Though Séguy's methods now look primitive, restricted as they were at the time to univariate comparisons and hand-made cartography, the numerical gradations across the maps rightly impressed many dialectologists as the first approximation of a visual

analogue for the dynamics of dialect gradation in space. Since then, dialectometry has advanced to multivariate statistical programs and computer-generated multidimensional displays that simultaneously compare all sites to one another. Dialectometry has become a generic term for all kinds of statistical dialect geography linked, as Goebl says, by a common goal: 'The preponderant aim of dialectometry consists in discovering, by the numeric combination of many low ranking patterns, higher ranking patterns which have remained hitherto hidden, in order to obtain a systematic insight into the problem of the basilectal management of space by HOMO LOQUENS' (Goebl 1993, p. 277). Practitioners of dialectometry can be found around the world from Japan to Canada. The numerous research programs remain largely uncoordinated and partly incompatible, but in the next decades the consolidation of methods and goals will undoubtedly crystallize into a powerful branch of dialectology unimaginable in the first century of the discipline.

8. *Sociolinguistic Dialectology*

The other revitalizing impulse for dialectology is sociolinguistics, which had its effective beginning in the 1960s with the dissemination of William Labov's fountainhead studies in Martha's Vineyard and New York's Lower East Side (collected in Labov 1972). Linguists began studying language variation with freer data-gathering methods, using larger and more representative subject samples, and they sought to understand its social significance with quantitative, acoustic and statistical analyses. The intellectual forebears of sociolinguistics, far removed from Linnaean taxonomy, were post-structural linguistics and the social sciences.

Dialect geographers, not surprisingly, did not immediately embrace the new currents, and it took a generation schooled primarily in sociolinguistics to recognize that the two disciplines were both, in essence, dialectologies. With hindsight, the rise of sociolinguistics can be viewed as a natural response to global social forces that have arisen since dialectology came into being, including urbanization, mobility of all three kinds—geographical, occupational and social—embourgeoisement, mass education and mass literacy. Those forces shrank the traditional domains of dialect geographers by reducing geographically isolated regions and socially isolated subjects to statistical insignificance in all the developed nations and beyond.

Observations of linguistic variation became refocused on social class, network, age, sex, ethnicity, and other social sub-groups as well as region, and the systematicization of those observations required new sets of independent variables and new methods for tracking them. In the social context that came into existence a century after Warelius and Wenker, the remaking of dialectology as sociolinguistic dialectology was inevitable. As Chambers and Trudgill said, 'A decade or two ago, it might have been possible to think that the common subject matter of dialectology and sociolinguistics counted for next to nothing. Now we know it counts for everything. Dialectology without sociolinguistics at its core is a relic. No serious perspective on dialectology can grant urban research and variation theory less than a central role' (Chambers and Trudgill 1998, p. 188).

One of the historical consequences of dialectology becoming sociolinguistic is that it has become an integral branch of linguistics. Like other branches of linguistics, its seminal works and formative investigations have been impelled and largely defined by specific issues, that is, by the need to develop or refine or refute particular hypotheses. The defining issues include these (discussed in Chambers 1993), among others: (a) How do the changes dialectologists observe in progress reflect the changes that occur in the history of languages? (b) How, if at all, do the grand concepts of the sociology of language—concepts such as diglossia, language shift, heteronomy, linguistic legislation and planning—affect social interaction, or become encoded emblematically in sociolinguistic variants? (c) How do dialect features diffuse throughout regions, and how does such diffusion affect the linguistic behavior of people in the community? (d) What is the adaptive function of dialect and accent? This last question, in particular, can be posed as a kind of ultimate question for all dialect studies.

There is a long tradition that presupposes dialect and accent to be dysfunctional, starting with the Babelian myth. Dialectology in all its methodological and intellectual guises shows that, on the contrary, in every human society linguistic variation prevails and thrives. It is a profoundly human attribute that is essentially irrepressible. The large, open-ended questions of dialectology can only begin to find their answers in fine-grained, minute research into the social significance of linguistic variation. The answers to those questions will ultimately elucidate the human language faculty. With that as its goal, dialectology constitutes a vital branch of modern linguistics.

Diaspora

This article considers the origin and changing use of the notion of diaspora, showing how, despite its specific reference to the history of the Jews, it has now come to be important in understanding many forms of international migration. How modern nation-states respond to the challenges of social and cultural pluralism is discussed. The different types of diaspora and diverse ways in which the concept is now used are also identified.

1. *Origins and Development*

The word 'diaspora' is derived from the Greek word *speiro* (to sow) and the preposition *dia* (over). When applied to humans the ancient Greeks thought of the word as signifying expansion through outward migration and settlement. 'Diaspora' soon acquired a more brutal and catastrophic meaning. In the Greek translation of the Old Testament it was used to describe the forcible dispersion of the Jews. The destruction of the Temple in Jerusalem in 586 BC led to the enslavement and displacement of the key military, civil, and religious leaders of Judah and their exile in Babylon. This fate was held to be predicted in Deuteronomy (28: 58–68) where God had warned that anybody who disobeyed his law would be scattered to all ends of the earth. There they would 'find no peace,' while they would additionally suffer 'an unquiet mind, dim eyes and a failing appetite.' 'Babylon,' then the capital of the Mesopotamian empire, become the code word for Jews (and later for Africans in the New World) signifying a place of loneliness and estrangement, where they were held in captivity.

This catastrophic meaning of diaspora, which may be described as the 'victim tradition,' was one that informed the historical and popular use of the term for nearly two millennia. Gradually, other groups saw themselves as victims of forcible dispersion in a manner similar to the ancient Jews and used the expression 'diaspora' as a self-description of their fate. Armenians, for example, allude to the period 1894–6 when their national movement was violently opposed by the Ottoman Sultan Hamid and some 300,000 Armenians were killed in Turkish Armenia. In 1915–16 'close to one million people' (Melson 1992, p. 146), about half the Armenian nation, were either killed or died of starvation. Armenian scholars and activists have accused the Turkish authorities of genocidal intentions, an interpretation that is generally accepted, though still hotly disputed by the current Turkish government. The subsequent dispersal of the Armenians to the USA, Iran, France, Lebanon, and other countries is now commonly described as a diasporic experience. The brutal Atlantic slave trade for New World Africans, the potato famine for the Irish, and (ironically) the return to Palestine of the Zionist part

of the Jewish diaspora for Palestinians are similarly considered the crucial traumatic events that triggered the creation of these other victim diasporas.

The above examples have an apparent theoretical and experiential coherence. A tragedy perpetrated by a hostile exogenous force generates movement to a number of countries. But because the displacement was forced and the traumatic event so encompassing, collective folk memories are developed, the populations remain psychologically unsettled, and a return movement gains some following. A number of conventional historians would wish to go no further with the idea of diaspora. However, from the 1980s, this relatively well-established meaning began to lose definition at its edges. Many ethnic groups of varying histories defined themselves as 'diasporas,' or were so recognized by scholars or journalists. The decisive intellectual movement for this new pluralism was marked by the launch of a journal called *Diaspora*, issued by the New York office of Oxford University Press in 1991 and edited by a US-based literary scholar of Armenian provenance. His opening manifesto was an impressive call for openness. The journal would be concerned with 'the way in which nations, real but imagined communities, are fabulated, brought into being, made and unmade, in culture and politics, both on the land people call their own and in exile' (Tölölyan 1991, p. 3). By 1998, the journal had published articles centrally identifying 34 ethnic groups as diasporas. Considerably more ethnic groups were more casually referred to as 'diasporas.'

2. *Types of Diaspora*

Natural scholarly caution would invite rejection of this profligacy. Yet, in fact, the pluralists have a good case. The paradigmatic example of the Jews, for example, shows that the communities abroad often arose from voluntary, not forced, movement, while the Babylonian experience can be characterized far more positively—as a place where new creative energies were released and challenging cultural encounters arose over a long period in a largely peaceful setting. Moreover, as has been mentioned, the original Greek meaning of diaspora allowed voluntary movement or even aggressive colonial settlement. Drawing on this etymology it would, for example, be perfectly consistent to allude to the British colonies in New Zealand, Australia, and Canada as comprising part of 'the British diaspora'—of an imperial, rather than victim, type.

In addition to the victim and imperial types, scholars have identified labour, trade, business, professional, religious, cultural, ethno-national, and refugee diasporas, as well as intermediate forms such as incipient, asylum, and 'new' diasporas (Safran 1991, Sheffer 1995, McDowell 1996, Cohen 1997, Van Hear 1998). These subtypes describe the predominant characteristic or characteristics of each diaspora, but cannot represent adequately the full complexity of each group in terms of its history, mixed motivations for emigration, and class diversity. It is apparent, for example, that the 50 million 'Chinese Overseas,' who have only recently been described as a diaspora, include people whose origins lay in semi-free 'coolie labor,' as well as those who migrated as entrepreneurs, traders, and skilled professionals.

Beyond the new pluralism, the key difference between 'diaspora' and more popularly recognized forms of migration is that in the first case cultural, linguistic, religious, historical, and affective ties with the place of origin remain strong. In the second, at least in theory, immigration from 'an old country' involves a one-way ticket, assimilation to the 'new country,' the adoption of a local citizenship and language, and the public acceptance of local ways and customs. As many studies of ethnicity in the USA and elsewhere have shown, in culture and endogamous practices the old ways were more resilient than public ideology proclaimed. Despite this finding, the myth and goal of full integration remain at the heart of the nation-building project and inform the difference between immigration in general and the specific case of diasporic migrant groups.

3. *Responses by Nation-states to Diasporas*

During the period of intense nation-building in the core European, South, and North American states a diasporic consciousness was either not sanctioned or firmly suppressed. The US state's motto '*Ex Pluribus Unum*' provided an example of the prevailing preference for assimilation or the creation of a new national culture. However, under the impact of diverse and accelerating immigration a number of important nation states (Canada, the USA, the Netherlands, Australia, and the UK might be cited) have lost their appetite and perhaps the capacity to assimilate immigrants to a single dominant political culture. By recognizing ideas of multicultural, multifaith, and multiracial societies, their political leaderships have reversed their previous disapprobation of the retention of pre-immigration ethnic identities.

Many social commentators are relaxed about this development and see no incompatibility between a national and an ethnic affiliation. Others, including those from the traditional liberal side of the political spectrum are anxious that the painfully achieved democratic and secular order in societies such as the USA will be undermined by the recognition of diasporas (Dickstein 1993). Even more alarming is the expressed fear that diasporas will become the means to foster religious zealotry, the international drugs trade, political instability, and cross-border terrorism. The involvement of exile groups, like the Tamils, Kurds, Sikhs, or Afghans, in the political life of their homelands or in movements to create nation states, has often created violent conflicts or embarrassing and difficult diplomatic and legal conflicts (Sheffer 1986).

By contrast, Shain (1999) argues that the democratic and liberal ways learnt in a the place of settlement are more likely to spread back into the countries of origin, with benign political effects for all parties.

The attitude of the countries of origin to their diasporic communities abroad has not gained much systematic discussion, though these states are increasingly important players in retaining and amplifying the links between 'home' and 'away.' Historically, countries like China and India have been hostile to their overseas communities, seeing them as painful reminders of colonial days when their labor forces could be captured by labor recruiters or, in the contemporary period, as 'brain-drain' migration. India, China and many other migrant-exporting countries now recognize that their diasporas can provide an important political lobby for advancing their countries' interests (American Jews seeking to influence US attitudes to Israel are cited as a positive example), a bridgehead for economic marketing of the home countries' goods, a means for acquiring transferable skills (for example in information technology) and, above all, a rich source for remittance and investment income. The Philippines has an expertly-run, state-supported set of agencies that promote labor export on a vast scale, help to channel return income, and seek to protect their workers from exploitative employers abroad. A diasporic consciousness is thus often preferred by a particular migrant group, tolerated by many host nation-states, and strongly supported by the country of origin. This is a significant change of policy and practice compared with the situation facing immigrants at the beginning of the twentieth century.

4. *Forms of Diaspora*

In addition to typologizing diasporas by examining their general characteristics, scholars have sought to classify the different 'forms' in which the term has been used, particularly by the different academic disciplines. A generally successful fourfold scheme has been proposed by Vertovec (1997) and modified in Vertovec and Cohen (1999).

The first form, advanced by sociologists and business studies specialists, is 'diaspora as social form,' alluding to the maintenance and development of transnational social organizations and networks, a collective identity, orientations to homeland and particular kinds of economic strategy (Safran 1991, Kotkin 1992, Cohen 1997). The second form is 'diaspora as consciousness.' Cultural studies theorists as well as those working in the fields of ethnic and race relations found in the notion of diaspora a means of breaking free from the 'essentialist' discourse that previously informed the subject matter. Notions of what constituted ethnicity became more fluid, hybrid, and negotiated, and 'diaspora' was a way of mapping how complexity and difference arouse as cultures travelled, interacted, and mutated (Clifford 1992, Brah 1996). The third is 'diaspora as mode of cultural production.' Though closely related to the second, this form is used by anthropologists to show how social and cultural formations, as well as cultural objects, images, and meanings have leaped from their old locales and crossed national lines (Hannerz 1996, Basch et al. 1994). Finally, 'diaspora as political orientation' has been considered by political scientists and international relations theorists. As noted earlier, such specialists concentrate on how the attachment to the politics of homeland can negatively and positively impact on the countries at both ends of the migration chain.

5. *Future of the Concept*

The concept of diaspora has firmly escaped its historical confines in the Jewish experience and at the beginning of the twenty-first century is used in a variety or settings and for a variety of purposes. The enduring logic is that the term conceptually connects home and abroad. The conflicting claims on group loyalties have been given an added emphasis in an age of global networks and the changing role, some would argue the relative decline, of the nation-state as a focus for group identification. 'Diaspora' will remain as an important means of interrogating and exemplifying this tension. It will also provide a useful means of describing the enhanced role for cyclical, transversal, and intermittent international migration.

Beyond this, the future of the term may be imperilled by having been commandeered to serve too many discrepant purposes and its use to describe cognate, yet different, phenomena. The use of 'diaspora' to describe transnational religious communities (as in 'Muslim diaspora') provides one example. In some cases, such as the Jews, Parsis, and Sikhs, religion, ethnicity, minority status, and peoplehood are so closely interpenetrated that the description 'diaspora' is apposite. 'Hindu diaspora' is acceptable, but undervalues the ethnic diversity under the expression 'Hindu.' However, 'Indian diaspora,' which expression is now in common use, misleadingly elides the differences between the three principal faith communities (Hindu, Muslim, and Sikh) and ignores well-organized national minorities (like the Kashmiris), with potentially confusing effects. The idea of a 'Turkish diaspora' presents similar issues. In addressing such problems, there may be some virtue in using the expression 'transnational communities' to characterize a number of different postnational and non-national forms of sociality and association. Examples so categorized can be virtual Internet communities, Christianity, Islam, transnational social movements, and international professional associations. Within the rubric of transnational communities can shelter 'diaspora' as a particular form of ethnically defined community. Some degree of self-restraint may, in

other words, prove necessary if the term is to retain its conceptual purchase.

Dictatorship

The term 'dictatorship' is one of Roman derivation, and originally signified the temporary suspension of constitutional constraints on governmental power and its unlimited transfer to one person. Among the Romans, there was provision for a temporary suppression of citizen rights during times of crises, and the equally temporary transfer of unlimited power, to a person chosen by the Senate and appointed by the Consul. At the end of a specified period—usually six months—the person so endowed, the dictator, surrendered power, and citizen rights were restored. The period of emergency stewardship was then duly reviewed, in accordance with constitutional requirements. During instances of emergency, over three centuries of republican constitutional rule, Rome appointed 88 dictators in conformity with law.

Following the rule of Julius Caesar, who exercised dictatorial powers for an unconstitutional length of time, the institution disintegrated and rulers assumed extraconstitutional powers in permanence. Rather than a traditional dictatorship, such rule took on the properties of what might more appropriately be called 'autocracy,' 'despotism,' or, perhaps, 'tyranny.'

Throughout the Middle Ages and more modern times in Europe, as well as during the institutionalization of dynastic rule in East and South Asia, 'autocracies' tended to be regularized through the agency of hereditary right—providing for succession without recourse to violence. Emperors, kings, and sultans could, and frequently would, allocate powers to 'noble' subordinates through a relatively well-articulated, rule-governed process. At times, as was the case in the rights embodied in the Magna Carta, some substantial rights were accorded subordinates.

1. The Modern Period

With the decline of the Middle Ages, it became increasingly common that adventurers would seize power in emerging city-states and principalities, and rule as despots or benevolent autocrats. The term 'dictatorship' was rarely, if ever, employed to identify such rule until the commencement of the modern period.

In regions such as Latin America, the term came into increasing vogue after the liberation from Spanish colonialism, irrespective of the fact that the ideal, throughout Central and South America—influenced by the North American model—was constitutional democracy and political stability. The basic charters of most of the nations of Central and South America had incorporated broad versions of the civil, political, and economic rights of citizens to the point of extravagance (Davis 1961). Unfortunately, governments in Latin America, throughout the remainder of the nineteenth and the beginning of the twentieth century, regularly came to power through violence and were commonly dislodged by revolution. During a 25 year period, from 1930 to 1955, for example, more than 50 violent, mainly military, revolutions took place in the region—to provide an impressive roster of

'military dictatorships' that ruled for variable periods of time (Lieuwen 1960).

In Africa, military dictatorships became the norm in the decades after the decolonization of European holdings that followed the conclusion of the Second World War. The African military—having a monopoly of coercion at its disposal, and often the only institution having logistical reach over the entire territory—acceded to absolute political power over inhabitants. Control, unconstrained by constitutional limitations, was more frequently than not secured by violence or the threat of violence.

In fact, the term 'dictatorship' (as distinct from terms like '*caudillismo*' used in Latin America) came into increased currency in Europe long before its employment elsewhere. At the commencement of the modern period, it came to be used, for example, to designate what was initially understood to be a temporary assumption of full power by what was called the Directorate under Cromwell in England, and in 1793, by the Committee of Public Safety, during the French Revolution.

After the conclusion of the First World War, the term was invoked to distinguish a pattern of rule by 'dictators' such as Benito Mussolini in Italy, Primo de Rivera in Spain, or Mustafa Kemal in Turkey. Actually, what such dictatorships signaled was a development that was far more portentous than simply the identification of the exercise of political power by a single ruler in any particular country. What was emerging was a singular political system, having a relatively specific syndrome of properties, that can be legitimately identified as 'modern dictatorship' (Talmon 1960).

2. *Modern Dictatorship*

The dislocations that attended the end of the First World War, gave rise to a wave of revolutionary ferment that involved Eastern and Southern Europe (Lee 1987). In Russia, revolutionaries first overthrew the Romanov monarchy, and then the provisional democratic government of Alexander Kerensky, in order to impose, in 1917, a 'dictatorship of the proletariat' under the leadership of V. I. Lenin.

According to the tenets of classical Marxism (the Marxism of Karl Marx and Friedrich Engels, the dictatorship of the proletariat was to be a transitional form of minority rule that marked the distance between 'bourgeois democracy'—what Marxists considered to be, in reality, a 'dictatorship of the bourgeoisie'—and communist democracy (see *Communism*). Lenin assumed full power over the emerging political system that followed the 'proletarian' revolution (see *Revolution*) by legitimizing it through an appeal to an ideological rationale (Furet 1999).

At approximately the same time, in 1922, Benito Mussolini led a collection of revolutionaries against the parliamentary and monarchial government of peninsular Italy (De Felice 1965). Initially what appeared to be a transitional government, calculated to deliver the nation from the crises that followed the First World War, the government of Mussolini quickly took on the features of a modern dictatorship. Through reforms commencing as early as 1925, Mussolini's Fascist regime assumed the properties of permanent minority rule under single-party auspices (De Felice 1968).

Lenin's proletarian dictatorship and Mussolini's Fascism provide a syndrome of traits that specifically characterize modern dictatorship (Johnson 1991). In both cases, a charismatic leader exercises almost total control over followers as well as the national community out of which they emerge. Leadership in both cases is epistemarchic in character. That is to say, leadership, in the absence of popular elections, is legitimatized by the leader's putative possession of an ideology (see *Ideology: Political Aspects*) that is an inerrant guide to policy, satisfying the needs of the collectivity (respectively the proletariat, or the nation). The inerrant ideology informs the belief system of an organization of believers, usually identified as a 'vanguard' of the revolutionary truth. In the course of time, that vanguard becomes the 'unitary party' of the political system—to the exclusion of alternatives. The inerrancy of the ideology and its attendant policy, in turn, is used to justify control over any and all political dissidence (which, under the circumstances, could only be in error) and any initiatives independent of the vanguard leadership (Manoilescu 1941).

In general, modern dictatorships maintain a military adjunct to unitary party rule. In the Bolshevik case that adjunct was the Red Army. In the case of the Fascist revolution, that adjunct was the Blackshirt militia. In the case of Adolf Hitler's National Socialism, that adjunct was the Schutz Staffel While military force remains an ultimate recourse of the system, modern dictatorships tend to be populist in disposition. They seek plebiscitary confirmation through controlled elections. Leadership, in modern dictatorships, because it is characteristically 'charismatic,' enjoys life tenure. The Democratic People's Republic of Korea (North Korea), as a case in point, exemplifies such a system. After the Second World War, Castro's Cuba, and Mao's China constituted illustrative instances. The system under the rule of Gamal I Abd' El-Nasser in Egypt, and Ghana under Kwame Nkrumah took on many of the same features. They took on the properties of a modern dictatorship however much their actual practice failed to fully satisfy the criteria for admission into the class.

In most cases, modern dictatorships, whatever their initial character, took on the features of an emphatic nationalism. Having begun as an ideology predicated on class, Bolshevism, as an instantial case, very quickly made recourse to 'patriotism' to sustain popular commitment. All classes and segments of classes in the

Soviet Union were expected to be supportive of what were unmistakably national purposes, however 'proletarian' they were supposed to be.

