom lectures. In many cases, annotated listings of useful Internet and web addresses are included.

1.2 Approaches to Further Improve Individual Learning

1.2.1 Reduce complexity by indexing. Free exploration of Internet resources proves to be overwhelming for many learners with little prior knowledge. Using the indexing strategy of web-based instruction, available topic-related web sites are selected, indexed, and evaluated by teachers or experts both for lecture preparation and follow-up, as well as for enriching classroom lectures.

1.2.2 Keep complexity, provide support. This approach highlights the importance of authentic and complex learning scenarios for the acquisition and transfer of knowledge. Instead of reducing the complexity of Internet-based resources, this approach emphasizes supporting learners to work effectively with these authentic materials. For instance, expert modeling of strategies, mapping techniques or strategy guidance have proved to be effective instructional tools in complex learning environments (see Mandl et al. 1999). Analysis and training of cognitive strategies for searching the web, and knowledge management strategies, are other variants of this approach (e.g., Hill and Hannafin 1997). In teletutoring or telecoaching approaches, the promotion of knowledge transfer to the workplace is the primary goal. Learners are at their workplaces and receive assistance via network technologies. This assistance is typically provided by a coach, who supports the learner in applying knowledge to new problems.

2. Computer Networking and the Group

2.1 Basic Scenarios

2.1.1 Technology-based learning within the classroom. A series of approaches focus on the new and enriching possibilities of network technologies for learning within traditional educational settings. Learners in a class are engaged in processes of collaborative knowledge construction and are supported by network technologies which are more or less specifically designed for group learning purposes. One central assumption is that in text-based communication in particular, social inequalities known from traditional settings can be partially resolved (e.g., Riel 1995). Variants of these approaches are 'classroom-meets-expert-community' projects. Students contact experts in the field via videoconferencing, by e-mail, or via newsgroups. It is an important goal of these projects to provide learners with acces to an appropriate expert community (e.g., Gomez et al. 1998).

2.1.2 Virtual learning environments. A further important use of computer networks is in connecting distant learners to form a virtual classroom, a virtual seminar, or a virtual tutorial (e.g., Harasim et al. 1995). In a large number of projects, the improved flexibility of learning with respect to both location and time is seen as the particular added value of computer networking in education. People can learn together who would hardly be able to do so in traditional instructional settings because of distance, disabilities, or incompatible time schedules.

2.1.3 Internet-based cultural encounters. In Internet-based encounters, socially or geographically distant groups or cultures are brought together on a classroom or seminar level by means of Internet facilities. In e-mail exchanges, learners should become aware of cultural diversity, are encouraged to reduce stereotypes, and to practice languages (Fabos and Young 1999). Moreover, electronic 'field trips' are arranged to explore a distant part of the world in order to enhance classroom lectures in different subject matter. Typically, an expedition team publishes its latest photos and reports on a journey on web pages and communicates by e-mail with several dozen classes all over the world.

2.2 Approaches to Further Improve Cooperative Learning

2.2.1 The moderation approach. In virtual cooperative learning environments, the role of the teacher or tutor will become more and more that of a facilitator or moderator, structuring group discussion according to certain theoretical principles.

2.2.2 The cooperative learning tools approach. This approach argues that today's networking tools are not genuinely designed for learning purposes (Roschelle and Pea 1999). There are efforts to develop, adapt, and apply networked collaborative learning tools to facilitate learning in groups. Shared active representation tools are designed to support learners and teachers in discussing complex subject matter by advancing domain-specific external representations, including text or graphic representations or mathe-

matical notations. Community-building tools are those which define social places and virtual worlds for new forms of cooperation (Roschelle and Pea 1999). Examples are MUDs (multiuser domains) as well as more complex environments using and combining technologies such as videoconferencing (Fischer and Mandl, in press), chat, or computer conferencing (Schwan 1997). Sociocognitive structuring tools organize learning activities according to successful patterns of tutorial dialogs or peer discussions. These tools prestructure or limit the kinds of possible contributions to a discussion and help to connect the messages in a meaningful way (Linn et al. 1999).

3. Computer Networking and Organizations

3.1 Learning Organizations

Schools, universities, and other places of learning are becoming 'learning organizations' themselves (e.g., Cavaleri and Fearon 1996). Learning organizations develop mechanisms helping them to adapt effectively to new situations and to use available resources more effectively to advance their members' development. It has been argued that such organizations will have crucial advantages in the competition among educational organizations. Computer networks (e.g., Intranets) may play an important role in these changes by supporting the sharing of resources, as well as by facilitating access to them. They enable new forms of communication and cooperation among learners and among educators as well as between learners and educators. Teachers and learners will have access to scientific resources and may contact other teachers as well as experts in the field. However, while implementing computer networks is an important step in establishing a culture of learning in an organization, it is not the decisive step. Students and teachers must be both enabled and motivated to contribute to shared resources of an organization.

3.2 Approaches to Further Improve Computer Networking in Organizations

An important way to advance a new culture of learning in educational organizations is represented by the 'learning communities' approach. In a learning community the major focus is on fostering collective knowledge and in that way supporting the growth of individual knowledge (Bielaczyc and Collins 1999). A learning community seeks out knowledge from multiple sources and shares its findings widely among the members. An excellent example of implementing a learning communities approach based on computer networks within a school context is the 'knowledge building communities' approach within the Computer Supported Intentional Learning Environments (Scardamalia and Bereiter 1994).

4. Computer Networking and Society

4.1 Globalization

Globalization has its impact on education as well. The possibilities of offering educational services and courses worldwide via computer networks are used more, and more particularly by large institutions. Increasing competition in the field of education might ensure that theoretical and practical innovations result in a positive modification of contents and methods of education. In recent work, however, both the clear dominance of Western culture and the issue of cultural specificity of education receive critical attention (Fabos and Young 1999).

An increasing reallocation of educational resources into network-based learning environments is frequently regarded as causing the emergence of a new 'two-class' society. People who do not have the basic knowledge necessary to use the new technologies have increasing difficulty in accessing relevant educational content. Fundamental prerequisites for the prevention of this development are missing at present; for instance, schools lack sufficient computers and network technologies.

4.2 Approaches to Improve Education

Providing educational institutions with an adequate supply of computer and networking technologies is often regarded as the basic condition for equal access to education. However, *media literacy* does not result from simply supplying the technologies. One can expect that all who take part in the processes of education—learners, teachers, researchers, parents—increasingly need media literacy to negotiate computer networks: knowledge and skills, which enable them to communicate, to learn and to become informed via such networks. Moreover, important capabilities of teachers and parents include being able to assess and reduce possible threats posed, for instance, by pornography and violence on the Internet.

Increasingly, technologies are seen as more or less flexibly developing tools which may advance societal visions and goals. For example, a number of American projects in the context of computer networking for education have aimed at nationwide educational reform goals such as equity or diversity (e.g. Garner and Gillingham 1996).

5. Outlook

A predominant trend in research on computer networking for education is to develop complex learning environments employing different tasks, as well as media mixes with multimedia, synchronous and asynchronous text-based communication or videoconferencing. With testbed designs or design experiments

(Gomez et al. 1998), researchers try to design and evaluate those prototypical scenarios based on instructional theories and tools as well as on constraints of the content to be learned, learners' needs, and organizational limitations. We believe that this important evaluative and design-related research should be accompanied by more controlled experimental studies analyzing specific interactive and cognitive effects resulting from specific types of cooperative learning tasks supported by specific technologies.

Computer-assisted Instruction

1. Towards a Broader Conceptualization of Computer Use in Education

Since the introduction of computer use in education in the 1960s, its terminology has continuously evolved. Some contributors to the new field adopted the term Computer Assisted Instruction (CAI) for a specific approach, either focusing on a type of program or a type of instructional process. Steinberg (1991), for example, emphasized CAI as computer-presented instruction that is individualized, interactive, and guided. Related terms are also used, such as computer-based instruction, computer-based education, and computer-assisted learning. Often, these terms refer to broader conceptualization, of different kinds of computer use in education. Watson (1994), for instance, used the term computer-assisted learning for the whole variety of ways in which the computer is used for learning.

The rather confusing terminology is partly due to rapid technological changes. At the time when computers were introduced in education, big mainframe computers were still in use. Computers were conceived as being able to realize programmed instruction and to replace teachers. By the twenty-first century, computers have become personal and networked. The potential for education has particularly increased due to the integration of computers with communication systems including audio and video technology. The term computer technology is now replaced by information technology (IT) in North America, or by information and communication technology (ICT) in Europe. The latter term—ICT—will be used throughout this contribution.

2. Views on the Use of ICT in Education

It is generally accepted that the increasing impact of ICT on our society is also influencing teaching and learning. Some expect that ICT can reduce several problems in present day education, such as the need for individualized instruction and the poor transfer of school knowledge to real life (Sandholtz et al. 1997). Also, new demands from society require education to focus on information management and communication skills. ICT can be a valuable essential tool in learning these skills. Further, in constructivist

approaches to teaching and learning, students are held responsible for their own learning. Information technology is considered to offer promising environments and tools to support this process.

The high aspiration level of ICT in education is well reflected in Dede's (2000) list of ICT capabilities for enhancing learning: centering the curriculum around authentic problems parallel to those in real world settings; involving students in virtual communities of practice, using advanced tools similar to those in today's high-tech workplaces; facilitating guided, reflective inquiry through extended projects that inculcate sophisticated concepts and skills and generate complex products; utilizing modeling and visualization as powerful means of bridging between experience and abstraction; enhancing students' collaborative construction of meaning via different perspectives on shared experiences; including pupils as partners in developing learning experiences and generating knowledge; and fostering success for all students through special measures to aid the disabled and the disenfranchised.

Itzkan (1994) made an effort to interpret developments in ICT in terms of educational innovations. He postulated that the potential of technology directs the way education will develop. In his view, three stages can be distinguished. The 'substitution' stage marks the ICT applications that are able to automate parts of the instructional process. In this stage, ICT is solely being used as a replacement for tasks of the teacher, with the specific aim to make education more effective, or to provide more possibilities for individualizing education. In the stage of 'transition,' ICT is not only used for replacing existing tasks, but it also requires that instructional practices and content are changed. In this stage, ICT applications not only structure the learning process, but students themselves need to increasingly structure their own learning process. In the 'transformation' stage, not only must instructional practices and content be altered, but also the underlying rationale of education should change. An example of the latter is the development in network technology that may result in virtual learning communities where students, teachers, and scientists are involved. Such a situation affords greater opportunities for learning to take place in interaction with practicing professionals than might otherwise be possible with a few field trips per year.

3. *Applications of ICT in Education*

Early software packages for education were mainly text based and used only simple graphics. In the twenty-first century software is much more sophisticated. Different combinations of modalities—pictures, moving images, sound and text—are integrated into electronic environments. An important development is the increasing possibility to distribute ICT applications not only via stand-alone computers, but also in a networked environment or via the World Wide Web (WWW). The teachers involved are able to guide their students from remote locations, creating new possibilities for distance education.

The following types of applications are designed for education.

3.1 *Drill and Practice, Tutorials*

Software programs in this category serve as an assistant for teachers by taking over some of their tasks. The software often has facilities to provide feedback to the learners and to keep track of their performance. With these applications it is possible to individualize instruction. Drill and practice software is used to automate practicing basic knowledge and skills. Tutorials can be used for learning new educational content. The programs differ greatly in their complexity. However, drill and practice programs are usually quite simple, while tutorials can be very complex (Watson 1994).

3.2 *Simulations and Modeling Systems*

Simulations are representations of a part of reality. By manipulating variables in these representations and studying the effects, students can gain an understanding of the reality. Through simulations it may be possible to study parts of reality which cannot otherwise be studied for reasons of safety, cost, required apparatus, or scale. Simulations can be an aid in visualizing abstract concepts. They serve as a bridge between reality and the student's mental model of reality. Simulations in the twenty-first century are not developed for education only, but also many have been made for entertainment purposes, used at homes outside the school context. With modeling systems students can build their own (mathematical) model of a part of reality. In doing so they may gain understanding of complex relations. Modeling systems generally do not have built-in teacher control, while simulations offer a certain kind of teacher control through the model, the display, and the framework of interactions (Cox 1994).

3.3 *Multimedia Cases*

Multimedia cases offer the possibility to study parts of reality by presenting illustrations of real world practice that can be discussed and studied from several perspectives. Multimedia cases usually combine video segments, audio, and textual commentary together with random access facilities and hyperlinks, and so create an open-ended student-centered learning environment. Though used in many fields of study, they are

increasingly used in teacher education for studying the complexity of the classroom from various points of view.

3.4 Microcomputer-based Laboratories

These provide an environment for science education. The computer is used as a support tool for students' laboratory work. Real-time data collection is possible. It becomes much easier to repeat experiments, to measure different variables at the same time, to use a very short or a very long time range, to analyze data, and to represent data graphically. Instead of spending instructional time on data collection, it can be used for analyzing and interpreting data (Voogt 1996).

In addition to applications that are specifically designed for education, many generic software tools are available that can be used to support the learning process. Lacking a particular instructional content renders such tools multi-functional. They are increasingly applied as a substantial part of the students' learning environment, going beyond the function of paper and pencil or a calculator.

3.5 Word Processor, Spreadsheets, Presentation Software, Graphics Software

The software programs in this category are part of the basic application software of nearly every PC. Their use in education is growing fast (Becker et al. 1999). They support students in their learning process, because of their capability to structure information, and to easily present information in different modes. Research related to the use of word processors in education in particular shows the potential of this tool to stimulate students to write and to support the writing process.

3.6 E-mail, Videoconferencing, Discussion Boards

This software represents the increasing role of ICT in communication. They have shown to be particularly useful in the design of computer-supported collaborative learning environments (Koschmann 1996).

3.7 Digital Encyclopedias and Databases

This category of multimedia is used as a local information resource, to be compared with the function of the traditional school library. Closely related to these applications is the WWW as a source of information. The multimedia in this category anticipates the major role information has in our present day society. The potential scope of available information requires that students possess excellent information management skills.

4. Current Patterns in ICT Use

A worldwide survey on computers in education (Pelgrum and Anderson 1999) shows a rapid decline between 1995 and 1998 in student–computer ratios in all levels of education. Despite this fact, the actual use of computers in schools is still rather limited. Recent figures from the USA (Becker et al. 1999) show that only about one third of the teachers use computers on a regular basis, although the majority has a computer in their classroom. Remarkable is that software programs used most by teachers are not the programs that are specifically designed for education. From a worldwide perspective, it is known that in all levels of education, word processing is the most popular ICT application used in schools. Only in elementary education is drill and practice software still frequently used. The use of more sophisticated software, such as simulations or microcomputer-based laboratories, are only used in very small numbers of schools in many countries. Becker (2000) found that these kinds of applications are more likely to be used by those few teachers that hold a constructivist teaching approach. However, also among this group of teachers, generic software tools are still used considerably more than applications specifically designed for education.

5. Implementation of ICT: The Central Role of the Teacher

There are several obstacles that hinder the integration of ICT in education. An important limitation of many educational software programs is that they are poorly attuned to the curriculum or they only cover minor parts of the curriculum (Van den Akker et al. 1992). This makes it less attractive for teachers to invest their efforts (and budgets) in applying new media in their instruction. The international study of Pelgrum and Anderson (1999) shows the difficulties of integrating computers into classroom practices. Not only are many educational software programs quite isolated, but it also appears that teachers lack the competence of integrating computers in their instructional processes. Compared to the early 1990s, at the start of the twenty-first century many teachers have received training in basic ICT skills and knowledge. However, very few have been fortunate to receive continuous education that centered on the pedagogical use of ICT in instruction. Olson (2000) argues that the use of ICT in schools often does not fit into the existing teaching culture and that it may even undermine the teacher's sense of efficacy. The use of ICT often assumes a change in pedagogical approaches and classroom management strategies, implying that teachers have to change their routines (Sandholtz et al. 1997). One possible way to support such teacher learning is with carefully designed and validated curriculum materials that contain procedural specifications in order to guide teachers on essential, but vulnerable, aspects of ICT

integration (Voogt 1993). The impact of this kind of curriculum materials on teacher learning benefits from use and sharing in teacher networks that focus on the integration of ICT in education (Moonen and Voogt 1998).

6. Attainments for Students

It is widely assumed that ICT has high potential for improving education. However, research has not yet provided convincing evidence regarding the impact of ICT on student performance. Until now, most research has been restricted to simple drill and practice kinds of programs. In a meta-analysis Niemiec and Walberg (1987) found a moderate effect of CAI on enhancing student outcomes. Other findings focus on other possible student gains, such as an increase in the rate of learning, better retention, and a more positive attitude towards learning.

An important problem in establishing the cognitive attainments for students is that the use of ICT often aims to contribute to the mastery of complex cognitive skills. These types of skills cannot be determined by means of simple, standardized tests. The complexity of the problem is illustrated in the *Computer as a Learning Partner* project (Linn and Hsi 2000). Students involved in that project did not score better on multiple choice items in standardized tests that required recall, but they outperformed students on items that required interpretation. Yet, the outcomes of the project had much more impact on student learning than could be determined in standardized tests. The project could demonstrate that comparing subsequent versions of an ICT-rich curriculum for science education resulted in a 400 percent increase—over eight versions of the curriculum—in student understanding of the complex science concepts that were dealt with in the curriculum.

7. Research on ICT in Education

Much research has guided the development of new ICT tools for education. These studies are often long lasting, but relatively limited in scale. *The Computer as a Learning Partner* project (Linn and Hsi 2000) is an outstanding example of such a study that shows the potential of ICT for curriculum and instruction. Over a period of 15 years, an ICT-rich science curriculum focusing on understanding of complex science concepts for middle school students has been developed, extended and refined. Another promising example was the Jasper project in the mathematics domain (The Coginition and Technology Group at Vanderbilt 1997). However, the implementation of such curricula and related ICT tools in typical classrooms appeared very difficult to achieve. Also large-scale survey studies have been carried out that investigated the implementation of ICT mainly with the purpose to inform policy makers. Although these studies revealed general problems with ICT integration, they could not provide concrete and specific suggestions for improvement of the situation. More recent studies carried out by the Organization of Economic Cooperation and Development and the International Organization for the Evaluation of Educational Achievement focus on existing 'best practices' of ICT use in education with the purpose to get a deep understanding of the teaching and learning practices that contribute to effective and innovative use of ICT and the conditions that contribute or hinder its implementation. All these studies underline that the integration of ICT use in the instructional practice will remain a fascinating but difficult endeavor.

Computerized Test Construction

Like many other areas of psychology, the availability of cheap, plentiful computational power has revolutionized the technology of educational and psychological testing. It is no longer necessary to restrict testing to the use of items with a paper-and-pencil format in a group-based session. We now have the possibility to build multimedia testing environments to which test takers respond by manipulating objects on a screen, working with application programs, or manipulating devices with built-in sensors. Moreover, such tests can be assembled from banks with items stored in computer memory and immediately delivered to examinees who walk in when they are ready to take the test.

Computerized assembly of tests from an item bank is treated as an optimization problem with a solution that has to satisfy a potentially long list of statistical and non-statistical specifications for the test. The general nature of this optimization problem is outlined, and applications to the problems of assembling tests with a linear, sequential, and adaptive format are reviewed.

1. Test Assembly as an Optimization Problem

The formal structure of a test assembly problem is known as a constrained combinatorial optimization problem. It is an optimization problem because the test should be assembled to be best in some sense. The problem is combinatorial because the test is a combination of items from the bank and optimization is over the space of admissible combinations. Finally, the problem is constrained because only those combinations of items that satisfy the list of test specifications are admissible.

The quintessential combinatorial optimization problem is the knapsack problem (Nemhauser and Wolsey 1988). Suppose a knapsack has to be filled from a set of items indexed by $i = 1,\ldots, I$. Each item has utility u_i and weight w_i. The optimal combination of items is required to have maximum utility but should not exceed weight limit W. The combination is found defining decision variables

$$x_i \equiv \begin{cases} 1 & \textit{if item } i \textit{ is selected} \\ 0 & \textit{otherwise} \end{cases} \tag{1}$$

and solving the problem

$$\max \sum_{i=1}^{I} u_i x_i, \quad (\textit{maximum utility})$$

subject to

$$\sum_{i=1}^{I} w_i x_i \leqslant W, \quad (\textit{weight limit})$$

$$x_i = 0, 1, \quad (\textit{range of variables})$$

for an optimal set of values for variables x_i.

Problems with this structure are known as 0–1 linear programming (LP) problems (e.g., see *Linear and Nonlinear Programming*). Several test assembly problems can be formulated as a 0–1 LP problem; others need integer variables or a combination of integer and real variables. In a typical test assembly model, the objective function is used to maximize a statistical attribute of the test whereas the constraints serve to guarantee its content validity.

1.1 Objective Functions in Test Assembly Problems

Suppose the items in the bank are calibrated using an item response theory (IRT) model, for example, the two-parameter logistic (2PL) model:

$$p_i(\theta) \equiv \Pr(U_i = 1 \mid \theta) \equiv \frac{\exp[a_i(\theta - b_i)]}{1 + \exp[a_i(\theta - b_i)]} \tag{2}$$

where $\theta \in (-\infty, \infty)$ is the ability of the examinee, and $b_i \in (-\infty, \infty)$ and $a_i \in [0, \infty]$ are parameters for the difficulty and discriminating power of item i, respectively (e.g., see *Factor Analysis and Latent Structure: IRT and Rasch Models*).

A common objective function in IRT-based test assembly is based on the test information function, which is Fisher's measure of information on the unknown ability θ in the response vector $U_1,\ldots, U_n$, where n is the number of items in the test. For the 2-PL model the test information function is given by

$$I(\theta) \equiv I_{U_1 \ldots U_n}(\theta) = \sum_{i=1}^{n} \frac{[p_i'(\theta)]^2}{p_i(\theta)[1-p_i(\theta)]}$$

with $p_i'(\theta) \equiv (\partial/\partial\theta)p_i(\theta)$. Test information functions are additive in the contributions by the individual items, which are denoted by $I_i(\theta)$.

The first step in IRT-based test assembly is to formulate a target for the test information function. The next step is to assemble the test to have its actual information function as closely as possible to the target. Examples of popular targets are a uniform function over an ability interval in diagnostic testing and a peaked function at a cutoff score θ_c in admission testing. An objective function to realize the former is presented in Eqns. (4) and (5) (Sect. 2). The latter can be realized using objective function

$$\max \sum_{i=1}^{n} I_i(\theta_c)x_i \tag{3}$$

under the condition of an appropriate set of constraints on the test. Other possible objective functions are maximization of classical test reliability and minimization of the length of the test. For a review of these and other examples, see van der Linden (1998).

1.2 Constraints in Test Assembly Problems

Formally, test specifications can be viewed as a series of upper and/or lower bounds on numbers of item attributes in the tests or on functions thereof. An important distinction is between constraints on (a) categorical item attributes, (b) quantitative item attributes, and (c) logical relations between the items in the test. Categorical attributes are attributes such as item content, cognitive level, format, and use of graphics. Examples of quantitative attributes are statistical item parameters, expected response times, word counts, and readability indices. Logical (or Boolean) constraints deal with such issues in test assembly as items that cannot figure in the same test because they have clues to each other's solution or items that are organized as sets around common stimuli.

Let V_j be a set of items in the bank with a common value for an attribute. The general shape of a constraint on a categorical item attribute in a test assembly model with 0–1 decision variables is

$$\sum_{i \in V_j} x_i \gtreqless n_j$$

where n_j is a bound on the number of items from V_j. This type of constraint can also be formulated on intersections or unions of sets of items.

Constraints on quantitative attributes are typically on a function of their values for a set of items. For example, if a typical test taker has response time t_i on item i and the total testing time available is T (both in seconds), a useful constraint on the test is:

$$\sum_{i=1}^{I} t_i x_i \leqslant T$$

As an example of a logical constraint, suppose that W_s represents a set of items in the bank with a common stimulus s, and that n_s items have to be selected if and only if stimulus s has. This requirement leads to the following constraint

$$\sum_{i \in V_s} x_i = n_s z_s$$

with z_s being an auxiliary 0–1 decision variable for the selection of stimulus s.

In a full-fledged test assembly problem, constraints may also be needed to deal, for instance, with stimulus attributes or with relations between different test forms if a set of forms is to be assembled simultaneously. For a review of these and other types of constraints, see van der Linden (1998, 2000a).

2. Linear-test Assembly

Linear tests have a fixed number of items presented in a fixed order. For measurement over a larger ability interval, it is customary to choose a discrete set of target values for the information function, $T(\theta_k)$, $k = 1,\ldots, K$. In practice, because information functions are well-behaved continuous functions, target values at three to five equally-spaced θ values suffice. The need to match more than one target value simultaneously creates a multiobjective decision problem.

An effective way to deal with multiple target values is to apply a maximin criterion. This criterion leads to the following core of a test assembly model

$$\max y \quad (\textit{common factor}) \tag{4}$$

subject to

$$\sum_{i=1}^{I} I_i(\theta_k)x_i \geqslant T(\theta_k)y \quad k = 1,\ldots, K, \qquad (\textit{minimum information at } \theta_k) \tag{5}$$

where y is a common factor in the right-hand side bounds in (5) that is maximized and coefficients $T(\theta_k)$ control the shape of the information function (van der Linden and Boekkooi-Timminga 1989). Constraints to deal with the remaining content specifications

should be added to this model. For a large-scale testing program in education, it is not unusual to have hundreds of those constraints.

Methods to solve test assembly models can be distinguished into algorithms that have been proven to lead to optimality and intuitively plausible heuristics which typically select one item at a time. Well-known heuristics are those that pick the items with the largest impact on the test information function (Luecht 1998) or with the smallest weighted average deviation from all bounds in the model (Swanson and Stocking 1993). Optimal solutions can be found using a branch-and-bound algorithm (Nemhauser and Wolsey 1988), or, if the structure of the models boils down to a network-flow problem, a simplified version of the simplex algorithm (Armstrong et al. 1995). Several algorithms and heuristics are implemented in the test assembly package ConTest (Timminga et al. 1996).

Sometimes it is necessary to build a set of linear test forms, for instance, parallel forms to support different testing sessions or forms of different difficulties for use in an evaluation study with a pretest-posttest design. Sequential application of a model of linear-test assembly is bound to show a decreasing quality of the solutions. A simultaneous approach balancing the quality of the individual test forms can be obtained by replacing the decision variables in Eqn. (1) by

$$x_{if} \equiv \begin{cases} 1 & \textit{if item } i \textit{ is selected for } f \\ 0 & \textit{otherwise} \end{cases} \tag{6}$$

using these variables to model the test specifications for all forms $f = 1,\ldots, F$, and solving the model for all variables simultaneously. If no overlap between forms is allowed, logical constraints must be added to the model to prevent the variables from taking the value of one more than once. Efficient combinations of sequential and simultaneous approaches are presented in van der Linden and Adema (1998).

3. Sequential Test Assembly

Sequential test assembly is used in testing for selection or mastery with a cutoff score on the test that represents the level beyond which the test taker is accepted or considered to master the domain of knowledge tested, respectively. An obvious linear approach is to assemble a test using the objective function in Eqn. (3), but a more efficient procedure is to assemble the test sequentially, sampling one item from the bank at a time and stopping when the test taker is classified with enough precision.

If the items are dichotomous, the number-correct score of a test taker follows a binomial distribution

$$\Pr(X = x) = \binom{n}{x}\pi^x(1-\pi)^{n-x}$$

with π being the success parameter and n the (random) number of items sampled. In a sequential probability ratio test (SPRT) for the decision to reject test takers with $\pi < \pi_0$ and accept those with $\pi \geqslant \pi_1$, with (π_0, π_1) being a small interval around cutoff score π_c, the decision rule is based on the likelihood ratio

$$\lambda_n \equiv \prod_{i=1}^{n} f(x_i|\pi_1)/f(x_i|\pi_0)$$

If $\lambda_n < A$ or $\lambda_n \geqslant B$ the decision is to reject or accept, respectively, whereas sampling of items is continued otherwise. The constants A and B are known to satisfy

$$\begin{aligned} A &\geqslant \beta(\pi_1)/\{1-\alpha(\pi_0)\} \\ B &\leqslant \{1-\beta(\pi_0)\}/\alpha(\pi_0) \end{aligned} \tag{7}$$

with $\alpha(\pi_0)$ and $\beta(\pi_1)$ being the probabilities of a false positive and false negative decision for test takers with $\pi = \pi_0$ and $\pi = \pi_1$, respectively. For more on sequential methods, see *Sequential Statistical Methods*.

Alternative sequential approaches to test assembly follow an IRT-based SPRT (Reckase 1983) or a Bayesian framework (Kingsbury and Weiss 1983).

4. Adaptive Test Assembly

If the items in the pool are calibrated using a model as in (2), adaptive test assembly becomes possible. In adaptive test assembly, the items are selected to be optimal at the ability estimate of the test taker, updated by the computer after each new response. Adaptive testing leads to much shorter tests; savings are typically over 50 percent relative to a linear test with the same precision.

To show the principle of adaptive testing, let $i = 1,\ldots, I$ denote the items in the pool and $k = 1,\ldots, K$ the items the test. It follows that i_k is the index of the item in the pool administered as the kth item in the test. The set $S_k \equiv \{i_1,\ldots, i_{k-1}\}$ contains the first $k-1$ items in the test. These items involve responses variables $U_{k-1} \equiv (U_{i_1},\ldots, U_{i_{k-1}})$. The update of the ability estimate after $k-1$ responses is denoted as $\hat{\theta}_{u_{k-1}}$. Item k in the test is selected to be optimal at $\hat{\theta}_{u_{k-1}}$ among the items in the set $R_k \equiv \{1,\ldots, I\}\backslash S_{k-1}$.

A popular criterion of optimality in adaptive testing is maximization of information at the current ability estimate, that is, selection of item i_k according to objective function

$$\max_{i \in R_k} I_i(\hat{\theta}_{u_{k-1}}) \tag{8}$$

Alternative objective functions are based on Kullback-Leibler information or on Bayesian criteria that use the posterior distribution of θ after $k-1$ items. These functions are reviewed in van der Linden and Pashley (2000).

Several procedures have been suggested to realize content constraints on adaptive tests. The four major approaches are: (a) partitioning the bank according to the main item attributes and spiraling item selection

among the classes in the partition to realize a desired content distribution; (b) building deviations from content constraints into the objective function (Swanson and Stocking 1993); (c) testing from a pool with small sets of items build according to content specifications; and (d) using a shadow test approach in which prior to each item a full linear tests is assembled that contains all previous items, meets all content constrains, and is optimal at the ability estimate, and from which the most informative item is selected for administration (van der Linden 2000b.)

Adaptive testing is currently one of the dominant modes of computerized testing. Several aspects of computerized adaptive testing not addressed in this entry are reviewed in Wainer (1990).

Computers and Society

Rapid and continuing advances in computer technology, and the related convergence of computing and telecommunications, has enabled the development of an array of information and communication technologies (ICTs), from the hand-held computer to the World Wide Web. The significance of these ICT innovations and their application across all sectors of society made the computer one of the defining technological transformations of the late twentieth century. Widespread fascination with personal computers (PCs), video games, digital TV, cell phones, wireless Internet, and a multitude of other ICTs often focuses on the technical ingenuity of their designs and their growing capabilities. But a narrow focus on technical advances overlooks the social impacts of ICTs as well as the ways in which social factors shape technical change as well as its societal implications.

When the social implications of computers are discussed they are most often viewed in utopian vs. dystopian perspectives. For example, many influential protagonists have argued that the Internet and the Web promote global community, electronic democracy (see *Electronic Democracy*) and an information economy, bringing fulfillment, empowerment, and jobs for the twenty-first century. Others fear the new networks and services on the Internet and the Web are isolating individuals, undermining democratic processes, and destroying jobs. Still others dismiss the importance of ICTs.

Such views of technology either as an 'unalloyed blessing,' an 'unmitigated curse,' or 'not worthy of special notice' oversimplify its role and fail to provide an understanding of the 'actual mechanism by which technology leads to social change' (Mesthene 2000). While a continuing debate between utopian and dystopian perspectives has illuminated the social and economic issues at stake, it has failed to inform policy and practice. It is, therefore, important to develop perspectives on the relationship between computers and society as a means to address broad social, economic, and political issues, and also guide social and technical choices about ICTs in a variety of contexts.

1. The Social and Technical Shaping of Access

All technologies are inherently social in that they entail physical artifacts or equipment, which are designed, produced, and used by people. Moreover, the design and use of technologies involves know-how, that is, expertise, which is in itself a social attribute (MacKenzie and Wajcman 1985, p. 3). Technologies are also social in that they define, but do not determine, how people do things, making some paths more economically, culturally, or socially rational than others. For example, computers and related ICTs define ways in which people can get information and communicate with one another. A student can get the news online via the World Wide Web or through a newspaper. ICTs not only reshape how people do things, they also shape and reshape what, when, and where things are done and what people know, who they know, and what they consume.

1.1 Dimensions of Tele-access

ICTs involve much more than just access to information or the technology of the computer, implied by conventional discussion of the information 'haves' and 'have-nots.' ICTs shape an individual's, household's, firm's, or nation's access to information, people, services, and technology. The concept of tele-access highlights how ICTs shape access—both electronically mediated and unmediated—to a wide array of social and economic resources.

Social and technical choices about ICTs can reconfigure electronic and physical access to four interrelated resources: information, people, services, and technology (Dutton 1999). The most commonly recognized is access to information. ICTs not only change the way people get information, but also alter the whole corpus of what a person knows and the information available to an individual at any given time and place. ICTs play a role in making some people information rich and others comparatively information poor. But access to information is only one set of relationships shaped by ICTs, and not necessarily the most socially significant.

ICTs also shape access to people. Choices about the design and use of ICTs not only change the ways individuals communicate with one another, but also influence whom individuals meet, talk to, stay in touch with, work with, and get to know. ICTs can connect or isolate people. For example, throughout the 1990s, the most common use of the Internet was for electronic mail (e-mail), that is, for gaining access to people, not for access to information *per se*.

Third, ICTs shape access to services. ICTs do more than simply change the way people consume information, products, and services. They also influence what products and services a person consumes and whom an individual purchases them from. ICTs can render obsolete a local business or an entire industry, but also create a new business or industry.

Finally, access to particular technologies—equipment, know-how, and techniques—shapes access to other technologies as ICTs interconnect and depend on one another in many ways. For instance, the Internet can provide access to vast numbers of computers around the world, yet a person needs a computer and other ICTs (such as a telephone line, a cable connection, or wireless device) to access the Internet.

There are many other ways in which ICTs can reduce, screen, reinforce, or alter tele-access, such as the content and flow of information, by accident or design. ICTs do not just provide access to more information or more people, many of whom a person would not be in touch with otherwise: they change patterns of interaction between people, information, communities, and organizations. As a substitute for face-to-face communication, for example, ICTs can provide benefits such as reducing travel, saving time, and extending the geography of human community. They may replace valuable human contact with a much less rewarding form of communication, fostering social isolation, or permit communication among people who might never have an opportunity to meet face to face. Tele-access encompasses all these substitutions, enhancements, and much more, by highlighting how people make social and technical choices about ICTs in ways that will reshuffle society, influencing who's in and who's left out.

1.2 Social Factors Shaping Choices and Their Implications for Access

ICT innovations and their social implications are not random or unstructured. For example, patterns of tele-access, such as the distribution of information haves and have-nots, are enabled and constrained by the social and economic contexts within which relevant actors at all levels make choices. Major sets of factors can be identified that facilitate or constrain the design and use of ICTs in ways that shape tele-access (Dutton 1999).

One set includes a variety of economic resources and constraints, such as the size, wealth, and vitality of nations, companies, and other actors. These place major constraints on the development and use of ICTs in all arenas of activity. A second set consists of ICT paradigms and practices. Ideas can become the foundation of powerful belief systems or 'paradigms' which create a way of interpreting reality that is very different to that perceived by people whose thinking is embedded in another paradigm. Concepts such as the 'information society' and the emergence of 'virtual universities,' for instance, have been important factors in shaping social and political choices in the design and implementation of ICTs, irrespective of their

descriptive validity. At the same time, experience and knowledge about ICTs can influence or even create a paradigm shift, which will have important implications for how people design and use ICTs within particular settings.

Another set of factors entails conceptions and responses of users of ICTs. Technologies are designed with a more or less well founded conception of the users—whether workers, consumers, managers, citizens, viewers, or audiences—who play an active role in shaping the implications of ICTs in ways that would not be expected by simply extrapolating from the perceived potential of the technology. Misconceptions of the user can undermine the diffusion of ICTs.

A set of factors related to the geography of space and place can also facilitate or constrain tele-access; for example, a person's location shapes access to ICTs. The use of computers and telecommunication technologies can depend on where ICTs are placed within a household or around the world. ICTs do not erase geography, as is often argued, but often make geography more important (Goddard and Richardson 1996). For instance, since ICTs can make location less significant for gaining electronic access, they enable individuals or firms to be more strategic in shaping physical access; that is, as ICTs enable more flexibility in location decisions, a firm can place a higher priority on other criteria, such as facilitating face-to-face communication with customers, or gaining access to skilled or low-cost labor, in choosing where to locate particular jobs and functions.

Finally, a wide variety of institutional arrangements and public policies, such as first amendment traditions within the USA, constrain choices about access. Technical, social, policy, and organizational innovation are interdependent (Freeman 1996). For example, the design of an organization influences the use of ICTs, but ICTs also create a variety of new options for radically redesigning organizations and interactions between organizations.

All these and other social factors shape and are shaped by tele-access in ways that can have both immediate and cumulative long-range consequences on most areas of modern life. However, a focus on the social and technical shaping of access is but one way to understand and study the social implications of ICTs. It is also useful to compare this perspective with a number of more conventional perspectives on the 'information revolution' and what it will mean for society, defined by the kinds of problems, assumptions, and frameworks guiding those who work within these traditions.

Much of the work on computers and society can be usefully classified under one of the following broad and overlapping labels, which capture the primary focus of each perspective. These include perspectives focused on impacts, influence, technology, strategy, and information (Dutton 1999). These theoretical foci have influenced policy and practice around the world by telling people what to think about and what to ignore, and can all be contrasted with a perspective focused on the shaping of tele-access.

2. *The Social 'Impacts' of ICTs*

The classic dystopian novel of the twentieth century, George Orwell's *1984*, pivoted around the emergence of two-way television—the telescreen—as an instrument of propaganda and electronic surveillance. Half a century later, the growing centrality of the Internet has generated updated Orwellian visions of multimedia surveillance.

These scenarios appear highly plausible because they are often based on the actual capabilities of ICTs. However, the actual impacts of ICTs are more difficult to forecast because they are shaped by social and political choices and not simply by features of the technology. The same can be said of more immediate concerns over the implications of ICTs on privacy, freedom of speech, and employment. Some of the earliest research on the social impact of ICTs was led by specialists involved directly in the development of computing and telecommunications who sensed that the public were failing to understand the full potential of the computer and the risks it posed to society. They formed interest groups within their respective professional associations and attempted to explain how the technology works and how it could affect individuals and society in terms of major issues, such as privacy and surveillance, which still remain central to policy debates.

2.1 *The Limits of Technological Determinism*

The social impact approach usually was based on rational forecasts of the social opportunities and risks created by particular features of the technology. For instance, the enormous storage capacity of the computer raised the potential for organizations to create huge databanks of information about individuals. However, empirical research usually found that rational expectations based on such capabilities of the technology were seldom realized (Kling 2000). For example, early study of the impact of computers on privacy found that computerized organizations did not change their record-keeping practices in the ways anticipated by those who were alarmed about databanks. Computers did indeed enable organizations to create huge databanks, but managers and professionals used the computer within prevailing data processing paradigms, leading them to employ this equipment to simply increase the efficiency of their existing practices. It has taken decades for new ICT paradigms to emerge, which would fundamentally alter the ways in which organizations obtain and keep

records in ways that changed the kinds of information they collect and created major new threats to privacy and surveillance.

Likewise, forecasts of the paperless office were based on technical capabilities and a rational expectation that people would want to save the time and costs associated with paper. However, these forecasts ignored the habits and values of readers and writers and the countervailing technical advantages of paper, such as the relative difficulty of reading an electronic screen. No one knows how long a transition from paper to electronic screen may take, but it will not be determined simply by advances in the technical features, such as screen resolution. It is clear that individuals and organizations have become dependent increasingly on electronic media, such as by replacing mail with e-mail. However, at the turn of the twentieth century, the production of paper has continued to grow with advances in ICTs, and is often supported by these advances, such as with online book stores spurring book sales.

This poor track record in forecasting the implications of technical change has led to fundamental criticisms of theories based on deterministic assumptions that particular real or potential technical features will have predictable 'impacts.' The public is often told that technology is on a predetermined trajectory, but different scientists forecast different trajectories. By contrast, much social research and analysis on the design and impacts of technologies has emphasized the decisive role played by social choices in determining ultimate paths of technological development as well as their social implications (Kling 2000).

Studies of the social bases of choices shaping technological design have, therefore, led social scientists to no longer look only at the social implications of technological change, but also consider the psychological, social, political, geographical, and economic factors that influence the design, production, and use of technology. This research on the 'social shaping' of technological change has been highly critical of the simplified, linear models of cause and effect used by technological determinists. This has led to a greater emphasis on exploring the underlying 'processes' of technical and social change, such as captured by the shaping of tele-access, rather than predicting their long-term impacts.

2.2 *Technology Matters in Shaping Access*

The study of technological change suggests, therefore, that tele-access—which is entailed in the key social impacts attributed to ICTs—should be viewed as the outcome of an indeterminate social and political process rather than being set on a predetermined technological trajectory. For example, the much promoted views that technological advances are democratizing access to ICTs or isolating individuals are based on deterministic assumptions that are empirically questionable. They are also dangerous because deterministic perspectives on the future can undermine the political will to make hard choices to ensure positive social and political outcomes.

The design and development of ICTs is not as deterministic of social outcomes as is often assumed by early theorists. Neither are they neutral. Advances in ICTs reshape access, but they do not determine access. Technology is like policy, because it tells us how we are supposed to do things, and makes some ways of doing things more rational and practical than another. Also, the biases designed into technological artifacts and systems can be even more enduring than legislation (Winner 1986, pp. 19–39), and create a momentum that is difficult to reverse (Hughes 1994). For instance, the rise of e-mail is biased toward the speed up of interpersonal communication. Individuals can choose to slow their communication down, but this often takes a conscious effort and strong political will within organizations and networks accustomed to Internet speed.

3. *The Study of Influence*

Another early perspective on computers and society, closely related to the study of impacts, evolved out of research on propaganda and the political implications of the mass media of newspapers, radio, television, and film in the aftermath of World War II. This media research tradition created a number of useful models of media effects (see *Media Effects*), including notions of the two-step flow (see *Communication, Two-step Flow of*) and agenda-setting (see *Agenda-setting*), which highlights the critical role of the media as a 'gatekeeper,' such as in shaping access to the news.

This media studies 'influence' tradition has extended into work on computers and society. The tradition focuses on the content of messages conveyed through the media and the messages' influence on those exposed directly or indirectly to them, such as in studies of the violent content of video games targeted at children. Those looking at ICTs within this influence tradition often ask whether the interactive character of emerging media, such as envisioned for digital and Web-TV, will make them more engaging and, therefore, more powerful in shaping attitudes, beliefs, and values. Others have focused on the way the profusion of media and channels can segment audiences in ways that might erode the quality and integrative effect of the mass media, and no longer provide the common experiences or shared text of a community.

Concern over audience segmentation provides an example of how technological change has challenged research in the influence tradition, which is built on a presumption of access to a mass audience. McLuhan anticipated this problem in the early 1960s when he argued that there had been too much emphasis on the content of the message rather than the more significant effect of the medium itself. In claiming 'it is the

medium that shapes and controls the scale and form of human association and action', McLuhan (1964, p. 9) indicated his belief that television's ability to reconfigure access to messages was more significant than whatever message was conveyed.

In this respect, McLuhan's perspective resonates more with a focus on tele-access than with those working within the influence tradition that shaped communication research over the decades. But technological change has challenged assumptions of communication research, which tended to take access to a mass audience for granted. Gaining access to audiences has become a central preoccupation of the communication industries, from popular music to broadcasting, cable and telephone industries, and a focus for research on the social implications of ICTs, including the media. The very idea of 'mass media' has been challenged as communication researchers saw technical change reconfiguring access to audiences. The influence perspective becomes even less applicable as one moves outside media studies, such as to assess the implications of ICTs for the economy.

4. *Studies of Technology and Society*

Outside the communications field, social scientists generally have looked at the computer and ICTs more generally as just special cases in a more general concern with the study of technology and society. Treatments of technology and society have flourished since the 1960s.

4.1 *The Role of Technology in Society*

Philosophers and social scientists have focused on how society is affected by the growing centrality of technology—and how technology, as a means, has become an end in itself. Researchers in this field have also analyzed the impacts of specific ICTs, ranging from the videophone to the Internet. Such technology assessments bring to the surface a wide range of multidisciplinary issues that go far beyond concerns with the mass media; they show, for example, how ICTs have become an integral component of a 'high-tech society' that pervades all aspects of our lives.

Another major contribution to this literature has focused on control as one impact of technological change. Many dystopian novels and films, such as *2001: A Space Odyssey* and *Jurassic Park*, capture the fear that technology is out of control and has created a new, unelected, high-tech élite which increasingly dominates decision making.

4.2 *Technology, Expertise, and Social Control*

Early discussion of computers and telecommunications reflected this concern that modern technology is becoming an unstoppable force which would support increasingly centralized control in organizations and society. Many observers of the social impacts of more recent advances in ICTs argue the opposite—that the convergence of computing and networking has decentralized control over the technology and placed more control in the hands of users (de Sola Pool 1983). Nevertheless, many others continue to argue that ICT innovations are empowering a new elite of experts, who have the skills and knowledge to control networks in organizations and society.

Technology concerns more than just equipment. It also encompasses the knowledge that is essential to its use (MacKenzie and Wajcman 1985, p. 3). The control of technology is, therefore, bound up with issues of who has access to the skills, equipment, and know-how essential to design, implement, and employ technology. Changes in technology can, therefore, restrict access to all these resources. For instance, early mainframe computers depended on programmers with knowledge of specialized programming languages. But technological change can equally expand access, for example, by the way simple graphical user interfaces with the Web have made access to information stored on millions of computers available to users round the world at the click of a mouse button. Likewise, social choices, such as the decision to learn a new human or computer language, affect access to technology, jobs, and people. The ways in which technical and social choices shape access to ICTs has been central to the technological perspective, but was often lost in a body of work covering myriad concerns at all levels of analysis and across all technology.

5. *ICT Strategies*

A focus on the goals and strategies of actors, instead of the capabilities of the technology, has been most fully developed within the management field, where some of the earliest empirical studies into the design and use of ICTs were conducted. Management researchers began to study computers in the 1950s. From early on, leading management science thinkers highlighted the significance of the convergence into 'Information Technology' (IT) of computing, telecommunications, and related management science techniques, such as modeling and computer simulation, but focused on how managers could employ IT (what later came to be called ICTs) to accomplish their objectives.

5.1 *Management Use of ICTs*

Through the early decades of its use, the computer was seen by management theorists as a strategic tool for enabling executives to boost centralized control by giving them access to information about the organization's resources and everyday operations. Centralization was not expected as an inevitable consequence

of computerization, but as an extension of and means for realizing the prevailing management paradigm of the time. It was a technical fix for problems that seemed immune to structural reforms, such as efforts to centralize functions or redraw organizational charts (Danziger et al. 1982).

From this strategic perspective, the major implications of ICTs extend from the strategies of management rather than the characteristics of the technology. This view remains central to contemporary management research, but with an ICT management paradigm that places less emphasis on the value of top management control and more on the virtues of innovation and networking (Castells 2000).

Instead of finding that computers inevitably increased centralization, early empirical research on computers discovered that those who control decision-making tend to adopt and use ICTs in ways that follow and reinforce existing patterns of control within the organization, whether they be highly centralized or decentralized (Danziger et al. 1982). This research highlighted the malleability of ICTs and the degree to which top managers are only one set of actors within a more complex and interdependent set of actors making decisions about the design and use of IT in organizations. The organizational and social implications of ICTs are the uncertain outcome of a struggle among actors over the design and use of these technologies. It is not taking place on a level playing field, since there are inequalities in existing institutions, cultures, and social and technical systems that favor some actors and choices over others, but neither does any single actor have a monopoly of control.

5.2 *The Interaction of Strategies Within a Broader Ecology of Games*

This struggle for control over ICT design and use generally takes place on a variety of different fields at the same time. All actors are not involved in the same struggle. Instead, individuals and groups are pursuing different goals within their own domains in an ecology of games (Dutton 1999, pp. 14–16). For instance, a technical expert might be pursuing a technically elegant solution to a network's design, while a top manager is primarily seeking cost reductions. This places major constraints on the predictability of outcomes based on an assessment of strategic goals, unless the varied goals of different actors involved in the broader ecology of games is well understood and orchestrated.

Global advances in ICTs, the momentum of technologies already in place, and the widespread application of ICTs throughout society place limits on the ability of any individual, household, organization, or nation to control the design and implementation of ICTs in predetermined ways. It is more realistic, for example, to view tele-access, and its consequences, as the outcome of a process of social and technical choices by many different actors within a variety of separate but inter-related technical, organizational, social, and policy arenas. It is the outcome of an ecology of games.

6. *The Information Society*

A very different and enduring perspective was introduced in the 1970s by discussion of the information society as a new stage in economic development. The information society theorists cite many of the social threats identified by others, such as to personal privacy and information inequality, but they focused more attention on the role of technology, and ICTs in particular, in the economy and society.

6.1 *The Information Age Thesis and its Critics*

The American sociologist Daniel Bell wrote a seminal work on the information society, which he first called the 'post-industrial society' (Bell 1999). He said information would be the key economic resource in this new era—not raw materials, or financial capital as in earlier agricultural and industrial societies. Citing the US economy as an exemplary case, Bell identified major trends in the development of an information society (see *Information Society*).

The most significant trend towards an information society was the shift in the majority of the labor force from agriculture (the primary sector) and manufacturing (the secondary sector) to services (the tertiary sector), largely through the growth of 'information work,' defined to include a broad array of jobs related to the creation, transmission, and processing of information, ranging from programmers and software engineers, to teachers and researchers. Another trend has been the increasing importance of knowledge and its codification to the management of social and economic institutions. A third set of information society trends involved power shifts, particularly the growing prominence of a knowledge elite, which forms a professional and managerial class who understand and know how to work with data, knowledge, information systems, simulation, and related analytical techniques.

Changes in work, technology, and power posited by this thesis have all been challenged (Freeman 1996). Yet conceptions of the information society have increasingly defined the public's understanding of social and economic change tied to the computer and related ICTs. Public and corporate policies and academic institutions and journals have been built on the concept of information as a new strategic resource. However, this focus can mislead policy and practice, particularly by the way it has substantially shifted

attention to the information sector and away from other parts of the economy.

More generally, the identification of information as the key central resource of the economy has also been widely questioned (Dutton 1999). For example, information has a highly variable currency: it is not always wanted or valued. As a resource, information can lose its value, such as in the case of a day-old newspaper, or retain its value after repeated use, as with a literary classic. If defined narrowly in the sense of being about 'facts,' the term 'information' becomes far too limiting as a depiction of the social role of ICTs. But if defined very broadly, for instance, as anything that 'reduces uncertainty,' then information seems to be so all encompassing that it becomes virtually meaningless.

Moreover, information can create, rather than reduce uncertainty. For example, those more informed about a topic are often less certain about its properties than many who are less informed. There is no linear relationship between information and certainty, but rather what MacKenzie (1999) has called a 'certainty trough.' And information is not a new resource. It has been important in every sector of the economy throughout history. Popular conceptions of the 'information society'—like the virtual society, or the cyberculture—capture the social significance of the ICT revolution (see *Information Society*). While these concepts emphasize the increasing centrality of ICTs to society, they fail to provide insights about the role of computers and related ICTs in social change. Moreover, if taken literally, many prevailing conceptions of the information society are misleading. They suggest that information is a new economic and social resource, when there is nothing new about the importance of information (Castells 2000). What is new is how you get access to information, but also to people, to services, and to technology itself (Dutton 1999).

6.2 *The Politics of Information: Communicative Power*

As people understand the limitations of seeing information as the pivotal concept in the study of ICTs, the central role of processes that shape tele-access has become more evident. The cliché that 'information is power' is seldom examined critically. It suggests that experts will gain power over politicians, managers, and the lay public. Yet this thesis ignores the degree to which economic resources enables access to knowledge—information, expertise, and the means for creating knowledge. It is not information *per se*, but the ability to control access to information that seems key. Social factors, such as institutional arrangements and public policy, or geographical proximity, as in gaining tacit knowledge from direct observation, can shape access, as well as technologies.

The role of ICTs in shaping access to information might be called 'information politics' (Danziger et al. 1982, pp. 133–5). This is also the concern of Garnham (1999), who has argued for a research agenda focused on study of the social processes involving producers, distributors, and users in negotiations over how information is created, disseminated, and consumed.

However, as explained above, information is only one element in what can be viewed as a far more general politics of access. ICTs also shape access to people, services, and other ICTs. So it is critical to define information politics broadly to include the choices shaping tele-access and the factors that constrain and facilitate them.

6.3 *Perspectives on the Information Age*

The idea of an information society entails a staged progression of an economy from an agricultural, to an industrial, to an information society (or 'information age') and to whatever comes next, such as a 'knowledge society.' An alternative forecast of social and economic evolution is posed by the notion of long economic development cycles caused by successive waves of technological revolutions (Freeman 1996). This approach argues that the invention of a new technology, like the steam engine or the computer, can have applications across the economy that affect many facets of our lives, for instance ICTs having effects well beyond what might be labeled as information work or information processing.

The concepts of staged and cyclical theories of economic and technological change are both attractive because they promise some level of predictability. However, there is no consensus on the identification and validation of these stages or cycles of economic development. Also, there is a long lag of from one to two decades between the invention of a radically new technology and its impact on the way things are done. It takes time for people to change their habits and beliefs and to accept a new paradigm for how they do things. This led to a new focus of attention on the role of ICT paradigms in shaping the impacts of technology in organizations and society (Freeman 1996).

Ideas like the information society, economic cycles and tele-access are important in part because they shape views about the way the world works and, thereby, influence the decisions of individuals, firms, and governments. That is one reason why alternative perspectives on the role of computers in society, such as the shaping of tele-access, are more than competing theories. They are also ideas that can shape decisions in everyday life as well as in once-in-a-lifetime choices.