Similarly, given the traits exemplified by such a class of polities, they all failed to allow for what parliamentary and constitutional systems understand to be voluntary association, formal opposition, free elections, the separation of legislative, judicial and executive powers, as well as popular freedom of expression and individual movement. In almost all cases, the charter constitutions of such systems change with some regularity (the constitutions of the People's Republic of China, for example, have changed with every change of leadership) and their provisions are subject to unconstrained interpretation (the provisions of the constitution of Fascist Italy, for example, were subject to the regular reinterpretation of Mussolini and the Grand Council of Fascism).

3. Modern Dictatorship and Totalitarianism

By the beginning of the 1930s, a subset of modern dictatorships began to evince characteristics that led political scientists to design them a specific identity: totalitarianisms (see *Totalitarianism*). Possessed of an elaborate security and control infrastructure, supported by a factitious or real consensus, and animated by an irrepressible conviction of their own aggressive moral superiority, such politically repressive systems destroyed millions of innocents, either as a measure of control, or in the pursuit of utopian intention (Horowitz 1997) .

The numbers killed by Stalin, Hitler, Mao, and the Khmer Rouge will probably never be accurately known—but the victims of Marxist–Leninist (see *Marxism/Leninism*) regimes probably exceed one hundred million (Courtois et al. 1999). 'Mild' totalitarianisms—like those of Mussolini's Italy, Chiang Kai-shek's China, or Castro's Cuba—neither particularly homicidal nor genocidal—employ incarceration and exile, together with the characteristic denial of voluntary association and freedom of expression, as means of control.

Whatever the subsequent qualifications on the use of the term 'totalitarianism,' throughout the twentieth century an imprecise subset of modern dictatorships have shared a number of reasonably well-defined traits that qualify them for entry into a specific class of modern political systems (Schapiro 1972, Soper 1985, Gleason 1995). How far into the twenty-first century exemplars of the totalitarian subset of modern dictatorships will persist remains a matter of conjecture.

That such systems can evolve into something like a democratic alternative has been established by the transformation of Chiang Kai-shek's Kuomintang on Taiwan into something very much like a vital democracy. The massive reforms on the mainland of China, that followed the death of Mao Zedong, suggest that such systems have the potential to undergo systemic change. How such change is effected remains uncertain.

Dictatorship in History

Originally, the word dictatorship had a limited and unambiguous meaning in that it defined an extraordinary magistrature of the ancient Roman Empire. During the nineteenth and, particularly, the twentieth century, the meaning of the term has been substantially modified. In contemporary parlance, 'dictatorship' is used to define any means of governing and any type of political regime based upon the *unlimited concentration of power* in the hands of one individual (or of a group of people, a party or institution) holding it for an indeterminate time and exercising it without being

controlled by either the state's institutions or by its citizens.

This article will trace the transformation of the concept of dictatorship within the main instances of government to which it has been applied and with regard to the principal interpretations of the phenomenon, that is, the governmental types defined as dictatorships produced during the twentieth century when the term first became the object of specific historical research and theoretical analysis.

1. Roman Dictatorship

1.1 Origins and Functions

Dictatorship was probably introduced into the constitutional order of the Roman Republic at the beginning of the fifth century BC, soon after the end of the monarchy. Today, the original interpretation of dictatorship as attributed to the survival of the monarchy tradition has been abandoned. A more plausible interpretation is that which sees Roman dictatorship as being derived of an already existing institution in other cities in the province of Latium (Sterling 1965). The role of dictator could be conferred for the performance of various public duties, the most important being that of the defence of the city and of its rule in situations of serious danger, in the case of external war (*belli gerundi causa*) or internal turmoil (*seditionis sedandae causa*). In these circumstances, full civil and military powers (*imperium maximum*) were conferred upon the dictator for a maximum period of six months. The nomination was made by one of the two consuls in office (who could not, however, nominate themselves) upon the request of the senate, which assessed the gravity of the situation. The dictator stepped down at the same time as the consul who had nominated him. All other magistrates were subordinate to the dictator. He himself, however, did not have the power to repeal them nor to pass or repeal laws, modify the constitutional order, or nominate his successor. Once the duty for which he had been nominated to fulfill was completed, even before the passing of six months, the dictator resigned power to the ordinary magistrates.

1.2 The Transformation and End of the Roman Dictator

The dictator remained in force until the third century BC. The last dictator to have maximum civil and military powers was nominated in 216 BC during the second Punic war between Rome and Carthage. When reinstated in the first century BC by L. Cornelius Sulla and later by Julius Caesar during the time of the civil wars that led to the end of the Republic, the dictator's function was radically transformed. The dictatorships of Sulla and Caesar, despite the outward appearance of legality, originated in the force of the army, were conferred for an indeterminate length of time, and were used to eliminate political adversaries and to change the order of the Roman State. Roman dictatorship was legally abolished by Mark Anthony in 44 BC, directly following the death of Caesar (*lex Antonia de dictatura tollenda*) and was not reinstated again during the Empire. The term 'dictator' also was not used for many centuries and was not in any case adopted again until the beginning of contemporary times in order to define new exceptional forms of personal power that appeared in the medieval and modern ages in the form of the 'Podestà' of the Italian communes, the Renaissance 'Signoria' or Oliver Cromwell's 'Protectorate' (see *English Revolution, The*; *Middle Ages, The*; *Renaissance*).

2. From Roman Dictatorship to Modern Dictatorship

2.1 The Model of Roman Dictatorship in the Modern Ages

The term 'dictatorship,' referring exclusively to the Republican magistrature, appeared once again in political writings of modern times such as those by Jean Bodin and Thomas Hobbes, who cited it as an example of the fulfillment of the principle of Reason of State and of absolute sovereignty. Niccolò Machiavelli made a decisive contribution to that which we may term the 'apology conception' of dictatorship, understood as exceptional personal government for the purpose of saving the Republic and defending its liberty against internal and external enemies. The value of dictatorship, according to Machiavelli, was the brevity of its duration. As long as this function should be retained, dictatorship '*fece bene e non danno alla Republica romana*' (*Discourses*, I, 10, 33, 35).

This apologetic conception of dictatorship was again proposed in the seventeenth century with the idealization by democratic thinkers of the Enlightenment of republican public spirit (see *Enlightenment*). Jean-Jacques Rousseau maintained that in periods of danger the democratic state could nominate a 'supreme chief who silences all the laws,' fixing a relatively short period for the fulfillment of this chief's role without the capacity for its being prolonged, because only in this way would it be possible to avoid the transformation of dictatorship into tyranny (Rousseau 1997, p. 138).

2.2 Dictatorship and Revolutionary Power

The term 'dictatorship' re-entered political language at the end of the eighteenth century with the democratic revolutions in America and Europe (see *American Revolution, The*; *French Revolution, The*). In France, following the experience of the Public Health Committee, nominated by the National Convention (1793–5) both a new conception and practical expe-

rience of dictatorship emerged. This was identified by the advent of *revolutionary power* as a form of absolute government, exceptional and temporary, yet personal, which claimed its legitimacy on the basis of the principle of popular sovereignty, the wish to create a new constitutional order and a more just society. After the fall of the Jacobins, François-Noël Babeuf theorized the necessity of dictatorship by a small revolutionary minority in order to seize power by means of insurrection with the aim of realizing a 'society of equals.' After the failure of his insurrectionary attempt (1796) the concept of revolutionary dictatorship was taken up by Filippo Buonarotti, a disciple of Babeuf.

3. *Dictatorship in the Nineteenth Century*

3.1 *'Bonapartism' and 'Caesarism' in Europe*

In the course of the nineteenth century, the term 'dictatorship' was used in its original meaning by the military leaders of the national revolutions. Simon Bolivar proclaimed himself dictator in 1813, and Giuseppe Garibaldi assumed the power of dictator in 1860 during the expedition of the Thousand. The idea of dictatorship was often associated, within nationalism, with the idea of exceptional government for national liberation. Most important, for the history of dictatorship and the transformation of the concept were the new forms of personal regimes founded in Europe by Napoleon Bonaparte (1799–1814) and later by his grandson Luigi Bonaparte, becoming Napoleon III (1851–70). Their dictatorship originated in a *coup d'état*. However, they attempted to legitimize their personal power later with a popular plebiscite and with the transformation of the monarchy without formally reneging on the principles of the French Revolution.

These two experiences of government gave rise to the term 'Bonapartism,' from then on used to define the new type of dictatorship imposed by a *coup d'état*, but claiming a democratic legitimacy by means of plebiscites. The introduction of the term 'Caesarism' was also used in the definition of this new type of dictatorship, in that Julius Caesar was considered the prototype for the modern dictator, emerging victorious after a period of serious social and civic conflict and imposing his personal power using military strength, but also with the support of the masses, presenting himself as the pacifier of the classes, above parties, restorer of stability and of the unity of the State, the incarnation and the interpreter of the national will.

3.2 *Dictatorship in Latin America*

A particular demonstration of a South American version of 'Caesarism' can be found in the presidential dictatorships installed in the majority of the Latin American Republics emerging after independence. These dictators were politicians or military men who elected themselves president and perpetuated their personal power for decades while, nevertheless, paying homage to liberal ideology, allowing for the survival of the constitutional order and, above all, imposing the centralization of state power against the *caudillos*, the local leaders who, in the first years following independence, instituted personal control with the help of the army, the personal fascination with virility, and the support of the indigenous and mestizo populations. Other president-dictators, followers of positivism, justified their dictatorship with the formula 'order and progress' as a necessary means for reinforcing the unity and cohesion of the state, as a pedagogical tool for the education of the people, and as a principal factor in the renovation of society and progress. This new version of the apologetic conception of dictatorship remained one of the principal formulas of populist self-legitimation for the dictators that successively dominated South America (see *Populism*).

3.3 *Apologists for and Critics of Dictatorship*

Other versions of the apologetic conception of dictatorship were elaborated in romantic culture, in Catholic reactionary thought, and in positivism: the dictator was variously exalted as the supreme guide of the people, the interpreter of God's will, or the political genius who actuated the laws of history and of progress. Liberal culture, on the other hand, held that the same possibility of conferring absolute power upon a single individual was incompatible with the concept of the modern state founded upon the liberty of citizens, on the sharing of power and on the principle of majority rule. Duclerc and Pagnerre's *Dictionnaire Politique* of 1848 explicitly refuted the treatment of dictatorship as 'an element of modern politics' because 'invoking dictatorship means invoking violence' and annihilating 'the most sacred principle of democracy, that of majority rule' (see *Crowds in History*; *Liberalism*).

3.4 *The Dictatorship of the Proletariat*

In socialist thinking, the concept of dictatorship as revolutionary power was developed. Louis-Auguste Blanqui theorized the necessity of the dictatorship of a revolutionary minority for the realization of communism. This conception was criticized by Karl Marx and Friedrich Engels because their idea of revolutionary dictatorship had to be the *impersonal power* of the working class. The Paris Commune of 1870 represented for Marx the first concrete attempt at proletarian dictatorship. In that in a society divided into classes every type of state is no other than the dictatorship of the dominant class, according to the idea sketched out by Marx in the *Critique of the Gotha Programme* (1875), 'proletarian dictatorship' was un-

derstood as the organization of the working class at the level of the state following the conquest of power in the transition period from capitalist to communist society.

The concept of 'proletarian dictatorship' was first elaborated with the conquest of power in Russia in 1917 by the Bolshevik Party led by Lenin (see *Communism, History of*). Lenin was a convinced and tenacious advocate of the necessity of dictatorship intended as an unlimited, inflexible, and implacable power in the repression of enemies of the proletariat because, in the absence of this power, the transition from capitalism to socialism would be impossible ('The immediate duties of Soviet power,' April 26, 1918, in Lenin 1971). However, against Marx, Lenin claimed that dictatorship of single individuals, endowed with unlimited power for the realization of the socialist revolution was not in fact incompatible with proletarian dictatorship, exercised by the Bolshevik Party as the vanguard of professional revolutionaries and interpreters of the historical role of the proletariat.

The Leninist conception of dictatorship and its practical activation were criticised by other revolutionary Marxists such as Rosa Luxemburg who claimed that proletarian dictatorship should consist of 'a means of applying democracy, not of its abolition,' and 'the work of the *class*, and not of a small minority of leaders in the name of the class' (Luxemburg 1970 pp. 570–94).

4. The Twentieth Century: A Century of Dictatorships

4.1 The Epidemic of Dictatorship in Europe between the Two World Wars

'In the Victorian era,' wrote Winston Churchill in 1930 in the introduction to one of the first attempts at the historical and theoretical analysis of dictatorship (Forst de Battaglia 1930), 'dictatorship was at once a monstrosity and an anachronism.' The triumph of parliamentary democracy in Europe in the aftermath of World War I was ephemeral. In 1922, the 'crisis of democracy' and the 'crisis of parliamentarism' were already being talked of (Guy-Grand 1922, Schmitt 1923), while with the affirmation of absolute power by the Bolshevik Party in the USSR a new type of dictatorship as a regime by a single party was being affirmed for the first time. The fascination with the Bolshevik experiment excited masses of European workers and prompted the birth of communist parties with the aim of violent conquest of power for the establishment of 'proletarian dictatorship.' Nevertheless, no attempt at communist conquest of power was successful. On the contrary, the fear of Bolshevism generated reaction on the part of the bourgeoisie and the middle classes in many countries which led to the creation of authoritarian, nationalistic, and anti-Bolshevik governments. After 1922, almost every year, more or less durable dictatorial nationalist governments emerged in Italy, Spain, Turkey, Poland, Greece, Portugal, Austria, Germany, the Baltic States, and the Balkans.

4.2 The Model of Fascist Dictatorship

At the end of 1922, with Mussolini's coming to government in Italy (28 October), for the first time a nationalist revolutionary movement organized around a new form of party, the 'party-militia,' conquered power in a country governed by a liberal democracy with the declared object of destroying it. This gave rise to the establishment of a regime that antifascists were the first to call a 'one-party state,' 'totalitarian system,' or 'totalitarianism,' defining a new type of dictatorship founded upon the predominance of a single party, the centralization of power in the hands of the party leader, the imposition of a singular ideology with the aim of realizing the subordination of society to the state by means of control by the singular party and its organizations (Gentile 1995).

Until the middle of the 1920s, fascism, and not Bolshevism, was considered the real threat to parliamentary democracy (Martin 1926). Italian fascism effectively became the model for other nationalist movements that proclaimed their dictatorial vocation, openly opposing the ideals of the French Revolution. At the beginning of the 1930s, Europe was invaded by an 'epidemic of dictatorship' (Sforza 1931). Initially, the dictatorial disease was considered to be exclusive to less developed countries (Cambò 1930). This interpretation was proved wrong after the rise of National Socialist dictatorship in Germany (see *National Socialism and Fascism*). In the second half of the 1930s, however, the 'seduction of fascism' seemed to grow (Drabowitch 1934). During World War II, most of Southern, Central, and Eastern Europe was governed by dictatorial systems.

4.3 Totalitarian States

In the period between the two world wars a new apologetic myth of the dictatorial figure as the 'strong man' who emerges in times of crisis to rescue the State and re-establishes order, discipline, and efficiency was diffused (Séché 1924, Béraud 1933, Massis 1939). At the same time, the first attempts at comparative analysis aimed at elaborating a unitary perspective on the phenomenon of dictatorship were begun. Already, by the second half of the 1920s, several analogies between the dictatorship of Bolshevism and that of fascism came to prominence, later compared also to the dictatorship of National Socialism. The classification of these new types of dictatorship under the category of 'totalitarian states' appeared at the end of

the 1920s and was already consolidated by the 1930s and 1940s when the first comparative analyses of fascist, communist, and national socialist regimes were carried out (see Kohn 1935, Hoover 1937, Sturzo 1938 1972, Borkenau 1939, American Philosophical Society 1940, Neumann 1942, Aron 1946).

These studies analyzed the new form of dictatorship from the point of view of its most original aspects, neatly distinguishing it from both Roman and nineteenth-century dictatorship. These aspects included:

(a) the peculiarities of the original phenomena of dictatorship, attributed to the legacy of war, the embitterment of class war, the radicalization of politics, and the incapacity of the parliamentary system to adapt itself to the tumultuous growth of mass society and to provide an effective solution to social and economic conflicts;

(b) the interest of the masses living through the turmoil of a society undergoing transformation and looking for simple and reassuring solutions by subordinating themselves to the command of a 'strong man' who promised to resolve the crisis with brutal yet efficient methods;

(c) the novelty of contemporary dictatorship as a one-party regime, created by a mass movement that used parliamentary channels, violence, and terror to conquer and maintain power, rendering permanent its own dictatorship and institutionalizing it as a fundamental pillar of a new political system;

(d) the personalities of the dictators brought to power by these parties such as Stalin, Mussolini, and Hitler, that is, 'new men' emerging from anonymity and rising to power solely due to their political capacity, exalted and revered like demigods by their followers and by the masses;

(e) the fanaticism and missionary spirit of the new dictators who endowed their ideology and action with the character of a secular religion;

(f) the use of methods of technological and organizational modernization for the mobilization of the masses and the development of an intense and constant activity of collective indoctrination; and

(g) the ambition of subordinating the collectivity and society to the permanent and capillary control of a single party with the aim of creating a new species of human being.

4.4 The Dictatorial Phenomenon After the End of World War II

In the aftermath of World War II, while parliamentary democracy was being re-established in Italy and Germany, liberal democracy was definitively consolidated in Western Europe and, after 1945, there were no new dictatorships in this part of the continent. From among the nationalist dictatorships emerging from the interwar period, only the Salazar regime in Portugal and that of Franco in Spain remained standing, both of which returned to democracy after the death of the two dictators in the second half of the 1970s. The only new dictatorship was that of the Colonels' regime in Greece (1967–1974).

The phenomenon of dictatorship, nevertheless, enjoyed a new and intensified period of expansion in almost all continents. Only North America and Australia remained uncontaminated by the new dictatorial epidemic. Directly after the end of World War II, East Germany, all of Eastern Europe, and the Balkans were put under the control of the new communist dictatorial regimes, the so-called 'popular democracies' (Fejtö 1969), completely subordinated to the political and military hegemony of Stalin's USSR from which only the communist regimes of Yugoslavia and Albania escaped. From 1949, with the victory of the communist revolution led by Mao in China, the world's most densely populated country became governed by a dictatorial regime with its own characteristics, different to the European communist dictatorships and to those of the USSR. During the 'Cold War,' the communist model, with variations original to each country, inspired the construction of several dictatorial regimes, both civilian and military, in Central America, Asia, and Africa with the help of the two largest communist countries, the USSR and the People's Republic of China, becoming, since the 1950s, rival and antagonistic states both for ideological reasons and for those concerning territorial conflict (see *Chinese Revolutions: Twentieth Century*; *Cuban Revolution, The*; *Vietnamese Revolution, The*).

The common characteristics of the communist dictatorships were (a) the adoption of Marxist-Leninism as their official ideology; (b) the supremacy of the Communist Party as the single and dominant party; (c) the exaltation of the party leader resulting in the institutionalization of the 'cult of personality'; (d) the policed repression of any opposition or dissidence, including the recourse to mass terror; (e) the nationalization and planning of the forces of production and of the economy; (f) the submission to control by the Communist Party of all political and social activities; and (g) the development of a particular form of 'communist patriotism,' centered upon the myth of the historical mission of the proletariat.

During the 'Cold War,' anticommunism was the motive and principal ideological justification for the establishment of right-wing, civilian, and, more often, military dictatorships sustained by the USA. These dictatorships, especially the military ones (Nordlinger 1977), when not based exclusively on terrorist repression and the arbitrary use of power in the interests of the dictator, his family, or acolytes, attempted to relate policed repression to a demagogic politics of nationalist populism all the while linked to programs of modernization and development (see *Modernization and Modernity in History*). In the second half of the twentieth century, dictatorship in the Third World became 'the normal form of govern-

ment' (Roy 1977). Almost all the new states emerging in Africa and Asia after the fall of the colonial empires were governed by dictatorial regimes, generally military with a single party created from above, a charismatic leader, and a populist ideology of national socialism with programs of secularization and modernization. In the second half of the 1970s, in several Islamic countries, religious fundamentalism became the matrix and ideology for new dictatorial governments.

The tendency towards the proliferation of dictatorships came to a halt in the last two decades of the twentieth century (Hamon 1982). The number of dictatorships—or governments considered as such—has notably diminished. In Latin America, parliamentary democracy has been reinstated in the grand majority of states previously governed by dictators. The fall of the USSR brought about also that of the communist regimes of Central and Eastern Europe that it sustained (see *Revolutions of 1989–90 in Eastern Central Europe*). The promotion of human rights has acquired new determination, albeit not always effective, in contesting antidemocratic, repressive, and terrorist governments and in the defeat of the various apologetic conceptions of dictatorship (see *Human Rights, History of*). Nevertheless, it would be too optimistic to use the above to declare the definitive death of dictatorship in the contemporary world and the victory of the democracy of human rights (Hermet 1993).

5. *Contemporary Dictatorship: Problems of Definition and Interpretation*

5.1 *Definitions and Typologies*

Contemporary dictatorships are extremely heterogeneous: civilian or military, personal or collective, conservative or revolutionary, traditionalist or modernizing, bureaucratic or charismatic, authoritarian or totalitarian. Moreover, not only do contemporary dictatorships have nothing in common with their ancient predecessor, apart from the concentration of power, they also differ extensively among themselves according to the geographical, historical, and cultural contexts in which they emerge and owing to the economic, political, and social situations that give rise to them. Furthermore, they differ as regards the social origins of their protagonists as well as the latter's political formation, the modes in which power and methods of action are organized, the ideologies they profess and the aims they propose. Finally, differences exist relative to the historical development of their emergence, the results they have achieved, and the legacies they have left.

Given the variety and complexity of the phenomenon of dictatorship in the twentieth century, it is very difficult to elaborate a general, unitary theory of dictatorship. Several fundamental problems therefore remain unsolved, particularly those which concern the specific nature of contemporary dictatorship with respect to other forms of absolute personal power. There are various definitions and typologies for classifying the numerous forms of unlimited concentration of power appearing during the course of the twentieth century, commonly adopting the term dictatorship albeit with a meaning varying widely from the original (see especially Schmitt 1928, Friedrich and Brzezinski 1956, Neumann 1957). There are some scholars, however, who prefer to use the term dictatorship in reference only to its original meaning, finding the term 'antidemocratic regime' more appropriate for defining the modern forms of unlimited concentration of power, be they authoritarian or totalitarian (Linz 2000). The identification of contemporary dictatorship with antidemocratic regimes is, however, only one aspect of a much more ambiguous relationship between contemporary dictatorship and democracy, understood as the affirmation of the principle of popular sovereignty and mass participation in political life. Contemporary dictatorship in fact 'belongs to the postdemocratic era' (Kohn 1935), that is, it presupposes the democratic process yet nonetheless searches for its own formula of legitimation within the principle of popular or national sovereignty (Duverger 1982).

5.2 *Dictatorship, Tyranny, Despotism*

In contemporary speech, dictatorship is often associated with tyranny or despotism. Terms such as dictator, tyrant, and despot are often used as synonyms or alternated between. The first students of the phenomenon of dictatorship in the interwar period, while maintaining that the concept of dictatorship is linked to the Roman model of an extraordinary, yet constitutional and temporary magistrature, preferred to speak of a 'new age of despots' (Spencer 1927), or of a new '*ère des tyrannies*' (Halèvy 1938). In more recent studies also the term 'tyrant' is preferred over that of dictator for defining the numerous ranks of those holding absolute personal power, dominating, in the second half of the twentieth century—and still in some cases dominating—in many countries of the Third World (Rubin 1987, Chirot 1994). In fact, contemporary dictatorship evokes some of the characteristics of Greek tyranny (Stoppino 1976), but there are also substantial differences. Above all, the origin of contemporary dictatorship is not always illegitimate. For example, Hitler came to power in 1933 through legal channels and many presidents who became dictators in Latin America were legally elected. Furthermore, the majority of modern dictatorships have a very complex structure of organization and exercise of power due to the mass dimension of the societies in which they operate, the methods they adopt, and the aims they propose. All the above makes contemporary

dictatorship substantially new and different to tyranny. Therefore, the thesis that holds that the difference between tyranny and contemporary dictatorship as a form of absolute personal power is not substantive, but regards solely the form, technique, and method of government should be forcefully rejected (Hallgarten 1957).

5.3 Dictatorship and the Dictator

Several scholars consider the figure of the dictator an essential and fundamental element in the definition of dictatorship (Cobban 1939). A large part of the general history of dictatorship consists of collections of biographies that sometimes link, in more or less chronological succession, Greek tyranny and the Roman dictators, Cola of Rienzi and Geralomo Savonarola, Cromwell and Robespierre, the two Napoleons, the 'caudillos' and the authoritarian and totalitarian dictators of the twentieth century (Funck-Brentano 1928, Bainville 1939, Hallgarten 1957). Some scholars maintain that governments in which unlimited power is not concentrated in one individual cannot be defined as dictatorships in the proper sense of the term (Sartori 1971).

The identification of dictatorship with the figure of the dictator is certainly justified in the majority of the cases in history. In almost all contemporary dictatorships, the dominant personality of one man emerged at the outset or was subsequently imposed, often surrounded by a charismatic and sacred fascination with the cult of the personality (Schweitzer 1984). At the same time, dictatorial governments exist without the figure of the dictator, for example, the USSR following Stalin's death and the dictatorial regimes governed by military juntas. Moreover, not even in totalitarian regimes that appear to be internally controlled by the personal power of a dominant and charismatic figure, can the nature and character of the dictatorship as a system of power founded upon the single party be identified in the personage of the dictator (Tucker 1972, Schapiro and Lewis 1970, Gentile 1998).

5.4 Conclusion: General Characteristics of Contemporary Dictatorship

The diversity in the experiences of power defined as dictatorship in the contemporary world, the variety of definitions and typologies and the problems remaining controversial regarding the nature of dictatorship do not, nonetheless, impede us from being able to identify at least some common characteristics enabling the definition of the specificity of the phenomenon of dictatorship in the modern era in their formative or stabilizing phases.

According to the definition given at the beginning of this article, all types of government and regime in which a single person, a group of people, a party, or a military or religious institution (a) conquers the monopoly over political power, by legal or illegal means, and maintains it for an indeterminate length of time; (b) suppresses, reduces, or impedes citizens' enjoyment of their civil or political rights; (c) forbids or represses the activities of dissidents or of the opposition with the use of force and with recourse to terrorist means; (d) excludes *de facto* the possibility of the legal and pacific repeal of the rulers by the ruled even while allowing for electoral consultations and plebiscites to take place, may be included under the category of contemporary dictatorship. Contemporary dictatorship is, thus, the antithesis of democracy understood as a representative political system based upon the division and balance of power, a respect for the personal and public rights of citizens, on freedom of speech and of association, and on the periodic election of the government by the electorate, by means of a free and peaceful political contest and according to legal procedures guaranteed by the constitution.

Differential Aging

Differential aging is a term within lifespan psychology that is intended to communicate the heterogeneity of developmental processes in the later years of adulthood. The concept of differential aging underlies many contemporary theoretical and empirical analyses; however, the introduction of this particular term can be traced back to the work of Thomae in the Bonn Longitudinal Study (Thomae 1979). More recently, investigation of differential aging was a central component of the Berlin Aging Study (BASE), a comprehensive study of over 500 adults between 70 to over 100 years living in Berlin, Germany (Baltes and Mayer 1998).

According to the principle of differential aging, the rate of functional losses and gains over time shows both inter-individual variability and intra-individual variability. Inter-individual variability is shown by the fact that there are differences across individuals in the rate at which changes occur over time. Intra-individual variability is demonstrated by the finding of differences in the rates of change over time within the same individual. The principle of differential aging stands in sharp contrast to the previously held views in developmental psychology that aging is a uniform process of decline, also known as dedifferentiation. Although it is true that death is the inevitable outcome of the aging process, this fact does not rule out the possibility that growth can occur in psychological functions even at the end of life. Plasticity is another component of differential aging, meaning that the potential exists throughout later adulthood for growth and adaptation.

1. *Evidence for Differential Aging*

Support for the concept of differential aging has emerged from a variety of sources within the field of gerontology. One of the strongest arguments used to support differential aging is a meta-analysis of a wide range of empirical studies based on data available through the late 1980s. This analysis yielded evidence of greater variability among older, compared to younger, samples of adults (Nelson and Dannefer 1992). However, without providing explicit tests of the concept of differential aging, many other investigations have led to similar conclusions. The concept of differential aging is becoming a well-established fact

within the field of psychology and aging (Whitbourne 2001). It is no longer unexpected to show heterogeneity across older samples and within areas of functioning in the same individual.

Explanations of differential aging relate to models in lifespan developmental psychology that emphasize the importance of person–context transactions as influences on development (Lerner 1995). Such transactions affect the rate of aging within and across individuals as they are exposed to and select environments that differentially affect their physical, psychological, and social characteristics. Furthermore, rates of aging across and within individuals may reflect exposure to opportunities for prevention and compensation as represented, albeit crudely, by the variable of socioeconomic status. The higher mortality rates of individuals from lower socioeconomic backgrounds may be viewed as a manifestation of these differential opportunities (Lantz et al. 1998). To the extent that higher mortality rates reflect a more rapid acceleration of deleterious changes either directly or indirectly linked to aging, variations among socioeconomic status may be seen as a critical contextual variable within the framework of differential aging.

A concept highly related to differential aging is that of selective optimization with compensation (SOC; Baltes and Baltes 1990). Selection refers to the process of actively or passively reducing the number of goals and domains in which to become involved. The purpose of selection is to conserve energy and motivation for more important goals or to select new goals that will serve particular developmental tasks, such as coming to terms with mortality. Compensation in this model is defined as searching for and using alternate means of reaching a goal once it is no longer possible to use previous methods to achieve that goal. For example, an individual may wish to remain physically active but when limitations occur in mobility, the method of involvement may change accordingly. Optimization is the process of refining the methods and resources needed to reach a goal and thereby achieve success in particular domains. Applications of the SOC model to the processes through which individuals attempt to control and regulate developmental change over the lifespan are providing further elaboration of this model (Heckhausen 1997).

1.1 Application to Physical Aging Processes

The physical aging process is a prime example of the concept of differential aging. Aging of the body occurs across all organ systems, but at different rates within and across individuals. These concepts are expressed in the multiple threshold model (Whitbourne 1996), which postulates a reciprocal relationship between the aging of the systems within the body and the individual's identity or self-conception throughout the years of adulthood. It is known that changes occur within bodily systems at varying rates over time, reflecting both genetic predisposition and the impact of the environment. A threshold is the point at which the individual becomes aware of having experienced an age-related change in an area of functioning. After the threshold is crossed, changes in identity occur as the individual becomes closer to defining the self as 'old.'

Predictions of the multiple threshold model were tested in an investigation of a large sample of adults from 40 to 95 years of age (Whitbourne and Collins 1998). Respondents were asked to indicate the extent to which they had experienced a set of physical and cognitive changes related to the aging process as well as the way that these changes had affected their identities. There were clear individual differences in the areas of functioning identified as significant, as well as variations in the responses that individuals had to these age-related changes. Changes with regard to aging were clearly distinguished within the minds of respondents in this study, who reacted differently to changes in cognitive processes compared to changes in mobility and physical strength.

Another facet of the multiple threshold model is that individuals vary in the preventive and compensatory mechanisms available to them across a wide area of functions. For example, in the case of aerobic capacity, it is well known that regular activity can help to offset the aging process, even if this activity is begun quite late in life. By contrast, individuals can also choose to alter the rate of the aging process by the adoption of harmful health habits, such as cigarette smoking or a sedentary life style. Their decision to engage in these activities may reflect social factors as well as psychological processes. As noted, education and occupational background are further contributing factors, as individuals from higher socioeconomic levels are more likely to be aware of the strategies they need to employ to moderate the rate of their own aging (Lantz et al. 1998).

The extent to which individuals possess resources based on their sensory, cognitive, personality, and social skills provide another factor to be considered in differential aging (Baltes and Lang 1997). People who are low in these personal and social resources have more difficulty negotiating the tasks of daily life in later adulthood. In part, differences between resource-rich and resource-poor older adults occur because these individuals have unequal opportunities to take advantage of compensatory measures that would help offset the negative effects of aging.

One caveat to the notion of increasing variability with age in physical functioning comes from the BASE (Mayer et al. 1998). Among the oldest-old in the sample, i.e., those over 85, there was a decline across a variety of abilities and a tendency for greater similarity across domains of functioning. This finding suggests that individuals in the latest period of life, until

recently not widely available for study, may be undergoing changes that are discontinuous with the earlier years of the lifespan. Changes in biological functioning may become more widespread after this point, affecting a broad range of abilities that depend on the integrity of the body's systems.

1.2 Application to Intellectual Development

Differential aging also appears in research on intellectual development in later adulthood. Researchers in this field recognized by the 1960s that there was a considerable discrepancy between age patterns based on verbal vs. non-verbal tests of intelligence as well as differences between cross-sectional and longitudinal studies. Findings from the Seattle Longitudinal Study (SLS) revealed an overall picture of intelligence in later adulthood as one of stability until the 50s or 60s followed by decline through the oldest age tested. However, there are important qualifications on this conclusion (Schaie 1996). First, although some individuals may show declines in intelligence by the mid-50s, significant losses do not occur overall until the decade of the 70s. A second point is deterioration of functioning does not occur across all abilities, even into the decade of the 80s. Third, most people are able to retain competent performance of familiar skills, particularly those that are of importance to them. Finally, there was evidence for plasticity as indicated by the success of training studies intended to improve the scores of older individuals on tests that had otherwise shown age-related declines.

A fundamental distinction has emerged in studies of intellectual functioning and age indicating that there are different trajectories over the lifespan for the two theorized components of intelligence: 'fluid' abilities, or the mechanics of intelligence, and 'crystallized' abilities, or the pragmatics of intelligence (Baltes et al. 1999). With increasing age in adulthood, losses occur in the functions that underlie the mechanics of intelligence, such as attention, working memory, and psychomotor speed. The pragmatic abilities involving mastery of a body of declarative and procedural knowledge, a well as expertise in specific domains, are maintained into later life. These abilities can allow older individuals to perform at relatively high levels despite the aging of functions that contribute to losses in the mechanics of intelligence. The area of wisdom, or optimal expression of knowledge in the fundamental pragmatics of life, provides a prime example of the growth of abilities in later life even in the face of sensory, perceptual, and cognitive losses (Baltes and Staudinger 1993).

1.3 Application to Personality and Social Functioning

The concept of differential aging, with the implication of variations in gains and losses across and within individuals, is implicit in the theory of socioemotional selectivity, the proposition that throughout adulthood, individuals reduce the range of their relationships to maximize the social and emotional gains and minimize risks (Carstensen 1992). According to this theory, aging is associated with a desire to become more focused on maximizing the emotional rewards of relationships and less involved in seeking information or knowledge through social interactions. The desire to maximize emotional rewards leads adults increasingly to prefer spending time in their relationships with people who are familiar to them rather than seeking out new friends and acquaintances. Although this theory postulates a universal process, that of seeking out the familiar rather than the new in relationships, it also has relevance to the differential aging principle. According to the theory, it is not aging but the recognition of limited time that stimulates the shift in motivation for relationships. Younger individuals will show similar tendencies to prefer spending time with close friends and family rather than strangers when they perceive that an ending is drawing near.

That older adults are able to maximize their feelings of well being by active steps they take to regulate their relationships is also reflected in research on subjective well-being in later adulthood. In one large-scale survey of a national sample of adults (Mroczek and Kolarz 1998) the majority of older adults were found to rate their happiness levels as 'high' or 'pretty high.' However, there were variations in the relationship between subjective well-being and age as a function of gender, personality, and marital status. Furthermore, the results differed according to which component of subjective well-being was investigated. Positive affect was higher in the older age groups, particularly so for women. For men, personality interacted with age in ratings of positive affect. Higher positive affect scores were found only in the older group of introverted men. Men who were extroverts had high positive affect scores throughout the adult age range tested. Only the married men showed a relationship between age and ratings of negative affect. The older groups of married men had lower scores than the younger married men in the sample. Although these data only reflect one study out of many conducted within the field (Diener 1998), they are of particular relevance to the principle of differential aging because they point to the roles of personality and contextual factors as influences on levels of well-being in middle and later adulthood.

2. Suggestions for Future Research

Despite the existence of the principle of differential aging, many researchers within psychological gerontology and lifespan psychology continue to focus their efforts on the search for consistent patterns of age differences that would characterize older adults as a homogenous group. Theories such as the general slowing hypothesis (Salthouse 1996) propose that the

aging process involves a unilateral loss of speed which in turn accounts for reductions in processing abilities. Trait theories of personality propose, in contrast, that there is overall stability of personality throughout the decades of middle and later adulthood (McCrae and Costa 1990). However, even within these frameworks, there are attempts to identify patterns of differences associated with biological or experiential factors. For example, experienced typists may preserve their abilities to perform well-learned tasks by compensating for loss of speed with changes in strategy (Salthouse and Saults 1987). Similarly, in the area of personality, although the search for universal trends continues (McCrae et al. 1999), researchers also attempt to identify patterns of life events that alter levels of personality traits or their expression in behavior (Helson et al. 1995).

3. Summary

The examples provided here of research supporting the concept of differential aging suggest the need for further empirical investigation that employs a multidimensional and multifaceted approach to the study of lifespan processes as these unfold in later life. It is no longer sufficient to document the existence of age differences or changes over time employing standard methods using correlation or analysis of variance. With the increasing availability of structural modeling techniques, lifespan researchers have the opportunity to translate the principle of differential aging into operational terms. Research based on this principle will not only reflect more accurately the nature of the aging process but can also provide the basis for effective interventions to improve the daily lives of older adults.

Differential Diagnosis in Psychiatry

Diagnosis (derived from two Greek words: *dia*, meaning through, and *gnosis*, meaning knowledge) is a key medical activity. Indeed, there is a sense in which it is the most fundamental of all medical skills because it is a necessary preliminary to treatment, and treatment is often carried out by others. The patient consults a doctor who assesses them and makes a diagnosis. Thereafter, depending on the nature of the problem, the patient may be treated partly or entirely by members of a wide range of other professions, including nurses, physiotherapists, clinical psychologists, and occupational therapists. Sometimes the diagnosis is a simple statement: the patient is suffering from disease or disorder X. More commonly, at least initially, it takes the form of a differential diagnosis: the patient complaining of recurrent upper abdominal pain is probably suffering from a hiatus hernia (an anatomical defect allowing regurgitation of stomach contents into the gullet), but the symptoms may be cardiac in origin (angina), or the result of a gastric or duodenal ulcer, or even of a gastric cancer, and it is important to exclude these possible alternative diagnoses before treatment starts. In principle, differential diagnosis in psychiatry is no different from that in any other branch of medicine. In practice, however, there are a number of important differences because of our limited understanding of the causes, or etiology, of most mental disorders.

1. *The Definition of Diseases*

In the seventeenth century all the diseases that were then recognized were defined by their clinical syndromes, that is by the symptoms the patient complained of, the clinical signs elicited by the physician on examination, and the evolution over time of these symptoms and signs. Over the last three or four hundred years, however, increasing understanding of the etiology of most of these diseases has resulted in their being redefined at some more fundamental level. Smallpox is now defined, not by its characteristic rash, high fever, and mortality, but by the presence of the variola virus. Cancer of the stomach is defined, not by the patient's rapidly worsening indigestion and palpable abdominal mass, but by the histopathology (detailed microscopical structure) of the tumor. Thyrotoxicosis is defined, not by the patient's goiter, weight loss, and bulging eyes, but by a raised blood level of the thyroid hormone thyroxin, and so on. As a result, the diagnosis of most diseases depends on the results of laboratory investigations. Although the physician usually has a shrewd idea which diagnoses are likely after examining the patient, the provisional clinical diagnosis needs to be confirmed by the laboratory. A diagnosis of smallpox is only provisional until the variola virus has been identified; a diagnosis of cancer of the stomach has to be confirmed by histological examination of the tumor; and a diagnosis of thyrotoxicosis has to be confirmed by demonstrating a raised blood level of thyroxin.

Because understanding of the etiology of most psychiatric disorders is still rather rudimentary they still have to be defined by their clinical syndromes. This means that diagnosis, and hence differential diagnosis, is determined by the patient's symptoms (abnormal or distressing subjective experiences reported by the patient) and behavior (observed or reported by others), and the temporal evolution of these abnormalities. Apart from age and sex, information of other kinds, particularly from laboratory and radiological investigations, is rarely relevant, and even if it is relevant it is not decisive. The difference between psychiatry and the rest of medicine is not absolute, however. Several neurological disorders, such as migraine and torticollis, are still defined by their syndromes, and so too are some skin disorders, such as pityriasis rosea. Conversely, some psychiatric disorders, such as Alzheimer's disease, vascular dementia, and Creutzfeldt-Jakob disease, are defined by their neuropathology. Their defining characteristics are comparable, in other words, with those of cancer of the stomach. But even here there is an important practical difference. The histopathology of a gastric tumor can be determined by taking a biopsy through a gastroscope, or at operation, whereas the histopathology of the brain can normally only be determined *postmortem*, and this means that the diagnosis on which treatment is founded still has to be based on the clinical syndrome.

At present there are only a few psychiatric disorders which are defined by the presence of a fundamental abnormality which can be identified or excluded during life. Down's and Klinefelter's syndromes are both defined by the presence of chromosomal abnormalities—the former by an additional chromosome 21 and the latter by an additional X chromosome. Huntington's chorea and the Fragile X syndrome are both defined by abnormal genes at specific sites, and phenylketonuria (like Fragile X, an important cause of mental retardation) is defined by a specific biochemical abnormality. Eventually, of course, as understanding of their causation develops, most psychiatric disorders will either be redefined in terms of an underlying abnormality of some kind, or be replaced by new diagnostic concepts defined in this way. At that stage differential diagnosis in psychiatry

will be no different from that in any other branch of medicine. Until then, however, problems of differential diagnosis have to be handled differently. In other branches of medicine diagnostic problems usually lead to more extensive laboratory and radiological investigations. In psychiatry this is rarely appropriate, and the best approach is usually to try to obtain a more detailed account of the development of the patient's illness, often from other informants, and to monitor its course and response to treatment as closely as possible. Because most psychiatric disorders are defined by the patient's symptoms and abnormal behavior, and changes in these over time, differential diagnosis has to be determined by information about these things, and uncertainties can only be resolved by obtaining more accurate or more detailed information, or by following the course of the illness.

2. *The Adoption of Operational Definitions*

Before the 1970s psychiatric diagnoses were alarmingly imprecise. There was broad agreement on the core symptoms of the major syndromes, and this was reflected internationally in textbook descriptions. It was generally agreed, for example, that the characteristic symptoms of schizophrenia were thought disorder, flattening of affect and delusions, and hallucinations of particular kinds, and that some patients also exhibited other typically schizophrenic symptoms such as apathy and stereotypies. There was no agreement, however, on which combinations of these symptoms were adequate to establish a diagnosis of schizophrenia. Indeed, that question was almost never posed, and different schools of psychiatry and individual psychiatrists made different assumptions, and in practice trainee psychiatrists learnt how to diagnose syndromes such as schizophrenia and mania largely by modeling themselves on their teachers. As a result, several studies of the reliability of psychiatric diagnoses in the 1960s found the reliability of the diagnoses even of experienced psychiatrists to be distressingly low, and international studies like the US/UK Diagnostic Project and the World Health Organization's International Pilot Study of Schizophrenia revealed major between-country differences in the usage of key diagnostic terms such as schizophrenia and manic-depressive illness, and even between different cities or teaching centers in the same country.

As soon as this chaotic situation became apparent it was agreed by the clinical research community that operational definitions were required, at least for all the major syndromes (see *Nosology in Psychiatry*). Essentially, an operational, or semantic, definition is a statement or set of statements which spells out precisely which combinations of symptoms and behaviors are adequate to establish the diagnosis in question. The first set of fifteen operational definitions for use in clinical research was published by the Department of Psychiatry in St Louis in the USA (Feighner et al. 1972) and other rival sets quickly followed. A few years later the American Psychiatric Association provided operational definitions for most of the 200 syndromes described in the third (1980) edition of its *Diagnostic and Statistical Manual of Mental Disorders* (*DSM-III*) (American Psychiatric Association 1980). It also demonstrated in the field trials conducted before the glossary was published that these operational definitions made it possible to achieve much higher levels of reliability than had previously been attained. Subsequently the World Health Organization provided similar operational definitions for most of the mental disorders listed in the tenth revision of the *International Classification* (*ICD-10*) (World Health Organization [WHO] 1993).