Comte, Auguste (1798–1857)

Auguste Comte is the founder of the 'philosophy of positivism,' the disciplines of 'sociology' and the 'history of science,' and the 'Religion of Humanity.' These innovations were inspired by his desire to reorganize society during the period of upheaval following the French Revolution of 1789. Living through several revolutions, monarchical regimes, republics, and empires, Comte rejected purely political and institutional reforms as ineffective. Instead, he argued that social harmony could only occur if individuals were brought together by a consensus that was both intellectual and emotional in nature. Ideas as well as feelings had to be reordered. Comte's search for a consensus derived not only from the anarchy of the post-revolutionary period but from the instability in his own life, which led him to view inner harmony as a sign of health. He created positivism and its keystone, sociology, to construct a new cohesive society that would encompass the conservatives' call for order and the leftists' preference for progress. This article will investigate Comte's personal and intellectual development as well as his contributions to knowledge and politics.

1. Life and Main Works

The son of a minor bureaucrat, Comte was born on January 19, 1798 in Montpellier, France. Growing up in this center of counter-revolutionary activity, he was deeply affected by the chaos stemming from the French Revolution. By age 14, he renounced both the monarchy and God, alienating his royalist, Catholic parents. Comte's rebelliousness was shared by many members of his generation, who longed for a sense of community and new principles of legitimacy that would stabilize moral and political life. His insubordinate behavior led to his expulsion from the *École Polytechnique*, the prestigious Parisian engineering school, which had admitted him in 1814. After his dismissal in 1816, he committed himself to fulfilling the radical revolutionaries' dream of erecting a secular republic.

Living in Paris, in 1817 he accepted the position of secretary to Henri de Saint-Simon. They became close collaborators in many journalistic enterprises. However, in 1824 they parted ways after Comte accused him of trying to take credit for his 'fundamental opuscule,' the *Plan des Travaux Scientifiques Nécessaires pour Réorganiser la Société*, which outlined his social ideas. Although Comte later denied Saint-Simon's influence, the older reformer showed him that they were in an era of transition that had to be completed by constructing a new society founded on industry and a new system of scientific knowledge—the 'positive philosophy.' This philosophy centered on the scientific study of society. Using his talent for synthesis and system building, Comte brought to fruition the seminal ideas strewn haphazardly throughout Saint-Simon's often-incoherent works.

In 1826 Comte launched a course in positive philosophy in his apartment. Yet he soon went mad and spent eight months in an asylum. He struggled

against manic depression and paranoia the rest of his life. After working as a mathematics tutor and journalist, he secured a lowly teaching and administrative position at the *École Polytechnique*, where he worked from 1832 to 1851.

Between 1830 and 1842 he wrote his most important work, the *Cours de Philosophie Positive*. It covered the history of the sciences, demonstrating that it was time for the study of society to become a science as well. The Cours attracted the attention of several famous writers, including John Stuart Mill, but they eventually became estranged from him.

Another person who experienced a bitter rupture with Comte was his wife, Caroline Massin. A penniless director of a reading room, she married him in 1824. They had a tumultuous marriage and separated in 1842. To punish her, he later called her a prostitute.

Comte fell in love in 1845 with Clotilde de Vaux, who was 17 years younger than he. Having been abandoned by her husband, this aspiring writer grew close to Comte but resisted his sexual advances. After she died of tuberculosis in 1846, Comte made her into his muse.

The Revolution of 1848 spurred Comte to activism. He established his own club, the 'Positivist Society,' to launch the positivist movement, and he wrote a manifesto, the *Discours sur l'ensemble du Positivisme*, which was a more extensive introduction to this work than his *Discours sur l'esprit Positif* of 1844. Disappointed that scientists and other intellectuals neglected him, he targeted two new groups, workers and women, whose social roles were highlighted in the *Système de Politique Positive*. Published in four volumes between 1851 and 1854, this work expressed his political and social ideas. It promoted the importance of the emotions, established the Religion of Humanity, and made morality the seventh science. Many scholars blame his relationship with de Vaux for Comte's alleged decline into religious, sentimental thinking. Yet there was no sudden break in his career, for from the start he distrusted the purely scientific spirit, committed himself to moral reform, and sought to create a new belief system to replace traditional religion.

The last years of Comte's life were marked by increasing seclusion and conservatism. Afraid of anarchy, Comte supported Louis Napoleon in 1851. Disappointed in workers' allegiance to socialism, he tried to gain the support of women, for whom he wrote the *Catéchisme Positiviste* (1852). His *Appel aux Conservateurs* (1855) aimed to persuade conservatives to join the positivist movement. Finally, in 1856 Comte published the *Synthèse subjective*, which explored the importance of images and the emotions in the context of mathematics and logic. Dependent financially on a small group of followers, he died in Paris on September 5, 1857.

Auguste Comte was a brilliant visionary. However, his paranoia, egoism, and dogmatism impaired on his personal relations and on his ability to launch a political and intellectual movement. In effect, he sought to create in society the harmony and stability that he could not find in his private life.

2. *Positivism and the History of Science*

Comte's original version of positivism, which is far from the scientism with which it is often associated, had both a theoretical component and a practical, or political, aspect. It did not celebrate the sciences for their own sakes or seek to be value-free as scientific systems claim to be. Instead, positivism promoted a new republic imbued with 'altruism'—a word he coined—in order to counteract the sense of disconnectedness coming from the French Revolution.

An idealist, Comte believed that intellectual confusion was at the root of the postrevolutionary anarchy because ideas always determined the social structure. Rejecting the conventional abstractions and practices of religion and politics as useless, he sought to create an intellectual revolution that would first lead to a moral revolution and then to a political and social revolution. An intellectual revolution would occur if one could place knowledge of society on a sure foundation to attain more control over it. To this end, he recommended the application of the scientific, or 'positive,' method to the study of politics and society.

The 'positive' method designated the certain, precise, useful, relative (as opposed to the absolute), and constructive (as opposed to the negative) method. Positive laws must avoid references to first and final causes or substances, which were incomprehensible. These laws had to show relationships between phenomena that would allow scientists to make predictions affecting the world of action. Indeed, each science should eschew pure empiricism and replicate as much as possible the deductive, rational approach of mathematics. Criticizing isolated facts as useless, Comte sought to free people from the tedious task of direct observation to enable them to construct abstract laws and theories. Individuals could not even make observations and retain facts without first formulating a theory to guide their perceptions. Provisional hypotheses were especially important to advance scientific understanding when concrete, observed facts were missing. Furthermore, scientists should use their imagination to create 'scientific fictions,' or hypothetical cases, to fill in poorly understood areas. Comte also recognized the role of esthetics and the subjective in formulating scientific hypotheses. To avoid giving reason excessive importance in scientific research, he refused to offer universal logical rules of scientific procedure and scientific proof. His only injunction was that every positive theory had to ultimately refer on some level to real, concrete phenomena that could be observed directly or indirectly.

Reflecting the impact of nineteenth-century historicism, Comte asserted, moreover, that one could not truly understand a phenomenon without grasping its history. To comprehend the positive method, one had to see its development in the major sciences, each of which had to be considered in relation to its own history, the history of the other sciences, and the history of society in general. The Cours highlighted the history of science, which Comte believed was the most neglected and important part of the development of humanity.

The Cours outlined Comte's famous 'classification of the sciences' and his equally renowned 'law of three stages.' This law demonstrated that as the mind went from one mode of thinking to another, it generated a different theoretical system, which in turn shaped the political and social system. There were three stages of development. In the theological stage, people used supernatural ideas, such as God, to link their observations. (There were three phases of this stage: fetishism, where gods were located in phenomena, polytheism, and monotheism.) In a theological society, priests and military men ruled. The theory of divine right was the reigning political doctrine, while conquest was the principal material activity. In the transitional, metaphysical stage, God was replaced by a personified essence or abstraction, like Nature or Reason. Lawyers and metaphysicians dominated society. The doctrines of popular sovereignty and natural rights were important in politics. More material activities were geared toward production. Finally, in the positive stage, supernatural and abstract forces would be replaced by scientific laws describing how, not why, phenomena functioned. Industrialists and positive philosophers would run the republic. Production would replace conquest as the goal of society.

According to the 'classification of the sciences,' each science went through the theological and metaphysical stages and finally became positive according to the simplicity of its phenomena and the distance of these phenomena from humans. Mathematics, which was not a 'direct' natural science, demonstrated the characteristics of the positive method. The positive method was then established in astronomy, physics, chemistry, and biology in that order. Each science depended on the simpler sciences that came before it in the hierarchy of sciences and could not advance to the positive stage until the preceding ones did. Comte argued against reducing one science to another, for each had its own distinctive subject matter and methodology. Moreover, Comte warned against the widespread use of mathematics in scientific investigation, especially in biology and sociology.

The point of Comte's laws of three stages and classification of the sciences was to demonstrate the inevitable triumph of the positive method in every area of study because all aspects of knowledge were interrelated and the mind sought homogeneity. Now that mathematics, astronomy, physics, chemistry, and biology were positive, it was time for the positive method to be extended to the study of politics and society, the last stronghold of theology and metaphysics.

3. *Sociology*

Comte named his science of society 'sociology' in 1839, giving it a distinctiveness and importance in his system that it never had in Saint-Simon's work. Once it was established, the positive philosophy, which encompassed all of the sciences, would be completed and unified. All our ideas would be scientific and homogenous. In addition, sociology would help unite knowledge by making the sciences focus on improving humanity. Because everyone would agree on the most significant intellectual and moral principles, the establishment of sociology would lead to the intellectual consensus required to build a stable industrial society. Sociology would also provide the rational principles necessary to reform society.

Comte's sociology had two parts, social statics and social dynamics. They stressed the interconnectedness of the members of the human species in space and time in order to counter the egoism and selfishness of the modern age. While social statics gave people a sense of solidarity with other members of contemporary society, social dynamics provided people with a feeling of connection with past and future generations of the human species. Social statics was the study of the social order. It explored forces, such as the family, that held society together. Social dynamics focused on historical progress. Its main principle was the 'law of three stages.'

4. *Positive Politics and the Religion of Humanity*

According to the 'law of three stages,' the unique characteristics of the human species—intelligence and sociability—became more dominant through exercise within both the individual and society. This theory reflects Comte's multi-dimensional view of human nature, which was reinforced by romanticism. To him, the emotions were closely connected with the intellect, which they simulated. Because social needs were both intellectual and emotional, social reorganization had to involve the heart as much as the mind. In the first phase of his development, Comte emphasized the importance of creating a system of ideas that could be shared by all people. In this positivist system, sociology led everyone to focus their thoughts on the needs of society, or humanity. In his second phase, Comte stressed the necessity of reinforcing the intellectual consensus by encouraging emotional ties among individuals through the Religion of Humanity. Everyone should not simply think about humanity but love it as well. In short, an increase in intellectual well roundedness would lead to a growth of altruism.

Comte's promotion of universal love was inspired by his horror of the abuses of modern industrial and capitalist society. He believed that the division of labor, which was necessary for progress, increased specialization and made people egotistic, narrow-minded, and selfish. The lower classes suffered the most from the indifference of the rest of society. Existing political parties, tied to the old theological and metaphysical principles, could not solve social problems.

Comte created a secular religious culture to bring individuals together. He designed new sacraments and a calendar of secular saints, called on the arts to aid in the process of continual socialization, and insisted that public schools offer boys and girls of all classes a broad education that cultivated feelings of sociability. The cult of Humanity, including a cult of 'Woman,' would honor individuals who had contributed to civilization. The 'Religion of Humanity' also assumed features of fetishism, the most emotionally intense and concrete form of religion. Everyone had to respect the earth, the 'Great Fetish.' Positivism, the most advanced stage of history, would lead full circle to the beginning of civilization, reflecting Comte's doubts about the benefits of science and progress.

Although Comte's doctrine was scientific in nature, he insisted on the limits and dangers of the sciences and recognized the importance of practical activity to which most people were drawn. To prevent the emergence of a dictatorship of scientists, Comte recommended that there be two separate powers that would hold each other in check. The temporal power would be composed of industrialists, who would control the practical, material activities of society. The spiritual power would consist of positive philosophers, who would govern the world of ideas, opinions, and feelings. The philosophers' chief assistants would be workers, who would be finally incorporated into society, and women, who would make nurturing the goal of public life.

5. *Assessment and Influence*

Comte's system was a grand synthesis designed to appeal to diverse philosophical and political positions. It incorporated ideas from many European thinkers, including Bacon, Descartes, Hume, Montesquieu, Condorcet, the Ideologues, the Scottish Enlightenment philosophers, Maistre, Gall, Kant, and Herder. In terms of politics, Comte supported the moral concerns associated with the counter-revolutionaries and remained committed to the leftist tradition that political authority must aid the people. In searching for a synthesis—a synthesis that was both objective and subjective in nature—Comte pursued the middle way between extremes in all realms. He sought to balance the needs of the heart and those of the mind, rationalism and empiricism, materialism and idealism, religion and science, feminism and patriarchalism, democracy and authoritarianism, and individuality and sociability.

Comte's philosophy is authoritarian, dogmatic, and grandiose. Many of his so-called scientific assertions, including the law of three stages, are replete with assumptions. Paradoxically, the very diffuseness of his endeavor caused him to lose support in his own day. The left found him illiberal and religious, while the right considered him blasphemous and anarchical.

Nevertheless, Comte's thought was extremely influential. Because it was vast and complex, people took from it what they wanted. Mill and Emile Littré made positivism into a manifesto for the scientific age. Politicians of the Third Republic used positivism in their campaign against the Church. Charles Maurras employed positivist principles to enhance the proto-fascist doctrine of the *Action Française*. Elsewhere, positivism attracted support from both liberals and conservatives in the UK, the USA, and Latin America. The Brazilian flag displays Comte's motto 'Order and Progress.'

Comte also influenced the humanities and social sciences. Philosophers of science have been interested in his approach to hypotheses. Logical positivists shared Comte's concern with problems of verification. Positivism long dominated European historiography. Lucien Lévy-Bruhl introduced many of Comte's ideas into anthropology. Through Emile Durkheim, positivism influenced sociology. Other social scientists affected by Comte include Alfred Espinas, Herbert Spencer, Hippolyte Taine, Ernest Renan, Charles Booth, and Patrick Geddes. Comte's thought remains relevant today, when people still grapple with many problems that he highlighted, such as the role of affectivity in education and the sciences, the roots of moral crises, and the significance of collective memory. Particularly at a time when global interests are paramount, Comte's call for a commitment to humanity as a whole and the environment bears renewed examination.

Concept Learning and Representation: Models

Concept learning describes the process by which experience allows us to partition objects in the world into classes for the purpose of generalization, discrimination, and inference. When children learn that certain objects in the world are apples and others oranges, their newly acquired knowledge allows them to make informed guesses about new objects they encounter ('this is an apple but that isn't … '), to tell members of these categories apart, and to make decisions which support various actions ('this is an apple so I can bite it').

Models of concept learning have adopted one of three contrasting views concerning category representation (see also *Knowledge Representation*). In prototype theories, the concept learning process is assumed to yield an abstract representation corresponding to the central tendency of the category exemplars on each of the dimensions of variation. In exemplar models, the concept is simply the set of mental representations of all of the category exemplars that have been previously observed, with each instance assumed to be stored as a separate trace. And in decision rule models, the learner is assumed to construct a boundary or rule in psychological space which partitions it into different category regions. These different perspectives, and some of the evidence supporting each of them, are considered in turn. Next, the role of selective attention in categorization, and the way in which the different models deal with selective attention, is discussed. Evidence that categorization may be controlled by multiple mechanisms is evaluated, and finally the fine-scale dynamics (i.e., time course) and some aspects of the neuropsychology of categorization are reviewed.

1. Prototype Theories

Prototype theories make a simple assumption about concept representation, namely that the concept is represented as the 'ideal' or 'average' category exemplar. Thus, representations of specific category exemplars do not influence classification. Numerous forms have been suggested for the (probabilistic) response rule; here we describe one common example (for other examples, see *Categorization and Similarity Models*). Assume that the probability that stimulus i is classified in category J, $P(\mathrm{R}_J/\mathrm{S}_i)$, is given by the equation:

$$P(\mathrm{R}_J/\mathrm{S}_i) = \frac{b_J s_{iPJ}}{\sum_K b_K s_{iPK}} \tag{1}$$

where b_J $(0 \leqslant b_J \leqslant 1,\ \Sigma b_J = 1)$ represents the bias towards making category response J and s_{iPJ} is the similarity between exemplar i and the prototype of category J. The idea is that classification depends on the similarity between exemplar i and the category J prototype relative to i's similarity to the prototypes of all other categories. Similarity is usually measured with multidimensional scaling methods (see also *Multidimensional Scaling in Psychology*; *Signal Detection Theory: Multidimensional*).

One piece of evidence favoring prototype models is that a previously unseen prototype may in some circumstances be classified with higher accuracy in the test phase than the actual training stimuli. Moreover, compared to the training stimuli, the prototype may be particularly resistant to forgetting (Homa et al. 1981). Despite this, and notwithstanding their attractive simplicity, there is an abundance of evidence against prototype models of concept learning, at least within the domain of perceptual classification. Prototype models have often been shown to provide poorer fits than other models to large sets of classification data, they make a number of predictions that have been falsified, and they fail to account for a number of well-established phenomena (see Nosofsky 1992 for a thorough review).

2. Exemplar Theories

Although it may seem implausible that classification is mediated by a 'chorus' of category exemplars, there is an enormous body of evidence consistent with the idea that a trace is created in memory for each category member that is observed and that the effects of individual exemplars on later classification are long lasting. For example, judging whether a letter string is a word or a nonword is influenced by a single prior encounter with that string, and this influence can persist for many days and can be specific to the exact surface form (e.g., font) of the string (Tenpenny 1995). The best-developed formal instance-based model of concept learning is Nosofsky's Generalized Context Model (GCM). In the GCM, $P(\mathrm{R}_J/\mathrm{S}_i)$, is given by the equation:

$$P(\mathrm{R}_J/\mathrm{S}_i) = \frac{b_J \sum_{j \in J} s_{ij}}{\sum_K (b_K \sum_{k \in K} s_{ik})} \tag{2}$$

where s_{ij} is the similarity between exemplars i and j and, as before, b_J represents the bias towards making category response J. The idea is that classification depends on the summed similarity between i and each of the members of category J, relative to i's similarity to the exemplars of all other categories. As in prototype models, similarity is usually measured using multidimensional scaling methods.

A sizable amount of evidence supports exemplar models such as the GCM (Nosofsky 1992). These models have been shown not only to provide excellent fits to parametric data sets but also to predict a number of qualitative phenomena. For example, they predict that a previously unseen prototype may in some circumstances be classified with higher accuracy in the test phase than the actual training stimuli, and that classification of test items may sometimes be almost completely unrelated to recognition of the same items.

There is also more direct evidence of preservation of the training exemplars in memory. Thomas (1998) first trained participants in a two-dimensional classification task in which values on the dimensions were highly correlated across exemplars. Next, participants were shown stimuli that possessed only one of the dimensions, together with the appropriate category label, and asked to predict the value of the stimulus on the other dimension. Consistent with exemplar theories, Thomas found that many participants were able to perform this task accurately, predicting values for the missing dimension consistent with the correlation observed across the exemplars during training. This implies that they retained quite detailed information about the conjunctions or correlations of feature values across exemplars. Many theories in which information about specific training exemplars is discarded (e.g., prototype theory) would be unable to account for this finding.

The major difficulties faced by exemplar models are that they do not fully reproduce individual differences in the distributions of responses across test stimuli (Nosofsky et al. 1994) and they do not account for certain base-rate effects in categorization (Nosofsky et al. 1992). We will also see below that some further data obtained by Thomas (1998) are very problematic for exemplar theories.

3. Decision-bound Models

In decision-bound or rule-based models, concepts are represented as regions in psychological space. A rule or boundary demarcates the dividing line between one category and another. In their most general form, decision-bound models can assume any mathematical form for these boundaries, but in practice most researchers have assumed that people can only learn 'simple' boundaries, and have therefore attempted to study the plausibility of special cases in which they are constrained to be linear or quadratic. Another reason for studying these particular forms is that the optimal boundary for discriminating between two bivariate normal distributions is either linear or quadratic, and it is reasonable to speculate that many natural categories are multivariate normal. The theory then assumes that, in a two-category situation, if a stimulus (or, more accurately, the percept of the stimulus) falls on one side of the boundary the participant assigns it to the corresponding category and if it falls on the other side it is assigned to the other category. Importantly, the distance of the stimulus from the boundary is assumed to be irrelevant as far as $P(\mathrm{R}_J/\mathrm{S}_i)$ is concerned. In that sense, categorization is assumed to be deterministic.

Decision-bound models have proved difficult to discriminate empirically from exemplar-based models such as the GCM—indeed, under some circumstances they are formally equivalent (Ashby and Maddox 1993). Decision-bound models are favored by data from non-normally distributed categories (Maddox and Ashby 1993) and by evidence that participants in some circumstances do not retain information about specific training exemplars. One compelling example was obtained by Thomas (1998) in the study described previously. Although many participants in Thomas' study were able to predict one dimension value on the basis of another in stimuli drawn from categories with correlated dimensional values, others were quite unable to do this and instead responded by essentially giving the mean value of the missing dimension, despite the fact that they had learned the initial classification. This strongly suggests that during the course of category learning they had extracted a decision bound and discarded information about the specific training exemplars.

Alternatively, there is rather little evidence, even in one-dimensional perceptual categorization tasks, that participants use all-or-none cutoffs as decision-bound theory predicts (Kalish and Kruschke 1997).

4. Selective Attention in Concept Learning

It has been recognized for many years that concept learning increases the amount of attention paid to stimulus dimensions that are relevant for solving a classification problem and decreases the amount paid to irrelevant ones. Goldstone (1994), for example, found that perceptual discrimination of highly confusable stimuli in a same–different judgment task increased as a result of category learning if the stimuli were assigned to different categories whereas, at least in some cases, it decreased if the stimuli were assigned to the same category.

In the GCM, this process of selective attention is accommodated by assuming that the similarity between a test item and category exemplars stored in memory is a function of their separation in psycho-

logical space, and that this space can be stretched or shrunk (thus altering the similarities) along orthogonal dimensions as a consequence of selective attention. A similar process can be incorporated into prototype theories. Nosofsky and his colleagues (e.g., McKinley and Nosofsky 1996) have now provided abundant evidence on the one hand that this process of selectively weighting the dimensions of stimulus variation in the generation of category decisions is essential in fitting categorization data within the exemplar-based framework.

On the other hand, decision-bound models have been paradoxically successful at fitting categorization data *without* needing to assume an explicit selective attention process. On this theory, the structure of the classification problem affects the placement of the decision boundary, but no additional notion of selective attention to stimulus dimensions is necessary. It is perhaps unclear how decision-bound theories would explain results such as those of Goldstone, which provide direct evidence for changes in the perceived similarities of stimuli as a consequence of category learning, but selective attention does not seem to be required for predicting categorization responses *per se*.

One possible resolution is based on the distinction between selective attention as a perceptual or as a decisional process. The former sees attention as directly altering the perceptual representation of a stimulus, while the latter assumes that attention operates later in the processing stream, perhaps weighting certain features of the stimulus more heavily than others in making a classification decision. Whereas Goldstone's data provide strong support for selective attention affecting the perceptual representation of stimuli, direct evidence for an influence on decisional processes—as assumed in the GCM—is currently lacking. Therefore there is scope for decision-bound models to dispense with selective attention as a decisional process so long as some dispensation is made for it to operate perceptually, for example via changes in the variances of stimulus percepts on the different dimensions. For further discussion, see Maddox and Ashby (1998).

5. *Hybrid Models*

An obvious possibility suggested by the evaluation of exemplar and decision-bound models is that people can use different categorization strategies in different circumstances, and indeed there is now a wealth of evidence in support of this conjecture. For example, Johnstone and Shanks (2001) asked participants to classify letter strings as either 'grammatical' or 'ungrammatical' after exposing them to strings, all of which were consistent with a complex rule. With incidental training conditions, classification was controlled purely by featural similarity of studied exemplars, but with explicit 'code-breaking' training conditions, classification of exactly the same items was controlled by the complex rule and was unrelated to similarity of studied exemplars. Erickson and Kruschke (1998) review the growing body of evidence for this 'multiple-mechanism' view of category learning and representation.

A natural question which arises is how one might computationally model a multiple-mechanism categorization system, and several attempts have recently been made. Erickson and Kruschke (1998), for example, had some success with a 'mixture-of-experts' model which incorporates both an exemplar and a decision-bound module. In this model, an adaptive learning rule (*Connectionist Models of Concept Learning*) determines the extent to which the final category decision is based on one module or the other, and the weight assigned to each module is an inverse function of the prediction error it generates for that particular classification problem. This sort of modular view of categorization is also supported by recent brain imaging data (Smith et al. 1998).

6. *Time Course of Classification*

An important recent development in the study of category learning and representation is the application of exemplar and decision-bound models to the fine-scale dynamics—specifically, the time course—of categorization. Until quite recently, research concentrated almost exclusively on categorization probabilities, but new methodological techniques provide researchers with powerful tools for studying more microscopic aspects of the categorization process.

Two rather different proposals have been advanced to extend exemplar models to deal with this issue (Lamberts, 2000). One approach is to assume that when an item is presented for classification, a race begins to retrieve exemplars from memory. The time to complete the race depends on how similar the stored exemplars are to the test item. When one race is completed, and an exemplar retrieved, a new race commences, and a classification response is only emitted when a random-walk process is driven to one or another decision barrier. The alternative approach is to assume that there is a gradual accumulation of perceptual information about the test stimulus and that similarity to stored exemplars varies during the construction of its representation. On this account, classification at any given moment is governed by Eqn. (2) but the summed similarity term in that equation is dependent on how much information about the test stimulus has been accumulated.

Proponents of decision-bound theory have advanced a rather straightforward hypothesis about the time course of categorization, namely that classification response times depend on distance to the decision bound, with greater distances leading to faster responses.

Attempts to distinguish between these accounts are in their infancy, but each appears to have strong merits. The articles cited in this section provide detailed reviews. Further study of the temporal dynamics of categorization is sure to be a major part of future research.

7. *Neuropsychology of Category Learning and Representation*

Neuropsychology raises two important issues concerning categorization (see also *Categorization and Similarity Models: Neuroscience Applications*). First, there is evidence that the mental representations controlling categorization are functionally and neuraly distinct from those accessed in standard 'explicit' tests of memory such as recall and recognition. If this is true, it suggests that models of memory are unlikely to provide any useful input to our understanding of categorization. The main piece of evidence is that amnesic patients suffering from anterograde amnesia seem to behave normally in category learning tasks while being profoundly impaired on tests of recall and recognition (e.g., Squire and Knowlton 1995). For instance, one densely amnesic patient (EP) performed normally in learning to classify dot patterns generated from a prototype, while performing at chance in a recognition test for those patterns. It has been concluded from this that the hippocampus, which controls explicit memory and which is damaged in amnesia, plays no role in category learning.