As a result of this general recognition, at least by clinical research workers and epidemiologists, of the need for operational definitions, and their incorporation into the two most widely used glossaries, *DSM-III* and its successors and *ICD-10*, diagnosis and differential diagnosis have been transformed. Reliability is now much higher; and the unrecognized differences in diagnostic criteria between different countries and schools, which had caused so much confusion previously, have either been eliminated or, if different operational definitions are being used, the differences are now overt and explicit. This in turn has transformed differential diagnosis.

3. *The Consequences of Definition by Clinical Syndrome*

There are, even so, still a number of fundamental problems arising from the fact that most mental disorders are defined by their clinical syndromes. The most important is that there is no scientific way of deciding which of two or more alternative operational definitions of a single disorder is correct, or even which is the best. The choice between alternative clinical definitions of Down's syndrome would be straightforward. One would pick whichever definition most accurately identified individuals with Trisomy 21 (an additional chromosome 21 in all the cells of the body), because Trisomy 21 is now the defining characteristic of Down's syndrome. In the case of most psychiatric disorders, however, there is no comparable external criterion to appeal to, because the clinical syndrome is itself the defining characteristic. This is why alternative operational definitions of disorders such as schizophrenia and agoraphobia remain in widespread use, side by side, and it is commonplace for individual patients to meet one of these definitions but not the other. A patient with typical schizophrenic symptoms for the past six weeks, for example, might well meet the

formal criteria for schizophrenia in *ICD-10*, but not the corresponding criteria in *DSM-IV*, because the latter require evidence of continuous signs of illness for at least six months. In practice this means that discussions about diagnosis need to take place in a context in which it is agreed which glossary (i.e., which set of operational definitions) is being used, and also with a clear recognition of the fact that the choice between alternative glossaries or sets of definitions is arbitrary.

4. *Single Versus Multiple Diagnoses*

In medicine as a whole an attempt is generally made to explain all the patient's symptoms with a single diagnosis, and to try to avoid multiple diagnoses. The rationale for this is that several important diseases, including infections such as tuberculosis and syphilis, and collagen diseases such as polyarteritis nodosa, can affect almost every organ in the body, and the correct diagnosis is more likely to be made if the physician consciously strives to account for all the patient's apparently unrelated problems with a single unifying explanation. In fact, of course, people often have several different things wrong with them simultaneously, particularly as they age. Old people are rather like old cars in this respect.

The same attempt to avoid multiple diagnoses is apparent in psychiatric practice, and the underlying rationale is similar. Patients are commonly given two diagnoses simultaneously if one is a lifelong state, such as mental retardation or a personality disorder, and the other an illness such as schizophrenia or a mood disorder with an identifiable onset and a distinctive course. A diagnosis of some form of substance misuse is also commonly combined with a wide range of other diagnoses. There is a deep-seated reluctance, however, to diagnose a neurotic or stress-related disorder in the presence of psychotic symptoms such as delusions and hallucinations, despite the fact that psychotic and neurotic symptoms commonly coexist, and there is a similar reluctance to diagnose any kind of nonorganic psychosis if there is evidence of brain disease. There is an even greater reluctance to diagnose two psychotic disorders simultaneously, or a mood disorder and a neurotic disorder simultaneously, despite the fact that depression and anxiety commonly coexist.

5. *The Hierarchy of Diagnoses*

This reluctance to make multiple diagnoses achieves formal expression as a diagnostic hierarchy. Organic disorders come at the top of this hierarchy. This means that if the patient has clear evidence of a brain disease—a tumor, for example—it is legitimate for them to have a wide range of other psychiatric symptoms, psychotic or neurotic, without any other diagnosis being required. Next in the hierarchy come the so-called functional or nonorganic psychoses. If the criteria for one of these disorders—schizophrenia, for example—are met, the patient may also be depressed or anxious, or have phobic or obsessional symptoms, without any additional diagnosis being required. They must not, however, have evidence of overt brain disease. Neurotic and stress-related disorders come at the bottom of the hierarchy, which means that diagnoses at this level cannot normally be made if psychotic symptoms or evidence of brain disease are also present. It is no accident, either, that this is the sequence in which disorders are listed in contemporary glossaries, and also the sequence of the decisions required by the flowcharts of computer programs for generating diagnoses from clinical ratings.

The requirements of this hierarchy are only relevant if the symptoms in question all appear at much the same time. If two groups of symptoms have a quite different time course from one another, it may be both legitimate and appropriate to make two independent diagnoses. In the past the hierarchy used to be implied rather than explicit. Now it is built into the operational definitions of individual disorders. At the same time it has become more complicated, particularly in situations where schizophrenic and affective symptoms coexist, or follow one another in quick succession.

It is also still uncertain whether the hierarchy is simply an artifact, a device for reducing multiple diagnoses to a minimum, or whether it is a reflection of a fundamental characteristic of psychiatric symptomatology. It is certainly true that a high proportion of people with psychiatric symptoms, but not all, move up and down the hierarchy as they relapse and remit. Phobic and obsessional symptoms almost invariably become more widespread and severe if depressive symptoms develop, for example, and the development of hallucinations and delusions is usually accompanied by affective and neurotic symptoms which do not wane until after the hallucinations and delusions have disappeared.

6. *The Boundary Problem*

There is an old axiom that the art of classification consists in 'carving nature at the joints.' This is an elegant way of saying that a good, or a valid, nosology places the boundaries between adjacent disorders, and between these disorders and health, where there are genuine discontinuities, either in symptomatology or in etiology. If the defining characteristic of the disorder is a fundamental biological abnormality of some kind it may be self-evident that a discontinuity is involved. An additional chromosome or an abnormal gene, for example, clearly involve qualitative deviations from normality. If, however, the defining characteristic of the disorder is still its syndrome, or a quantitative deviation of some kind, such as a raised blood pressure or a raised blood level of thyroxin, it is not self-evident

Figure 1
Variation in symptomatology expressed by a linear variable (reproduced by permission of Royal College of Psychiatrists from the *British Journal of Psychiatry* 1980, **137**: 325)

that there is a valid boundary between the syndrome in question and normality, or between this syndrome and others. Indeed, the fact that there are several rival operational definitions for many mental disorders, each of them encompassing slightly different populations of patients, strongly suggests that it is not obvious where the boundaries of those syndromes should be drawn.

Ideally, a point of rarity needs to be demonstrated between each syndrome and its neighbors (Kendell 1975). For example, it is widely assumed that schizophrenic and affective psychoses are distinct conditions. Indeed, the distinction Kraepelin drew at the end of the nineteenth century between what he called dementia praecox and manic-depressive insanity is still regarded as a fundamental feature of our contemporary classification of mental disorders. The fact that patients with a mixture of schizophrenic and affective symptoms—so called schizo-affective patients—are quite common does not in itself prove that there is no genuine boundary between the two syndromes, provided that these mixed forms are less common than the pure forms. The 'greys' must be less common than the 'blacks' and the 'whites'; or to express the issue graphically, the distribution of symptomatology along an axis extending from typical schizophrenia through schizo-affective states to typical affective psychoses must be bimodal rather than unimodal (see Fig. 1). A number of attempts have been made to address this issue using discriminant function analysis and the results are summarized below.

An alternative to demonstrating discontinuities in the distribution of symptomatology is to identify a discontinuity in the relationship between symptomatology and some other important variable, such as prognosis or response to treatment. For example, it is well established that, on average, the outcome of affective psychoses is much better that that of schizophrenic illnesses, both in the short and the long term. The key issue, however, is not whether the two disorders have a significantly different outcome, but whether, when the variation in symptomatology is

Figure 2
Relationship between symptomatology and outcome when symptomatology is converted to a linear variable (reproduced by permission of Royal College of Psychiatrists from the *British Journal of Psychiatry* 1980, **137**: 325)

portrayed as a linear dimension (as described above) there is a discontinuity at some point in the relationship between symptomatology and outcome, or whether there is simply a linear improvement in outcome as the symptomatology becomes increasingly more affective (see Fig. 2).

To date, most attempts to demonstrate valid boundaries by these means have been concerned with the boundaries between what used to be called endogenous and reactive depressions, between schizophrenic and affective psychoses, and between major depressive disorder and normality. The attempts to demonstrate a valid boundary between endogenous and reactive depressions were unsuccessful; when representative populations of patients were studied the distribution of individual patients along the discriminant function was consistently unimodal rather than bimodal. Partly for this reason, contemporary glossaries such as *ICD-10* (WHO 1993) and *DSM-IV* (American Psychiatric Association 1994) no longer distinguish between these two types of depressive illness. Similar attempts to demonstrate a valid boundary between schizophrenic and affective psychoses, either in symptomatology or in the relationship between symptomatology and outcome, were also unsuccessful, but a bimodal distribution of scores was subsequently demonstrated on a linear function discriminating between schizophrenia and all other psychiatric disorders combined. More recently, an attempt to identify a valid boundary between major depression and normality by demonstrating, in a population of 2,000 twins, a discontinuity in the relationship between depressive

symptomatology and either outcome or concordance between twin pairs ended in failure (Kendler and Gardner 1998).

7. *The Consequences of Failure to Validate Boundaries*

None of these studies proves that there are no valid boundaries between the syndromes in question. For one thing, it is always possible that more extensive data, or a different choice of criterion, might have provided a different result. Cumulatively, however, the failure of most of these attempts to demonstrate valid boundaries between syndromes emphasizes that it is unsafe to assume that there are valid boundaries there to be found. We must take seriously the possibility that we are not yet 'carving nature at the joints,' or even that there are no 'joints' there, and that we are trying to impose an artificial set of discrete categories on what is in reality continuous variation.

This state of affairs holds several important implications for the differential diagnosis of psychiatric disorders. The first is the importance of recognizing that most of the categories of disorder recognized in contemporary nosologies, even those such as schizophrenia with pedigrees dating back to the nineteenth century, have not yet been adequately validated, and that their formal definitions are simply agreed conventions. The second is a consequence of the first. All decisions about diagnosis, and all discussions about differential diagnosis, should take place in a setting in which it is agreed which set of diagnostic categories and corresponding set of operational definitions (in effect, which glossary) are being used, and with a clear understanding that both the categories and the definitions are arbitrary and inadequately validated, and therefore likely to be modified as understanding of the underlying etiology accumulates.

The third implication is a consequence of the likelihood that many existing boundaries, either between syndromes or between psychiatric disorder and health, are not situated at points of rarity in the distribution of symptomatology. To the extent that this is the case, relatively minor changes in the operational definition of a syndrome, which produce corresponding changes in the position of its boundaries, may result in quite large changes in the numbers of people, or patients, who fall within those boundaries. This is almost certainly why small changes in the definition of common disorders such as major depression or generalized anxiety—particularly changes in the number of typical symptoms required, or in their duration—have been associated with major changes in the recorded prevalence of these disorders in community surveys.

Finally, if it is indeed the case that there are no genuine boundaries within large tracts of the territory of psychiatric disorders, and we are imposing an artificial set of discrete categories on what is in reality continuous variation, psychiatrists will have to consider seriously the possibility of replacing their traditional categorical classification of disorders with a dimensional classification. This would never be done lightly, if only because the rest of medicine has always been committed to and content with categorical classifications of its disorders. If a dimensional format ever were to be adopted for mental disorders, however, the consequences for differential diagnosis would be profound. Disputes about which disorder or combination of disorders an individual was suffering from would be replaced by discussions about the precise locus in a multidimensional space at which that individual should be located. These discussions would probably also be calmer than the previous disputes, because in most cases it would be clear that the alternative loci under discussion were all quite close to one another, and not separated by dividing lines implying major differences in treatment or prognosis.

8. *Practical Issues in Differential Diagnosis*

As in other branches of medicine, some differential diagnoses are more critical than others. The most important functions of a diagnosis are to determine treatment and to predict outcome, and the most important differential diagnoses are those involving a disorder requiring urgent and specific treatment. All psychiatrists are keenly aware of the importance of diagnosing, or at least suspecting, cerebral tumors, and other brain diseases such as viral encephalitis and subdural hematoma, which may also present with psychiatric symptoms, as quickly as possible. Because these conditions may all present with depressive symptoms, with apathy or other behavioral changes, or even with psychotic symptoms, and because they all require urgent treatment, they enter into the differential diagnosis of a wide range of psychiatric disorders. Many reputations for diagnostic acumen are, rightly, based on successful detection of relatively uncommon brain diseases of this kind, or of metabolic disorders such as thyrotoxicosis and Cushing's syndrome, which underlie some anxiety states and depressions. It is also important to detect brain diseases such as Creutzfeldt–Jakob disease, which sometimes present with psychiatric symptoms even though there is not yet any treatment capable of altering the course of the disease, because of the implications for prognosis. If someone has an illness which is inevitably going to result in permanent disability or death, the sooner that is established the better, both for the patient and the family.

There are other circumstances in which the critical diagnosis in the differential diagnosis between brain disease and psychiatric disorder is the latter rather

than the former. Dementias are common in old age and most are associated with progressive decline to dependency and death. Sometimes, however, depressive illnesses present with such widespread evidence of intellectual impairment that they closely resemble a dementia. Because depressions are eminently treatable it is vital that these 'depressive pseudodementias' are quickly recognized and treated, and depression is therefore an important part of the differential diagnosis of dementia. Similar considerations apply to rare curable dementias, such as those associated with a deficiency of thyroid hormone or vitamin B12.

Traditionally, much time and intellectual effort have been devoted by psychiatrists to distinguishing accurately between schizophrenic and affective psychoses. To some extent this is appropriate. The two disorders require different treatments and there are major differences in long-term prognosis between them. Some disagreements are due simply to undisclosed differences in diagnostic criteria which would be resolved by the adoption of an agreed operational definition. However, a more fundamental conceptual issue may also be involved. Although there are many instances, including the differential diagnosis between schizophrenic and affective psychoses, where no valid boundary has yet been demonstrated between the two syndromes, psychiatrists often still behave as though they were discussing the distinction between two 'disease entities.' In reality, if the patient's symptoms are 'schizoaffective,' it may not matter much which side of an arbitrary boundary they are deemed to lie, because their therapeutic needs and their prognosis may both be genuinely intermediate between those of the two classical syndromes.

To diagnose schizophrenia is always a grave decision. Although some people develop schizophrenic illnesses which resolve completely, even without treatment, and never recur, for many more a schizophrenic episode is the prelude to a life of invalidism and the death knell of hopes and ambitions. It is understandable, therefore, that many psychiatrists are reluctant to diagnose schizophrenia, particularly in an adolescent, unless the evidence is incontrovertible. If some less doom-laden diagnosis, such as depression, is plausible they will opt for that, and hope that time will justify their decision. Scandinavian psychiatrists sometimes make a diagnosis of psychogenic psychosis with similar motives. Recently, however, psychiatrists have become increasingly convinced by the evidence that early treatment with neuroleptics improves the long-term outcome of schizophrenic illnesses and reduces the risk of a 'defect state.' Although this evidence is not yet buttressed by random allocation trials it is sufficiently strong to swing the balance of advantage in patients with ambiguous symptomatology in favor of early diagnosis. A similar mix of social and therapeutic considerations has an influence on differential diagnosis in other areas too.

Other important issues of differential diagnosis arise when patients with psychiatric disorders present to other medical disciplines, as they commonly do. Depressive illnesses are extremely common at all ages and depressed patients may present with a wide variety of complaints, particularly if they are reluctant to accept that they may have a psychiatric disorder. They may complain of 'feeling off color', of loss of appetite or weight, of difficulty sleeping, or of ill-defined pain almost anywhere in the body. As a result, the correct diagnosis is often missed unless questions are asked about characteristic depressive symptoms such as difficulty concentrating or loss of the ability to enjoy things. Phobic anxiety is another common disorder which often presents with somatic symptoms such as palpitations, or recurring bouts of upper abdominal discomfort or difficulty breathing. Unless specific questions are asked about the environmental circumstances in which these symptoms develop, their phobic nature may easily be missed and the patient may be subjected to a long series of irrelevant investigations. In both cases the fundamental problem is that the doctor concerned does not realize, or remember, that a depressive illness or phobic anxiety should be important elements in the differential diagnosis of the patient's presenting complaints, even though these may be entirely somatic.

Differentiation: Social

Social differentiation is an important attribute of society, especially modern society (see also *Societies, Types of*). The concept of differentiation spread within sociology since Herbert Spencer's evolutionary theory of societal development 'from incoherent homogeneity

to coherent heterogeneity'. Later on, Emile Durkheim, Georg Simmel, Talcott Parsons, and Niklas Luhmann were important proponents of the concept. Other social thinkers, such as Karl Marx and Max Weber, who did not use the term 'differentiation' prominently nevertheless contributed to a proper understanding of the social structures and dynamics it designates. At the start of the twenty-first century, the theoretical and, more and more, empirical debate about social differentiation is continued, especially by American 'neo-functionalists' in their discussion of Parsons' legacy, and some German sociologists who keep up the critical debate about Luhmann's theory of society.

Social differentiation means both a process and a structure. In structural terms, it refers to the fact that a unit of analysis, such as a society, consists of a number of distinct parts. These parts may be of the same kind, such as families as the basic components of tribal societies. Or the parts may be different, such as the subsystems—economy, politics, mass media, etc.—making up modern society. As a process, social differentiation is the dynamic that brings about and changes a given structure of differentiation.

Two fundamentally diverging views of the social differentiation of modern society have been put forward in sociological thought. These views do not strictly contradict, but balance each other in important respects. In the following, the partly opposing but mostly complementary relationship between both views will be sketched, with respect to the features, causes, and consequences of social differentiation. The focus of attention will be put on the differentiation of modern society.

1. *Social Differentiation as Decomposition or Emergence*

For Durkheim and Parsons as the most important representatives of the first view of social differentiation, it is a process of decomposition of a functionally diffuse unit—a role, or an institution—into several, functionally more specific units. This idea is modeled after the division of labor in work organizations, a process which fascinated nineteenth-century thinkers (see also *Labor, Division of*). Durkheim's major illustration is the widespread specialization of occupations in industrial society. In Parsons' more abstract analysis, the theoretical and structural-functional analytical framework of society is composed of four principal subsystems (economy, polity, societal community, and fiduciary system) each of which fulfills one of the four fundamental functional prerequisites of societal reproduction. Social differentiation as a process of social change tends towards a successive decomposition of each of these subsystems into four second-level subsystems (see also *Exchange: Social*). Parsons called this 'functional differentiation,' a term that is still used to describe the type of differentiation of modern society. His analytical perspective, Parsons suggests, is validated empirically over time by the concrete differentiation of social roles and institutions.

In structural terms, the decomposition perspective on social differentiation highlights the advantages of specialization for society, which are basically the same as on the organizational level. Specialization greatly improves performance. For instance, if formal education in schools is differentiated from the family, where education was previously concentrated, both sides profit in terms of functional efficiency and effectiveness—teachers can rely on primary socialization accomplished by parents and are able to focus on secondary socialization, and vice versa.

In contrast to this perspective of social differentiation as a fruitful division of labor, Weber portrayed the birth and composition of modern society as the emergence of a number of autonomous 'value-spheres.' One after another, science, law, art, politics, economics, sexuality, and others freed themselves from their former domination by religious ideas. These value-spheres became societal domains of their own which cultivate their particular central value without concern for the value orientations of other domains. Science, for instance, does not care about economic profits, aesthetic beauty, legality, or the conformity of its truths with religious doctrine. Weber (1919, pp. 27–8) speaks graphically about the 'polytheism' of value-spheres in modern society.

Luhmann formulates this second perspective on social differentiation even more to the point. To him, society consists of about a dozen subsystems in each of which communication is guided by a specific binary code. For example, the science systems binary code is true/untrue, the legal systems legal/illegal. The binary code of each subsystem establishes a highly selective searchlight onto the social world, illuminating certain corners of it and leaving the rest in the dark.

The binary codes generate self-referentially closed universes of communication. Thus, a societal subsystem consists of chains of communications each of which refers to other communications of the same kind. For this fundamental feature, Luhmann picks up the concept of 'autopoiesis' from biological thinking (see also *Biology's Influence on Sociology: Human Sociobiology*). To illustrate, in the social system of science assertions of truth are the specific kind of communication. These assertions, usually made in scientific publications, lead to other such assertions, and—within science—not to political declarations or declarations of love. Any scientific publication, if it provokes any reactions at all, is either affirmed or rejected by later publications. Which of these two eventualities happen does not matter with respect to the reproduction of science as a societal subsystem. In both instances science continues as an open-ended sequence of publications.

Luhmann's conceptualization is better suited than Weber's to grasp the basic dynamics of continual

reproduction of a societal subsystem or value-sphere. For both, each subsystem can take only its own code-determined perspective on social events. In science, nothing but its own concerns are important, and the same holds true for all other subsystems. The overall result is an effective multiplication of society with respect to the communicative meanings of events. An event, such as a train accident, looks totally different from the point of view of the economy, compared to the point of view of science, compared to the point of view of the health care system, compared to the point of view of the mass media, and so on. Borrowing a term from philosopher Gotthard Guenther, Luhmann (1997) calls this the 'polycontexturality' of modern society.

Although all subsystems have, in this sense, no 'window' to the social world outside, this basic autonomy goes along with an openness to their societal environment with respect to resources and functional performance. The science subsystem, for instance, needs financial resources among other things, and gets them from the political subsystem, or the economy. In the other direction, science provides these and other societal subsystems with knowledge. Since all societal subsystems make essential contributions to the reproduction of many others and none of them can substitute any other one, each is a functional prerequisite of modern society. Modern society would break down without economy, but also without mass media, or without a health care system, and the latter could not be replaced, for example, by politics or education.

Despite these manifold mutual dependencies, Luhmann insists that it makes no sense to understand the ensemble of societal subsystems as a division of labor. In a division of labor, the subsystems as parts are teleologically oriented towards the performance and maintenance of the whole society. Thus, the whole comes first, historically and logically, and decomposes itself for its own benefit. By contrast, Weber and Luhmann emphasize that social differentiation consists of a simultaneous birth and liberation of the parts. They emerge and become autonomous from each other and from the whole. Even more, the whole vanishes in the sense that it becomes nothing more than the—often tension-ridden and antagonistic—interrelationship of the parts.

2. *Causes of Social Differentiation*

Both analytical perspectives identify different driving forces of social differentiation. Four kinds of causal factors can be distinguished, improvements of performance, evolution, cultural ideas, and interests of actors.

The first causal factor, improvements of performance by specialization, was especially emphasized by Parsons and structural-functionalist studies of social differentiation (see also *Functionalism in Anthropology*). Such specialization is initiated either by performance deficits of existing structures of differentiation, or by opportunities to improve a satisfactory level of performance. An example of the problem-driven dynamic is the previously mentioned differentiation of the education system. Schools, and a duty of all children to attend them, were established because other societal subsystems, especially the economy, needed a general level of cognitive skills and social discipline within the population that could no longer be provided by the family alone. A differentiation dynamic driven by opportunities was the spur for differentiation of the radio and television sector within the mass media. Entirely new possibilities of public communication opened up by the technological innovations of radio and television, rather than any perceived performance deficits of newspapers, caused the sectoral differentiation of roles and organizations within mass media.

By contrast to a planned division of labor within organizations, on the societal level performance improvements by differentiation occur often as unintended results of actions motivated by quite different reasons. In this sense, Parsons already relied on evolution as the mechanism that brings about performance improvements (see also *Social Evolution, Sociology of*). In contrast, Luhmann gives up all connotations of evolution with progress. Adopting neoDarwinian evolutionary thinking from biology, he conceives of evolution as an interplay of three mechanisms, variation, selection, and retention. Each societal subsystem has its own specific evolutionary mechanisms. For instance, in the science subsystem most publications are variations of the existing body of knowledge. Selection happens whenever one of these publications is cited affirmatively. Retention occurs when this new knowledge is incorporated into overview and review articles and into textbooks for students. As in biological evolution, most variations are not selected, and most of those selected do not reach the stage of retention. This evolutionary cognitive growth and differentiation goes along with a social differentiation of scientific specialties.

Luhmann does not deny that this evolution of the science system may bring about performance improvements usually called 'scientific progress.' But for him, this is no necessary outcome of evolutionary differentiation. Evolution may also lead to dysfunctional differentiation. For instance, the growing quest for interdisciplinary research indicates an over-specialization in more and more scientific fields. An understanding of evolutionary differentiation as progress becomes even more dubious in other societal subsystems, such as art, politics, or the mass media. But even if evolutionary differentiation on the level of each subsystem would result in performance improvements of all of them, the overall result for society would not add up to progress but only to an increase of societal

complexity which manifests itself particularly in a growing destabilization of society. Each evolutionary change within one subsystem is also a change of the societal environment of all other subsystems. For them, often adaptive changes become necessary each of which again changes the societal environment, with new adaptive pressures arising. Thus, social differentiation becomes permanently autodynamic. Until now, these dynamics often brought about increasing differentiation. But Parsons' statement that this is a linear and unlimited social process is clearly wrong as not only Luhmann's theoretical reflections point out but also empirical cases presented especially by the 'neofunctionalists' demonstrate.

A third driving force of social differentiation was already mentioned with respect to Weber: an autodynamic rationalization of cultural ideas. In premodern societies the values that today constitute the guiding principles of the various societal subsystems were closely interwoven with each other and, moreover, integrated into an encompassing order of religious values. The differentiation of the principal subsystems of modern society is understood by Weber as a gradual but irresistible separation of economic, political, scientific, aesthetic, legal, erotic, and other values, first, from the religious context, and second, from each other. This dynamic is triggered and sustained by the compelling intellectual urge to contemplate extensively the implications and consequences of each value for everyday life. When this rationalization reaches the point where each value is rigorously reflected in its own terms, without regard to others, soon a self-referential closure of value-spheres occurs, giving way to a corresponding differentiation of roles, organizations, and subsystems.

The fourth driving force of social differentiation is the general interests of individual, collective, or corporate actors who are involved in constellations with each other (see also *Interests, Sociological Analysis of*). One explanation of an ongoing division of labor mentioned by Durkheim is growing 'social density' resulting in an intensification of competition among actors. This constellation evokes an interest to preserve one's own domain of action, be it an occupation for an individual or a market position for a firm. This interest, in turn, leads many of the respective actors to find new niches for themselves where they are relieved from high competitive pressure. The aggregate effect of such domain-preserving activities is social differentiation on the level of roles and organizations.

Other general interests of actors that often stimulate dynamics of social differentiation are the preservation or extension of one's autonomy, of one's control of other actors, and of one's resource base. Some professions, especially those guided by such interests were strong carriers of the differentiation of certain societal subsystems including science, law, education, and health care (see also *Professions, Sociology of*). Sometimes, a particular kind of social differentiation is the explicit goal of certain groups of actors who believe that this will serve their interests best. In other cases, social differentiation is an unnoticed, unforeseen, or unwanted effect of actors' pursuit of their interests. Outcomes often diverge markedly from intentions because usually the relevant constellation consists of actors in quite different positions: catalyzers and promoters of the respective process of change; followers who join in when a 'critical mass' has been mobilized; defenders of the *status quo* who resist any change; more open-minded defenders with whom compromises are possible; and those who are indifferent or indecisive at the beginning and whom the promoters of change as well as the defenders of the *status quo* try to recruit as allies.

Each of these four kinds of driving-forces is causally relevant in the dynamics of social differentiation, although the combination varies greatly from one case to another. Often these factors are interrelated. Thus, what actors understand as their interests are framed by cultural ideas. Cultural ideas as well as actors' interests are explicit or implicit criteria to judge the performance of a given differentiation structure; and *vice versa*, performance deficits provoke actors' interests. Finally, the evolution of societal subsystems creates new challenges, restrictions, and opportunities for the pursuit of interests and the spelling out of cultural ideas.

3. *Consequences of Social Differentiation*

The differentiation of modern society became a central theme not just of sociological thought but also of public discourse in the nineteenth century, and still is today. This is because social differentiation has far-reaching consequences for society at large, as well as for each individual member of it. These consequences are neither totally positive nor totally negative but a mixed blessing.

To begin with, the modern individual profits from role differentiation and an enormous increase of options in every sphere of life, from economic markets for goods and services to opportunities of political participation, sports activities, lifelong education, and cultural life. The abundance of options is the result of performance improvements in all societal subsystems and of an inclusion of all members of society into the status of customers, clients, and public of the subsystems. In connection with the polycontexturality of modern society, role differentiation and the growth of options allow each person to become an individual in the proper sense of the word: a person who creates a unique biography for himself or herself. However, options are only one side of a person's 'life chances' (Dahrendorf 1979). The other side includes 'ligatures,' meaningful attachments which tie a person to certain institutions, cultural worlds, social groups, or communities. In this respect, the functional differentiation of

modern society seems to neglect important psychic needs of persons. Ligatures are eroded by 'polycon texturality' and individualization. As a consequence, anomy, alienation, and other experiences of meaninglessness are present in modern society, not just as individual misfortunes and temporary phenomena, but as structurally produced permanent vulnerabilities of everyone.

Looking at society at large, social differentiation exhibits the same kind of ambivalence. First, it is obvious that functional differentiation is evolutionary highly successful. All kinds of premodern, traditional societies were overrun by those national societies from Europe and North America that converted to functional differentiation since the sixteenth century. Worldwide, there was no alternative to the adoption of functional differentiation. As shown by the socialist experience, those countries that tried to stop halfway failed. Countries where the political system attempted to control all other subsystems were beaten by the fully developed functional differentiation of Western countries, as Parsons, among others, had anticipated in the 1960s.

However, global supremacy of a fully-fledged functional differentiation implies serious problems. Their common denominator is an endangering of the integration of modern society. More precisely, systems integration, social integration, and ecological integration must be distinguished.

Systems integration seems to be the least problematic aspect. Coordination and cooperation among different subsystems of modern society is obviously possible, despite the fact that each of them is governed by its own self-referential binary code. But there are manifold interrelationships by which subsystems adapt to each other in a decentralized way. Where this does not suffice, representatives of subsystems, such as the respective interest groups, meet and bargain for common solutions in the political arena. Finally, political guidance may support or promote intersystems adaptation and bargaining among subsystems. Thus, problems of systems integration remain fragmented and manageable for modern society.

With social integration, it is different (see also *Integration: Social*). The integration of individual members into modern society may be precarious as a result of the already mentioned erosion of ligatures. More important could be the fact that the increase in individual options might put excessive demands on all subsystems' abilities in the long run. In this respect, social inequality and the subsystems' unlimited drive to improve their performance work hand in hand (see also *Inequality*). In conflicts among those who, as individuals, profit more and those who profit less from a particular subsystem's performance, the former will try to avoid redistribution. One way to achieve this is a growth of the subsystem's performance so that those whose claims were not satisfied can be served somewhat better without those who were better of giving up anything. For instance, children from the lower classes have got access to higher education. But this has been no zero-sum conflict in which the higher classes have lost some of their educational opportunities but a positive-sum constellation because the higher education sector has been extended—which has fitted also the interests of the respective groups of teachers and professors and has been reinforced by the cultural imperative of 'progress.' Such dynamics, driven by complementary interests and backed by powerful cultural ideas could go on forever, were there no limits to subsystems' growth. But because these limits exist, for example with respect to resources, continuing inequalities contain a potential for serious social conflict to which functional differentiation has no ready answer.

Finally, the functional differentiation of modern society is a major cause of the growing problems of ecological integration. Modern society's path away from a 'sustainable' relationship with its natural environment has occurred as a result of two basic characteristics of all societal subsystems, their growth tendencies, and the neglect of ecological aspects by their binary codes. The modern economy is the most obvious example, but the same is true of the family, the subsystem primarily responsible for population growth. No societal subsystem exists now that takes care of the ecology, only social movements address their protest to the political system. But this subsystem, following its binary code of maintaining and increasing power, must listen to many other demands from society and so often disregards ecological concerns.

Thus, the functional differentiation of modern 'world society' is a high-risk outcome of social evolution. No alternative to this type of social differentiation is apparent as an option for the future. But whether modern society can survive in this way or will ruin itself sooner or later is an open question that sociological theories of social differentiation cannot answer. Theorists can only observe what has happened previously and infer warnings from this.

Diffusion and Random Walk Processes

Random walk and diffusion models form one of the major classes of models in the response time domain. They best apply in situations in which subjects make two-choice decisions that are based on a single, 'one shot', cognitive process, decisions for which response times do not average much over one second. The basic assumption of the models is that a stimulus test item provides information that is accumulated over time towards one of two decision criteria, each criterion representing one of the two response alternatives. A response is initiated when one of the decision criteria is reached. The researchers who have developed random walk and diffusion models take the approach that all aspects of experimental data need to be accounted for by a model. This means that models should deal with both correct and error response times, with the shapes of the full distributions of response times, and with the probabilities of correct versus error responses. It should be stressed that dealing with all these aspects of data is much more of a challenge than dealing with only one dependent variable.

Random walk models have been prominent since the 1960s (Laming 1968, Link and Heath, 1975). Diffusion models, continuous versions of the random walk, appeared in the late 1970s (Ratcliff 1978, 1980, 1981). The random walk and diffusion models are close cousins and not competitors of each other as they are with other classes of models (e.g., accumulator models and counter models, e.g., LaBerge 1962, Smith and Vickers 1988).

The earliest random walk models assumed that the accumulation of information occurred at discrete points in time, each piece of information either fixed or variable in size (e.g., Laming 1968, Link and Heath 1975). The models succeeded in accounting for mean correct response time and accuracy, and were sometimes successful with mean error response times, but they rarely addressed the shapes of response time distributions.

In diffusion models, the accumulation of information is continuous over time. Ratcliff's (1978) diffusion model is illustrated in Fig. 1. One parameter of the model is the mean rate of accumulation of

Figure 1
Illustration of Ratcliff's diffusion model

information. In the figure, two processes are shown one with mean drift rate v_1 (solid arrows) and the other with mean drift rate v_2 (dashed arrows). Drift rate varies around the mean as shown by the arrows for the average, the fastest and the slowest processes for the means v_1 and v_2 (these are meant to be illustrative; real processes are highly variable). Besides mean drift rate, the other parameters of the model are the separation of the boundaries (a), the starting point (z), the variability in drift rate across trials (η), and a parameter (T_{er}) that represents all the nondecisional components of response time, such as encoding and response preparation. There is also a parameter representing variability in processing (drift) within a trial (s). This is a scaling parameter; if it were doubled, for example, all the other parameters could be changed to produce the same identical predictions as before the change. s is a fixed parameter(not a free parameter) in fits of the model to data.

The basic diffusion process is used in many areas of research, including heat transfer, Brownian motion, neural processes, financial calculus, and fluid mechanics. As a result, the process has been examined in great detail and many explicit solutions for the distributions of the 'first passage' times ($G(t, \xi)$) and probabilities of reaching a boundary ($P(\xi)$) (where ξ is drift rate) are available.

$$P(\xi) = (e^{-(2\xi a/s^2)} - e^{-(2\xi z/s^2)})/(e^{-(2\xi a/s^2)} - 1)$$

$$G(t, \xi) = P(\xi) - \frac{\pi s^2}{a^2} e^{-(z\xi/s^2)} \times \sum_{k=1}^{\infty} \frac{2k \sin(k\pi z/a)\, e^{-\frac{1}{2}(\xi^2/s^2 + \pi^2 k^2 s^2/a^2)t}}{(\xi^2/s^2 + \pi^2 k^2 s^2/a^2)}$$

But stochastic differential equations are difficult, and numerical solutions are required for examination of

more complex characteristics of the diffusion process, such as the effects of changes in drift rate and boundary positions during the course of information accumulation. Smith (2000) has developed alternative numerical methods to solve for the first passage times above; these are based on recursive expressions for the passage of a process to a response boundary. The idea is that the probability that a process will hit a response boundary at time t is the integral over time t_1 of the product of the probability that it first hit the boundary at time t_1 and the probability that it reaches the boundary starting at time t_1 and ending at time t. This solution allows the calculation of first passage times even when drift rate and boundary positions are not fixed. Another solution is to model the diffusion process with a discrete random walk process with very small step sizes, using Monte Carlo methods to obtain response probabilities and first passage time distributions for correct and error responses.

Ornstein-Uhlenbeck (OU) models are variants of diffusion models in which drift rate is offset by a decay term that tends to push the accumulation of information back towards the starting point. The size of the decay term is a linear function of the distance moved away from the starting point. OU models have been used to describe the behaviors of single neurons, they have been applied to simple reaction time tasks (Smith 1995), and they have been applied to decision-making and choice behavior (Busemeyer and Townsend 1993). Ratcliff and Smith (1999) have found that the OU process mimics the diffusion process, and vice versa, in many situations, but further work is needed to decide whether and how the two kinds of models can be discriminated.

1. *Diffusion Models and Empirical Data*

1.1 *Scaling and Distribution Shape*

The two dependent variables, response time and accuracy, have different scale properties. Response time has a minimum value and its variance increases as response time increases. Accuracy is bounded at probabilities 0.5 and 1.0, and as probability correct approaches 1.0, variance decreases. Diffusion models account for these scale properties automatically as a result of the geometry of the diffusion process. When mean drift rate is high, the probability of a correct response is near 1.0 and decision processes approach the correct boundary quickly with little spread in arrival times (e.g., the processes with mean v_1 in Fig. 1). When mean drift rate is nearer zero (processes with mean v_2 in Fig. 1), variability leads some processes to hit one boundary, other processes to hit the other boundary, and accuracy nears 0.5; the arrival times at boundaries are long and highly variable. In addition to these scale properties, the geometry of the diffusion process also gives response time distributions skewed to the right; as mean response time increases (e.g., from drift rate v_1 to v_2), the fastest responses slow a little and the slowest responses slow a lot.

1.2 *Speed vs. Accuracy*

Human subjects can manipulate their speed performance relative to their accuracy performance. For example, if in some blocks of an experiment they are instructed to respond as quickly as possible, and in other blocks they are instructed to respond as accurately as possible, mean response times can vary between the two kinds of blocks by as much as 500 ms and mean accuracy can vary by 10 percent (Ratcliff and Rouder 1998). Ratcliff's diffusion model can account for these differences with only the boundary separation parameter; moving the boundaries close together produces fast responses for which variability in drift can cause large numbers of errors; moving the boundaries apart produces slower responses that are more likely to be accurate.

1.3 *Error Response Times*

A major problem that restricted the development of random walk and diffusion models was their inability to accurately predict error response times. According to the models, errors and correct responses should have the same mean response times when the correct and error boundaries are equidistant from the starting point. However, experimental data showed that in some situations, errors are faster than correct responses and in some situations they are slower, and both patterns can even occur in different conditions in the same experiment (Luce 1986, Ratcliff et al. 1999, Ratcliff and Rouder 2000, Smith and Vickers 1988). In early attempts to deal with this problem, Laming (1968) added variability to the starting point to produce fast errors, and Link and Heath (1975) used variability in the sizes of the steps toward correct and error boundaries to account for fast errors in some experiments and slow errors in others.

Recently, a more complete solution has been provided by Ratcliff et al. (1999; see also Ratcliff 1981), showing that the complete patterns of error versus correct response times can be explained by combining variability in starting point and variability in drift rate across trials. This solution to the problem was so late in coming because earlier applications of diffusion models did not have enough computer power to automatically search the complete parameter space (e.g. Ratcliff 1978).

1.4 *Time Course of Accumulation of Information*

Diffusion and random walk models are explicitly based on a process that accumulates information over

Figure 2
Illustration of the distribution of nonterminated processes within a diffusion process at two times T_0 and T_1. The top curve represents the distribution of finishing times

Figure 3
An illustration of the way drift rate might change in the diffusion process. At some point T_0 the drift rate changes and the distribution of nonterminated processes becomes a distribution of starting points for the second phase of the diffusion process

time. Empirical examination of the time course of processing is possible with deadline and response signal procedures in which subjects are asked to respond at experimenter-determined times (a signal is presented after each test item to indicate exactly when a response to the item is to be made). The dependent variable is accuracy. The first diffusion model approach to this kind of data was to assume that there are no boundaries on the diffusion process; when the signal to respond is given, the position of the process is evaluated and, if it is above the starting point, one response is given; if it is below the starting point, the other response is given. This assumption leads to a simple formula for d' (see *Signal Detection Theory*) as a function of time:

$$d'(t) = d'_a / \sqrt{(1 + s^2/(\eta^2 t))}$$

An alternative approach (Ratcliff 1988), more in line with subjects' intuitions, is to assume that responses come from a mixture of two kinds of processes: processes that have not yet reached a boundary, like those just described, and processes that have reached a boundary. Figure 2 shows what happens with a test item for which the mean drift rate is v. The figure shows the distribution of the processes not terminated with this mean drift rate at time T_0. Most of these processes are above the starting point z, and so, if a signal to respond is given at time T_0, most responses from processes not yet terminated at a response boundary will produce the response represented by the top boundary. At time, T_1, responses will be a mixture of processes with mean drift rate v, which have terminated, and other processes which have not.

1.5 Nonmonotonic Functions

With some kinds of test stimuli, it can be shown empirically that the accumulation of information does not proceed at a constant rate. One source of information drives the process early in the time course and a different source of information drives the process later (e.g., Ratcliff and McKoon 1982). If the two sources of information contradict each other, then drift rate changes substantially during the time course of processing. Typically, it is the latter source of information that yields a correct response, and so accuracy first decreases from chance, and then later increases above chance, showing a nonmonotonic function across time. Figure 3 shows how this is handled in Ratcliff's diffusion model (Ratcliff 1980). When the second source of information becomes available, at time T_0, mean drift rate for nonterminated processes changes from a positive to a negative value and the distribution of nonterminated processes at T_0 serves as the starting point for the second process.

1.6 Constraints on Diffusion Models

In many paradigms, accuracy is high and differences in accuracy values across experimental conditions are too small to be statistically significant. The consequence is that the effects of experimental manipulations can be observed only in response time. Data like this do not provide strong tests of diffusion models because they can be fit with any of a number of different parameter values.

Strong tests are provided when the models must account jointly for a broad range of response times (and the shapes of the response time distributions) and accuracy values from experimental conditions that are

Figure 4
A quantile-probability function. The points represent the quantiles from the data and the solid lines the fit of a model to the data. Errors are to the left of the 0.5 probability point and correct responses corresponding to the errors to the right (mirror images). Each vertical line of quantiles represents a different condition in the experiment

manipulated in such a way that subjects cannot alter response criteria as a function of test item type (e.g., number of repetitions of words in a list where some studied items have few repetitions, some many). The manipulations should yield accuracy values varying from near floor (50 percent correct) to near ceiling (100 percent correct).

The issue arises of how to display this amount of data. Latency-probability functions have been used to simultaneously display mean response times and probabilities, with mean response time plotted on the y-axis and response probability on the x-axis. Different conditions are different points on the function, each condition represented by a pair of points, one for correct responses at probability p and a mirror image for errors at probability $1-p$. A latency-probability function gives a good picture of how accuracy and response time covary, showing, for example, whether response time changes quickly in conditions for which accuracy is high and changes little, or whether errors are faster than correct responses.

However, latency-probability functions do not show information about the shapes of response time distributions. One way to show this information is to plot the quantile response times for each of several quantiles (e.g., fifths) of the distributions as a quantile-probability function. Figure 4 shows an example using five quantiles. The numbers represent the data and the solid lines show a theoretical fit of the diffusion model. The figure shows that the speed of the fastest responses (the 0.1 quantile) does not change much across conditions (i.e., across response probability values). Responses do slow from the conditions with high accuracy to the conditions with lower accuracy (where probability of a correct response is about 0.6), but they slow because the distributions spread out with the slowest responses (in the fifth quantile) increasing the most in response time.

2. *Applications*

Diffusion and random walk models have been applied to a wide variety of tasks. Here, we summarize the most frequent and salient applications.