Recently, however, the conclusion that categorization and memory are functionally and neuraly unconnected has been questioned on the basis of demonstrations that exemplar models such as the GCM can, just like EP, show dissociations between classification and recognition. In Nosofsky and Zaki's (1998) modeling approach, only a single parameter, the sensitivity parameter, was varied in order to account for a general learning difference between amnesics and controls. This parameter represents the ability to discriminate among distinct exemplars stored in memory, an ability which is plausibly reduced in amnesics as a result of their deteriorated memory capacity. Nosofsky and Zaki showed that decreasing the value of this parameter reduced classification performance only slightly, but reduced recognition performance considerably. Thus, the GCM successfully accounts for the dissociation between classification and recognition observed by Squire and Knowlton (1995).

Second, there is now a wealth of evidence concerning the brain localization of category knowledge. Brain imaging studies have suggested that knowledge is organized structurally at the neural level. Martin et al. (1996) studied neural organization of conceptual knowledge by presenting normal participants with pictures of animals and tools to name while brain activity was recorded by positron emission tomography (PET). As a control, participants saw nonsense objects. Compared to the control condition, brain activity for the meaningful objects was increased in the ventral temporal lobes bilaterally and in Broca's area in the left hemisphere. The latter is probably related to word generation. Relative to pictures of tools, pictures of animals produced increased activation in the left medial occipital lobe. Relative to pictures of animals, pictures of tools produced increased activation in the left dorsal temporal lobe and the left premotor region. This premotor area is also activated by imagined hand movements, suggesting that part of the conceptual representation of tools is a specification of the hand movements they afford. Overall, Martin *et al.*'s results confirm that gross category distinctions are present in the way the brain organizes conceptual knowledge.

For a fuller review of recent psychological and neuroscience research on models of concept learning and representation, see Lamberts and Shanks (1997).

Conceptual Blending

Conceptual blending is a basic mental operation that leads to new meaning, global insight, and conceptual compressions useful for memory and manipulation of otherwise diffuse ranges of meaning. It plays a fundamental role in the construction of meaning in everyday life, in the arts and sciences, and especially in the social and behavioral sciences. The essence of the operation is to construct a partial match between two inputs, to project selectively from those inputs into a novel 'blended' mental space, which then dynamically develops emergent structure. It has been suggested that the capacity for complex conceptual blending ('double-scope' integration) is the crucial capacity needed for thought and language.

1. Some Simple Examples

1.1 Ritual of the Newborn Baby

In a European ritual, the newborn baby is carried up the stairs of the parents' house as part of a public event. The ritual is meant, symbolically, to promote the child's chances of rising in life. One input is the ordinary action of carrying a baby up the stairs. The other input is the schematic space of life, already structured so that living a life is metaphorically moving along a path, such that good fortune is up and misfortune is down. In a partial match between these inputs, the path up the stairs corresponds to the course of life, the baby is the person who will live this life, the manner of motion up the stairs corresponds to how the person 'goes through' life, and so on. In the symbolic ritual, the two inputs are blended, so that the ascent of the stairs is the course of life; an easy ascent is an easy rise in life for the person that the baby will become; stumbling or falling might take on extraordinary significance.

1.2 Boat Race

A famous example of blending is 'the boat race' or 'regatta.' A modern catamaran is sailing from San Francisco to Boston in 1993, trying to go faster than a clipper that sailed the same course in 1853. A sailing magazine reports:

> As we went to press, Rich Wilson and Bill Biewenga were barely maintaining a 4.5 day lead over the ghost of the clipper *Northern Light*, whose record run from San Francisco to Boston they're trying to beat. In 1853, the clipper made the passage in 76 days, 8 hours (Great America II, 1993 *Latitude 38* **190**: 100).

Informally, there are two distinct events in this story, the run by the clipper in 1853 and the run by the catamaran in 1993 on (approximately) the same course. In the magazine quote, the two runs are merged into a single event, a race between the catamaran and the clipper's 'ghost.' The two distinct events correspond to two input mental spaces, which reflect salient aspects of each event: the voyage, the departure and arrival points, the period and time of travel, the boat, its positions at various times. The two events share a more schematic frame of sailing from San Francisco to Boston; this is a 'generic' space, which connects them. Blending consists of partially matching the two inputs and projecting selectively from these two input spaces into a fourth mental space, the blended space (see Figure 1).

Figure 1
The blended space

In the blended space, we have two boats on the same course, that left the starting point, San Francisco, on the same day. Pattern completion allows us to construe this situation as a race (by importing the familiar background frame of racing and the emotions that go with it). This construal is emergent in the blend. The motion of the boats is structurally constrained by the mappings. Language signals the blend explicitly in this case by using the expression 'ghost-ship.' By 'running the blend' imaginatively and dynamically—by unfolding the race through time—we have the relative positions of the boats and their dynamics.

Crucially, the blended space remains connected to the inputs by the mappings, so that real inferences can be computed in the inputs from the imaginary situation in the blended space. For example, we can deduce that the catamaran is going faster overall in 1993 than the clipper did in 1853, and more precisely, we have some idea ('four and a half days') of their relative performances. We can also interpret the emotions of the catamaran crew in terms of the familiar emotions linked to the frame of racing.

The 'boat race' example is a simple case of blending. Two inputs share structure. They get linked by a cross-space mapping and projected selectively to a blended space. The projection allows an emergent structure to develop on the basis of composition, pattern completion (based on background models), and elaboration ('running the blend').

1.3 Clinton and Roosevelt

The type of conceptual blend just discussed (technically called a 'mirror network' because the same frame organizes both inputs) is very general. For example, a political comment on Clinton's presidency after he had been in office a few months might have been: *by this point*, *Roosevelt was far ahead of Clinton*. The two inputs are Roosevelt's and Clinton's presidencies. They are mapped onto each other in a natural way: starting points, mid-points, and so on are matched. In the blend, Roosevelt and Clinton are brought together within the same timeframe, so that they are competing against each other. Blends of this sort are routinely elaborated for reasoning purposes in political analysis.

1.4 Fictive Motion

Languages have means of describing static scenes in terms of fictive motion: *The fence runs all the way down to the river*. This works by having an 'imaginary' trajector move along the relevant dimension of an object, in this case the fence, or along some 'imaginary' path linking two objects. This is a remarkable mode of expression: it conveys motion and immobility at the same time. Objective immobility is expressed along with perceptual or conceptual motion. This apparent contradiction is a consequence of conceptual blending, which allows several connected but heterogeneous mental spaces to be maintained simultaneously within a single mental construction. An input space containing a static scene of a fence and a river is blended with an input space that contributes a moving trajector on a path with a reference point.

1.5 Counterfactuals

Human thought depends heavily on the capacity for counterfactual thought, and counterfactuals are complex blends. Most of us can effortlessly understand statements like 'In France, Watergate would not have hurt Nixon.' This counterfactual is intended to highlight some differences between the American and French cultural and political systems. It is a blend that brings in aspects of the French system from one input and the Watergate scandal and President Nixon from the other. In the blend, we have a Watergate-like situation in France. Running this blend delivers attitudes quite different from those in the American input, and so in the blend, the president is not harmed. Counterfactuals can blend frames and identities in powerful ways (*If I were you*, …). Such blends have been shown to play a major role for reasoning in the natural and social sciences.

1.6 Computer Interfaces

A nice example of conceptual blending in action and design is the 'desktop' interface, in which the computer user moves icons around on a simulated desktop, gives alphanumeric commands, and makes selections by pointing at options on menus. Users recruit from their knowledge of office work, interpersonal commands, pointing, and choosing from lists. All of these are 'inputs' to the imaginative invention of a blended scenario that serves as the basis for integrated performance. Once this blend is achieved, it delivers an amazing number of multiple bindings across quite different elements, bindings that seem, in retrospect, entirely obvious. A configuration of continuous pixels on the screen is bound to the concept 'folder,' no matter where that configuration occurs on the screen. Folders have identities, which are preserved. The label at the bottom of the folder in one view of the desktop corresponds to a set of words in a menu in another view. Pushing a button twice corresponds to opening. Pushing a button once when an arrow on the screen is superimposed on a folder corresponds to 'lifting into view.' Of course, in the technological device that makes the blend possible, namely the computer interface, there is no ordinary lifting, moving, or opening happening at all, only variations in the illumination of a finite and arranged number of pixels on the screen. The blend is not the screen: the blend is an imaginative

mental creation that lets us use the computer hardware and software effectively. In the blend, there is lifting, moving, opening, and so on happening, but imported not from the technological device at hand, which is only a medium, but from another input, namely our mental conception of work we do on a real desktop.

2. The Network Model

Conceptual blending is described and studied scientifically in terms of integration networks. In its most basic form, a conceptual integration network consists of four connected mental spaces: two partially matched input spaces, a generic space constituted by structure common to the inputs, and the blended space. The blended space is constructed through selective projection from the inputs, pattern completion, and dynamic elaboration. The blend has emergent dynamics. It can be 'run,' while its connections to the other spaces remain in place. Neurobiologically, it has been suggested that elements in mental spaces correspond to activated neural assemblies and that linking between elements corresponds to neurobiological binding (e.g. co-activation). On this view, mental spaces are built up, interconnected, and blended in working memory by activating structures available from long-term memory. Mental spaces can be modified dynamically as thought and discourse unfold.

Four main types of integration networks have been distinguished: Simplex, Mirror, Single-Scope, Double-Scope. In Simplexes, one input consists of a frame and the other consists of specific elements. A frame is a conventional and schematic organization of knowledge such as 'buying gasoline.' In Mirrors, a common organizing frame is shared by all spaces in the network. In Single-Scopes, the organizing frames of the inputs are different, and the blend inherits only one of those frames. In Double-Scopes, essential frame and identity properties are brought in from both inputs. Double-Scope Blending can resolve clashes between inputs that differ fundamentally in content and topology. This is a powerful source of human creativity. The main types of networks just mentioned are actually prototypes along a continuum that anchors our intuitive everyday notions about meaning to a unified understanding of the unconscious processes at work. Varieties of meaning traditionally considered unequal or even incommensurable—categorizations, analogies, counterfactuals, metaphors, rituals, logical framing, grammatical constructions—can all be situated on this continuum. Conceptual blending has been shown to operate in the same way at the highest levels of scientific, artistic, and literary thought, and at the supposedly lower levels of elementary understanding and sentence meaning. Elaborate blending is at work in superficially very simple expressions like 'safe gun' vs. 'safe child,' 'guilty pleasures,' 'caffeine headache,' or 'money problem.' Emergent structure arises routinely, as in 'This surgeon is a lumberjack', which suggests that the surgeon is incompetent, although *incompetence* is neither a feature of *surgeon* nor of *lumberjack*.

There are opposing pressures within an integration network to maximize topology matching, integration, unpacking of the blend, web connections, compression, and intentionality. More complex integration networks ('multiple blends') allow multiple input spaces and successive blending in which blends at one level can be inputs at another.

3. Compression

Blending is a remarkable tool of compression over vital relations like time, space, cause-effect, identity, and change. In the Newborn Ritual, time is compressed: an entire lifetime becomes, in the blend, the short time it takes to climb the stairs; in the Nixon counterfactual, space is compressed (Watergate can be in France); in the desktop interface, the complex sequence of events which move the mouse horizontally and cause an apparent vertical motion of the arrow (and other 'objects') on the screen is compressed and integrated into a single action, moving the arrow. This is a compression of space, cause-effect, and change.

4. Range of the Cognitive Operation

A systematic study of conceptual blending was initiated in 1993 by Gilles Fauconnier and Mark Turner (1998), who discovered the structural uniformity and wide application of the notion. Since then, important work has been done on the theory of conceptual blending (Coulson 2001), and its empirical manifestations in mathematics (Robert 1988), social science (Sweetser in press, Turner 1996a, 1996b), literature (Freeman 1997, Oakley 1998, Turner 2000), linguistics (Lidell 1998, Mandelblit 1997), and music (Zbikowski 1999). There have been proposals for the mathematical and computational modeling of the operation (Goguen 1999, Veale 1999), and experimental research within neuroscience on the corresponding neural and cognitive processes (Coulson 2001, Grush and Mandelblit 1997). Additional information and an extensive bibliography can be found on website (http://www.wam.umd.edu/~mturn/WWW/blending.html).

G. Fauconnier

Conceptual Change, Cognitive Psychology of

Conceptual change was one of the most popular notions in the areas of cognitive development and science education in the 1980s and 1990s. This notion, inspired by ideas proposed by philosophers of science such as T. Kuhn (1970), was originally introduced to denote a fundamental change in a concept, conception, or conceptualization with an increase in age, expertise, or instruction.

1. *Inevitability of Conceptual Change*

The key idea of conceptual change presupposes the domain-specificity of cognitive growth, instead of focusing on general logical structures across domains, as Piaget's developmental view assumed. It also presumes, unlike Piaget's view, that even young children have coherent bodies of knowledge about important aspects of the world. Proponents of conceptual change claim that such bodies of knowledge often constitute naive 'theories' containing ontological distinctions, coherent organizations among pieces of knowledge, and causal devices or explanations as essential components (Wellman 1990). They assume that humans have a basic tendency to construct a model or theory to make sense of an observed set of data. Some innate principles constrain this process of construction in a few selected domains that are critical for survival. However, because construction of the initial theory is based on a limited database, it has to be revised as more and more facts are incorporated into the body of knowledge, unless the initial set of observed facts constitutes a representative sample of all relevant facts. Some of the innate principles may be weakened or given up, as accumulated pieces of prior knowledge come to serve as constraints, which also makes conceptual change during childhood inevitable.

2. *Conceptual Change as Fundamental Restructuring*

The notion of conceptual change in cognitive development has been proposed as an alternative to 'enrichment views' (Carey 1985); it denotes that conceptual development involves not just enrichment or elaboration of the existing knowledge systems but their considerable reorganization or restructuring. Conceptual change involves change in core concepts, conceptions, or conceptualizations. Knowledge systems before and after the conceptual change may sometimes be locally incommensurable; that is, some pieces of knowledge in one system cannot properly be translated into the other, as exemplified by the shift from children's undifferentiated concept of heat/temperature to adults' separate concepts of heat and temperature, or the shift from the simple disjunction between animals and plants to a single, integrated concept of living things.

Conceptual change often takes the form of theory change, because concepts are considered to be embedded in theories; changing one core concept in a

theory generates changes in related concepts and eventually leads to a change in the whole set of concepts. Theory change involves changes in causal devices or explanations and/or changes in the phenomena or entities that are included. Four types of theory change can be distinguished with regard to the relationship between an old theory (as the prechange system) and a new theory (as the postchange system). First, a new theory emerges from an old theory with the latter being subsumed in, or replaced by, the former. For example, between ages 2 and 4–5, the early theory of mind, which is based solely on desire and perception, is transformed into the 'representational theory of mind', which includes beliefs as well (Gopnik and Wellman 1994).

Second, a new theory emerges and develops from an old one, and the latter continues to exist, although it becomes less salient. Sometimes the old theory is even extended by the new theory. For example, Perner (1991) claims that, although at about 4 years of age children's understanding of the mind changes from a 'situation theory' (where mental states are construed in relation to situations) to a 'representational theory' (where mental states are understood as serving representational functions), the latter does not replace the former but merely extends it; even adults may be situation theorists when possible, but they, unlike young children, can take a representational view when necessary. Another example is the conceptual change in naive biology that takes place approximately between ages 6 and 10 or older. Young children tend to understand biological phenomena by relying on vitalistic causality, whereas older children and adults use mechanistic causality. However, vitalistic causality continues to function as a basis of understanding and to be used in situations where people do not think they are required to reason using so-called scientific biology (Hatano and Inagaki 1996).

Third, a new theory emerges from an old one through differentiation, and new and old theories develop separately afterwards. For example, when considering biological phenomena, very young children often apply a theory in which psychology and biology are undifferentiated, whereas older children rely on a purely biological theory (Carey 1985). Another example is the emergence of a theory of matter from a theory of physics in which objects and the materials from which they are made are not fully distinguished (Smith et al. 1985).

Fourth, a new theory emerges through the integration of old subtheories. For example, young Israeli children consider plants neither living things nor nonliving things, but 'growers' (Stavy and Wax 1989). In contrast, they easily recognize animals as living by attending to their self-initiated movement. In other words, young children seem to possess different theories for animals and plants. As they grow older, they acquire a theory of living things by integrating these different subtheories of animals and plants.

It should be noted that conceptual change seldom occurs suddenly, just as it has taken years for concepts, conceptions, or conceptualizations to change in the history of science. The process of conceptual change tends to be slow and gradual, even if its end result is drastically different from its initial state.

3. *Spontaneous vs. Instructionally-based Conceptual Change*

Forms of conceptual change can also be distinguished in terms of whether the change occurs spontaneously or is induced by instruction (Hatano and Inagaki 1996, Vosniadou and Ioannides 1998). Spontaneous conceptual change is the change that results from children's enriched experience in their physical and sociocultural environment. In other words, it occurs without systematic instruction, though schooling certainly has some general facilitative effects on it. This form of change seems to occur readily, because it is usually found among most children growing up in highly technological societies. An example is the change that occurs in young children's naive biology, i.e., the change from a biology that is personifying and vitalistic in nature to one relying on inference based on complex, hierarchically organized biological categories and mechanistic causality (Hatano and Inagaki 1997). Another example, drawn from physics (Vosniadou and Ioannides 1998), is the change from the internal force model (that there is an internal force within stationary and moving heavy objects) to the acquired force model (that there is an acquired force within moving objects only).

Instructionally based conceptual change occurs as a product of systematic science education, more specifically, by incorporating scientific concepts and thereby correcting 'misconceptions' (alternative conceptions based on limited databases). The acquisition of synthetic mental models of the earth (Vosniadou and Brewer 1992) or of scientific biology having conceptual devices such as 'photosynthesis' or 'evolution' (Hatano and Inagaki 1996) is a good example of instructionally based forms of conceptual change. This form of conceptual change requires systematic teaching, and even with good teaching, only a limited portion of older children and adults may achieve it. Many studies in science education have reported that instructionally based conceptual change is difficult to induce (e.g., Clement 1982).

Cognitive developmentalists have been primarily concerned with spontaneous conceptual change, and have focused on specifying the initial state (initial theory) and just sketching the consequences of changes, rather than specifying the exact mechanisms of its change. Science educators, in contrast, have primarily been interested in instructionally based conceptual change, attempting to achieve the goal state (an understanding of scientific theory) as an

instructional aim. Both research groups have been working in parallel until recently. However, developmentalists have now become interested in instructionally based change as an aid for specifying the possible mechanisms of spontaneous conceptual change. Meanwhile, science educators are trying to incorporate findings on spontaneous conceptual change into the design of their instruction.

4. Mechanisms of Conceptual Change

We have three sets of data on how conceptual change occurs: from the history of science, conceptual development, and science education. Although these different sets of data differ markedly in terms of time span, the complexity of target entities and phenomena, the degree of intellectual sophistication of the individuals involved, and many other variables, they all illuminate some mechanisms of conceptual change.

It is clear that in every case increased knowledge is required for conceptual change, and that the prechange system serves as a cognitive constraint in conceptual change. A general mechanism for change is the spreading of the truth-value alteration. When new inputs change the truth-value of some pieces of knowledge, the changes bring about changes in the truth-value of other connected pieces, which may induce further changes in their neighbors. Thus, there can be a drastic change in almost all pieces through continued spreading and recurring effects. Those individuals who monitor the truth-value of pieces of knowledge constituting a theory (e.g., scientists) may be sensitive to and respond to a small amount of disconfirmation or discoordination. A good example is the 'thought experiment' including limiting case analyses, as indicated by Galileo's famous thought experiment showing that heavier objects do not fall faster than lighter ones (Nersessian 1992).

However, the spreading of the truth-value alteration works as a mechanism of conceptual change only when constituent pieces of knowledge of both old and new theories are available in the knowledge structure. Individuals may stick to the old theory even when predictions from it are not supported, if they do not think of any alternative theory, model, or interpretation. Thus, conceptual change may be triggered by analogy that suggests an alternative view. Using analogies, people map their knowledge about the source to the present new case (target) so that they can make a coherent interpretation of the set of observations for the target, or even build a tentative theory. Dunbar (1995) reports that scientists in real-world laboratories often rely on analogy to generate new ideas when faced with inconsistent experimental findings.

Social interactions, including group discussion, can be sources for generating inconsistencies or discoordinations in individuals' existing knowledge systems, because different perspectives are presented in the interactions, and they can also be sources for providing possible solutions. In this sense, discussion or question answering can contribute to the occurrence of conceptual change. Thus, conceptual change may be induced through discursive interactions even among less sophisticated thinkers (Hatano and Inagaki 1997). It can also be a powerful mechanism of inducing conceptual change among scientists, as reported by Dunbar (1995).

5. Issues Yet to Be Studied

Some psychologists emphasize the roles of motivational factors such as goals, interests, values, and so on as mediators of the process of conceptual change. A number of studies on classroom learning, for example, strongly suggest that learners' different goal orientations lead to different processes of conceptual change (Pintrich et al. 1993). However, we know very little about these variables.

Another unsolved issue is how the conscious monitoring of multiple knowledge systems and the flexible switches among the systems are acquired. One of the differences between young children's naive theory and adults' intuitive theory is that the latter has metaconceptual components, probably as a result of conceptual change. We do not know much about this issue because it has been neglected in conceptual change research.

Conditioning and Habit Formation, Psychology of

Research on *conditioning and habit* broadly is concerned with how organisms learn the *what*, *where*, *and when* of their niche: what prey and threats they have to deal with, where they may be found, and when they are most likely to be encountered. These are complex problems but their solutions can be surprisingly simple, so long as they are clever.

Conditioning and habit involve learning about *contingencies*—if-then relationships—between biologically important stimuli and behavior. Conditioning involves learning signals for *stimuli*, *stimulus–stimulus* contingencies, such as between the odor of a lemon and acidity; habits involve learning about the consequences of behavior, *response–stimulus* contingencies, such as learning how to crack open an oyster to extract its flesh. The *mechanisms* of learning serve the organism by *selecting* the best signals for stimuli and the effective actions leading to reward. In terms of adaptation, conditioning helps the organism to prepare for forthcoming stimuli and habit learning allows the organism to learn from experience. Despite its apparent plasticity, learning is highly biologically constrained, every species is differently affected by particular stimuli and consequences as defined by its ecological niche, while the processes of learning themselves remain identical across species.

Learning is studied by arranging environmental *operations*, such as response–stimulus contingencies, and analyzing the behavioral *process* they generate. Behavior is sensitive to many interacting variables. For this reason, much research in learning has been carried out with animal subjects for whom stricter control of operations is possible, but most findings have been replicated with human subjects. Meanwhile, however, people with pragmatic interests in managing human behavior in educational, clinical, industrial, and correctional facilities, have benefited greatly from our understanding of learning.

1. History

Psychological investigation has been responsible for unraveling the intricacies of learning, but the central questions were first recognized by philosophers and biologists. The philosopher Descartes proposed two sources of behavior, a reflexive–mechanical body that connected the body to the physical world and a rational–spiritual mind that explained language, memory, and intellect. Intuitively, the Cartesian dualism captures the striking contrast between reflexes we all share, and the many idiosyncratic differences that make each unique. The first half of the Cartesian dichotomy was supported in the eighteenth century when Whytt and others isolated the spinal reflexes, but the assumption of native mental knowledge was harder to endorse. *Empiricist* philosophers such as Locke supplied a viable alternative position, that complex knowledge could be explained by the accumulated experience of *associated* ideas. By the mid nineteenth century Alexander Bain offered an associationist theory of *action*. Prompted by speculation of the physiologist, Johannes Müller, Bain proposed that in addition to reflexes, organisms randomly emitted spontaneous nonpurposive movements. When one of these movements produced a pleasurable outcome, it would be repeated because the 'muscle sense' produced by the action would be associated with pleasure. This early conception of habit acquisition gained acceptance amidst the rising tide of Darwinism by providing a mechanistic alternative to the creationist spirit implicit in Descarte's mentalism.

Approximately 40 years later, Edward L. Thorndike published the first experimental demonstrations showing how behavior could be affected by its consequences. One of his cat 'puzzle boxes' is shown in Fig.

Figure 1
Thorndike's 1898 cat puzzle box and Skinner's 1938 rat lever box. Pulling on (A) the ring opens (B) the door, giving the cat access to (C) the food. The inset above the puzzle box is a learning curve, showing how latency to pull the ring decreased over trials. In the rat lever box, (A) the white light signals when pressing (B) the lever will produce (C) a food pellet. The inset above the lever box shows a cumulative record, recording lever presses and reinforcements in real time

1. Latency to escape from the box was long initially but gradually shortened. Thorndike called the behavior he observed in the puzzle-box, 'trial-and-error learning' and formulated the *Law of Effect*, stating that pleasurable consequences 'stamped in' responses and annoying consequences 'stamped out' responses.

Coincident with Thorndike's research, the Russian physiologist Ivan P. Pavlov accidentally discovered the *conditioned salivation reflex* in the dog. In the course of studying digestive reflexes, Pavlov noted that his dogs began to salivate while their food was being prepared, before the food made contact with the dog's mouth. He realized that more than a simple reflex was involved—the dog had learned a signal for food—initiating an extensive research program to study *conditioned reflexes*. Fig. 2 shows the setup he used to study stimulus–stimulus contingencies. Pavlov demonstrated conditioning with many other reflexes, leading him to claim that conditioned reflexes could explain all complex behavior including language.

Initially Pavlov's work eclipsed Thorndike's because of arguments that the Law of Effect might be explained by conditioned reflexes. But in the 1930s, B. F. Skinner endorsed the present view that Thorndike and Pavlov had discovered different processes. In time, conditioned reflexes became identified with *Pavlovian conditioning* and habit with *operant conditioning* (emphasizing that responses *operate* on

Figure 2
Pavlov's 1904 apparatus to study conditioned reflexes in the dog. In a typical conditioning trial, the dog was first presented with (A) a tone from a tuning fork, and closely followed by (B) food presented through a trap door. Saliva from the mouth was measured by (C) a recording device before and during each trial

the environment). Skinner made a number of important contributions to the study of operant behavior, including an automated experimental chamber to study reinforcement with rats and a *cumulative recorder* to record behavior in time (Fig. 1). His simplest box contained a lever, a food dispenser, and a light to signal the availability of food. Unlike puzzle boxes and mazes that studied learning in a trial-by-trial format, Skinner's automated apparatus permitted analysis of 'free-operant behavior,' the real-time interaction between behavior and the environment. He used his apparatus to conduct numerous critical experiments on reinforcement, including studies of discrimination learning and reinforcement schedules.

The genesis of experimental psychology in the early twentieth century was accompanied by disputes over the proper methods of investigation and the role of inference from behavior to mechanism. John B. Watson in 1913 proposed a 'Behaviorist' program, arguing that psychology should reject the introspective methods popular in his day and instead be founded only on publicly observable behavior. Watson's program is now called *methodological behaviorism*, and to the extent that psychological concepts are founded on observable behavior, his ideas have been widely accepted. Thorndike, Pavlov, and Watson, among many others, were committed to physiological *reductionism*, explaining behavior by inferring its underlying physiology. Skinner pushed for a truly independent science of behavior based entirely on the study of behavior–environment interactions, a program he called *radical behaviorism*. Behaviorism in turn was countered by *cognitivism* and *neo-behaviorism*. Both argue that behavior can be used to make reductionist inferences about nonphysiological mechanisms that mediate between the environment and observable behavior, such as *memory* and *associative* processes. The later half of the twentieth century has witnessed the rise of mathematical, dynamic models of behavior, called *quantitative behaviorism*, that describe mediators of behavior in terms of mathematical functions. This alternative to cognitivism seeks to model behavior–environment interactions mathematically, but the models are seen only as analytical tools to determine the minimum set of mechanisms required to explain behavior, and not to make mediational inferences. Despite philosophical differences, all of these views continue to have proponents and make contributions to the understanding of behavior.

Researchers and theorists have since broadened the relevance of Pavlovian and operant conditioning to economics, language, problem solving, and other varieties of complex behavior. At the same time, the science of learning has come increasingly to recognize that behavior is constrained by biological endowment. Despite repeated attempts to reduce Pavlovian and operant conditioning to a single process, they differ in essential ways. Although strong parallels occur in the effects of contingencies and contiguity, and in stimulus functions, response functions differ markedly.

2. Contingency and Contiguity

In a *reflex*, a stimulus *elicits* a response; in an *operant*, an *emitted* behavioral response produces a stimulus and the behavior becomes more or less likely to occur in the future, depending on whether the consequence is a *reinforcer* or a *punisher*. Fig. 3 illustrates these basic relationships.

Organisms are very sensitive to stimulus situations, or signals, present when stimuli occur. Signals impart enormous complexity in behavior by giving rise to the *conditioned reflex* and *discriminated operant* (Fig. 3). In Pavlov's conditioned reflex experiments with dogs, food was paired with a tone, and the dog began to salivate upon hearing the tone. In Skinner's discriminated operant experiments with rats, lever presses could produce food pellets when a stimulus light was on but not when the light was off, and the rats came to press the lever only when the light was on. For a conditioned reflex, the *conditioned stimulus* (CS) *elicits* a *conditioned response* (CR); for a discriminated operant, the discriminative stimulus (S^D) *occasions* an *emitted response*.

2.1 Contingency

Effects of operant and Pavlovian operations depend on *contingencies*, the conditional probabilities between stimuli and responses shown in Fig. 4. Operant behavior and Pavlovian conditioning require a *positive* contingency in which a consequence or a US is most likely after a response or a CS, respectively. A *zero* contingency, in which the occurrence of a stimulus is independent of other events, will not support operant behavior or Pavlovian conditioning. The inadequacy of a zero contingency shows that *contiguity*, the concurrence between an operant response and a

Figure 3
Reflex and operant relationships between stimuli and responses. Unfilled arrows in the upper diagrams show causal directions in reflex and operant behavior: in the reflex, a stimulus produces a response (R, *a*); in the operant, an operant response produces a reinforcing stimulus (S^R, *b*). Lower diagrams illustrate the addition of signals (indicated by bold lines). In the *conditioned reflex*, the conditioned stimulus (CS) signals the presentation of an unconditioned stimulus such as food (US); the US elicits an unconditioned response (UR; *a*) and the CS elicits a conditioned response (CR; *c*). In the *discriminated operant*, a discriminative stimulus (S^D) signals when responses (*d*) are scheduled to have consequences (S^R; *b*), responses occurring in the absence of stimuli (*e*) have no consequences. The S^D can also become a CS because of the way it is paired with the S^R

Figure 4
Operant and Pavlovian contingencies. Diagrams on the left depict the occurrence and non-occurrence of operant responses (R) and stimuli (S^R) over 10 intervals of time. Diagrams on the right show the occurrence and non-occurrence of a Pavlovian CS and US over 10 conditioning trials. Contiguous occurrences of events are indicated by arrows labeled *a*. In the *positive* operant contingency (upper left), there are four responses and each produces a *contiguous* reinforcer and there are no reinforcers without prior responses: the probability of a stimulus given a response (i.e., a consequence) is higher than the probability of a stimulus given no response. In the operant zero contingency (middle left), the two conditional probabilities are equal. And in the operant *negative* contingency, (bottom left) the probability of a stimulus given a response is lower than the probability of a stimulus given no response. Operant contingencies are complicated by the fact that a stimulus may follow a response after a delay (indicated by arrow *b*). In Pavlovian conditioning, positive, zero, and negative contingencies are defined in the same manner except that probabilities are calculated for the US given a CS and given no CS

consequence or between a CS and US, is not sufficient for learning; there must also be a positive contingency. While zero contingencies do not generate reinforcement effects, prior exposure to noncontingent, unpredictable stimuli can significantly retard subsequent learning of reinforcement contingencies.

2.2 Contiguity

Operant consequences are most effective if they are contiguous with responses and less effective if they are delayed—contingency is necessary but not sufficient. In animals, delays of just a few seconds can severely weaken a reinforcer; and reinforcers that are delivered independently of responses, as in a zero contingency, diminish the effect of contiguous reinforcers. Negative contingencies, also called *differential reinforcement of other behavior*, are an effective way to reduce problem behavior in applied settings.

Pavlovian conditioning is also sensitive to the temporal relation between the US and CS—contingency is not sufficient. Of the five possible temporal relations shown in Fig. 5, the most effective is *short-delay* conditioning in which the onset of the CS precedes the onset of the US by no more than a second. *Simultaneous* conditioning is least likely to produce conditioning; *backward* conditioning tends to make the CS an *inhibitory* stimulus because it is correlated with the absence of the CS; and *long-delay* and *trace* produce intermediate levels of conditioning. Taken together, these findings indicate that Pavlovian conditioning is strongest when the CS is a good predictor of the US in time. The one exception is *taste aversion learning*, an example of ecological *preparedness*—illness can produce aversion to a food even if it follows consumption by several hours.

2.3 Extinction

Conditioned reflexes and operant responses can be weakened by *extinction*. Operant behavior maintained by reinforcement can be reduced in frequency by terminating the reinforcement contingency or by delivering reinforcers independently of responses.

Figure 5
Temporal relations between CS and US in Pavlovian conditioning

Discontinuing a punishment contingency almost always results in the recovery of the punished behavior. A CS can be *extinguished* by presenting it without the US or by removing the correlation with the US. Extinction procedures do not erase the effects of contingencies but instead produce additional learning. In the case of operant behavior, organisms stop responding because they learn that the operant contingency is broken—extinguished responses reappear without additional training when a reinforcement contingency is reinstated. In the case of Pavlovian extinction, the organism learns that the CS now signals the absence of the US.

2.4 Operant–Pavlovian Interactions

Conditioned reinforcers and *conditioned punishers* can be generated by Pavlovian procedures. For example, if an odor is paired with food, the odor will elicit salivation as a CS but it can also serve as a conditioned reinforcer for an operant response. Conditioned punishers are created in the same way. Conditioned stimuli greatly enhance delayed consequences, for example, a delayed reinforcer will still be very effective as long as a stimulus bridges the gap between the response and the reinforcer (as in long-delay conditioning in Fig. 5). However, the effects are transitory unless the association between the conditioned stimulus and the reinforcer is maintained.

An operant S^D can become a Pavlovian CS for operant consequences such as food. The S^D then serves two functions that may produce competition between elicited and emitted responses. An example from the animal-training literature is shown in Fig. 6. A pig was reinforced with food for depositing coins in a bank. Shortly after learning the operant, the pig began 'rooting' the coins—pushing them along the ground, the pig's species-typical food handling behavior. As a result of the operant contingency the coin enters into a positive Pavlovian contingency with food and elicits rooting.

Figure 6
'Misbehavior' in the pig—conflicting operant and Pavlovian responses. The pig was trained to deposit coins in the bank for food reinforcers, but extended periods of rooting come to disrupt the operant contingency. The inset shows that, in the pig's natural behavior, food elicits reflexive rooting and eating. This creates a Pavlovian contingency between the coin CS and the food US, whereby the coin comes to elicit conditioned rooting

Punishment can reduce the frequency of operant behavior for a similar reason—a painful, punishing consequence reduces behavior because it elicits species-typical defensive behavior such as escape and avoidance. The result is that 'punisher' reduces the target behavior but not just by being a consequence of that behavior; it would still reduce the operant behavior even if arranged in a zero contingency. A

conditioned aversive stimulus, such as a tone paired with shock, will similarly interfere with operant behavior. As a rule, reinforcers are most effective when the responses they elicit are identical to or compatible with a reinforced response and punishers are most effective when the responses they elicit are incompatible with the punished response. For example, it is easy to reinforce pecking in the pigeon with food because food elicits pecking.

3. *Response Functions*

Consequences in operant behavior and US's in Pavlovian conditioning can be *appetitive*, like food, or *aversive*, like a very loud noise. The same stimulus can generate different kinds of adaptive behavior depending on the contingency, the kind of organism, and the organism's previous experience.

3.1 *Operant Responses*

In operant behavior, responses can accrue or remove stimuli, and the stimuli can be appetitive or aversive. In positive reinforcement and negative reinforcement response rate increases by addition of appetitive stimuli or removal of aversive stimuli; positive punishment and negative punishment decreases response rate by addition of aversive stimuli or removal of appetitive stimuli. Negative reinforcement includes escape, removal of an already present aversive stimulus, and avoidance, prevention or postponement of an aversive stimulus.

Operant responses can include everything from a rat's lever press maintained by food, an infant's crying maintained by maternal attention, and small talk maintained by social companionship. The form of an operant response depends on (a) environmental constraints, such as the height of a reinforcement lever and force required to operate it, (b) the behavior emitted by the organism, and (c) behavior elicited by the consequence (illustrated by Fig. 6). Once a response is reinforced, its form tends to be repeated in a stereotyped manner. Reinforcement will 'capture' whatever behavior the organism emits that is contiguous with the reinforcer; even if some features are unessential to the reinforcement contingency.

Reinforcement narrows the range of variability in emitted behavior by *selecting* its successful forms (not necessarily the most efficient behavior), making them more frequent and thereby displacing less effective forms. Predatory species, for example, show adjustments in hunting behavior as a result of their effectiveness. The *differential reinforcement* of some responses to the exclusion of others is called *shaping*. Shaping is analogous to natural selection in that different responses function like the phenotypic variations required for evolutionary change. Without variation, changes in reinforcement contingencies could not select new forms of behavior. Despite the tendency for reinforcement to produce stereotyped behavior, it never reduces variations in behavior entirely. Variability returns to emitted behavior in extinction, a potentially adaptive reaction to dwindling resources. Creativity can also serve as the basis for reinforcement (e.g., if reinforcers are contingent on the emission of novel behavior.)

Restriction operations, such as food deprivation, are necessary for reinforcement—the response elicited by the reinforcer, such as feeding, must have some probability of occurring for the reinforcer to be effective. In rats, restricting an activity such as running in a wheel will make the activity a reinforcer for drinking, even thought the rat is not water restricted. Findings like this suggest that reinforcers may best be understood in terms of the activities they produce and that the reinforcement process involves the organism's behaving in order to maintain set levels of activities.

Once an organism learns a response-reinforcer contingency, the likelihood of the response will reflect the value of the reinforcer. For example, if a rat drinks sugar water and becomes ill, it will no longer emit behavior previously reinforced with sugar water.

A great deal of behavior is maintained by negative reinforcement, including *avoidance* in which responses prevent the occurrence of aversive stimuli, and *escape* in which responses terminate an existing aversive stimulus. Much research has been directed to avoidance because it is maintained in the absence of contiguity—*responses prevent reinforcement*. In some cases, avoidance is maintained by deletion of an immediately present *conditioned* aversive (warning) stimulus, an avoidance condition that preserves contiguous reinforcement. But organisms will work to prevent or delay aversive events without the benefit of warning stimuli, showing that avoidance does not require a Pavlovian aversive contingency. Avoidance is closely linked to punishment because organisms frequently learn to avoid places associated with punishment, a pragmatic concern for advocates of punishment.

The timing, rate, and persistence of an operant response depends on its *reinforcement schedule*, a constraint on earning reinforcers that requires the organism to wait for the next available reinforcer, emit a number of responses, or some combination of both. Fig. 7 shows typical patterns of behavior on four simple schedules. In an *interval* schedule, a reinforcer is produced by the first response after the passage of a specified interval of time. In a *ratio* schedule, a reinforcer is produced after the emission of a specified number of responses. Time or response requirements can either be a fixed or variable. Response rate on both ratio and interval schedules increases with reinforcement rate up to a point, and then decreases again at high rates of reinforcement. At low rates of reinforcement or during extinction, behavior on ratio schedules alternates between bouts of rapid responding and

Figure 7
Typical response patterns on four simple schedules of reinforcement: fixed interval, fixed ratio, variable interval, and variable ratio. Ratio schedules produce higher rates of responding than interval schedules at a giver rate of reinforcement, and fixed schedules show longer pausing after reinforcement than variable schedules

pauses, while responses on interval schedules simply occur with lower frequency. Extinction is prolonged after exposure to reinforcement schedules—especially after exposure to long interval- or large ratio-schedules.

When rate of reinforcement in interval and ratio schedules is equated, organisms respond at higher rates on ratio schedules (although the difference is small at very high rates of reinforcement). Organisms are sensitive to the fact that the rate of reinforcement in ratio schedules increases directly as a function of response rate, but not in interval schedules.

Characteristic pausing or *waiting* occurs after earning a reinforcer. Waiting is determined by the currently expected schedule and not because of the reinforcer. Fixed-interval and fixed-ratio schedules produce long wait times, and variable-interval and variable-ratio schedules produce short wait times. Waiting on fixed-interval schedules is reliably a fixed *proportion* of the interval value. In VI and VR schedules, wait times are heavily influenced by the shortest inter-reinforcement intervals or ratios in a schedule. Waiting is obligatory—organisms will wait even when doing so reduces the immediacy and overall rate of reinforcement. In schedules that require a single response, with the reinforcer occurring a fixed time after the response, the optimal strategy is to respond immediately in order to minimize delay, but organisms still wait a time proportional to the fixed time before making the response that leads to reinforcement.

Schedules can be combined in almost limitless ways to study questions dealing with choice, conditioned reinforcement, and other complex behavioral processes. In experiments on choice between two *concurrent* variable-interval schedules, the relative preference of many organisms, including humans, will closely match the percentage of reinforcement provided by each schedule. With choices between different fixed-interval schedules, the preference for the shorter interval is far greater than predicted by the relative intervals, indicating that the value of a delayed reinforcer decreases according to a decelerating function over time. Conditioned reinforcers have been studied with *behavior chains* in which one signaled schedule is made a consequence of another, for example, a one-minute fixed interval schedule signaled by a red stimulus leads to another one-minute fixed interval signaled by a green stimulus, until a terminal reinforcer is obtained. Behavior extinguishes in the early schedules of chains with three or more schedules, to the extent that reinforcement is severely reduced. Possibly conditioned reinforcers must be contiguous with primary reinforcers to effectively maintain behavior; alternatively obligatory waiting in the early schedules extends the time to the terminal reinforcer, lengthening the time to reinforcement, and generating even longer waiting.

3.2 Pavlovian Responses

Pavlovian conditioning, based on reflexes that serve prey capture, feeding, defense, escape, reproductive behavior, and care of offspring, has been demonstrated with a vast number of conditioned stimuli. Conditioned responses include fear (e.g., acceleration in heart rate and perspiration), sexual arousal, and immunological responses. Pavlovian conditioning serves the organism by permitting it to anticipate the stimuli that elicit these reflexes, so it should follow that the conditioned response should resemble the unconditioned response. (A notable exception occurs with drug US's, for example, the UR to morphine is euphoria, but the CR to a CS for administration (e.g., a syringe) is illness rather than euphoria.)

The form of the conditioned response can be influenced by both the US and CS. For example, in the rat, a localized-light CS paired with a food US produces rearing on the hind legs, but the same localized-light paired with shock will produce muscular tension; while a tone paired food leads to an increase in activity. A Pavlovian positive contingency produces excitatory conditioning in that the CR becomes more likely; while a Pavlovian negative contingency produces inhibitory conditioning in that the CR becomes less likely (Fig. 4). For example, fear will be elicited by a tone CS that reliably precedes a shock US; but a light that reliably precedes periods of

Figure 8
Acquisition, maintenance, and extinction of a Pavlovian CR, eye-blink in the rabbit, with different percent pairing between the CS and US (from Gibbs et al. 1978)

no shock will inhibit fear when paired with CS for shock. A conditioned inhibitor can also be produced by occasionally pairing a stimulus with an excitatory CS (a compound CS) while omitting the US or when a CS is extinguished.

Acquisition of a CR proceeds in a negatively accelerated pattern, illustrated in Fig. 8. Also shown in Fig. 8 is the effect of reducing the probability of a US given a CS (keeping the probability of a CS given no US at zero). Reducing the number of times a CS presentation is followed by a US has the effect of slowing acquisition, reducing the asymptotic number of trials with a CR, and slowing extinction. The acquisition and probability of the CR is also greatly affected by the ratio of CS duration divided by the inter-US interval, with smaller ratios producing higher CR probabilities.

A number of experiments have addressed the question of whether Pavlovian conditioning involves learning associations between the CS and the US, or between the CS and the UR. In experiments in which the CS is paired with a US while the UR is pharmacologically blocked, subjects show a CR to the CS after the block is removed, suggesting CS–US learning. But the matter has not been resolved because the US might still be activating efferent centers in the nervous system.

4. *Signal Functions*

Organisms can only respond adaptively to contingencies if they provide reliable signals in the form of CS's and discriminative stimuli. In order to maximize

efficiency, an organism must learn a signal after minimal trials, recognize variations, and reject similar but invalid stimuli. Moreover, the organism can't afford to make too many mistakes or spend too much time learning each variant. The ecological constraints are similar in Pavlovian and operant conditioning, so stimulus functions in both share many features.

4.1 Attention, Blocking, and Preparedness

Organisms do not attend to all stimuli that they can sense when a US or a reinforcer is presented; instead, they are selective. When discriminative stimuli contain multiple dimensions, such as shape and color, organisms may show attention to one dimension and ignore the other. A previously learned CS or discriminative stimulus can also block attention to a stimulus. For example, after pairing a light CS with a food US, further training with a light + tone CS will not produce learning of the tone CS. This blocking effect shows that contingency and contiguity are not sufficient for learning about signals—learning will only take place if there are no other reliable signals present.

Attention has a strong genetic component because contingencies associated with a particular niche tend to have predictable signals. Rhesus monkeys will fear a snake CS if it is presented with a fear response US from another monkey, but not a flower CS paired with the same US. In operant behavior, several food-storing birds selectively attend to the spatial locations of food sites and not their non-spatial aspects such as colors. In each case, the animal attends to the most ecologically relevant cue.

4.2 Discrimination and Generalization

An organism must generalize responding to stimuli that are different to the training stimulus, but not too different. With many stimuli, such as tones and colors, generalization shows a peak around the CS or discriminative stimulus that is called a *generalization gradient*—the probability of responding decreases as a function of difference from the training stimulus. Fig. 9 shows a typical generalization gradient for operant behavior. Discriminative stimulus control is tighter (peaked gradient) when reinforcement in the presence of the discriminative stimulus was alternated with periods without the stimulus (presence–absence training), in comparison to training without extinction periods (nondifferential training). This finding illustrates that discrimination requires differential training; without differential training, organisms generalize broadly.

Signals in the natural environment are likely to be plants, insects, odors, and so forth. Animals readily learn these *natural concepts*. Experiments investigating the basis of concept learning in animals find that some concepts such as cars require training with several examples but others, such as an oak leaf, can be learned after a single exemplar.

Figure 9
Generalization gradients from pigeons after nondifferential training with a 1000 Hz tone, and presence-absence training with and without the tone (from Jenkins and Harrison 1960)

4.3 Conditional Discrimination and Occasion Setting

Reinforcement can be made contingent on conditional relationships between stimuli. In an identity matching task, a pigeon is reinforced for responding on the basis of similarity: selecting the 'triangle' comparison is conditional on the 'triangle' sample. Conditional discrimination is the basis of symbolic behavior. For example, when prompted with 'What color?' in the presence of a blue square, we say 'Blue'; and with 'What shape?' we say, 'square.'

Animals and humans can learn conditional discriminations such as 'same' and 'different,' as well as symbolic matching between arbitrarily related stimuli such as words and their referents. However only humans can demonstrate certain kinds of emergent conditional discriminations. Once humans learn the symbolic stimulus relation, 'if stimulus A then B,' they can respond correctly to a symmetry test, 'if B then A,' without further training. The variables that explain symmetry are not yet understood; the ability may be a uniquely human accomplishment possibly emerging with language. Interestingly, however, both humans and other species show transitivity: 'if A then B' and 'if B then C'; therefore, 'if A then C.'

In Pavlovian conditioning, a stimulus that signals when a CS will be followed by a US will modulate the CR to the CS. For example, if tone + light CS is followed by a food US, but light by itself signals no food, then light will only show a food CR if tone is also present. Tone in this example is called an *occasion*

setter, and its effects can be shown to be generalized to modulate a CR to other CS's trained with other occasion setting stimuli and US's.

5. *Applications*

The principles of Pavlovian conditioning and operant behavior have been applied to solve numerous practical problems. Pavlovian extinction procedures have proven effective in the treatment of phobias; and clinics have found that conditioned nausea to hospitals after chemotherapy can be prevented by giving patients flavored candy to eat during administration, producing nausea to the flavor and not the hospital. Reinforcement procedures have similarly found many applications. The concept of conditioned reinforcement is behind token economies used in schools and correctional institutions; shaping procedures are being used in programmed instruction with computers; the matching principle has been applied to the reduction of maladaptive behavior in persons with mental retardation without the need for punishment; various principles have been applied to problems of treatment adherence in drug dependency programs; and principles of discrimination learning have been used to develop highly effective language training programs for children with autism. Our understanding of Pavlovian and operant conditioning mechanisms continues to provide simple yet sophisticated approaches to complex problems.

Conduct Disorder

Conduct disorder (CD) refers to antisocial behaviors in children and adolescents. These behaviors encompass a variety of acts that reflect social rule violations and actions against others such as fighting, lying, truancy, and stealing (Robins 1991, Kazdin 1995). Many of these behaviors are seen in most children over the course of development. CD is reserved for instances in which antisocial behaviors lead to impairment in everyday functioning, as reflected in unmanageability at home and at school or dangerous acts that affect others. This article discusses characteristics, onset, and course of CD and intervention strategies.

1. *Key Characteristics*

1.1 *Diagnosis and Prevalence*

CD is the psychiatric diagnostic category for antisocial behavior among children and adolescents (American Psychiatric Association 1994). Table 1 lists the main symptoms. A diagnosis of CD is provided if (a) the individual shows at least three symptoms; (b) within the past 12 months; (c) with at least one of the symptoms evident in the last 6 months.

The prevalence of a disorder refers to the percentage of cases in the population at a given point in time. Among community samples of school-age samples, the prevalence of CD is ~ 2–6 percent. The estimate is conservative in representing the scope of the problem. Children who approach but do not quite meet the

Table 1
Symptoms included in the diagnosis of conduct disorder

1	Bullying or threatening others
2	Fighting
3	Using a weapon that can cause serious physical harm to others
4	Being physically cruel to people
5	Being physically cruel to animals
6	Stealing and confronting a victim (e.g., mugging, purse snatching, extortion, armed robbery)
7	Forcing someone into sexual activity
8	Firesetting
9	Destroying property of others
10	Breaking into someone else's house, building, or car
11	Frequent lying or 'conning' others
12	Stealing without confronting a victim
13	Staying out late at night despite parental prohibitions
14	Running away from home
15	Being truant from school

Table 2
Long-term prognosis of youths identified as conduct disorder: overview of major characteristics likely to be evident in adulthood

Characteristic in adulthood[a]	Description
Psychiatric status	Greater psychiatric impairment, including antisocial personality, alcohol and drug abuse, and isolated symptoms (e.g., anxiety, somatic complaints); also, greater history of psychiatric hospitalization
Criminal behavior	Higher rates of driving while intoxicated, criminal behavior, arrest records, and conviction, and period of time spent in jail
Occupational adjustment	Less likely to be employed; shorter history of employment, lower status jobs, more frequent change of jobs, lower wages, and depend more frequently on financial assistance (welfare). Served less frequently and performed less well in the armed services
Educational attainment	Higher rates of dropping out of school, lower attainment among those who remain in school
Marital status	Higher rates of divorce, remarriage and separation
Social participation	Less contact with relatives, friends, and neighbors; little participation in organizations such as church
Physical health	Higher mortality rate; higher rate of hospitalization for physical (as well as psychiatric) problems

a These characteristics are based on comparisons of clinically referred children identified for CD relative to control clinical referrals or normal controls or from comparisons of delinquent and nondelinquent youths (Pepler and Rubin 1991, Peters et al. 1992)

criteria are likely to have significant impairment in everyday lives. Boys show ~ 3–4 times higher rates of CD than girls. The sex differences may be explained by differences in predispositions toward responding in aggressive ways. Age variations reveal interesting patterns in prevalence rates. Rates of CD tend to be higher for adolescents (~ 7 percent for youths aged 12–16 years) than for children (~ 4 percent for children aged 4–11 years).

1.2 Correlates and Associated Features

Children who meet diagnostic criteria for CD are likely to show a number of other problem behaviors (Robins and Rutter 1990, Pepler and Rubin 1991). They are likely to argue with adults, lose their temper, actively defy and refuse to comply with requests, deliberately annoy others, and are angry and resentful. A large percentage of children (e.g., 40–70 opening) diagnosed with CD also evince hyperactive behavior and meet criteria for attention-deficit/hyperactivity disorder (ADHD). The core symptoms of ADHD include inattention, impulsiveness, and hyperactivity.

Children with CD are also likely to show academic deficiencies. They are more likely to repeat a grade, to show lower achievement levels, and to end their schooling sooner than their peers. Such children often are socially ineffective in their interactions with adults (e.g., parents, teachers, community members) and engage in behaviors that promote deleterious interpersonal consequences such as peer rejection. In general, CD is associated with a wide variety of other child characteristics that reflect maladjustment in everyday life.

Several parent and family characteristics are associated with CD, including parent psychopathology and maladjustment, criminal behavior, and alcoholism. Parents of children with CD are likely to show especially harsh, lax, erratic, and inconsistent discipline practices. Within the families, there are often less supportive and more defensive communications among family members, unhappy marital relations, and interpersonal conflict. Untoward living conditions are also associated with CD including overcrowding, poor housing, and high-crime neighborhoods.

1.3 Onset and Course of Conduct Disorder

Research has identified subtypes in an effort to find meaningful ways of grouping various sets of symptoms and accounting for prevalence differences over the course of development. Two patterns are currently receiving major attention. *Child-onset CD* begins in early childhood and with such behaviors as stubbornness, noncompliance, and hyperactivity that can progress to conduct problems. Youths with child onset are more likely than those with adolescent onset to engage in aggressive and criminal behavior and are more likely to continue their dysfunction into adulthood. *Adolescent-onset CD* is more common than child onset. During adolescence, many youths engage in criminal behavior. For many of these youths, the acts are isolated and short-lived (Ketterlinus and Lamb 1994). Both child- and adolescent-onset CD youths engage in illegal behavior during adolescence. However, those with child onset are more likely also to engage in aggressive acts and to be represented primarily by boys.

Longitudinal studies show that CD in childhood predicts aggressive and antisocial behavior up to 30 years later. Among CD youths identified in childhood, slightly less than 50 percent continue their CD into adulthood. If all diagnoses are considered, rather than continuation of CD alone, slightly over 80 percent are likely to show a psychiatric disorder as adults. A broad set of characteristics CD youths are likely to show when they become adults are highlighted in Table 2. As the table indicates, individuals with a history of CD evince a broad range of untoward outcomes.