2.1 *Recognitions Memory*

Diffusion models were first applied in the recognition memory domain (Ratcliff 1978). They provide a good account of correct response times, response probabilities, and the shapes of response time distributions. With the assumptions of variability in starting point and across-trial drift rates, they can also explain the patterns of correct vs. error response times.

2.2 *Signal Detection*

In one class of signal detection experiments, subjects are presented with stimuli and probabilistic feedback to those stimuli (e.g., Ratcliff et al. 1999). The diffusion model provides an extension to signal detection theory to explain the standard accuracy-based results as well as reaction time. Experimental manipulations allow accuracy to be varied from ceiling to floor and the experimental paradigm has served as a useful procedure for testing the diffusion model (Ratcliff and Rouder 1998, Ratcliff et al. 1999). This procedure also serves as one of the main procedures to test and evaluate models of categorization (e.g., Ashby 2000, Nosofsky and Palmeri 1997).

2.3 *Perception*

Ratcliff's diffusion model has been used to study the time course of processing when a stimulus is presented briefly, then masked (Ratcliff and Rouder 2000). In this situation, the amount of information coming into the decision process could either increase during stimulus presentation and then begin to fall during mask presentation, or the information coming into the decision process could be an integration of the

total information available from the stimulus, from its onset until the mask is presented. Only with the latter assumption could the data be well fit by the diffusion model.

2.4 Simple Reaction Time

Simple reaction time tasks require the subject to respond when a stimulus is presented. Smith (1995) used an OU model with assumptions about sustained and transient processing channels to model the effects of stimulus intensity in these tasks. The model was able to simultaneously account for the shapes of response time distributions as a function of stimulus intensity and the time course of the availability of stimulus information (see *Stochastic Dynamic Models (Choice, Response, and Time)*).

2.5 Decision Making

Busemeyer and Townsend (1993) developed a dynamic model of decision making using an OU process to represent the time course of processing for decision making under uncertainty. This model has been further developed to provide an integrative framework for understanding several seemingly diverse empirical phenomena in the area of multialternative preferential choice and also this kind of model has been extended to represent the time course of processing for multi-attribute decision making (see *Dynamic Decision Making*; *Sequential Decision Making*).

2.6 Categorization

Random walk and diffusion have been married to models of categorization to account for response time data in categorization. In exemplar-based models (Nosofsky and Palmeri 1997), each exemplar provides an increment in a random walk. In decision-bound models (Ashby 2000), the drift rate is determined by the distance of the test stimulus from a boundary that separates the categories on the relevant dimensions. These models generalize the earlier categorization models to allow them to account for response times as well as accuracy and similarity measures.

2.7 Neural Processes

Recent data suggest that neural processes can be represented by random walk or diffusion processes (Hanes and Schall 1996). Neurons in the eye movement system in monkeys behave as though they increase their firing rates until a fixed response criterion is reached and this is the signal for the response (in the form of an eye movement) to be made. Diffusion processes are continuous processes and so are not exactly consistent with neural processes that are discrete. But if the diffusion process is replaced with a random walk with one step corresponding to 1 ms (about the same time scale as neural counts), then the approximation between the diffusion process and a discrete random walk (with time steps of 1 ms) is very good. Also, if a diffusion decision process were to be represented neurally, it would be represented by a population of neurons and this would lead to quite a good approximation between a population firing rate and a continuous process.

3. Conclusion

Random walk and diffusion models are under continuous testing. As members of the class of sequential sampling models, they appear to account for experimental data more successfully than any other class of models. Perhaps the most encouraging sign is that fits of the models to data are beginning to show invariances in parameter values across subjects and across tasks, which means that some experimental variables are represented in the model by single parameters. This kind of success is something we do not always see in modeling in psychology.

Diffusion: Anthropological Aspects

In anthropology, diffusion has been taken to be the process by which material and immaterial cultural and social forms spread in space. A number of specialized fields of inquiry in cultural diffusion developed in anthropology throughout the twentieth century. At the beginning, and going back to the late nineteenth century, stood cultural history. After World War I came acculturation and culture contact studies, which continued for several decades. The 1970s marked a growing anthropological interest in world-system studies and questions of cultural imperialism. In the late 1970s and early 1980s, transnational and globalization studies became a subfield of anthropology. This is a rough chronology without claim to comprehensiveness—in particular if one considers that so much of anthropology has been about cultural interaction and change and thus, in some sense, about the distribution of cultural and social forms across space.

The anthropological interest in diffusion began as an argument against evolutionary interpretations of history. Such interpretations had become part of popular culture in late-nineteenth-century Europe and Euro-America. The general idea was that cultural evolution and cumulative reason had taken humankind from a stage of savagery to one of civilization. The title of one of Lewis Henry Morgan's (1818–81) works put it succinctly: *Ancient Society, or Researches in the Lines of Human Progress from Savagery through Barbarism to Civilization* (1877). Evolutionary theoreticians like Morgan, Edward B. Tylor (1832–1917), and Adolf Bastian (1826–1905), held that, while cultural borrowing between social groups certainly had occurred throughout human history, similar cultural and social forms emerged in different places and times, mostly due to the psychic similarity of humans the world over, and to a general uniformity in evolutionary stages.

Friedrich Ratzel (1844–1904) was the first to explicitly reject this explanation for cultural and social similarities. He argued that no culture had evolved in isolation, and that contact and borrowing between groups should be considered to be far more common in human history than instances of social and cultural innovation. Since Ratzel believed that the principal mechanism of diffusion was migration, he arrived at the conclusion that 'migration theory is the fundamental theory of world history' (Ratzel 1882, p. 464). The object of study for Ratzel was the reconstruction of how cultural and social forms had spread from centers of innovation. This reconstructive effort went under the name of cultural history (*Kulturgeschichte* in German). Among the most notable cultural historians were: Bernhard Ankermann (1859–1943), who, unlike the majority of cultural historians who wrote universal histories of humankind, believed that insufficient data only allowed for the reconstruction of diffusion in particular regions; Leo Frobenius (1873–1938), a student of Ratzel who elaborated the latter's migration theory into a theory of cultural areas (*Kulturkreise* in German); and Fritz Graebner (1877–1934), the author of *Methode der Ethnologie* (1911), arguably the most influential theoretical and methodological work of cultural history. At the University of Vienna, Fathers Wilhelm Schmidt and Wilhelm Koppers formulated a theory of primary cultural units, which were said to be at the root of all existing cultures and to have evolved through processes of diffusion from the primeval culture of hunters and gatherers. At University College, London, Grafton Elliot Smith and his disciple William Perry tried to prove that from a single center of innovation, namely ancient Egypt, culture had diffused to the rest of the world:

> towards the close of the period of the New Empire, or perhaps even a little later, a great many of the most distinctive practices of Egyptian civilization suddenly appeared in more distant part of the coast-lines of Africa, Europe, and Asia and also in course of time in Oceania and America (Smith 1916, p. 3).

As chief agents of diffusion, Smith and Perry identified the Phoenicians.

At Cambridge, UK, worked W. H. R. Rivers, who had been a member of the Torres Strait Expedition, and who had emerged as the most influential British anthropologist in the first two decades of the twentieth century. After conducting fieldwork among the Todas of southern India in 1902, Rivers turned to 'ethnological analysis'—that is cultural history (cf. Rivers 1911). In two volumes, Rivers (1914) subsequently reconstructed the history of Melanesia by mapping the process of cultural diffusion in the area.

In the USA, Franz Boas (1858–1942) collected specimens, information in the native language about these specimens, and grammatical information necessary for the interpretation of this information. His ambition was to reconstruct a cultural history of the nonliterate people he studied. In particular, Boas developed his diffusionary analyses in the field of linguistic studies. At the same time, Boas was highly critical of cultural history's reconstruction by way of presumption. Boas thought that too much in cultural history was guesswork. Also, he formulated his own ethnographic method in contradistinction to the logic of museum exhibitions, which, at the time, placed specimens next to one another without concern for the cultural and social context they had once been part of.

Common to the work of all cultural historians was a research orientation toward topics that can be summarized in the following four concepts: (a) cultural origins; (b) material culture; (c) culture areas; and (d) culture strata.

(a) Cultural origins: cultural history shared with evolutionary theory a profound interest in ultimate origins and long-term diachronic developments. It is this preoccupation that put the question of independent innovations versus diffusion into stark relief. Evolutionary theory suggested that the origins of cultural elements should be sought in innovation because cultural similarities indicated similar mental dispositions and similar reactions to similar environmental conditions ('like causes produce like effects'). Cultural history responded that the origins of cultural elements could be found in the diffusion from centers of innovation since it was far more likely that similarity was an indication of contact than of similar dispositions and conditions.

(b) Material culture: methodologically, cultural history relied to a considerable extent on typologizing artifacts. Everything from techniques of mummification and architectural styles to types of domesticated animals, dyeing techniques, weapons, and tools were used as indicators of cultural diffusion. Specimens were taken to be cultural elements, and single artifacts, institutions, and ideas were studied like museum objects detached from their cultural and social context.

(c) Cultural areas (*Kulturkreise* in German) were conceptualized as areas of homogenous culture. Alfred Kroeber (1931, p. 646) considered culture areas to be organized in a center-periphery fashion, with centers 'in which the culture is most typical and intensive and which are to be construed as foci of radiation,' and border areas that intergrade with adjacent areas.

(d) Cultural strata (*Kulturschichten* in German) were considered to be layers of cultural diffusion, that is, superimpositions of cultural elements upon one another originating from waves of diffusion.

In the face of a methodological shift in anthropology, with direct observation during extended times of fieldwork replacing the study of museum specimens and survey studies with the help of questionnaires, the question of cultural origins waned. Consequently, the reconstructive work of cultural history, and its great reliance on artifacts, fell into disrepute in much of anthropology. Cultural interaction, however, continued to be a core issue and was now studied under the headings of culture contact, acculturation, and culture change. Acculturation, the key concept in this context, was defined as follows: 'Acculturation comprehends those phenomena which result when groups of individuals having different cultures come into continuous first-hand contact, with subsequent changes in the original cultural patterns of either or both groups' (Redfield et al. 1936, p. 149). Following World War I, culture contact had become a matter of self-conscious reflection:

> The great world-shattering changes of the past decade, the War, the Russian Revolution, the Treaty of Versailles and the consequences of these events, have led men to question for the first time many of the previously unchallenged assumptions implicit in their own civilization, whilst it has prompted them to regard with real concern and a desire to understand civilizations unlike their own (Pitt-Rivers 1927, p. xii).

Some acculturation studies, like Pitt-Rivers', were explicitly directed at the types of political domination that in so many instances produced culture change during colonialism. Thus, Richard Thurnwald (1932, p. 568f) distinguished between two kinds of acculturation through colonial relations: on the one hand, the biological and cultural mixing between men and women, on the other, formal relations of tutelage. In the one instance, acculturation was a matter of intimate relations, of primary socialization into local traditions in the form of care, which attributed to women as 'principal caretakers' the role of keepers of tradition. In the other case, the social relations were ones of formal education or secondary socialization through 'channels by which the new and foreign flows,' such as 'missions, schools, governmental ordinances, control of courts, etc.'

Soon, however, leading American anthropologists made acculturation studies turn on the issue of why some cultural groups resisted formal colonial tutelage and the 'modernization' it was to bring, and others did not. The cause was sought in the rigidity and closedness of some societies versus the adaptability and openness of others. One suggestion was that it was possible to distinguish 'hard-shelled, vertebrate' from 'soft-shelled, invertebrate' cultural systems (Social Science Research Council Summer Seminar 1954, p. 978). For instance, two Native American groups were studied with regard to how they received tribal members who returned as World War II veterans (Adair and Vogt 1949). One group was described as engaging in 'antagonistic acculturation,' that is, to resist culture change. The other group was described as 'receptive,' 'flexible,' and 'intensely curious about the outside world' (Adair and Vogt 1949, pp. 558–60)—what Margaret Mead (1938) once characterized as an 'importing culture.' These characteristics were attributed to different types of social organization, ritual systems, and collective dispositions. The attention to relations of domination that had been present in studies like those of Pitt-Rivers and Thurnwald had given way to a perspective that, at least implicitly, valued cultures that were open and adaptive to modernization.

Not all studies of culture change, however, were framed in a modernization-friendly perspective. Some classical studies—such as Eric Wolf's (1958) of syncretism (i.e., the synthesis of old and diffused cultural elements) in the case of the Virgin of Guadalupe—attempted to provide an analysis of the specifics of acculturation. Other studies were explicit arguments against modernization-friendly theories. In particular, a critical anthropology of colonialism and neocolonialism developed under the influence of Andre Gunder Frank's (1969) thesis that underdevelopment was not a result of traditionalism, but of colonialist exploitation, and of Immanuel Wallerstein's (1974) synthetic work about the dynamics of European expansion and the center-periphery structure of the world-system.

This type of anthropology tended to treat cultural diffusion as a secondary effect of economic structures and relations. The exceptions to this tendency—such as Michael Taussig's ethnography, *The Devil and Commodity Fetishism in South America* (1980)—are noteworthy. Taussig's work was, in part, an argument against the idea that European, colonial, or capitalist expansion would result in the sort of cultural imperialism that would erase all cultural differences and bring about the 'coca-colonization' of the world. Ethnographers had for some time provided examples of culturally creative responses to capitalism's local encroachments in different parts of the world (see Nash 1981 for a review of this genre). World-systemic approaches also deviated from theories of cultural imperialism's homogenizing effects in that they, in accordance with Wallerstein's interpretation, saw the rise of national ideologies in response to globalization. They did not grant independent cultural logic, however, to the global periphery. Instead, they held the periphery to be open to radical change initiated by the center. Marshall Sahlins (1985, p. viii) has called this 'a confusion between an open system and a lack of system.'

Increasingly, local responses and resistance to colonial and capitalist diffusion became a major research orientation in anthropology and ethnographic genre in its own right. At the theoretical level, work progressed toward an analysis of the channels, types of social organization, and cultural imaginations through which diffusion occurred in the late twentieth century. Much of this effort went under the name of globalization and transnational studies. One of its representatives, Ulf Hannerz (1992, p. 46), identifies four major organizational frameworks within which cultural diffusion now takes place: form of life (i.e., everyday life or life world), market, state, and movement. The frameworks differ with regard to centering and decentering tendencies, power–culture relationships, and their cultural economies. The social organization of cultural diffusion is thus complex, exhibiting great variation in scale, rhythm, encompassment, and types of responses. Another anthropologist of transnational processes, Arjun Appadurai (1991), identifies a number of 'landscapes' of modernity—ethnoscapes, ideoscapes, financescapes, etc.—which replace previous notions of well-bounded, highly localized entities such as ethnic groups, national cultures, and market centers. The landscapes are in themselves diffusionary, so that for example ethnoscapes 'around the world are no longer familiar anthropological objects, insofar as groups are no longer tightly territorialized, spatially bounded, historically unselfconscious, or culturally homogenous' (Appadurai 1991, p. 191). People travel, migrate, seek refuge and work, and live with images and ideas that also travel—and the people know that they do, would be one way of summarizing Appadurai's diffusionary argument.

> In a world of rapid communication technologies, mobile populations, a culturally saturated international economy, and transnational connections that transcend national borders and local lives, anthropologists must reckon with 'the new power of the imagination in the fabrication of social lives,' Appadurai (1991, p. 199).

The kind of diffusionary approach that Hannerz, Appadurai, and theoretically related anthropologists have developed has tended to emphasize certain types of diffusion. Rather than to focus on the diffusion of fairly isomorph cultural and social forms—like bureaucratic, educational, and scientific models—it investigates new forms of cultural diversity that are more likely to emerge in and through market, as well as other, socially more loosely organized networks (at

least where the capitalist market is not a primary source of standardization and cultural isomorphism).

Since the late nineteenth and early twentieth century, the debate in the anthropology of diffusion has shifted from the question of cultural origins to the issue of the future of culture. If cultural historians argued against the idea that the origin of similar cultural elements was to be found in independent innovations due to the psychic unity of humankind, anthropologists of globalization and transnational connections argue against the idea that current processes of diffusion will result in a homogenous world void of cultural diversity. In the 1920s, anthropologists thought they witnessed the end of cultural diversity as colonialism and capitalism increased the levels of diffusion and acculturation even in remote areas. At the beginning of the twenty-first century anthropologists, while knowing that cultural diversity did not end with the rise of colonialism, search for answers about the character and consequences of contemporary forms of diffusion. Diffusion is at the heart of current anthropological debate in so far as it asks a fundamental question: to what extent is anthropology about cultural diversity, and could anthropology survive in a world without it?

Diffusion: Geographical Aspects

1. Introduction

From a geographic perspective, diffusion involves the propagation of a phenomenon in a manner such that it spreads from place to place, leading to maps that differ from one time to another. Most commonly the phenomenon is an innovation—a new product, new idea, new technology, new organizational structure, new way of doing things—where 'new' means new to a particular place by way of adoption. Hence, diffusion phenomena cover a wide range that includes transportation modes such as the automobile, farming techniques, family planning, credit cards, broadcast and cable television, shopping centers, production practices, such as the assembly line or just-in-time inventorying, political movements, cultural practices, frontier development, modernization in Third World settings, epidemics, urban ghettoes, and urban areas themselves. The enormous range of phenomena studied under the diffusion rubric is further indicated by

Brown (1981), Gould (1969), Morrill et al. (1988), and Rogers (1995).

While geographers have studied diffusion through most of the twentieth century, the focus has shifted over time, often with marked departures from prevailing norms. Consequently, diffusion studies by cultural geographers earlier in the century may be hardly recognizable as similar in genre to those at the end of the century, focusing on entrepreneurial agents in diffusing products or technologies.

2. *The Cultural Geography Tradition*

Diffusion has been a subject of geographic enquiry for much of the twentieth century. The spread of a phenomenon, idea, or technique through a population or region incorporates basic geographic elements of distance, direction, and spatial variation. Within geography, diffusion studies originated in cultural geography, whose research goal is:

> … to identify environmental features characteristic of a given culture and…discover what role human action…has played in creating and maintaining given geographic features (Wagner and Mikesell 1962, p. 1)

The cultural geography tradition dominated pre-World War II scholarship and focused on change in indigenous cultures, often centuries ago. Culture and the human or cultural landscape are the main concern, and diffusion studies are relevant in clarifying questions concerning culture origins, the spatial configuration of culture areas, and culture-related or culture-influenced features on the earth's surface. Carl Sauer was the central figure in this approach, which tends to be closely aligned with and complementary to some concerns of anthropology (Mikesell 1967, 1978).

Within this framework, many studies aim to assess the relative importance of diffusion vs. simultaneous invention in development of cultural landscapes. They employ an empirical, inductive approach with emphasis on landscape development in prehistory and/or over considerable periods of time. Often investigation considers a single phenomenon, seen as a culture trait, and explains its observed spatial distribution as the outcome of processes unfolding over space and time. A typical procedure is to examine a phenomenon's spatial distribution at different times or its frequency of occurrence in different locations at a single time. Inferences are drawn regarding origins (or cultural hearths), means, and routes of dispersal of both the observed phenomenon (or culture trait) and ideas–techniques–culture for which it is a surrogate. Attention also is given to cultural and environmental conditions necessary for adoption of particular phenomena (Bobek 1962) and to macroscale, big picture phenomena, such as the domestication of plants and animals, their origins, routes of dispersal, and destinations (Sauer 1952).

In stressing the role of diffusion in development of the human landscape, many cultural geography studies proceed further to consider indirect effects of the culture trait innovation on physical and cultural environments. A basic notion is that the diffusing item is both a stimulus to new innovation and itself subject to modification as it spreads. The relation between diffusion, the item being diffused, and the human landscape is therefore complex and subject to continual change.

3. *The Hagerstrand Tradition*

Sauer's counterpart in later diffusion research is Torsten Hagerstrand who, in the early 1950s, initiated a shift towards the generative processes underlying diffusion and modern-day products and practices. Since this focus is consistent with Sauer's conceptualization, why was process less prominent in earlier research? One reason may be that identification of processes controlling locational change is less feasible in the sparsely documented situations studied by cultural geographers. Second, Hagerstrand's main impact was on researchers in economic and urban geography who were primarily concerned with location and locational processes rather than landscape. Illustrative is Haggett's (1965, pp. 10–13) classification of research under the Sauer school as landscapist or ecologist and research under the Hagerstrand school as locationalist.

Hagerstrand's research (1952, 1967) focuses on diffusion of contemporary innovations such as the automobile and bovine tuberculosis control. His first study, *The Propagation of Innovation Waves* (1952), continues the cultural geography tradition by its use of an inductive approach and concern with diffusion pattern rather than process. At a somewhat later date (1953), however, Hagerstrand observed that

> … spatial order in the adoption of innovations is … so striking that it is tempting...to create theoretical models which simulate the process and make predictions achievable (Berry and Marble 1968, p. 370)

This statement indicates a change from description and inductive generalization to a more deductive approach focusing on generative processes. The work marking this shift is Hagerstrand's Ph.D. dissertation of 1953, subsequently translated into English as *Innovation Diffusion as a Spatial Process* (1967). Hagerstrand made three contributions that continue to play a role in diffusion research.

3.1 *Empirical Regularities in Diffusion*

Three regularities characterize diffusion. Over time, a graph of the cumulative level of adoption is expected to approximate an S-shape that rises with the passage of time. In an urban system, diffusion is expected to

proceed from larger to smaller centers, a regularity termed the hierarchy effect. Within the hinterland of an urban center, diffusion is expected to proceed in a wave-like fashion outward from the urban center, first hitting nearby rather than farther-away locations, and a similar pattern is expected in diffusion among rural populations. This regularity is termed the neighborhood or contagion effect.

Hagerstrand (1952) also provides a framework that connects these regularities. For diffusion in an urban system, this posits three phases: a primary stage, during which initial diffusion centers are established; a diffusion stage, during which neighborhood-type diffusion occurs in areas near diffusion centers and secondary diffusion centers are established in lower-order urban places; and a condensing or saturation stage, during which filling-in occurs and diffusion eventually ceases.