2. *Factors that Influence Onset of Conduct Disorder*

Risk factors refer to characteristics, events, or processes that increase the likelihood (risk) for the onset of a problem or dysfunction. Risk factors, as antecedents to the dysfunction, may provide clues as to development and progression of CD, possible mechanisms and processes through which the dysfunction comes about, and foci for possible intervention. Several factors that predispose children and adolescents to CD are highlighted in Table 3.

Even under very adverse conditions with multiple risk factors present, many individuals will not experience adverse outcomes. *Protective factors* refer to characteristics, events, or processes that decrease the impact of a risk factor and likelihood of an adverse outcome. Protective factors are identified by studying individuals known to be at risk show several risk factors and by delineating subgroups of those who do, versus those who do not, later show CD. Among a high risk sample, children are less likely to develop CD if they are first born, are perceived by their mothers as affectionate, show high self-esteem and locus of control, and have alternative caretakers in the family (than the parents) and a supportive same-sex model who played an important role in their development. Other factors that reduce or attenuate risk include above-average intelligence, competence in various skill areas, getting along with peers, and having friends.

It is not clear how risk and protective factors operate. As an exception, parenting practices (e.g., harsh punishment, attending to aggressive child behavior) have been well studied. These practices directly contribute to CD and altering these practices reduces aggressive and antisocial child behavior (Pepler and Rubin 1991, Patterson et al. 1992).

3. *Interventions*

3.1 *Treatment*

Conduct problem symptoms constitute the most frequent basis for which children and adolescents are referred for treatment. Consequently, there is a need for effective interventions. Many different treatments have been applied, including psychotherapy, pharmacotherapy (medications), home, school, and community-based programs, residential and hospital treatment, and assorted social services. Few treatments have been carefully evaluated in controlled studies and shown to reduce CD problems and to improve functioning of the child in everyday life (Kazdin 2000). Three of the more well studied treatments are highlighted here.

Parent management training refers to a treatment in which parents are trained to interact with the child in ways that promote prosocial behavior. The treatment focuses on the use of reinforcement (e.g., praise, tokens), mild punishment (e.g., brief time out, response cost), and related techniques (e.g., prompting, shaping) to develop child behavior. Extensive research has shown that many parent–child interaction patterns in the home unwittingly foster and escalate child aggressive behavior. Parent management training teaches skills to the parent, develops interactions between parents and the child that promote positive parent and child behavior, and in the process decreases aggressive and antisocial behavior.

Cognitive problem-solving skills training is based on research showing that conduct problem youths often show distortions in various cognitive processes (e.g., how individuals perceive, code, and experience the world, as reflected in beliefs, attributions, and expectations). A variety of cognitive processes pertain to interactions with others, including the ability to generate solutions to interpersonal problems and consequences of action (e.g., what would happen after a particular behavior). Problem-solving skills therapy develops skills in approaching interpersonal situations and teaches ways to identify prosocial or adaptive solutions and alternative consequences of actions. Children practice using the approach in treatment sessions and at home with their parents.

Multisystemic therapy focuses on the child behavior within the context of various systems (e.g., the family, peer group, schools) that may contribute to the child's problem behavior or could be used to help alter that behavior. A focus on the family as a system is designed to build better communication, to reduce negative interactions, and to improve the ability of the parents to function. Factors that can affect these interactions and the child's problems, such as stress that the parent experiences, marital conflict, association of the child with a deviant peer group, are focused on also. Many different techniques are applied to address these areas. Parent management training and problem-solving skills training, mentioned previously, are often incorporated into treatment.

3.2 *Prevention*

Prevention programs come in many different forms (McCord and Tremblay 1992, Mrazek and Haggerty

Table 3
Factors that place youths at risk for the onset of conduct disorder

Factor[a]	Description
Child factors:	
Child temperament	A more difficult child temperament (on a dimension of 'easy -to-difficult'), as characterized by more negative mood, lower levels of approach toward new stimuli, and less adaptability to change
Neuropsychological deficits and difficulties	Deficits in diverse functions related to language (e.g., verbal learning, verbal fluency, verbal IQ), memory, motor coordination, integration of auditory and visual cues, and 'executive' functions of the brain (e.g., abstract reasoning, concept formation, planning, control of attention)
Subclinical levels of CD	Early signs (e.g., elementary school) of mild ('subclinical') levels of unmanageability and aggression, especially with early age of onset, multiple types of antisocial behaviors, and multiple situations in which they are evident (e.g., at home, school, the community)
Academic and intellectual performance	Academic deficiencies and lower levels of intellectual functioning
Parent and family factors:	
Prenatal and perinatal complications	Pregnancy- and birth-related complications including maternal infection, prematurity and low birth weight, impaired respiration at birth, and minor birth injury
Psychopathology and criminal behavior in the family	Criminal behavior, antisocial personality disorder, and alcoholism of the parent
Parent–child punishment	Harsh (e.g., severe corporal punishment) and inconsistent punishment increase risk
Monitoring of the child	Poor supervision, lack of monitoring of whereabouts, and few rules about where youth can go and when they can return
Quality of the family relationships	Less parental acceptance of their children, less warmth, affection, and emotional support, and less attachment
Marital discord	Unhappy marital relationships, interpersonal conflict, and aggression of the parents
Family size	Larger family size, i.e., more children in the family
Sibling with antisocial behavior	Presence of a sibling, especially an older brother, with antisocial behavior
Socioeconomic disadvantage	Poverty, overcrowding, unemployment, receipt of social assistance ('welfare'), and poor housing
School-related factors:	
Characteristics of the setting	Attending schools where there is little emphasis on academic work, little teacher time spent on lessons, infrequent teacher use of praise and appreciation for school work, little emphasis on individual responsibility of the students, poor working conditions for pupils (e.g., furniture in poor repair), unavailability of the teacher to deal with children's problems, and low teacher expectancies

a The list of risk factors highlights major influences. The number of factors and the relations of specific factors to risk are more complex than the summary statements noted here (Robins and Rutter 1990, Peters et al. 1992, Kazdin 1995)

1994). Early intervention programs with the family have been effective in reducing conduct problems. High-risk families are identified, usually by such factors as low socioeconomic status, low educational attainment, and high-stress living conditions. Intervention programs sometimes begin before the child is

born to provide counseling regarding maternal care, to provide support in the home to reduce stress, and to prepare the parents for child-rearing demands. After the infant is born, the program may continue for a few years to help support parents, to develop cognitive skills of the child, and to enroll the child in a preschool program. Youths who have received such programs, as they become adolescents, show lower arrest rates, higher levels of educational attainment, and less substance use and abuse than other youths who did not receive early intervention.

Prevention programs are often conducted in the schools because there are opportunities to provide programs to youths in larger numbers, in the context of peers, and on a regular basis for extended periods. Programs often focus on developing positive skills and success experiences at home and at school. The reason for this focus is that bonding to deviant peers and poor connections with the family are risk factors for such behaviors as delinquency and substance abuse. Developing such success experiences in the schools among elementary school children has increased bonding to families and decreased rates of antisocial behavior and substance abuse. To date, the evidence shows that preventive interventions can have a significant impact on CD.

3.3 Social Policy

Social policy refers to governmental and legislative efforts to implement changes to benefit society or a particular segment of society and, in this sense, is a social intervention. There are many influences on the levels of aggression and violence that are society wide, depending on the country and culture. For example, the use of corporal punishment in child-rearing and school discipline, violence in the media (television and films), and social practices that permit or facilitate violence (e.g., availability of hand guns) influence aggressive and antisocial child behavior.

There have been many promising large-scale programs to curb influences on child conduct problems. For example, the use of corporal punishment (i.e., physical aggression against children) contributes to child aggression. Corporal punishment in child discipline at home and at school has been banned in a number of countries (e.g., Austria, Denmark, Finland, Norway, and Sweden) (Greven 1992). As another example, a large-scale effort was implemented in Norway to curb bullying among children. Parent, teachers, and peers were involved in a national effort that was effective in changing the ethos of interactions among youths. In the USA, preschool educational programs (Head Start) are designed to improve child development in disadvantaged families and to have a broad impact on child functioning. In general, social policy interventions are more difficult to implement and to evaluate than treatment and prevention. Policy practices are often subject to changes in laws, are often expensive, and require special monitoring procedures to ensure effective implementation (American Psychological Association 1993).

4. Conclusions

Conduct disorder in children and adolescents is a very active area of research. Efforts focus on understanding the emergence and course of disorder and the many child, parent, family, contextual, and societal influences that may operate. Research also focuses on interventions. Although treatment, prevention, and social policy changes were distinguished, the general view among professionals is that interventions at each of these levels are required in order to have a marked impact on the problem. For many individuals, severe antisocial behavior and associated dysfunction in multiple spheres represent a life-long pattern. Because the disorder is often passed from parents to children, efforts to understand and intervene are critically important. Many questions remain about CD and its course. Even so, much of the available knowledge can have an impact on the problem.

Confessions: Psychological and Forensic Aspects

A confession is any written or oral statement in which a person admits to having committed some transgression, often indicating acknowledgement of guilt for a crime. In some settings, confessions are considered necessary for absolution, social acceptance, freedom, or physical and mental health, making it easy to understand why people often exhibit an 'urge to confess.' However, in other settings confessions predictably result in personally damaging consequences to the confessor—such as a loss of money, liberty, or life itself—making it difficult to understand this aspect of human behavior.

Confessions have played a multifaceted and powerful role throughout history. There are three venues of human social interaction in which one person's confession to another has proved important: religion, psychotherapy, and criminal justice. In religion, the scene of the penitent with the Catholic priest, occurring inside a small, private, and hallowed stall known as a confessional, serves to remind us that all of the world's major religions advise or oblige adherents to confess to their transgressions as a means of moral cleansing. In psychotherapy, the image of the emotionally distressed patient laying on a couch, in tears, while self-disclosing deep, dark, personal secrets to his or her analyst, illustrates the widely held belief in the healing power of 'opening up' the past—including memories of one's actual or imagined misdeeds. In criminal justice, of course, the classic image of the beleaguered suspect being grilled by police behind the locked door and under the bright light of the interrogation room, serves as a stark reminder that, in the law, the self-incriminating statement is considered the most potent evidence of guilt.

1. *Confession in Religion*

All major religions of the world—Buddhism, Christianity, Hinduism, Islam, and Judaism—provide a mechanism and encouragement for followers to acknowledge and disclose their transgressions. The purposes served by such confessions are twofold: to cleanse the individual's soul and to police the community, thus serving as a deterrent to wrongdoing.

Religions vary in terms of how, when, where, and to whom confessions are given, and even whether they are made in private or in public. Profound differences exist even within Christianity. For example, the Quakers, Unitarians, and others are encouraged to confess their sins to themselves, through private prayer. Others, such as Catholics and the Greek and Russian Orthodox have more formal rituals whereby followers confess, often at a designated time or place, to ministers or priests. The adoption of this model was particularly explicit in the year 1215 when the Roman Catholic Church, in the Fourth Lateran Council, made the rite of an annual confession obligatory for all adherents. In other religions, the confession to be given depends on the nature of the misdeed. Among American Southern Baptists, for example, people are required to disclose their sins to those they have specifically harmed—such as a spouse, an employer, or the entire congregation.

2. *Confession in Psychotherapy*

People in many parts of the world have long believed that confession is good not only for the soul but also for the body and the mind. Several years ago, anthropologist Weston La Barre (1964) found that many Native Americans of North and South America believed that physical and mental health required purity, which in turn required exposure—often through elaborate confession ceremonies involving shamans and witch doctors. Similar notions have permeated Western medicine ever since Josef Breuer and Sigmund Freud (1895) observed that patients often felt better after purging their minds of material buried in the unconscious. This discovery gave birth to Freud's *Psychoanalysis*, the first systematic form of 'talking cure,' and now forms the basis for many modern psychotherapies and social support groups.

Recent research confirms the healing power of opening up to someone else about one's problems, transgressions, victimizations, and other unpleasant truths. In a series of controlled experiments, James Pennebaker (1997) and others brought research subjects into a laboratory and asked them to talk into a tape recorder or write for 20 minutes either about past traumas or about trivial daily events. While speaking or writing, the subjects were upset and physiologically aroused. Many tearfully recounted accidents, failures, personal wrongdoings, instances of physical or sexual abuse, and other issues. Soon, however, the subjects felt better than ever. Thus, while systolic blood pressure levels rose during the disclosures, they later dipped below pre-experiment levels. The subjects even exhibited a decline in their number of doctor visits over the next six months.

Other studies, too, have shown that keeping confessional secrets can be stressful and that 'letting it out' and 'getting it off your chest' can have therapeutic effects on health—effects that are especially strong when the events being described are highly traumatic (Smyth 1998). For example, in a study of women who had an abortion, those who talked about it to an experimenter—compared to those who did not talk about it—were later less haunted by intrusive thoughts about the experience (Major and Gramzow 1999). In another study, researchers identified 80 gay men newly infected with the HIV virus but who had no symptoms, administered various psychological tests, and monitored their progress every six months for nine years. They found that in men who were partly 'in the closet'—compared with those who had openly confessed rather than concealed their homosexuality—the infection spread more rapidly, causing them to die sooner (Cole et al. 1996). This provocative correlation does not prove that 'coming out' is healthier than 'staying in.' In a controlled laboratory experiment, however, subjects who were told to suppress rather than express turbulent emotional thoughts exhibited a temporary decrease in the activity of certain immune cells (Petrie et al. 1998).

3. *Confessions in Law*

In criminal law, confession evidence is a prosecutor's most potent weapon—so potent, as one legal scholar put it, that 'the introduction of a confession makes the other aspects of a trial in court superfluous' (McCormick 1972). On the one hand, confessions play a vital role in law enforcement and crime control. On the other hand, they serve as a source of recurring controversy, with questions often arising about whether a statement is authentic, voluntarily given, the product of a competent waiver of rights, and in accord with the law. For all of these reasons, confessions have been described as 'troubling' (Brooks 2000).

3.1 *Rules of Confession Evidence and Procedure*

To guard the integrity of the criminal justice system, to protect citizens against violations of due process, and to minimize the risk that innocent people would confess to crimes they did not commit, American courts have erected guidelines for the admission of confession evidence. According to the historical overview proposed by Wigmore (1970), the modern law's treatment of confession evidence has evolved through a series of stages. In England, during the sixteenth and seventeenth centuries, there was no restriction on the use of confessions. All avowals of guilt were accepted at face value. Thus, at least through the middle of the seventeenth century, physical torture was used to extract self-incriminating statements. In contrast, by the nineteenth century, the judiciary was highly cynical of confessions and quick to repudiate them for a lack of reliability. Currently, as in the twentieth century, confessions are not accepted or rejected outright but, rather, each is judged according to a 'totality of the circumstances' and the requirement that it be considered voluntary. Thus, confessions are typically excluded if elicited by brute force, prolonged isolation, a deprivation of food or sleep, threats of punishment or harm, promises of immunity or leniency, or without notifying a suspect of his or her rights (Grano 1993 Kamisar et al. 1999).

In cases involving a disputed confession, a preliminary hearing is typically held in which a judge determines whether a confession was voluntary and hence admissible as evidence. In American courts, the trial judge will then either admit confessions deemed voluntary without special instruction, or he or she may specifically direct the jury to make an independent judgment of voluntariness and disregard statements found to be coerced.

3.2 *Methods of Police Interrogation*

Many years ago, interrogators used bright lights, brute force, the rubber hose, and physical intimidation to get confessions. Today, the police are required to warn suspects of their 'Miranda' rights to silence and to an attorney (Leo and Thomas 1998)—and the use of physical force has given way to psychologically oriented techniques such as feigned sympathy and friendship, appeals to conscience and religion, the presentation of false evidence, the alternation of good cop and bad cop, and other forms of trickery and deception. Today, a number of manuals are available for training the police in how to elicit confessions through interrogation. The most popular of the manuals is Inbau et al. (2001) *Criminal Interrogation and Confessions*, first published in 1962 and now in its fourth edition.

Inbau et al. (2001) advise the police to put suspects into a small, barely furnished, soundproof room—a physical environment designed to promote feelings of social isolation, helplessness, and discomfort. They then present a nine-step procedure for overcoming the suspect's resistance. According to this method, the interrogator begins by confronting the suspect with his or her guilt (Step 1), then develops psychological 'themes' that justify or excuse the crime (Step 2), interrupts all statements of denial (Step 3), overcomes the suspect's factual, moral, and emotional objections to the charges (Step 4), ensures that the increasingly passive suspect does not mentally withdraw (Step 5), shows sympathy and understanding, and urges the suspect to tell the truth (Step 6), offers the suspect a face-saving alternative explanation for his or her guilty action (Step 7), gets the suspect to recount the details of the crime (Step 8), and converts that statement into a full written confession (Step 9).

Kassin and McNall (1991) note that there are two general approaches contained within this method of interrogation. One is to pressure the suspect into submission by expressing certainty in his or her guilt—a goal that, at times, leads interrogators to falsely state or imply that they have damaging evidence such as fingerprints or an eyewitness. In this way, the accused is led to believe that it is futile to mount a defense. The second approach is to befriend and sympathize with the suspect and 'minimize' the offense by offering face-saving excuses—such as suggesting that the crime was provoked by the victim, or was accidental. This technique may lead a suspect to anticipate leniency, which provides an inducement to confess. Research shows that these tactics are often used (Gudjonsson 1992, Kassin 1997). In an observational study of 182 interrogations, for example, Leo (1996) found that detectives used an average of five to six tactics per suspect.

3.3 The Psychology of False Confessions

As prescribed, police interrogations should lead guilty suspects to incriminate themselves by reducing the perceived negative consequences of confessing while, at the same time, increasing the anxiety associated with continued deception. It could be argued that interrogation is not overly coercive in that innocent people do not confess to crimes they did not commit. This assumption is incorrect. Nobody knows the incidence of false confessions or has devised an adequate method of calculating their prevalence. The pages of history and current events make it clear, however, that there are many documented false confessions on the record (Borchard 1932, Gudjonsson 1992, Leo and Ofshe 1998, Radelet et al. 1992, Wrightsman and Kassin 1993). In fact, among the first 62 prisoners to be exonerated by DNA evidence, 15 had given full or partial false confessions (Scheck et al. 2000).

Regardless of the precise numbers of such cases, Kassin and Wrightsman (1985) identified three different types of false confession: voluntary, coerced-compliant, and coerced-internalized. This categorization scheme has provided a useful framework for the study of false confessions and has been adopted by other researchers in the field.

A 'voluntary false confession' is a self-incriminating statement that is offered without external pressure from the police. When Charles Lindbergh's baby was kidnapped in 1932, 200 people confessed. Why would anyone volunteer a false confession? There are several possible motives. Sometimes the goal is to protect a friend or relative—a problem often revealed in interviews with juvenile offenders. Other possible motives include a pathological need for fame, acceptance, recognition, or self-punishment.

In contrast to voluntary false confessions are those in which suspects confess as a result of intense interrogation pressures. Within the category of coerced false confessions, it is necessary to further distinguish between two forms of social influence: compliance and internalization. In the common language of social psychology, compliance refers to a change in one's public behavior for instrumental purposes. This form of influence was observed in early studies of conformity by Asch (1956) and research on obedience to authority by Milgram (1974). In contrast, internalization refers to a private acceptance of the beliefs espoused by others. This deeper form of influence was exhibited in early autokinetic studies on the formation of group norms (Sherif 1936) and later research on minority influence (Moscovici 1985).

'Coerced-compliant false confessions' occur when a suspect confesses to escape or avoid an aversive interrogation, or to gain a promised or implied reward. In these cases, the confession is an act of decision-making compliance by a suspect who privately knows that he or she is truly innocent. Psychologically, coerced-compliant false confessions are easy to understand, as they arise whenever a suspect comes to believe that the short-term benefits of confessing—such as being left alone, fed, or released—outweigh the long-term costs associated with prosecution, the loss of reputation, and incarceration (Hilgendorf and Irving 1981). Individuals who are characteristically predisposed to exhibit compliance in social influence situations are particularly vulnerable in this regard (Gudjonsson 1989). The pages of legal history are filled with documented false confessions of this nature. In one instance, four young men confessed independently to the massacre of six Buddhist monks in a Phoenix Arizona temple. In that case, a psychiatric inpatient called the police, volunteered a confession, and implicated three other men. His 'accomplices' were then seized and interrogated for several hours through the night. All eventually confessed and spent 70 days in jail—until the real murderers were discovered via ballistics evidence (Parloff 1993).

'Coerced-internalized false confessions' are those in which an innocent person—anxious, sleep-deprived, confused, and subjected to a highly suggestive interrogation that often includes the presentation of false evidence—actually comes to believe that he or she committed the crime. This type of false confession is particularly frightening because the suspect's memory may be altered, rendering its original contents potentially irretrievable. This phenomenon is closely related to recent laboratory and field studies involving the creation of false memories for words in a list, visual images, and past experiences (Garry et al. 1996, Hyman et al. 1995, Loftus 1993, Roediger and McDermott 1995).

Several cases of this sort have appeared in recent years. Consider, for example, the story of 18-year-old Peter Reilly, who returned home one night to find that his mother had been murdered. Immediately he called the police. Despite Reilly's distraught mental and

emotional state, the police interrogated him for 24 hours, during which time they administered a polygraph, which they described as infallible—and which, they claimed, he failed, thus indicating that he murdered his mother despite having no memory of having done so. Transcripts of the interrogation session revealed that Reilly underwent a stark transformation from denial through confusion, self-doubt, conversion ('well, it really looks like I did it'), and the signing of a full written confession. Two years later, independent evidence revealed that Reilly could not have committed the murder, that the confession he came to believe was false (Barthel 1976). Over the years, a number of other such cases have surfaced (Gudjonsson 1992, Kassin 1997, Leo and Ofshe 1998).

Is it really possible to convince people that they are guilty of an act they did not commit? Based on an analysis of past cases, Kassin and Kiechel (1996) theorized that two factors increase the risk: (a) a suspect who lacks a clear memory of the event in question, or whose memory is vulnerable to manipulation, and (b) the presentation of false evidence. To test this hypothesis, they recruited pairs of college students to work on a fast- or slow-paced computer task. At one point, the computer crashed, and students were accused of having caused the damage by pressing a key they had been specifically instructed to avoid. All students were truly innocent and denied the charge. In half the sessions, however, the second student (a confederate) said that she had seen the student hit the forbidden key. Demonstrating the process of compliance, many of the subjects confronted with this false witness signed a confession handwritten by the experimenter. Next, indicating internalization, some subjects later 'admitted' their guilt to a stranger (also a confederate) after the experiment was supposedly over and the two were alone. In short, innocent people made vulnerable to suggestion can be induced to confess and to internalize guilt by the presentation of false evidence—an interrogation tactic commonly used by the police.

3.4 Confessions and the Jury

Legal scholars have long speculated that confessions are the most persuasive form of evidence against a criminal defendant. Research shows that this assumption is correct. In a series of mock jury studies, Kassin and Neumann (1997) inserted a confession, eyewitness identification, or character testimony into various cases otherwise containing only weak circumstantial evidence. Consistently, they found that confessions raised the conviction rate more than did the other common and potent forms of evidence. Whenever a suspect confesses during a coercive interrogation but then withdraws the statement, claiming it was false, the jury is confronted with an attributional dilemma, needing to determine whether the defendant had confessed because he or she was truly guilty (a personal attribution) or because he or she merely sought to avoid the aversive consequences of silence (a situational attribution). According to the logic of attribution theory, jurors should lack certainty about confessions made in response to external pressure. But over the years, studies have shown that people, at least in Western cultures, frequently fall prey to the 'fundamental attribution error'—that is, they tend to make dispositional attributions for another person's actions, while neglecting the role of situational factors (Gilbert and Malone 1995, Jones 1990).

Is it similarly possible that jurors view suspects who confess as guilty, even if they were highly pressured by an interrogator? To examine this question, Kassin and Sukel (1997) had mock jurors read one of three versions of a murder trial. In a control version that did not contain a confession, only 19 percent voted guilty. In a low-pressure version in which the defendant was said to have confessed immediately upon questioning, the conviction rate rose considerably, to 62 percent. But there was a third, high-pressure condition in which subjects were told that the defendant had confessed out of fear and with his hands cuffed painfully behind his back. How did subjects in this situation react? Reasonably, they judged the confession to be coerced, and they said it did not influence their verdicts. Yet the conviction rate in this situation significantly increased, this time to 50 percent. In short, people were powerfully influenced by evidence of a confession—even while conceding that this confession was coerced.

The jury's reaction to confession evidence also depends on how that evidence is presented. Today, it is mandatory in the UK and common in some American police departments to videotape confessions for presentation in court. But how are these events staged for the camera? Attribution research has revealed that observers who watch two people engage in a conversation overemphasize the influence on that interaction of the person who is visually salient (Taylor and Fiske 1978). The same is true of interrogator–suspect interactions. Lassiter et al. (2001) reviewed a series of studies in which researchers taped mock confessions from three different camera angles so that either the suspect or the interrogator or both were visible. All subjects heard the same exchanges of words, but those who focused on the suspect saw the situation as less coercive—and the suspect as more guilty—than did those focused on the interrogator. When the camera directs all eyes on the accused, jurors are thus likely to underestimate the amount of pressure exerted by the 'hidden' interrogator.

3.5 Psychologists as Confession Experts

The problems raised by confession evidence are fundamental to criminal justice, substantial, and

important. Thus, there is a great deal about this aspect of the legal system that warrants the intervention of psychologists for educational and research purposes. It is important to note that intervention in this regard may take several forms, including but not limited to in-court testimony from 'confession experts.' In recent years, a growing number of psychologists have testified, often on behalf of criminal defendants who confessed but then retracted their statements and went to trial. Typically, these experts testify in general terms about the social influence processes of compliance, persuasion, and obedience to authority; suggestibility effects in memory; personality and psychopathology; and other relevant phenomena; in other cases, they offer opinions concerning a specific defendant based on interviews and clinical test results. As both the law and empirical foundations for such expert testimony evolve, it remains to be seen what impact psychological research on confessions will have on police, judges, juries, defendants, and others in criminal justice.

Confidentiality and Statistical Disclosure Limitation

1. *Data Quality Rests on Usefulness and Confidentiality Protection*

We capture enormous numbers of rich personal and proprietary records, store them in data warehouses measured in terabytes, analyze them using sophisticated computers and algorithms, and disseminate them worldwide via telecommunications channels that are cheap and fast. This explosive progress in information technology—look at the World Wide Web—heightens the tension between confidentiality and data access. Accepted principles of information ethics (Duncan et al. 1993) require that promises of confidentiality be preserved and that citizens have substantial access to information. Policies and procedures are needed to reconcile the data provider's interest in confidentiality and the data user's demand for data (Dalenius 1988). Government statistical agencies, such as the US Census Bureau, play a particularly significant and delicate brokering role in this reconciliation of competing demands. They often have legal authority to compel individuals and firms to provide data, and the data are both sensitive—like personal income—and so comprehensive and accurate to be in substantial demand by a broad range of data users. Academic researchers, corporate planners, journalists, and government analysts all seek such data. Other organizations, such as health care providers, necessarily collect data in treating patients that is highly personal. These data are of substantial research value for issues spanning medical quality assurance, cost containment, and access to medical treatment by the poor (Duncan and Kaufman 1996).