This framework thus illustrates the complementarity of hierarchy and neighborhood effects and their temporal positioning within diffusion. Also, if locales of adopters were tabulated, higher-order urban places characterize the left tail of the S-curve of adoption; lower-order urban places characterize the middle, sharply rising portion of the S-curve, along with rural hinterlands in proximity to urban centers; and remote rural hinterlands characterize the S-curve's right tail.

3.2 Hagerstrand's Conceptualization of the Diffusion Process

Hagerstrand's conceptualization of innovation diffusion across the landscape holds that adoption is primarily the outcome of a learning or communications process. Factors related to the effective flow of information are most critical and, therefore, a fundamental step in examining diffusion is identifying spatial characteristics of information flows and resistance to adoption.

In Hagerstrand's conceptualization, information originates from the mass media or past adopters. The destination of personal messages depends on a sender's network of social communications (interpersonal contacts), and configuration of this network reflects various social and terrestrial barriers that impede, divert and/or channel communications. Particular attention is given to terrestrial barriers such as lakes, forests, difficult terrain, and geographical distance separating potential communicants.

The conceptualization further recognizes that resistance levels differ among individuals, and that higher levels of resistance require more information for adoption to occur. This leads to a dichotomy of resistance as either the result of values which are inconsistent with adoption (social resistance) or practicalities which make adoption difficult or impossible (economic resistance).

To address diffusion at different geographical scales, a hierarchy of networks of social communication is posited. One network might operate locally and another regionally. The first would control diffusion among farmers in a single locale, whereas diffusion at the central-place level of aggregation might utilize a regional network of persons in different urban areas that communicate with one another. Superimposition of these two levels provides a comprehensive picture of diffusion in the area represented.

In summary, Hagerstrand's conceptualization proposes transformation of a population from a low proportion of adopters to one with a high proportion, by means of information dissemination through media and interpersonal contact. Spatially, the principal mechanisms of transformation are networks of social communication characterized by biases and distortions that, in turn, effect and are reflected in spatial patterns of innovation diffusion.

3.3 Hagerstrand's Methodological Framework

To implement his conceptualization, Hagerstrand used Monte Carlo simulation. Adoption takes place after a specified number of messages are received, the specified number varying according to an individual's resistance to adoption, which is randomly assigned. Time is treated in discrete units of equal interval, and each past adopter sends a message in every time interval. The destination of messages depends on the probability of contact between tellers and potential receivers. This probability is a function of distance between them unless a water or forest barrier intervenes. A distance decay function is employed to compute the probability of interaction between each of 25 cells in a 5-by-5 cell grid and the center cell of that grid. The resulting grid of probabilities, termed the mean information field (MIF), is employed with a map gridded in a similar manner, but with many more than 25 cells. The MIF is centered over a map cell containing an adopter of the innovation at time t; a random number is then drawn to determine which of the 25 surrounding map cells receives a message to adopt in time $t+l$. If the message passes over a water or forest barrier, it is either nullified or a new random number is drawn, depending on the level of obstruction. This procedure is repeated for every adopter in every time interval. If a previous adopter receives a message, the message is lost, that is, it has no effect and is not repeated. If a message is received by a non-adopter who, owing to resistance level, requires more than one message before adoption, the message is stored until sufficient messages for adoption are accumulated.

This model mechanism is crude by today's standards of computational capability, but in the 1950s it was highly innovative. Accordingly, Hagerstrand's diffusion model played an enormous role in Geography's quantitative revolution of the 1960s and 1970s, as both an example and standard of excellence (Berry and Marble 1968). This observation also applies to social

science overall; the model is included, for example, in books such as Coleman's (1964) *Introduction to Mathematical Sociology*.

4. *The Market and Infrastructure Perspective*

Hagerstrand's formulation, and those of the many other social scientists studying diffusion from the 1950s onward, took an atomistic view of society as individuals with free will, any of whom could adopt an innovation. Thus, the onus of adoption was on individuals, who were classified on a scale ranging from innovator to laggard, with the social meaning each term implies (Rogers 1995). This is termed the adoption perspective, focusing primarily on the demand side of innovation diffusion.

The market and infrastructure perspective focuses on supply or availability of the innovation (Brown 1981). Rather than assuming all have an equal opportunity to adopt, this is seen as purposely and egregiously unequal, so that adoption represents a choice within a constraint set; government, non-profit, and entrepreneurial institutions establish these constraints; and attention is given to the process by which innovations and conditions for adoption are made available to individuals, households or firms. Hence, focus shifts from the individual to the structure within which individuals operate, paralleling realignments in social science overall (Brown 1999). Nevertheless, the market and infrastructure perspective is put forth as complementary, not contradictory, to the adoption perspective. Broad outlines of diffusion are shaped by where (and to whom) innovations are (made) available, but within those outlines, more detailed variation in diffusion patterns reflects adoption behavior.

Central elements of this perspective include the propagator of the innovation, the entity behind its diffusion; diffusion agencies (outlets) through which innovation is distributed to the population at large; and diffusion strategy, which is designed to encourage adoption and includes decisions on agency location, pricing, advertising, population segments targeted by promotional efforts, etc. Hence, locations and temporal sequencing of diffusion agencies determine where and when an innovation will be available and provide the general outline of the diffusion pattern. Diffusion strategy further defines the pattern by creating different levels of access depending on a potential adopter's economic, locational, demographic, and social characteristics. The final pattern occurs via adoption behavior, the last stage of the process. Interacting with these factors are infrastructures like transpotation and utility networks that are independent of the innovation's propagator and diffusion agencies, but distinctly affect adoption.

Hence, the market and infrastructure perspective emphasizes the marketing aspects of diffusion, especially strategies for market penetration. Whether the propagator is profit or non-profit motivated, broad acceptance is a common goal, and a strategy will be designed to accomplish this, that is, to best penetrate the market. This also is true whether propagation involves centralized decision making, decentralized decision making with a coordinating propagator, or decentralized decision making without a coordinating propagator, although such distinctions affect procedures by which diffusion occurs. Similarly, diffusion agencies may be represented by salespeople or agricultural extension agents, but either should be guided by marketing strategy and, accordingly, make selective decisions, regarding which potential adopters will be contacted or cultivated, and to what degree. Considering the role of infrastructure, broadcast television stations were needed before television sets diffused. Today, cable and satellite services vary enormously from place to place, affecting innovation availability. Enhanced accessibility through communication or transportation improvements increases the market areas of diffusion agencies, and renders innovations more attainable to potential adopters. Also, for example, irrigation infrastructure is often critical to the success of high-yielding variety seeds in agriculture.

Finally, this framework calls into question hierarchy and neighborhood effect regularities, because relevant factors from a marketing perspective are often not arranged in that manner. The diffusion of cable television in Ohio, for example, occurred initially in small, more remote places where broadcast signals were weak or nonexistent, because cable was a means of enhancing television sales by appliance stores.

5. *Technological Diffusion*

Agricultural technology has been a major focus of diffusion studies. Beginning in the 1930s, and accelerating thereafter, rural sociologists and agricultural economists, working through agricultural experiment stations and extension agents, carried out an enormous number of studies focused on farm innovations, such as hybrid corn, fertilizers, silage methods, high-yielding varieties, and the like (Rogers 1995). Until recent industrial agriculture, the adopting unit was the farm household, thus joining this effort with diffusion research concerned with consumer innovations. Manufacturing firms that are well beyond household size, also adopt technological innovations, as do service and retail firms. This has been studied extensively, but rarely joined with the body of diffusion research described previously.

Rather than emphasizing communications, studies of firm adoption give more attention to characteristics of the firm and innovation itself. Also significant is the fact that innovation replaces an older technology with a newer one, highlighting comparative costs, benefits, and risks; factors such as relative profitability, in-

vestment, sunk costs, and the like. In this regard, there is greater emphasis on innovation as a continuous process; one that might be tailor-made for a particular firm or firm setting, rather than as a singular, unchanging phenomenon; and one that involves a more intimate and ongoing relationship between the innovation's supplier and user. Issues such as competition among firms and relative factor prices, favoring one technology over another, also play a role.

As these factors indicate, economic perspectives are important to investigating the diffusion of technological innovations among firms (Brown 1981). But spatial considerations enter in two ways. First, there has been a tendency to assume that larger firms in larger urban agglomerations are earlier adopters, giving rise to a self-reinforcing (cumulative and circular causation; Myrdal 1957) hierarchy-effect pattern of diffusion. In fact, earlier adopters are just as likely to be less-than-the-largest in size, which may correlate with aggressiveness and innovativeness of management. There also may be a spatial order to innovative change, such that newer economic regions are favored, leading to regional rotation or spatial succession; Silicon Valley provides an example (Malecki 1997). The second way spatial considerations come into play is that the study of technological innovation has become closely intertwined with regional development and regional economic change (Malecki 1997). Hence, the questions may not be inherently geographic in terms of process, but very geographic in outcome.

6. *Development as a Diffusion Process*

Seen as integral to economic development, diffusion of innovations in Third World settings has received much attention. Examples include improving agricultural production and living conditions; generating entrepreneurial activity and related employment; promoting family planning, and improving infrastructure. Research and policy have largely employed the adoption perspective, but examples of a market and infrastructure approach are also evident (Brown 1981, Rogers 1995).

More broadly, development itself has been treated as a diffusion process. One approach involves choosing an index of development, and tracing its spread across the landscape; this approach is similar methodologically to the culture trait studies of earlier diffusion research. Such indices include agricultural cooperatives, banking, communications (telegraph, telephone), educational facilities, electricity, employment patterns across economic sectors, medical services, police organizations, postal agencies, transportation modes (roads, rail), urbanization, and other artifacts of a market economy (Gould 1976, Pedersen 1975, Riddell 1976, Taaffe et al. 1963).

Frontier expansion also has been viewed in a diffusion framework (Hudson 1969). Substantively, these studies focus on aspects such as capital generation and control; migration, travel, and trade interactions; the role of particular economic sectors such as banking and wholesaling; and transportation linkages (Meyer 1980, Pred 1980)

Finally, formal models of development have a distinct diffusion dimension. Modernization, dual economy, core-periphery, growth center, and stages of growth frameworks put forth the notion that Third World settings are composed of traditional and modern elements, and that development consists of transforming traditional to modern. Dependency and related theories take a similar tack, albeit one that differs in emphasis. These models divide Third World landscapes into dynamic, propulsive, modern cores and traditional peripheries; development is represented by transformation and expansion of the modern; and this occurs through mechanisms such as information and capital flows, migration, human capital developments, and more generally, backwash, trickle-down, and imitation effects (Brown 1991).

7. *Overall Observations*

Diffusion comprises a long tradition of research in geography. From epoch to epoch in social science, it has changed focus and content. Geographical studies of diffusion also represent only one approach in that the topic is highly multi-disciplinary including, at least, contributions from anthropology, communications, economics, marketing, political science, psychology, and sociology. Accordingly, concepts used by geographic studies of diffusion may be found in research by other disciplines; for example, interpersonal interactions, mass media effects, utility-maximization, and marketing strategies. In all these instances, as well as in purely geographic studies, the critical contributions of a spatial perspective to understanding the dynamics of diffusion are apparent.

L. A. Brown

Diffusion, Sociology of

The diffusion of social practices, beliefs, technologies or moral rules is a subject of interest for both sociologists and anthropologists. In both cases, diffusion process analysis points out how individuals, groups, or communities may incorporate, reject, or adapt practices, rules, or social representations designed by others. For both sociologists and anthropologists, analyzing such processes opens a debate about the construction of existing social situations.

1. *Tarde's Contribution and the Issue of Diffusion*

According to (Tarde [1890] 1979), imitation comprises the integration of initially isolated and individual inventions into collective and social practices. When such inventions disseminate, mix, or interfere with one another, they form the basis of society:

> Renewing initiatives stand as a starting point. They bring new needs and new satisfactions to the world, then spread or tend to do so through forced or spontaneous, chosen or unconscious, quick or slow imitation, always responding to a regular pace, as a light wave or a family of termites (Tarde 1979, p. 3).

The diffusion of inventions assumes that social structures, at least at the time of their appearance, result from actions that are not determined by a certain state of the world: 'Every invention arises as one achieved possibility among thousands of others, as one between other different possibilities' (p. 49). The three processes mentioned by Tarde—imitation, diffusion, and the creation of social situations—are to be found in future works related to the issue of diffusion, even though these processes are progressively rethought.

Thus, it is assumed that new social practices and new cultural features ('novelty') are integrated and transformed at the same time: one should therefore not only speak of 'imitation' (Boas 1949). The impacts resulting from the use of novelty also interfere with the other variables of the social system, knowing that the importance of such impacts has little in common with the restricted integration of a new element: when the Tanalas of Madagascar began to grow rice and, therefore, to build terraces, the entire organization of property and laws as well as the social organization changed together (Linton 1936). In all cases, what is adopted is not a single practice or a specific cultural feature, but the principle which founds them: in the Canadian northern territories, the inhabitants learnt how to harness reindeers while observing how to harness horses.

Tarde's works also tackle the issue of the relationship between individual choices and collective conducts, that is, the progressive construction of norms. The analysis of fashion phenomena belongs perfectly to that sort of approach (Hurlock 1929): fashion is effectively the result of an individual choice, but it also matches a norm in this domain. And the aggregation of individual choices shapes the norm. A study of first-name choices in France during the twentieth century explicitly examines phenomena of that type (Besnard

1979). It also underlines the cyclic dimension of fashions: the choice of new first names is decided by superior social classes, as the renewal of such choices enables them to be distinguished from other social classes, who then imitate them. Fashion therefore fits the process of novelty diffusion and reflects the tension between the will for imitation expressed by some and the search for distinction expressed by others (Simmel [1904] 1956). In addition to this 'vertical diffusion,' there is also a horizontal process: people who work in the media or in show business and, in a wider sense, all those who hold a key position in relational networks, disseminate fashions. The social groups who remain close to fashion are the middle classes and the upwardly mobile.

However, the most important issue raised by Tarde lies in the transformation of social structures through the constant integration of novelty. This perspective is addressed in two different ways: anthropologists observe the construction of society according to a diffusionist paradigm, whereas sociologists focus on social forms and forces that may enable or limit novelty diffusion.

2. *Diffusionist Anthropology*

While contesting the evolutionist idea according to which every society faces different development stages in the field of social, economic, technological, and institutional practices, diffusionist anthropology examines the processes and spaces required for the propagation of these dimensions, as means to design societies. It pays special attention to the migration of practices rather than to their local elaboration. But it often forgets that, in the field of social relationships, a diffusion flow from A to B also involves a reverse movement from B to A, so that practice or belief diffusion also includes interaction diffusion (Sorokin 1964).

Graebner (1911) underlines the existence of 'areas of social practices,' which share similar origins (i.e., which originate from a common central point), and which find expression in comparable forms of collective life, beliefs, or economic practices. It may for instance concern the 'totemic complex' in Australia: this complex can be characterized by housing, arms, funeral rituals, and astral mythology. But local populations seldom incorporate the features of social practices or beliefs entirely. They especially proceed to some selection among the elements of the system, as well as to some alteration or adaptation to local practices. Every cultural circle that is worked out this way regularly increases, until it meets the development of another cultural circle: their encounter leads to the fusion of both areas.

The analysis of the spatial sharing out of cultures therefore comprises the trajectory of their diffusion and, in that sense, their own history. According to Boas, the cultural areas may be continuous or discontinuous. In the latter case, all the features that typically characterize a social practice or a belief (e.g., the themes and sequences of a myth) can be found in the center of the area, whereas the other features remain at the periphery. During their trajectories, practices and beliefs may be enriched or, on the contrary, may lose some of their dimensions, due to encounters with elements coming from other spaces. There are strong similarities between the Eastern Siberian populations' culture and that of British Columbian Indians, whereas Eskimo populations, while not so recent, are less culturally close, even though they live in an intermediate territory.

These perspectives are of double interest. They renew the methodology of anthropology as they contribute to replacing general reflection with empirical enquiries. For instance, Lowie (1934) explains that all known varieties of bananas intended for sale come from new shoots, rather than seeds; it is therefore possible to follow human migrations on the basis of their consumption. Within the northern American tradition, these perspectives result from a reasonable epistemological position, which aggregates internal and external causes of change and gives a key role to the specificity of living conditions and to the nature of the contacts that characterize geographical areas. Boas therefore gives up defining general rules, and turns to questioning the diversity of social and cultural practices within a limited region. However, some of the positions expressed by advocates of diffusionist anthropology seem to result more from their conflict with those who defend natural evolution than from empirically founded research. Thus, one may explain that the majority of civilizations originate from ancient Egyptian culture, which was disseminated by sea. For example, the pyramids erected by Native Americans are considered to be reproductions of those designed by the Cambodians or the Japanese, who would also have taken the Egyptian ones as their model.

3. *The Statistical Form of Diffusion*

When linking the age of cultural features or observed social practices with the number of people that may use them, anthropologists often compare the diffusion process to a logistic, epidemiological 'S' curve (e.g., Pemberton 1936). In so doing, they encounter the works of numerous sociologists (e.g., Mendras and Forsé 1983). At the beginning of the process, a limited number of people are affected by the novelty: the speed of diffusion is therefore rather low; then, the speed regularly increases, and the growing number of informed people leads others to adopt the novelty; finally, the curve decreases, and the number of noninformed people regularly diminishes. This form of diffusion can also be considered as a process of inverted norms: in the first stage, a few pioneers only behave differently from usual; then their behaviors progressively shape new norms and impose themselves

on the 'followers'; during the last phase, 'resistants' may slowly and partially accept the integration of new norms. In both perspectives, the 'S' curve seems to reflect the diffusion process adequately.

However, this kind of curve seldom reflects the real development of the phenomenon, especially when looking at its complexity. Its existence requires specific conditions with regard to the homogeneity of the populations and to the regularity of the process—conditions that real social situations seldom show. Regarding rumors, Boudon and Bourricaud (1982) identify three statistical forms of diffusion. When a rumor appears to be disseminated by word of mouth within a vast and homogeneous population, the increase in the number of people informed at every stage is roughly proportional to the number of people already informed; the diffusion curve is somewhat exponential. Whenever the population is simultaneously homogeneous and limited, the process shapes a logistic 'S' form, which characterizes the epidemiological approach. And if the information is only disseminated through the media (in other words, if the members of a population have few interpersonal relationships), the pace of the increase in the number of informed people is proportional to the number of those not yet informed. Thus, the epidemiological curve is only a rare possibility among other diffusion processes for a novelty, a belief, or a rumor. Referring to the 'S' curve, Sorokin ([1937] 1964), while reading his contemporaries' works, explains that such a phenomenon occurs if and only if the novelty remains of the same kind, and if the civilization, the channels of communication, and the means of support (here including physical strength) it is based on remain similar.

The interest in this kind of analysis resides in the identification of factors, phases, or actors who take part in the achievement of the diffusion process designed to integrate a novelty. Within this perspective, Katz and Lazarsfeld (1955) underline the determining role of influencing networks. As for decision criteria and mechanisms related to Midwest women's practices in food shopping, clothes, political issues, or the cinema, they observe that choices are inspired by two sequences of influence. The first one refers to the media, who transmit information to everyone; the second is undertaken by influential people, who use the information to implement new social practices (in this case, women coming from the same social class). When observing the prescription of a new medicine, Coleman et al. (1966) perfectly underline the heterogeneous dimension of a population and, in that sense, the first complex mechanisms of innovation adoption. The first doctors to prescribe a medicine ('the innovators') 'test' it after it has been marketed, and therefore tend to slow down the diffusion process; then, when they are convinced of its advantages, they speed up the diffusion process by actively influencing the diffusion to other doctors who may have hesitated before. These innovating and influencing doctors are those who have kept a close relationship with the world of hospitals and research; they globally benefit from wider and denser relational networks than others. They play the same role of 'intermediaries' as the minority of farmers who have 'specialized' in links with other regions of the same country, whereas the majority limits its relationships to neighborhood contacts (Hägerstrand 1965).

The diffusion of social practices, cultural features or novelties thus follows a rather unpredictable trajectory: It depends on the kind of interactions that occur. It also depends more on the recognition gained by a novelty when being used than on its own characteristics. With this in mind, the sociological analysis of diffusion is based, at least partially, on the diffusion of rumors; the latter finally create the effective use of novelty. In that sense, the 'self-fulfilling' prophecy (Merton 1949) remains at the top of diffusion issues.

4. *The Conditions of Diffusion*

The novelty diffusion processes may not always be perfectly comparable; however, the conditions required for their existence always relate to the initial action of 'pioneers,' 'innovators,' 'intermediaries,' or 'cosmopolitans' (Merton 1949). These types of actors are the first ones who effectively use it. They benefit from their own capability to behave regardless of the norms, as opposed to the rest of the population, because they benefit from an additional background of cultural references: The 'stranger' character often harmonizes with the diffusion analysis. But the ability to reverse norms, the type of ability which allows a pioneer's behavior to be seen as a normal one, assumes that cultural differences refer to a group's substantial weight (Moscovici 1976); to put it more simply, such an ability requires that the novelty becomes a matter of interest for the rest of the population, the reasons for such an interest being cultural, economic, or strategic.

Such conditions are obviously not always immediately fulfilled. Therefore, the researcher's interest may turn to the analysis of obstacles and resistance faced by the diffusion process. Within such a perspective, Bloch (1935) examines the reasons that may explain the relatively slow diffusion of water mills (a one millennium process), knowing that such mills show marked advantages in productivity increase and labor reduction. The water mill cannot be set up everywhere, as it has to be supplied with numerous and regular streams; in the Middle Ages, the risk of a city being besieged led the lord to keep a significant number of traditional millstones, as these mills operate regardless of the natural environment, which could be controlled by the enemies. Building a water mill also requires that the builders legally possess the supplying stream, although one stream may run through different rural

properties. It also assumes that builders are able to finance the effective erection of the building, whereas their available financial capital is actually low. It finally requires that they make profit on the investments, by dedicating them to a wider community use than the one offered by traditional techniques; but social structures are based on family farming. Nonetheless, such objective dimensions are not the only reasons that may explain the slow diffusion of water mills. From the lords' point of view, being obliged to keep an important workforce available in order to use the millstones also represents an indicator of power as well as an opportunity to keep everybody in their own social position within the existing division of labor. There are symbolic and political dimensions involved in such a process. Despite fines and police force activities to make the use of common mills compulsory, despite the payment of high taxes when millstones are in use, despite courts' decisions in favor of the owners of water mills, despite all these efforts, the use of mills remains an issue.