A compromise of the confidentiality pledge could harm the agency, the respondent, the public, or some other group. A statistical disclosure occurs when the data dissemination allows data snoopers to gain excessive new information about respondents whereby the snooper can isolate individual respondents and corresponding sensitive attribute values. Miller (1971, p. 176) illustrates the problem.

> Some deficiencies inevitably crop up even in the Census Bureau. In 1963, for example, it reportedly provided the American Medical Association with a statistical list of one hundred and eighty-eight doctors living in Illinois. The list was broken down into more than two dozen categories, and each category was further subdivided by medical specialty and area residence; as a result, identification of individual doctors was possible…

As shown in Fig. 1, the process of assuring confidentiality through statistical disclosure limitation has the following components:

(a) a data quality audit that, beginning with the original collected data, evaluates data utility and assesses disclosure risk;

(b) a determination of adequacy of confidentiality protection;

(c) if confidentiality protection is inadequate, the implementation of a disclosure limitation procedure; and

(d) a return to the data quality audit.

Figure 1
Statistical disclosure limitation process

2. Data Quality Audit: Data Utility and Disclosure Risk

A statistical agency audits the collected data, both to evaluate the utility of the data and to assess disclosure risk. Typically, with good survey design and implementation, the data utility is high. But, also, the risk of disclosure through the release of the original, collected data is too high, even when the data collected have been deidentified, i.e., apparent identifiers (name, e-mail address, phone number, etc.) have been removed. Reidentification techniques have become too sophisticated to assure confidentiality protection (Winkler 1998). A confidentiality audit will include identification of (a) sensitive objects, and (b) characteristics of the data that make it susceptible to attack.

Based on its confidentiality pledges, a statistical agency seeks to protect certain sensitive objects. An agency seeks to protect the instantiation of sensitive objects in the data from a data snooper. Sensitive objects can be the instantiations of a variety of variables associated with a subject entity (person, household, enterprise, etc.). Examples include the values of numerical variables, such as household income, a realization of an x-ray of a patient's lung, and a specific patent application. A second class of sensitive objects is instances of relationships, whether social or mathematical. An example of the former is 'Who is friends with whom?' in a social network; an example of the latter is an Internal Revenue Service formula to trigger a tax audit.

Collected data having particular characteristics pose substantial risk of disclosure. Characteristics that suggest vulnerability include:

(a) geographical detail (Greenberg and Zayatz 1992);

(b) longitudinal or panel structure;

(c) outliers;

(d) many attribute variables;

(e) population data, as in a census, rather than a survey with small sampling fraction; and

(f) existence of databases that are publicly available, identified, and share individual respondents and attribute variables with the subject data.

Data with geographical detail, such as census tract data, may be easily linked to known characteristics of respondents. Concern for this leads statistical agencies to place minimum population levels for geographical identifiers that they will release. Longitudinal data, which tracks entities over time, also poses substantial disclosure risk. Many electrical engineers lived in the Chicago area in 1998 and many electrical engineers lived in the Phoenix area in 1999, but few did both. Outliers, especially on variables like net worth, can easily lead to identifiable respondents. Data with many attribute variables allows easier linkage with known attributes of identified entities, and entities, which are unique in the sample, are more likely to be unique in the population. Further, population data, i.e., a census or near census, pose more disclosure risk than data that arise from a survey having a small sampling fraction. Finally, special concern must be shown when other databases are available to the data snooper and these databases are both identified and share with the subject data both individual respondents and certain attribute variables. Record linkage may then be possible between the subject data and the external database. The shared attribute variables provide the key.

3. Types of Statistical Disclosure

The legitimate objects of inquiry for statistical research are aggregates over individual records, for example, the median annual income of Hispanic social scientists in the United States. The statistical agency seeks to provide users with data that will allow accurate inference about such population characteristics. At the same time, because of confidentiality the statistical agency seeks to thwart the data snooper who might seek to use the disseminated data to draw accurate inferences about, say, the income of a particular Hispanic sociologist who now works in New York City. This capability by a data snooper represents a statistical disclosure.

There are two major types of disclosure—identity disclosure and attribute disclosure. *Identity disclosure* occurs with the association of a respondent's identity and a disseminated data record (Spruill 1983). *Attribute disclosure* occurs with the association of either an attribute value in the disseminated data or an estimated attribute value based on the disseminated data with the respondent (Duncan and Lambert 1989, Lambert 1993). In the case of identity disclosure, the association is assumed exact. In the case of attribute disclosure, the association can be approximate. Most statistical agencies place emphasis on limiting the risk of identity disclosure, perhaps because of its substantial equivalence to the inadvertent release of an identified record—a clear administrative slip up. On the other hand, an attribute disclosure, even though it invades the privacy of a respondent, may not be so easily traceable to actions of the agency.

4. Measures of Disclosure Risk

In the context of identity disclosure, disclosure risk can arise because a data snooper may be able to use the disseminated data product to re-identify some de-identified records. Spruill (1983) proposed a measure of disclosure risk for microdata: For each 'test' record in the masked file, compute the Euclidean distance between the test record and each record in the source file. Determine the percentage of test records that are closer to their parent source record than to any other source record. She defines the risk of disclosure to be the percentage of test records that match the correct

parent record multiplied by the sampling fraction (fraction of source records released).

More generally, and consistent with Duncan and Lambert (1986, 1989), the agency will have succeeded in protecting the confidentiality of a released data product if the data snooper remains sufficiently uncertain about a protected target value after data release. From this perspective, a measure of disclosure risk is built on measures of uncertainty. Further, the agency may model the decision making of the data snooper as a basis for using disclosure limitation to deter inferences about a target. Data snoopers are deterred from publicly making inferences about a target when their uncertainty is sufficiently high. Mathematically, uncertainty functions provide a workable framework for this analysis. Examples include Shannon entropy, which has found use in categorizing continuous microdata and coarsening of categorical data (Willenborg and de Waal 1996, p. 138).

Generally, a data snooper has *a priori* knowledge about a target, often in the form of a database with identified records (Adam and Wortmann 1989). Certain variables may be in common with the subject database. These variables are called *key* or *identifying*. When a single record matches on the key variables, the data snooper has a candidate record for identification. This candidacy is promoted to an actual identification if the data snooper is convinced that the individual is in the target database. This would be the case either if the data snooper has auxiliary information to that effect or if the data snooper is convinced that the individual is unique in the population. The data snooper may find that according to certain key variables that a sample record is unique. The question then is whether the individual is also unique on these key variables in the population. Bethlehem et al. (1990) have examined detection of records agreeing on simple combinations of keys based on discrete variables in the files. Record linkage methodologies have been examined by Fuller (1993) and Winkler (1998).

5. *Restricted Data Through Statistical Disclosure Limitation*

Direct transformations of data for confidentiality purposes are called *disclosure limiting masks* (Jabine 1993). With masked data sets, there is a specific functional relationship, possibly as a function of multiple records and possibly as a stochastic function, between masked values and the original data. Because of this relationship, the possibilities of both identity and attribute disclosures continue to exist, even though the risk of disclosure may be substantially reduced. The idea is to provide a response that, while useful for statistical analysis purposes, has sufficiently low disclosure risk. As a general classification, disclosure-limiting masks can be categorized as suppressions, recodings, or samplings.

5.1 *Suppression*

A suppression is a refusal to provide a data instance. For microdata, this can involve the deletion of all values of some particularly sensitive variable. In principle, certain record values could also be suppressed, but this is usually handled through recoding. For tabular data, the values of table cells that pose confidentiality problems are suppressed. These are the primary suppressions. Often, a cell is considered unsafe for publication according to the (n, p) dominance rule, i.e., if a few (n), say 3, contributing entities represent a percentage p, say 70 percent, or more of the total. Additionally, enough other cells are suppressed so that the values of the primary suppressions cannot be inferred from released table margins. These additional cells are called secondary suppressions. Tables of realistic dimensionality even with only a few primary suppressions present a multitude of possible configurations for the secondary cell suppressions. This raises computational difficulties that can be formulated as combinatorial optimization problems. Typical techniques that are employed include mathematical programming (especially integer programming), and graph theory (Chowdhury et al. 1999).

5.2 *Recoding*

A disclosure-limiting mask for recoding creates a set of data for which some or all of the attribute values have been altered. Recoding can be applied to microdata or to tabular data.

Examples of recoding as applied to microdata include data swapping, adding noise, and global recoding and local suppression. In data swapping (Dalenius and Reiss 1982, Spruill 1983), some fields of a record are swapped with the corresponding fields in another record. Concerns have been raised that while data swapping lowers disclosure risk it may excessively distort the statistical structure of the original data (Adam and Wortmann 1989). A combination of data swapping with additive noise has been suggested by Fuller (1993). Masking through the introduction of additive or multiplicative noise has been investigated (e.g., Fuller 1993). A disclosure limitation method for microdata that is used in the μ-Argus software is a combination of global recoding and local suppression. Global recoding combines several categories of a variable to form less-specific categories. Topcoding is a specific example of global recoding. Local suppression suppresses certain values of individual variables (Willenborg and de Waal 1996). The aim is to reduce the set of records where only a few agree on particular combinations of key values. Both methods

make the data less specific and so result in some information loss to the legitimate researcher.

Some common methods of recoding for tabular data are global recoding and rounding. Under global recoding, categories are combined. This represents a coarsening of the data through combining rows or combining columns of the table. Under rounding, every cell entry is rounded to some base b. The controlled rounding problem is to find some perturbation of the original entries that will satisfy (marginal, typically) constraints and that is 'close' to the original entries (Cox 1987). Multidimensional tables present special difficulties. Methods for dealing with them are given by Kelley et al. (1990).

Markov perturbation (Duncan and Fienberg 1999) makes use of stochastic perturbation through entity moves according to a Markov chain. Because of the cross-classified constraints imposed by the fixing of marginal totals, moves must be *coupled*. This coupling is consistent with a Gröbner basis structure (Fienberg et al. 1998). In a graphical representation, it is consistent with data flows corresponding to an *alternating cycle*, as discussed by Cox (1987).

5.3 Sampling

Sampling as a disclosure-limiting mask creates an appropriate statistical sample of the original data. Alternatively, if the original data is itself a sample, the data may be considered self-masked. Just the fact that the data are a sample may not result in disclosure risk sufficiently low to permit data dissemination. In that case, subsampling may be required to obtain a data product with adequately low disclosure risk.

Whether for microdata or tabular data, many of these transformations can be represented as matrix masks (Duncan and Pearson 1991), $\mathsf{M} = \mathsf{AXB} + \mathsf{C}$, where X is a data matrix, say $n \times p$. In general, the defining matrices A, B and C can both depend on the values of X and be stochastic. The matrix A (since it operates on the rows of X is a record-transforming mask, the matrix B (since it operates on the columns of X is a variable-transforming mask, and the matrix C is a displacing mask (noise addition).

6. Synthetic or Model-based Data

The methods described so far have involved perturbations or masking of the original data. These are called *data-conditioned* methods by Duncan and Fienberg (1999). Another approach, while, less studied, should be conceptually familiar to statisticians. Consider the original data to be a realization according to some statistical model. Replace the original data with samples (the synthetic data) according to the model. Synthetic data sets consist of records of individual synthetic units rather than records the agency holds for actual units. Rubin (1993) suggested synthetic data construction through a multiple imputation method. It remains an open research question as to what the impact of imputation of an entire microdata set is on data utility.

Rubin (1993) asserts that the risk of identity disclosure can be eliminated through the dissemination of synthetic data and proposes the release of synthetic microdata sets for public use. His reasoning is that the synthetic data carries no direct functional link between the original data and the disseminated data. So while there can be substantial identity disclosure risk with (inadequately) masked data, identity disclosure is, in a strict sense, impossible with the release of synthetic data. However, the release of synthetic data may still involve risk of attribute disclosure (Fienberg et al. 1998).

Rubin (1993) cogently argues that the release of synthetic data has advantages over other data dissemination strategies, because

(a) masked data can require special software for its proper analysis for each combination of *analysis* × *masking method* × *database type* (Fuller 1993);

(b) release of aggregates, e.g., summary statistics or tables, is inadequate due of the difficulty in contemplating at the data-release stage what analysts might like to do with the data; and

(c) mechanisms for the release of microdata under restricted access conditions, e.g., user-specific administrative controls, can never fully satisfy the demands for publicly available microdata.

The methodology for the release of synthetic data is simple in concept, but complex in implementation. Conceptually, the agency would use the original data to determine a model to generate the synthetic data. But the purpose of this model is not the usual prediction, control, or scientific understanding that argues for parsimony through Occam's Razor. Instead, its purpose is to generate synthetic data useful to a wide range of users. The agency must recognize uncertainty in both model form and the values of model parameters. This argues for the relevance of hierarchical and mixture models to generate the synthetic data.

7. Summary

A society based on democratic and free market principles cannot function without broad access to data, nor can it sustain those principles without affirming the individual autonomy assured by privacy and confidentiality. Statistical disclosure limitation methods work to ensure that the tension between data access and confidentiality can be resolved in ways that are favourable to both. This methodology draws on disparate fields of mathematics and is challenged to develop in response to the growing capability of information technology to capture, store and dis-

seminate data. To learn more about this topic, see *Private Lives and Public Policies: Confidentiality and Accessibility of Government Statistics* (Duncan et al. 1993), two special issues of the *Journal of Official Statistics* (Jabine 1993 and Fienberg et al. 1998), the Federal Committee on Statistical Methodology 1994 and Duncan and Fienberg (1999).

Configurational Analysis

Configurational analysis (CA) operates at the interface of (a) Stern's (1911) general approach to analyzing variables on the one hand and (b) the person-oriented approach (Magnusson 1998, Bergman and Magnusson 1991) and Stern's differential approach to analyzing individuals on the other. Just as the standard, aggregate approach, CA uses variables to describe individuals. However, the inter-relationships among the variables are not assumed to be necessarily the same for each individual or group of individuals. In this article, CA is described, a theoretical embedding is provided, and methods of CA are introduced, specifically configural frequency analysis (CFA). Sample results from CA are taken from clinical research.

1. Profiles and Configurations

William Stern introduced in 1911 the distinction between the notions of variability and psychography. Variability is the focus when many individuals are observed in one characteristic with the goal to describe the distribution of this characteristic in the population. Psychographic methods aim at describing individuals in many characteristics. Stern also states that these two methods can be combined.

When describing an individual, results are often presented in form of profiles. For example, test results of the (Minnesota Multiphasic Personality Inventory)

personality test typically are presented in form of individual profiles, and individuals are compared to reference profiles. A profile describes the position of an individual on standardized, continuous scales. Thus, one can also compare the individual's relative standing across several variables. Longitudinally, one can ask, whether an individual's relative standing and/or the correlation with some reference change. For example, a profile may resemble the pattern typical of schizophrenics. Individuals can be grouped based on profile similarity.

In contrast to profiles, configurations are not based on continuous but on categorical variables. Specifically, the ensemble of categories that describes a cell of a cross-classification is called configuration (Lienert 1969). Consider, for example, the variables Gender (female–male), Marital Status (married–not married), and Happiness (yes–no). The cross-classification of these three variables has eight cells. The combinations of categories that describe these cells are the configurations. For example, the three categories female and married, and happy constitute the first configuration. The combination male and not married, and unhappy constitutes the last configuration.

CA investigates such configurations from several perspectives. First, CA identifies configurations. This involves creating cross-classifications, or, when variables are originally continuous, categorization and then creating cross-classifications. Second, CA asks, whether the number of times, a configuration was observed, could have been expected from some *a priori* specified model. Significant deviations will then be studied in more detail. Third, CA asks whether the cases found displaying different configurations also differ in their mean and covariance structures in variables not used for the cross-classification. This question concerns the external validity of configurational statements. Other questions are conceivable.

In the following section, a theoretical background for CA is provided. Specifically, CA will be embedded in differential psychology and the person-oriented approach. In Sect. 3, configural frequency analysis, a chief method for CA will be described. In Sect. 4, other methods such as cluster analysis and log-linear modeling will be described briefly.

2. *Configurational Analysis: Theoretical Embedding*

This section covers two roots of configurational analysis (CA), differential psychology, and the Person-Oriented Approach. The fundamental tenet of differential psychology is that 'individual differences are worthy of study in their own right' (Anastasi 1994, p. ix). This is often seen in contrast to General Psychology where it is the main goal to create statements that are valid for an entire population. General Psychology is thus chiefly interested in variables. The data carriers themselves, e.g., humans, play the role of replaceable random events. They are not of interest *per se*. In contrast, Differential Psychology considers the data carriers units of analysis. The smallest unit would be the individual at a given point in time. However, larger units are often considered, e.g., all individuals that meet the criteria of geniuses, alcoholics, and basketball players.

Differential psychology as both a scientific method and an applied concept presupposes that the data carriers' characteristics are measurable. In addition, it must be assumed that the scales used for measurement have the same meaning for every data carrier. Third, it must be assumed that the differences between individuals are measurable. In other words, it must be assumed that data carriers are indeed different when they differ in location on some scale. It is well known that this is often not the case with questionnaires and tests in the social sciences.

The Person-Oriented Approach (see Magnusson 1998, Bergman and Magnusson 1991, 1997, von Eye et al. 2001) is a relative of Differential Psychology. It is based on five propositions (Bergman and Magnusson 1997, von Eye et al. 2000; see also *Person-centered Research*) that stress the individual nature and complexity of functioning, process, and development (FPD); the lawfulness and structure of FPD; and the organization of FPD in patterns. Most important from the present perspective is Proposition 5, which states that some patterns and configurations will be observed more frequently than others are, or more frequently than expected based on prior knowledge or assumptions. These patterns can be called common types. CFA defines types as configurations that occur more often than expected from some chance model. Accordingly, there will be patterns or configurations that are less frequently observed than expected from some chance model. CFA terms these the antitypes.

Thus, the person-oriented approach and CA meet where (a) patterns of scores or categories are investigated, and (b) where the tenet of differential psychology is employed that it is worth the effort to investigate individuals and groups of individuals. The methodology employed for studies within the framework of the person-oriented approach is typically that of CA. The following section describes configural frequency analysis, one of the central statistical methods of CA.

3. *Configural Frequency Analysis (CFA)*

Configural frequency analysis is introduced by using a data example. Consider the three variables, Gender (G) (1 = Male, 2 = Female); Motive for Suicide Attempt (M) (1 = Illness, 2 = Psychiatric Disorder, 3 = Alcoholism); and Outcome of Suicide Attempt (1 = Survived, 2 = Dead) (see Lienert 1978, von Eye et al. 1996). Crossed, these three variables form a $2 \times 3 \times 2$

Table 1
CFA suicide data

Variable GMO[a]	Frequencies		Statistics		Type/ Antitype?
	Observed	Expected	z	$p(z)$	
111	64	59.42	0.635	0.263	
112	18	24.57	1.360	0.087	
121	76	67.49	1.117	0.132	
122	47	27.91	3.724	0.0001	T[b]
131	7	28.74	4.182	0.00001	A[b]
132	8	11.88	1.141	0.127	
211	86	70.76	1.962	0.025	
212	16	29.26	2.529	0.006	
221	61	80.37	2.367	0.009	
222	25	33.23	1.480	0.069	
231	47	34.23	2.265	0.012	
232	27	14.15	3.467	0.0003	T[b]

a G = Gender; M = Motive for Suicide Attempt, O = Outcome of Suicide Attempt. b T = CFA Type, A = CFA Antitype.

contingency table. This table appears in Table 1, along with results from CFA.

The first column of Table 1 lists the configurations. The first configuration is the combination of the categories, Male and Illness and Survived Suicide Attempt. The second configuration is the combination Male and Illness and Died, and so forth. The second column displays the frequency with which each of the configurations occurred. CA allows researchers to investigate cross-classifications of the kind presented in Table 1 from the perspectives listed above. The following paragraphs illustrate the first two perspectives using CFA as a sample method of analysis.

3.1 Identification of Configurations

The first perspective involved identification of configurations. The 12 configurations in Table 1 are identified as the cells of a $2 \times 3 \times 2$ cross-classification of three categorical variables. Each individual in the sample displays one of the 12 possible patterns and can therefore be unambiguously assigned to one of the cells.

3.2 Comparison of Observed with Expected Cell Frequencies: CFA Types and Antitypes

When inspecting the observed frequencies in Table 1, it becomes immediately obvious that the 12 configurations were observed at different frequencies. Whereas seven alcoholic males were counted to have survived a suicide attempt, 86 ill females were counted to have survived an attempt. While it does make sense to compare raw frequencies, more often researchers try to explain the observed frequency distribution based on an underlying model. Such a model is said to explain the observed data if no significant discrepancies between the observed distribution and the distribution predicted by the model exists.

CFA goes the opposite route. It specifies a so-called base model that is not supposed to explain the data (examples of base models follow in Sect. 3.3). Discrepancies from this model indicate what is going on, that is, the effects that created the observed distribution. These effects manifest in the above mentioned common types and common antitypes. More specifically, let f_i be the observed frequency for Cell i, and e_i the expected frequency for Cell i. The base model is used to estimate the expected cell frequencies. Then, if statistically $f_i > e_i$, the configuration that describes Cell i constitutes a CFA type. If $f_i < e_i$, the configuration constitutes a CFA antitype. If $f_i = e_i$, the configuration constitutes neither a type nor an antitype.

3.3 CFA Base Models

Admissible CFA base models meet the following three criteria (von Eye and Schuster 1998). The first criterion is that there be only one way to deviate from the base model for clearcut interpretation of types and antitypes. For example, first order CFA uses the log-linear main effect model for a base model. This model implies no interactions among variables. Deviations from this model are only possible if there are interactions.

The second criterion, introduced by von Eye and Schuster (1998), is that the sampling scheme be considered. Specifically, the multinomial and the product multinomial sampling schemes have major implications for the selection of base models and interpretation of results (von Eye et al. 1999).

Parsimony is a third criterion for the selection of base models. More specifically, a base model must take into account interactions of the lowest possible order.

Base models can be subdivided in two groups. The first group is that of global CFA models. Models in this group assign the same status to all variables in the analysis. There is a hierarchy of global models. It begins at the level where no effects are assumed at all. Thus, the expected cell frequency for Cell i is estimated as $e_i = t/N$, where t is the total number of cells in the cross-classification and N is the sample size. This model is termed zero-order CFA. At the next higher level, first-order CFA proposes that main effects can exist for each variable, but no interactions. First-order CFA is the original approach to CFA (Lienert 1969). The expected cell frequencies for Table 1 were estimated using the first-order CFA base model (this model will be explained in more detail later in this section). Accordingly, second order CFA proposes that first-order interactions exist between all pairs of variables, and so forth. In each of these models types and antitypes can emerge only if effects of orders higher than the ones assumed in the base model exist.

Regional CFA models distinguishes between two or more groups of variables. Examples of regional CFA models include Prediction CFA (P-CFA) which assumes that the variables are grouped into predictors and criteria. P-CFA types (antitypes) allow one to predict the occurrence (lack of occurrence) of criterion configurations from particular predictor configurations.

Most CFA base models can be expressed in form of simple log-linear models. Thus, expected cell frequencies can be estimated from the marginal frequencies of the variables involved in the cross-classification. A general expression for log-linear models and, thus, log-linear CFA base models, is $\log F = X\lambda$ where F is the array of expected frequencies under study (the third column in Table 1), X is the design matrix (comparable to a design matrix in analysis of variance), and λ is a parameter vector. Estimation is typically performed using maximum likelihood methods. Many CFA base models lead to very simple computational equations.

Once the expected cell frequencies are estimated, they can be compared with the observed frequencies. A large number of statistical tests have been proposed for these comparisons. One of the best of these tests is the binomial approximation of the z-test. The test statistic is $z_i = (f_i - e_i)/\sqrt{(e_i(1 - e_i/N))}$. Inserting the values from the data example in Table 1 yields for the first configuration the test statistic $z_{111} = (64 - 59.416)/\sqrt{59.416(1 - 59.416/482)} = 0.635$. This value is the same as the one for the test statistic for Configuration 111 in Table 1. Other tests include the exact binomial test, the χ^2-component test, Lehmacher's (1981) hypergeometric tests, and the F-test (cf. von Eye and Rovine 1988).

3.4 Statistical Decisions Concerning Types and Antitypes

For each of the configuration specific test statistics a tail probability is then calculated. Recent results suggest that standard testing as described above tends to underestimate the probability of antitypes (Indurkhya and von Eye 2000). Future research will have to devise methods that eliminate this asymmetry. One very important characteristic of the tests performed in CFA is that they are not independent of each other. Rather, they can be dependent because (a) the available information has already been exhausted or (b) capitalizing on chance. Therefore, measures must be taken to protect the significance level α. A number of adjustments have been proposed for protection of α. One of the most conservative yet most frequently employed adjustments is known as Bonferroni adjustment. This procedure creates an adjusted significance level, α^*, that is $\alpha^* = \alpha/t$, where α is the original, nominal significance level, and t is the total number of tests performed. In the example in Table 1 we test each cell. Therefore, $t = 12$. For $\alpha = 0.05$ we obtain $\alpha^* = 0.05/12 = 0.0041667$. Obviously, the adjustment makes the decision as to whether a type or antitype exists more conservative. Therefore, the Configurations, 211, 212, 221, and 231 for which the tail probabilities are below the usual $\alpha = 0.05$ fail to constitute types and antitypes. Still, even under this conservative decision rule, CFA manages to identify two types and one antitype in the data in Table 1. The first type is constituted by Configuration 122. It suggests that more men suffering from psychiatric disorders than expected from the base model of variable independence do not survive a suicide attempt. The second type is constituted by Configuration 232. It suggests that more alcoholic women than expected from the base model die in suicide attempts. The antitype, Configuration 131, indicates that fewer alcoholic men than expected from the base model survive a suicide attempt.

3.5 Interpretation of Types and Antitypes

When interpreting results from CFA, researchers use two sources of information. The first source includes the identified types and antitypes. Most typically (see, for example, Table 1), only a subset of configurations deviates from the CFA base model to the extent that types or antitypes are constituted. If there exist only few significant deviations, the base model is contradicted locally, and in the other sectors of the data space spanned by the cross-classification under study the base model holds.

The second important source of information is the CFA base model. In the analyses for Table 1 the base model proposed that the three variables, Gender, Motive, and Outcome of Suicide Attempt be unrelated throughout. The two emerging types and the one

antitype, however, suggest that there exist local associations such that particular categories of these variables, that is, particular configurations surface more often (and less often) than could be expected under the base model. Thus, the base model experiences local violations in three sectors, yet it holds in the remaining nine sectors. The base model for the CFA of the data in Table 1 can be violated by any relationship among the three variables.

It is important to realize that the application of CFA within the context of Configurational Analysis implies a perspective of variables that is different than the perspective taken when analyzing variables. Within CA, variable interactions and main effects are of interest only in so far as they are part of a CFA base model. The main focus of interest, however, lies in the possible local deviations from the base models. Such deviations are always interpreted at the level of configurations, that is, locally. There have been only a small number of attempts to interpret groups of types and groups of antitypes (von Eye and Brandtstädter 1997, Gutiérrez-Peña and von Eye 2000).

3.6 Variants of CFA

By far most CFA base models are derivatives of log-frequency models. However, there exist circumstances under which the estimation of expected cell frequencies from the observed frequencies might be problematic. An example where the probabilities of configurations are determined by information other than the observed distribution can be found in longitudinal CFA (von Eye 1990). When change scores are calculated for ordinal variables, the top and the bottom ranks have fewer possibilities for change. Whereas the middle ranks can stay the same, move up, or move down, the top rank can only stay the same or move down. Accordingly, the bottom rank can only stay the same or move up. These differences must be considered when estimating expected cell frequencies (for details see von Eye 1990, Chap. 6).

A second domain of development of methods for CFA is that of Bayesian CFA. Bayesian methods differ from standard, frequentist methods in that conclusions about a parameter or about unobserved data are made in terms of probability statements that are conditional on the observed value of the dependent measure. Implicitly, statements are conditioned on known values of the independent variable. In contrast, standard, frequentist statistical inference is based on an evaluation of the procedure used to estimate the parameter for the distribution of possible values of the dependent measure, conditional on the true yet unknown value of the parameter (Gelman et al. 1995). One interesting and important characteristic of Bayesian statistics is that prior information can easily be taken into account.

Thus far, there have been only a small number of attempts to formulate a Bayesian CFA (Wood et al. 1994, Gutiérrez-Peña and von Eye 2000, von Eye et al. 2000). Each of these approaches is (a) unrelated to log-linear modeling methods for estimation of expected cell frequencies, and (b) uses the so-called noninformative priors. The rationale for using this kind of priors is to let the data speak for themselves, that is, without consideration of information external to the data under study (Gelman et al. 1995). However, in many instances such information exists. Thus, future developments will discuss methods of incorporating prior information in the form of prior distributions.

A second route of development that has just begun to be traveled is that of defining types of types (and antitypes). Traditionally, CFA types and antitypes are defined in a way similar to residuals in log-linear models, that is, as significant discrepancies from some base model. In 1991, Goodman made explicit that there are many ways to deviate from expectancy. Three of these ways were used by von Eye, Spiel, and Rovine (1995) to define different concepts of types and antitypes. The first concept is a marginal-dependent relative of the correlation, ρ. The second is a marginal-free variant of the odds ratio, and the third concept is a marginal-dependent variant of the odds ratio. Results of simulation studies suggest that the patterns of types and antitypes identified under the three concepts can differ dramatically. In addition, these patterns can be different than the patterns identified using the original concept of CFA types and antitypes. Gonzáles Dében (1998) proposed a fourth approach to defining types and antitypes that is based on a residual definition by Rudas et al. (1994).

3.7 Alternative Methods of Configurational Analysis

Section 3 suggests that configuration frequency analysis is the chief method of data analysis in CA. However, other methods have been proposed and used. Two of these methods will be briefly reviewed here, log-linear modeling and cluster analysis.

Cluster analysis (see Hartigan 1975, von Eye et al. 1999) is a method that allows researchers to identify groups that were unknown to exist before analysis. Cluster analysis creates groups (clusters) that contain cases that are more similar to each other than to cases from other groups. The cluster formation process typically follows one of the following three strategies: (a) an existing sample is subdivided until some optimality criterion is reached; (b) the individuals in a sample are agglomerated until some optimality criterion is reached; and (c) density centers are formed and individuals gravitate to the nearest center. For more detail on the decision making involved when searching for clusters see von Eye et al. (1999). Cluster analysis and CA meet where researchers hold the assumption that data analysis at the aggregate level

can obscure interpretable differences between individuals or groups of individuals.

The typical application of log-linear modeling focuses on variables. Thus, this method finds more applications in standard, aggregate level analysis (Agresti 1990, Bishop et al. 1975). However, several variants of log-linear modeling can be fruitfully employed in CA. Two sample approaches will be briefly reviewed in this context. The first approach concerns models that specify effects that are specific to subtables. For instance, Clogg and Shockey (1988) proposed models that allow one to ask whether, in two-way cross-classifications, an association between the two variables that constitute the table is the same throughout. In an example with the variables Riding a Car for Fun and Drug Use, the authors showed that there is an association such that those respondents who ride a car often for fun also tend to consume stronger drugs. However, those respondents who never ride a car for fun tend to consume stronger drugs than those who ride a car a few times a year for fun do. This pattern suggests that the association between the two variables switch as one inspects different regions of a cross-classification.

The second approach is linked to nonstandard log-linear models (Rindskopf 1990). Standard log-linear models specify main effects and interactions in terms of coding schemes that are parallel to the ones used for analysis of variance (see, e.g., Christensen 1997). Nonstandard models include contrasts that cannot be expressed using these terms. Rather, these effects, comparable to planned mean comparisons, are added to the model to test specific hypotheses. These hypotheses typically concern effects that occur only in specific regions of a cross-classification. Von Eye and Brandtstädter (1998) proposed using nonstandard log-linear models to test hypotheses about causal effects. While such models may suffer from problems of parameter intercorrelations that can be viewed parallel to multicollinearity in analysis of covariance or multiple regression, they allow researchers to ask questions that go beyond standard questions of variable associations.

These and other approaches to log-linear modeling meet CA where hypotheses are formulated and tested that do not apply to everybody in a population but only to distinct groups. It is assumed that the variable relationships in these groups differ from the ones found for the rest of the populations.

To conclude, configurational analysis (CA) represents a methodology that allows researchers to counterbalance the far more frequently used methodology that focuses on variables rather than on individuals. Its chief representatives, cluster analysis and configural frequency analysis are well-developed statistical techniques that allow researchers to specify statements about individuals and groups of individuals. Variables play in these statements the role of carriers of information.

Conflict and Conflict Resolution, Social Psychology of

The term 'conflict' has two broad meanings: *overt conflict*, which refers to clashing actions by two or more parties, as in a fist fight or war, and *subjective conflict*, which refers to perceived divergence of interest or annoyance attributed to another party. Subjective conflict is often a source of overt conflict, as when annoyance about a neighbor's loud music leads to a shouting match. But subjective conflict can produce other outcomes as well, including use of the following four basic strategies: contending, problem solving, yielding, and inaction. Only one of these, contending, leads to overt conflict.

Conflict occurs at all levels of society, from the interpersonal to the international, and hence is of interest to most branches of the social and behavioral sciences. Conflict has attracted the attention of researchers because of its large costs and benefits. Costs are incurred when conflict escalates to the point of harming relationships, destroying property, or injuring people. Benefits accrue because conflict presides over most significant social change; contributes to solidarity within conflicting groups; and in its milder forms, often leads to the reconciliation of legitimate interests, thus strengthening relationships and safeguarding the peace.

1. Sources of Conflict

The modern social psychology of conflict began with a demonstration field experiment by Sherif (1966). Sherif ran several summer camps in which he produced overt conflict between two cabins of preadolescent boys and then resolved this conflict. Conflict was produced by means of the two sources of subjective conflict mentioned above: divergence of interest (for example, competitive games) and annoyance attributed to the other group (for example, the counselors vandalized one cabins' campgrounds and blamed it on the other cabin).

What conditions produce divergence of interest and annoyance from others? One answer is scarce resources. A second is role differentiation that produces disparate values, as between buyer and seller, parent and child, sales and production. A third is any condition that causes aspirations to rise rapidly (such as a sudden improvement in outcomes) or to become inconsistent with those of another party (such as ambiguity about which party is more powerful). A fourth is any source of distrust, because distrust tends to block cooperation and produce defensive behavior, which often annoys or frightens the other party.

When groups rather than individuals are involved, additional mechanisms encourage conflict. Groups are less trusted than individuals. Also, a perception that one's group is deprived relative to a reasonable standard (*fraternalistic deprivation*) has been shown to be a major source of political conflict. Arguing that Sherif's 'realistic conflict theory' is too narrow, Tajfel (1978) proposes that intergroup conflict often arises because group members compete with other groups in an effort to feel good about their social identity and hence about themselves. Another unique aspect of groups is the role of leadership. Leaders and would-be leaders often dramatize frustration at the hands of other groups, exacerbating conflicts while strengthening their position with their constituents.

2. Strategic Choice in Conflict

Rubin et al. (1994) have put forward a *dual concern model* of the psychological states that affect choice

Figure 1
The dual concern model (after Pruitt and Carnevale 1993, p. 105)

among the four basic strategies mentioned earlier. Shown in Fig. 1, this model postulates two kinds of concern: concern about own outcomes ('self-concern') and concern about the other party's outcomes ('other-concern'), each ranging from weak to strong. People with strong self-concern have high, inflexible aspirations and are resistant to concession making. People with strong other-concern place importance on the other party's interests. Self-concern and other-concern are independent dimensions rather than opposite ends of a continuum. Beginning in the upper left-hand quadrant of Fig. 1, low self-concern coupled with high other-concern is assumed to produce a strong altruistic orientation, which encourages yielding. High self-concern combined with high other-concern is assumed to produce a strong cooperative orientation, which encourages problem solving. High self-concern combined with low other-concern is assumed to produce a strong individualistic orientation, which leads to the use of contentious tactics. Low self-concern coupled with low other-concern is assumed to produce inaction, an absence of efforts to achieve anything.

The dual concern model, though not a comprehensive theory of strategic choice, fits a lot of data from psychometric and experimental research. The psychometric tradition, which employs factor analysis and multidimensional scaling, views strategic preferences as individual differences in 'conflict style.' The experimental tradition, which involves studies of negotiation behavior, examines conditions that affect the likelihood of choosing each strategy. These studies have identified several sources of self-concern, including having high aspirations or fallback positions, being an accountable representative, and negatively framing the issues so that concessions are interpreted as loss rather than failure to gain. Sources of other-concern include having a close relationship with or dependence on the other party, and being in a positive mood. Other research suggests that contentious tactics are more likely to be adopted the greater the annoyance or perceived divergence of interest, the more dehumanized the target, and the more deindividuated the actor or target.

When increasingly harsh contentious tactics are used in a conflict, *escalation* is said to occur. Escalation usually results from a conflict spiral in which each party is reacting to the other party's most recent actions. However, some escalation consists of one party's reactions to persistent annoyance from another party (Pruitt 1998). Escalation is often accompanied by other changes: issues proliferate, negative attitudes and partisan perceptions develop, distrust sets in, goals change from doing well for oneself to hurting the other party, and broader communities polarize into hostile camps (Rubin et al. 1994). If groups are involved, ingroup solidarity usually increases and militant leaders often become more prominent. These changes tend to outlive the conflict in which they are generated, hurting the broader relationship between the parties and making the next conflict episode more likely to escalate (Coleman 1957).

3. *Conditions that Encourage Conflict Resolution*

Conflict resolution refers to any reduction in the severity of conflict or mitigation of its underlying causes. It may entail de-escalation of an overt struggle or reconciliation (in whole or in part) of divergent interests.

Social psychologists have long been interested in the role of *social contact* and *communication* in the resolution of conflict. Research has shown that these procedures help to alleviate mild conflict but may be worse than useless in severe conflict, allowing arguments and fights to develop (Deutsch 1973). Sherif (1966) found that a better way to reverse escalation in his camps was to get the boys to cooperate on *superordinate* (i.e., shared) *goals*. The value of this technique has been confirmed in other settings.

Zartman (1997), an international relations scholar who takes a psychological approach, has argued that severe conflict is most likely to be resolved when both sides become motivated to escape the conflict, a condition he calls *ripeness*. He finds that superordinate goals ('mutually enticing opportunities') seldom underlie ripeness in international conflict and civil war. Rather, ripeness is usually produced by a *mutually hurting stalemate*, in which the parties find that they are enduring unacceptable costs in a struggle they cannot win, sometimes augmented by the perception of an *impending catastrophe* if the conflict continues.

It can be argued that severe conflicts of the kind discussed by Zartman will only move toward resolution if ripeness is supplemented by *optimism* about the success of conciliatory actions. Optimism derives from two sources: *working trust*, a belief that the other

side is also motivated to resolve the conflict, and *perceived common ground*, a perception that a mutually acceptable agreement is actually possible.

Optimism can develop in a number of ways. Sometimes one of the parties takes *unilateral conciliatory initiatives* that encourage the other party to become more trusting. Such initiatives are especially effective when they are noticeable and unexpected, are fully explained, and cannot be construed as a trick or sign of weakness (Rubin et al. 1994). In severe conflicts, optimism more commonly arises out of intervention by *intermediaries*. Sometimes the psychological and social distance between adversaries is so great that a chain of two or more intermediaries is necessary to bridge the gap.

4. *Negotiation*

Conflict resolution can begin in a number of ways, but to be successful, it usually must culminate in *negotiation*. In other words, the parties must eventually try to work out their differences.

Research on negotiation has been the centerpiece of the social psychological approach to conflict for many years. Most of it is done in the laboratory with experimental games, but case studies and questionnaires are also sometimes used. At one time, research on negotiation was mostly performed in departments of psychology, but today, the main locus of this research is in management schools, where investigators who are basically social psychologists conduct dozens of studies each year. Early experimental research dealt with negotiation about a single issue (e.g., a price or a wage rate), where one party's gain is the other's loss. But current research usually looks at more complex settings that have *integrative potential*, in the sense that all parties can do well if they engage in problem solving. An important generalization, which applies to both kinds of settings, is that higher demands and slower concessions make it harder to reach agreement but, if agreement is reached, produce more favorable outcomes. Summaries of the psychological research on negotiation can be found in Bazerman et al. (2000) and Pruitt and Carnevale (1993).

5. *Third Party Intervention*

When conflict threatens to escalate and negotiation is ineffective, third parties often intervene. Five intervention procedures will be reviewed here: mediation, arbitration, relationship therapy, peacekeeping, and the design of conflict management systems.

In *mediation*, a third party assists the disputants with their negotiation. (Mediation includes the activities of intermediaries, a topic discussed earlier.) Among the most important mediator tactics are building rapport with the disputants, facilitating communication, questioning unrealistic aspirations, reframing the issues, encouraging disputant creativity, and thinking up new solutions if the disputants fail to do so. Several studies support a broad generalization, that vigorous mediator intervention tends to be effective when the parties are hostile toward each other or lack the motivation to escape their conflict but is counterproductive when the opposite is true (Rubin et al. 1994). Mediators are especially likely to succeed when the parties are highly motivated to resolve the conflict, resource shortages are not severe, and the issues do not involve general principles. Mediator neutrality usually contributes to the success of mediation but is not as essential, as formerly believed. Indeed, success is sometimes achieved because the mediator is closer to the side that must make the larger concessions (Kressel et al. 1989).

In *arbitration*, the third party renders a judgment about the proper solution to the conflict. Several studies have examined the impact of *med-arb*, a procedure in which binding arbitration occurs if agreement is not reached in mediation. This procedure usually motivates the disputants to try harder to solve their dispute during the mediation phase, because they fear loss of control over their outcomes if arbitration occurs (Kressel et al. 1989).

When disputants have a distressed relationship, third parties sometimes engage in *relationship therapy* (Pruitt 1998). Relationship therapy, which has been pioneered by marital therapists, usually involves problem solving training, in which the parties are taught skills of listening, clear communication, avoiding blame, analyzing needs, and brainstorming for solutions. The therapist may also help the disputants identify repetitive patterns of interaction that are contributing to the conflict. Kelman (1992) has developed *problem solving workshops*, a form of relationship therapy for intergroup and international conflict. In these workshops, selected members of both groups meet for several days to analyze the conflict.

When conflicts become violent or threaten to do so, third party intervention may take the form of *peacekeeping*. Examples include separating fighting children, arresting abusive spouses, and United Nations operations within ethnically divided countries. Fisher and Keashly (Fisher 1990) have proposed a normative model which recommends that third parties: (a) use peace keeping in violent conflicts, (b) provide incentives to encourage ripeness in heavily escalated but nonviolent conflicts, (c) offer relationship therapy (they call it 'consultation') in moderately escalated conflicts, and (d) mediate mildly escalated conflicts. This model assumes that each of these strategies produces the conditions necessary for the success of the next strategy in the list.

A final third-party role is the design of *conflict management systems* for large social entities such as

schools, factories, and communities. Guidelines put forward by Ury et al. (1988) include identifying potentially antagonistic groups, appointing and training prospective negotiators on each side who will meet if conflict develops, appointing and training prospective mediators to help these negotiators, and agreeing to observe an immediate cooling-off period whenever conflict develops. Such systems work better if they involve early warning systems that allow negotiators and mediators to mobilize in advance of hostilities.

6. *Disputant Preferences among Conflict Resolution Procedures*

A number of studies have examined disputant preferences among the procedures available for conflict resolution. A persistent finding is that arbitration is preferred to autocratic decision making. According to Lind and Tyler (1988), this shows that having a voice in the proceedings contributes to a sense of procedural justice. Preferences among negotiation, mediation, and arbitration depend on the circumstances. For example, high time pressure enhances attraction to arbitration, presumably because it can be finished up quickly. On the other hand, people in close relationships tend to reject arbitration, presumably because of its coercive features. Sequences of preferences are often found, a common one being to start with negotiation and move to third-party intervention if negotiation is unsuccessful (Pruitt and Carnevale 1993).

Some recent research has concerned cultural differences in preferences among conflict resolution procedures. For example, when dealing with ingroup members, people from collectivist societies prefer nonconfrontational procedures, hence, they are less attracted to direct competition and problem solving than people from individualist societies (Bazerman et al. 2000). But when dealing with outgroup members, collectivists tend to be more competitive than individualists (Pruitt and Carnevale 1993).

7. *Conclusions*

Conflict and conflict resolution are vigorous research fields. The interdisciplinary nature of these fields can be seen in the annual conferences of the International Association for Conflict Management and the pages of the *Journal of Conflict Resolution*, the *International Journal of Conflict Management*, and the *Negotiation Journal*. Social psychologists in psychology departments were more prominent in these fields at an earlier time than they are today. But the contribution of social psychology is readily apparent in the work of investigators from most other disciplines.

Three criticisms of these fields seem appropriate. The first is that they lack an overarching theory and mainly depend on ideas from other disciplines, a problem shared with many other branches of the social sciences. The other two criticisms concern the study of negotiation. One is that there is too much emphasis on the phase of actual negotiation, in which joint decisions are made, as opposed to the pre- and postnegotiation phases. Indeed, the latter two phases are often longer and more complex than the phase of actual negotiation and have more bearing on whether conflict is resolved (Druckman 1986). The other criticism is that there is too much research on negotiation altogether. Negotiation is, after all, only one star in a much larger universe.

Conflict and Socioemotional Development

1. Conflict Defined

Conflict is a broad term, widely invoked in the common vernacular and in the scientific literature to suggest a state of disagreement or opposition. The term carries different connotations depending upon whether the experiencer is singular or plural. Intrapersonal conflict describes a state of emotional turmoil or intellectual dissent that occurs within an individual. Interpersonal conflict describes a social interchange that is marked by opposing goals and that involves two or more persons. The earliest English usage of each term dates to the fifteenth century; both have common roots in the Latin *conflictus*, meaning throw or strike together (Shantz and Hartup 1992). This shared etiology tends to muddy distinctions between these two distinct forms of conflict.

1.1 Intrapersonal Conflict

Intrapersonal conflict encompasses two broad domains. At the emotional level, conflict reflects competing impulses or desires. Freud (1965) attributed these tendencies to contradictory aggressive and sexual proclivities with origins in the id (the unregulated physical self) and to irreconcilable differences between these selfish urges and constraints imposed by the superego (the social mores conveyed by family and culture). At the cognitive level, conflict reflects dissonance produced by incongruent facts, opinions, or modes of thought. Piaget (1985) attributed these tendencies to equilibration, the innate tension between a preference for stability and a drive to master the environment. Assimilation encourages stability by incorporating new information into existing mental schema. Should this prove insufficient for mastering the environment, accommodation is required to alter mental schema in a manner consistent with the information available.

Intrapersonal conflict is by definition a private experience. It cannot be observed and it has no reliable metric. Early scientific psychologists relied on introspection to glean insight into thoughts, a practice modified and popularized by psychodynamic psychologists to probe unconscious emotional states. Subjective experience as a topic of study fell out of favor with the behavioral revolution. Reaction times, physiological cues, and projective responses were employed as proxies for inner conflict, but poor reliability and the absence of face validity undermined these efforts. With the cognitive (counter)revolution, new introspective methods gained legitimacy as advances in measurement and instrumentation were applied to mental processes. Scholars began to focus on the diverse experiences of different cultural and ethnic groups, and in so doing it became apparent that scientific inquiry into intrapersonal conflict cannot proceed in the absence of valid and reliable self-report data.

1.2 Interpersonal Conflict

Interpersonal conflict may take place at the level of the dyad or the group. Dyadic conflict is a social episode marked by overt behavioral opposition. The function of such conflicts and the manner in which they unfold vary according to characteristics of the participants and their relationship, the issue and context of the disagreement, the tactics employed, and their consequences (Deutsch 1973). Group conflict refers to negative or incompatible attitudes and behaviors directed by members or representatives of one group toward those of another group. The nature and significance of intergroup conflict differs according to leadership styles and prevailing norms, member cohesion, resource availability, and the individual and collective talents and experiences of each group (Sherif et al. 1961).

Interpersonal conflict is a quantifiable, ofttimes public event. It consists of a sequence of easily recognized and well-defined components including the initial opposition, and the tactics, resolution, and outcome. That said, empirical studies of dyadic and group conflict suffer from inconsistent operational definitions. The conflict measures employed differ in terms of whether they assess unilateral or mutual oppositions, and in terms of whether the frequency of an event is distinguished from its affective intensity (Laursen and Collins 1994). Distinct patterns of interpersonal conflict emerge when considering reciprocated as opposed to unreciprocated disagreements and when angry disputes are examined apart from the mundane. Early work on interpersonal conflict focused on groups and dyads in experimenter-contrived conditions designed to elicit disagreements. Concerns about the ethical treatment of participants and a lack of generalizability prompted improvements in ecological validity; unobtrusive observations in natural settings have been integrated with running assessments of psychophysiological states and moment-by-moment accounts of participant cognitions and affect (Gottman 1994). The utility of self-reports increased once scholars realized that participant reports of conflict differ not only from one another but also from observer reports, suggesting that what was once considered measurement error may in fact represent important individual differences in how conflict is perceived and experienced.

2. The Role of Conflict in Development

Conflict is inherent in growth, and human development cannot proceed without conflict. Wisdom,

emotional maturity, and social skills may be tied to a series of developmentally defined tasks and the conflicts specific to each. Scholars agree that intrapersonal and interpersonal conflict each shape developmental trajectories, but there is little consensus as to the exact mode of transmission. The developmental effects of conflict appear to be limited to specific domains of influence circumscribed by individual timetables and characteristics of the disagreement such as the issue and participants.

2.1 Intrapersonal Conflict and Development

Intrapersonal conflict is instrumental to the attainment of several important milestones in socioemotional development. First, conflict may prompt changes in internal schema and mental structures. Accommodation (Piaget 1985) exemplifies this process: A child confronted with a difficult moral dilemma may be forced to disregard views previously held dear in order to objectively consider different perspectives and reach a fair solution. Alternatively, conflict may give rise to changes in perceptions and priorities. Cognitive dissonance (Festinger 1957) typifies this mechanism: A child forced to select a single partner for an outing may find that, in so choosing, the esteem of one friend has been enhanced at the expense of others. Finally, conflict may alter affect and impulse control. A child who opts to delay gratification in the hopes of improved rewards will learn to succeed by cultivating strategies that minimize emotional arousal and divert attention from proximate stimuli.

Theory concerning the ontogenetic significance of intrapersonal conflict has outpaced research on the topic. There is less research on emotional development than on cognitive and social–cognitive development, but the available evidence supports the assertion that the influence of intrapersonal conflict is defined by the topic of disagreement and the cognitive or affective domain invoked. Furthermore, effects are qualified by individual timetables: Development mediates the influence of conflict. The likelihood that some developmental periods are more susceptible to alterations than others leads to the provocative suggestion that intrapersonal conflict is neither a necessary nor sufficient condition for development but rather a factor that may, at certain times, facilitate advances in the specific emotional or cognitive arena in which it arises (Shantz and Hartup 1992).

2.2 Interpersonal Conflict and Development

Social skills and social development are entwined with interpersonal conflict. Disagreements, especially those in close relationships, are one of the primary means whereby individuals define themselves and delimit their interactions with others. Three influence pathways merit mention. First, conflict may prompt changes in self-understanding and self-evaluation. Critical disagreements force participants to re-evaluate goals and tactics, offering opportunities to hone social perspective taking and interpersonal negotiation skills (Selman 1980). Second, conflict helps to determine patterns of social interaction in close relationships that may impact developmental outcomes. Coercive exchanges tend to be self-perpetuating and, once started, they interfere with the dividends that normally accrue from positive affiliations (Patterson 1982). Third, conflict may define and alter expectations about individuals and relationships. In some cases, roles and responsibilities are negotiated directly, but in other cases, behavior is evaluated for cues as to whether current expectations are consistent with the demands of the situation and the maturity of the participants (Hinde 1997).

There is considerable support for the premise that the developmental significance of conflict depends on the relationship in which it arises (Laursen and Collins 1994). Three relationship properties are germane: closeness, permanence, and power. Disagreements in close relationships have the potential to alter developmental trajectories profoundly; few disagreements in other relationships have such effects. Disagreements in voluntary relationships are more apt to bring about individual change than those in obligatory relationships; participants in the former must behave in a manner that affords mutually satisfactory outcomes if the affiliation is to continue, whereas participants in the latter worry little about the dangers of relationship dissolution. Disagreements in horizontal or mutual relationships provide especially fertile ground for improved social skills because when power is shared, negotiation is necessary for an amicable resolution; in vertical or unilateral relationships, resolutions are more often the product of power differentials than of negotiation abilities. These variations notwithstanding, developmental shifts in conflict man agement may be identified such that the practice of coercion is gradually replaced across childhood and adolescence by negotiation and withdrawal.

3. Conclusion: the Paradoxical Influence of Conflict

Conflict is often unpleasant and aversive. Given the option, most people would choose to avoid it. For this reason, it is commonly assumed that conflict hinders development. This assumption has been challenged on the grounds that linear models overlook the beneficent role that conflict plays in maturation. A curvilinear model of influence captures this alternative perspective: moderate conflict provides experience necessary for optimal socioemotional development, whereas too little conflict limits the potential for growth and too

much conflict overwhelms mechanisms for coping with it.

3.1 Future Directions

Most research on the significance of interpersonal conflict has focused on its potential for adverse consequences. Few studies have addressed the possibility that conflict promotes socioemotional development. Strong evidence supports the assertion that children who experience high rates of angry conflict suffer from low self-esteem, poor social skills, interpersonal rejection, and adjustment problems. Yet the nature of this research is such that it is impossible to determine whether maladaptation is the cause or the consequence of interpersonal conflict. Neither can it be determined whether there are sensitive periods during which conflict exerts a particularly strong influence on development, although a few studies suggest that conflict mediates difficult transitions through precocious puberty, marital reconfiguration, and school entry. Of particular importance to this field of inquiry is research that makes a full and nuanced account of the dynamic interplay between conflict and developmental outcomes. Studies of change over time are needed to specify the paradoxical influence of conflict on concurrent individual adjustment and on long-term developmental trajectories.

Conflict and War, Archaeology of

Archaeology is the study of patterns of effects; repetitions of human behavior that leave an enduring mark on the physical world. War, the armed conflict between social units, is such a pattern and leaves very enduring effects. Such effects include the remains of victims of homicide and warfare, fortifications, specialized weapons, destroyed settlements, and depictions of combat. Ancient violent conflicts also had important consequences, correlates, and causes involving human ecology, the distribution of settlements, production and exchange, social organization, ideology, and symbolism.