The factors interfering in novelty diffusion are diverse: legal, symbolic, strategic, economic, and cultural. Their number and their interdependency do not allow for any forecast about the end of the novelty. Within novelty diffusion, the competition between different rationalities may interfere in a positive or in a negative way (Alter 2000). In addition, many novelties are implemented in favor of a restricted minority of the population; the diffusion may be very quick, and it will only concern a fraction of the population (Edmonson 1961). In other words, the price to be paid to adopt innovation may slow down its diffusion, whereas the expected income would speed it up (Griliches 1957). The diffusion analysis therefore comprises a nondiffusion one. It could not be purely diffusion oriented.

Finally, the lessons to be drawn from these different perspectives are threefold. The diffusion of an object, a belief, or a political system does not depend on its own intrinsic qualities but more on the involved social actors' rationalities. Novelty diffusion leads to the transformation of social norms; this transformation is based on the existence of social actors who break the established social order. A novelty does not disseminate without radically changing; it could therefore always be described as an innovation, at least partially.

Digital Computer: Impact on the Social Sciences

The invention of the computer has been described as the third information revolution—after the advent of writing and the printing press. Computers transformed our world, in reality and fiction: from online library catalogues and the World Wide Web to the vision of machines that will eventually surpass humans in intelligence and even replace us by self-replicating computers divorced from biological evolution. This revolution was difficult to foretell. Howard Aiken, the Harvard mathematician and builder of the Mark I calculator, predicted in 1948 that there would be no commercial market for electronic computers; he esti-

mated that the USA would need only five or six such machines, but no more. As early as the 1960s, electrical engineer Douglas Carl Engelbart had designed the first interactive computer tools, including the mouse, on-screen editing, screen windows, hypertext, and electronic mail. However, at this time, human–computer interaction still seemed science fiction—computers were for processing punched cards, not for interacting with humans. The impact computers had on society and science was difficult to imagine, and we may be in the same position with respect to the future.

The impact goes in both directions: computers and humans coevolve. This coevolution is illustrated by the work of Charles Babbage (1791–1871), the English mathematician who is often credited with the invention of the digital computer.

1. *The Computer as a Factory of Workers*

Babbage's Analytical Engine, a mechanical computer, was inspired by and modeled on a new social organization of work: the large-scale division of labor, as evidenced in the English machine-tool industry and in the French government's manufacturing of logarithmic and trigonometric tables for the new decimal system in the 1790s. Inspired by Adam Smith's praise of the division of labor, French engineer Prony organized the project in a hierarchy of tasks. At the top were a handful of first-rank mathematicians, including Adrien Legendre and Lazare Carnot, who devised the formulae; in the middle, seven or eight persons trained in analysis; and at the bottom, 70 or 80 unskilled persons who performed millions of additions and subtractions.

Once it was shown that elaborate calculations could be carried out by an assemblage of unskilled workers—rather than by a genius such as Gauss—each knowing very little about the larger computation, it became possible for Babbage to conceive of replacing these workers with machinery. Babbage, an enthusiastic 'factory tourist,' explicitly referred to this division of mental labor as the inspiration for his mechanical computer, and he used terms from the textile industry, such as 'mill' and 'store' to talk about its parts. Similarly, he borrowed the use of punched cards from the Jacquard loom, the programmable weaving machines that used removable cards to weave different patterns. Thus, in the beginning there was a new social system of work, and the computer was created in its image.

2. *The Hierarchical Organization of the Mind*

Babbage's Analytical Engine was never completed. Around 1890, the first 'digital calculators' were manufactured, so named because they represented numbers by cogged wheels whose positions corresponded to the *digits* in the numbers denoted. (An abacus was still cheaper and faster.) Analog computers, in contrast, are devices in which continuous quantities, such as electrical potential or mechanical motion, are used instead of discrete (e.g., on/off) states. Until the first third of the twentieth century, digital calculators remained essentially mechanical. In the late 1930s, electromechanical relay switches started replacing gears and cogs in calculators. The electronic computer based on vacuum tubes and containing no movable parts appeared during World War II and was invented three times: in Germany for airplane design, in the USA for calculating artillery tables, and in the UK for breaking German secret codes. Vacuum tubes were eventually replaced by transistors, and finally by silicone chips, which allowed the transition from large mainframes to minicomputers. The first personal computers—complete with keyboard, screen, disk drive, and software—were marketed by Apple in 1977, and by IBM in 1981.

Through these dramatic improvements in hardware and speed, Smith's ideal of the division of labor became the basis for a fresh understanding of the human mind. Herbert Simon and Allan Newell proposed that human thought and problem solving were to be understood as a hierarchical organization of processes, with subroutines, stores, and intermediate goal states that decomposed a complex problem into simple tasks. In fact, a social system rather than a computer performed the trial run for the Logic Theorist, their first computer program. Simon's wife, children, and graduate students were assembled in a room, and each of them became a subroutine of the program, handling and storing information. This was the same as the nineteenth-century French '*bureaux de calculs*' and the Manhattan project, where calculations were done by an unskilled workforce—mostly women, at low pay. Similarly, Marvin Minsky, one of the founders of artificial intelligence, regarded the mind as a society of dumb agents, collectively creating true intelligence. Similarly, anthropologists have begun to use computer analogies to understand how social groups make decisions, such as how the crew on a large ship solves the problem of navigation by storing, processing, and exchanging information. The direction of the analogy thus eventually became reversed: originally, the computer was modeled on a new social system of work; now social systems of work are modeled on the computer.

3. *From Calculation to Computation*

A crucial insight occurred when the early designers of computers realized that a computer could be used not only for calculation but more generally for symbol processing. The switch positions inside the machine

could take on other meanings than numbers; they could stand for symbols representing concepts. This insight fueled the view of *cognition as computation*, that is, symbol manipulation. A computer that merely performed fancy calculations would not have suggested itself as a model of human thought. During the Enlightenment, proficient calculation indeed was seen as the essence of intelligence and even moral sentiment, but after the introduction of the large-scale division of labor around 1800, prodigious mental reckoning had became the mark of the idiot savant rather than the genius.

The notion of computation led to two questions: Can computers think? Is human thought computation? To avoid endless philosophical debate on exactly how to define the first question, Alan Turing (1912–54) suggested the 'imitation game,' now known as the Turing test: A human interrogator must distinguish between a computer and a human subject based on their replies to the interrogator's questions. In a series of such experiments, a computer's ability to think could be quantified as the proportion of interrogators who misidentify the machine as the human subject. Turing asked whether the computer is like a mind: whether it thinks, has free will, and whether one can teach machines to become intelligent using the same psychological principles used to teach children. Those who focused on the second question—is the mind like a computer?—saw the analogy pointing in the other direction. For instance, they tried to teach children using the same principles that had worked for computers. This analogy of the mind as computer fueled the cognitive revolution in psychology during the 1960s and 1970s.

The 'physical symbol system' hypothesis proposed by Simon and other researchers in artificial intelligence assumes that human cognition *is* computation in the sense of symbol manipulation. According to this view, symbols represent the external world; thought consists of expanding, breaking up, and reforming symbol structures, and intelligence is nothing more than the ability to process symbols. Information processing became the key to understanding human thought, and the tools of programming provided the mechanisms of thought: production systems, subroutines, recursion, iteration statements, local naming, interpreters, and so on. This view was not easily reconcilable with prevailing theories of thought, from Freud's theory of mind as manipulating biological energies, to the behaviorists' view that thought is simply silent speech, or to the Gestalt psychologists' view emphasizing the context dependency, interconnectedness, and emergent quality of thought. In essence, the vision of cognition as symbol manipulation revived the Enlightenment view of thought as a combinatorial calculus. For Condillac, d'Alembert, Condorcet, and other Enlightenment philosophers, the healthy mind worked by constantly breaking down ideas and sensations into their minimal elements, then comparing and rearranging these elements into novel combinations and permutations.

The view of thought as symbol manipulation also revived the old dream of a logic of scientific discovery, the existence of which Karl Popper had so vehemently disclaimed. Computer programs such as BACON managed to infer scientific laws from data, and artistic creativity was modeled on the same combinatorial principles. Computer programs were written that composed music, wrote stories, and designed new Palladian villas and prairie houses. Leibniz's dream of a Universal Characteristic that would assign to each concept a number, and reduce each problem to calculation, seemed to have come true. Like Babbage and Pascal, Leibniz had designed one of the first computers.

Through the medium of the computer, the Enlightenment psychology re-entered modern psychology. This is, however, only half the story. Just as George Boole had set out in the mid-nineteenth century to derive the laws of logic and probability from the psychological laws of human thought, researchers such as Simon and Newell tried to enter into their computer programs the results of psychological research about human thought. For instance, the concept of heuristics that speed up search in a problem space proved to be essential for intelligent programs. Heuristics are smart rules of thumb that humans apply in everyday reasoning when optimization, such as maximizing expected utility, is impossible or would cost too much time (see *Decision Making: Nonrational Theories*).

The metaphor of the mind as computer must be distinguished from John von Neumann's (1903–57) metaphor of the brain as computer. Von Neumann, known as the father of the modern computer, was concerned with similarities between the nervous system and computer, neuron and vacuum tube—but added cautionary notes on their differences. Turing, in contrast, thought the observation that both the modern digital computer and the human nervous system are electrical was based on a superficial similarity. He pointed out that the first digital computer, Babbage's Analytical Engine, was mechanical rather than electrical, and that the important similarities to the mind are in function rather than in hardware.

How quickly did the metaphor of the mind as computer come to be accepted by cognitive psychologists? Consistent with the tools-to-theories heuristic—which says that new scientific tools suggest new metaphors of mind, society, or nature but are accepted by a scientific community only after the members have become users of the tool—the broad acceptance of the mind as computer metaphor was delayed until the 1970s and 1980s, when personal computers became the indispensable tool of researchers. Before the advent of personal computers, researchers had little direct contact with the large mainframe computers,

and for those who did, computers were a source of constant frustration. For instance, in an average week in 1965–66, the PDP-4C computer of the Center for Cognitive Studies at Harvard saw 83 hours of use, but 56 of these were spent on debugging and maintenance. A 1966 technical report of the Center was entitled 'Programmanship, or how to be one-up on a computer without actually ripping out its wires.' The metaphor of the mind as computer only became widely accepted after the tool had become part of the daily routine in psychological laboratories.

4. *From Thought Experiments to Simulation*

Thought experiments, from physics to political science, have been a research tool in situations where no data could be obtained, such as counterfactual historical scenarios. The computer created a new species of thought experiments: computer simulation. Jay Forrester's Club of Rome world resource model—which predicted worldwide famine followed by war in the first third of the twenty-first century—is one of the best-known early social science simulations. Robert Axelrod's classic 'prisoner's dilemma' computer tournament demonstrated the success of a simple social heuristic called tit-for-tat and became the model for numerous simulations on game theory, reciprocal altruism, and political science. Simulations force researchers to specify their theoretical ideas precisely, and they have become a tool for discovering new implications of these ideas. In some fields the need to specify assumptions precisely has become a requirement for what constitutes a theory: what cannot be simulated does not deserve to be called a theory.

Computer simulation allows the modeling of dynamic systems, such as the evolution of social structures through the repeated interaction between individuals. Computer simulation is a truly new form of experiment, but social scientists are divided over what role it should have in research. In artificial intelligence, organizational theory, and demography, for instance, simulation has a long tradition. In sociology, in contrast, simulation is still rare and little respected. Simulation tends to be rare in fields where a distinction (or even hostility) between theoretical and empirical research is deeply entrenched, such as sociology, and where computers are heavily used for the analysis of empirical data. Perceived as the instrument of the 'other,' number crunching camp, the computer's theoretical possibilities tend to be forgotten.

5. *A World of Numbers and Statistics*

When the statistician Karl Pearson assembled the famous *Biometrika* statistical tables between 1914 and 1934, he used a 50-lb Brunsviga calculator and numerous clerks. The 1946 ENIAC—which is commonly referred to as the first modern digital electronic computer using vacuum tubes—could calculate 5,000 additions per second, that is, it did the work of a whole factory of clerks. Fifty years later, a tiny and relatively inexpensive Pentium chip could conduct over 500 million operations per second. This explosion of calculating power together with decreasing cost and size has had a dramatic influence on the social sciences, both positive and negative. The emphasis has shifted from collecting qualitative observations to quantitative data, and from *a priori* theoretical thinking to the *post hoc* interpretation of significant correlations.

At the end of World War II, half of the articles in the *American Sociological Review* and *American Journal of Sociology* lacked any kind of quantitative mathematical analysis; thirty years later this number had decreased to about 13 percent. In psychology, as in sociology, the predominant quantitative methods before the advent of electronic computers were descriptive statistics, such as means, variances, percentages, correlations, and cross tabulations. With the advent of fast calculators, the social sciences have witnessed a rapid growth in the usage of computationally expensive statistical methods, including factor analysis, cluster analysis, analysis of variance, and multiple regression. The computer also provided tools that could make data structures visually transparent and help researchers see underlying structures—called exploratory data analysis. Sociologists, demographers, and anthropologists were finally able to analyze large samples in a short time, such as census data and voting polls.

Computerized statistical packages such as SPSS (Statistical Package for the Social Sciences) have not only helped but also have hurt progress. Their ease of application (e.g., compute 'everything by all') has often replaced statistical thinking with statistical rituals. One widespread ritual is null hypothesis testing, in which the researcher mechanically tests whether data significantly deviates from a null hypotheses ('chance'), without ever specifying the predictions of the research hypothesis and of competing hypotheses, and without measuring effects and constructing substantive theories of some depth. As a consequence, researchers tend to skim through computer printouts looking not at the data but at the significance level of the correlations or chi-squares and engage in *post hoc* explanations for whatever comes out significant.

6. *Research and Teaching Assistance*

Next to data analysis, the most common use of computers in the social sciences is that of an efficient and patient research assistant. A computer can serve as a librarian who searches for relevant publications and historical records; as a data bank manager who stores and retrieves narrative information, qualitative

and numerical data; as a secretary who edits and files texts, keeps track of footnotes and references; and as a fast electronic mail system that facilitates contacts with colleagues worldwide. In experimental psychology, computers run entire experiments with humans and animals; they present the experimental stimuli and record the participants' responses.

This interactive use of computers would not have been possible without the invention of the personal computer that replaced the large mainframes. Engelbart's invention of the mouse exemplifies how human abilities such as hand–eye coordination can be exploited to design appropriate tools with which humans can almost intuitively interact with computers. In social science teaching, human–computer interaction can increase the participation of all students, whereas in the traditional classroom small groups of students often tend to dominate the discussion. Chat rooms on the World Wide Web have become a new and cheap data source for anthropologists and psychologists. The Web in turn has generated legal and ethical problems concerning secrecy and data protection, motivating revisions of the copyright law, tax law, and criminal law.

7. *The Computer Revolution*

Has the computer fundamentally changed the social sciences? As we have seen, the kind of impact differs across the social sciences. The invention of the modern computer has increased interdisciplinarity through the creation of *cognitive science*, consisting of artificial intelligence, psychology, philosophy, linguistics, anthropology, and neuroscience. However, sociology is notably absent from that list. Electronic mail and the Internet have made international collaboration easier and faster than ever. Simulation, expert systems, neural networks, and genetic algorithms would be unthinkable without high-speed computers, and so would be statistical analyses of large bodies of data. In these respects, the social sciences today have available a repertoire of powerful new tools and opportunities.

Has the computer revolutionized our conception of mind and society? The answer seems to be yes if we use the original meaning of the term—a re-volution, that is, a return to earlier conceptions. The metaphor of the mind as computer, for instance, has brought back the combinatorial view of cognition of the Enlightenment and Adam Smith's ideal of a division of labor. Thinking, problem solving, creativity, and scientific discovery came to be explained by a hierarchically organized mind that decomposes complex problems into simpler subroutines. In this way, theories of mind and society that had existed before computers, were expanded and perfected.

Diglossia

Although the French term *diglossie* was introduced by the Arabist William Marçais in 1930 (Marçais 1930), it is the late Charles A. Ferguson who is most often credited as the first to introduce the notion of a 'high' (H) and a 'low' (L) variety or register of a language in a classic (Ferguson 1959) article with the now famous one-word title, 'Diglossia.' The gist of his widely

influential essay, which has been reprinted several times, was to demonstrate that the idea of H and L registers best explained the pervasive linguistic distinctions observable in a few speech communities concerning the strict complementary distribution of formal vs. informal usage. For Ferguson, who calqued the term from the French, there were only four 'defining' languages which he considered representative: Arabic, Swiss German, Haitian Creole, and Modern Greek. Since then, many other languages (in actuality, the speech communities which speak them) have been re-evaluated as diglossic, although most, to be sure, are far less diglossic than Arabic is (see further Ferguson 1991). In fact, Ferguson predicted what was to come when he affirmed (Hymes 1964, p. 429): 'it is likely that this particular situation in speech communities is very widespread, although it is rarely mentioned, let alone satisfactorily described.' It is important to emphasize that Ferguson's original conception of diglossia sharply contrasted with bilingualism, since he states that diglossia is different from 'the analogous situation where two distinct (related or unrelated) languages are used side by side throughout a speech community, each with a clearly defined role' (Hymes 1964, p. 429).

I focus in this essay on the case of Arabic, the area of my fieldwork expertise. Although Arabic diglossia is similar to that of other diglossic speech communities, there are some noteworthy differences. Ferguson (Elgibali 1996, p. 63) points out that, until recently, an after-dinner speech in Greek would have had to be given in katharevousa (H), but nowadays, demotiki (L) is acceptable. However, in south India, the Telugu community would never use H that way, and Ferguson further elucidates: 'People write articles, and especially poetry, in it, but it is never used in speaking on formal occasions' (Hymes 1964).

Over the past few years, the notion of the continuum has proven useful in attempts to redefine diglossia as it relates to triglossia, tetraglossia, and multiglossia or polyglossia (Kaye 1994). This latter perspective represents the current linguistic scene, particularly as it applies to the world's most complicated, in my opinion, diglossic situation, viz., Arabic (see, e.g., Kaye 1994 and Hary 1996). As illustrative, consider that 'what do you want (m. sg.)' is *maa(ðaa) turiid* in Modern Standard Arabic (hereafter MSA, a modern version of Classical Arabic), whereas an Egyptian would say in Egyptian Colloquial Arabic (ECA) for the very same thing *Gaawiz* or *Gaayiz eeh*, a Sudanese *daayir šinu*, and a Lebanese *šu baddak*. Diglossia can, however, border on bidialectalism, perhaps even on bilingualism, depending on the situation, since some native speakers of Arabic would be hard-pressed to understand a radio or TV news broadcast in MSA, let alone comprehend the oral rendition of an essay on a modern technological or literary theme. Native oral and written knowledge of and fluency in MSA are entirely different matters, however, which need not concern us here (see Parkinson 1991, 1993). Of course, it is important to recognize that an Arab deprived of an education will have far less knowledge of MSA than a university graduate.

Let us now consider an English parallel (although it is a rough one only) to the classical diglossia of Ferguson 1959. English has a formal style or register: 'To whom do you wish to speak?' corresponds to its informal equivalent 'Who do you want to talk to?' Further, one may also compare the triglossic verbs wed—get married or marry—get hitched, the diglossic verbs 'put out' (say, a cigarette) vs. extinguish, and the different nuances conveyed by the nouns kids vs. children vs. offspring vs. progeny (see Kaye 1991 for details). English even has a difference in H and L prepositional usage. Consider upon vs. on, as in 'Upon arrival, go directly to the baggage claim area.' Further down the continuum ladder in the mesolect, one may utter: 'On arrival …,' or 'On arriving … .' If one were uttering this sentence to a friend (toward the basilect), though, it would come out something like, 'When you get there, go straight to get (or pick up) your luggage.' It is the different vocabulary items in particular which instantaneously mark a speaker as using the H 'classical/standard,' or the L 'colloquial/vernacular/*patois*.' A particularly good example of this phenomenon is MSA *ðahaba* 'to go' vs. the very widespread vernacular *raaħ* or *maša/miši*. It is the utilization of the former which would be interpreted by a native speaker as a symbol of H, whereas the use of the latter would be indicative of L.

Let us now turn to the intricate phenomenon of register mixing/switching/variation. First of all, even Ferguson himself admits that he failed to examine this topic in the 1959 paper (Elgibali 1996, p. 61). It would be considered very odd to mix registers in the wrong fashion, although all sorts of register-dialect mixing regularly occur throughout the Arab world. Thus, *maa(ðaa) Zaawiz* (MSA 'what' + ECA 'want') would be perceived as most awkward—in fact, downright bizarre. It simply does not and would not occur. By a similar token, speaking MSA to one's maid at home or bargaining over the price of an item in a crowded market in MSA would be absurd, even ludicrous (unless one was trying to be facetious, weird, or sarcastic; however, non-Arabs can and often do use MSA in these and related situations, and can get away with it). This violates the 'normal' functional constraints on when and how to mix MSA and a colloquial dialect. On the other hand, ECA *da ma biyustaxdamš* 'this is not used' is perfectly acceptable, with its MSA imperfect internal passive plus the ECA *-š* 'negative.' The aforementioned examples bolster the viewpoint that native speakers possess an overall 'communicative competence' rather than a mere 'grammatical competence.'

Before taking up the details concerning the function, acquisition, grammar, and phonology of MSA and colloquial Arabic dialects, let me state that a phenom-

enal number of works on diglossia stemming from Ferguson (1959) have been published. In fact, one might wonder if any other sociolinguistic topic has generated such a prodigious research effort over the same 40-year time span. There is one book-length bibliography (Fernández 1993), and another monographic compilation appeared at about the same time in the leading sociolinguistic journal (Hudson 1992). Much of this prolific scrutiny has centered around investigating diglossia in other speech communities. Indeed, we possess studies of diglossia in Bengali, Sinhalese, Kannada, Tamil, Telugu, Malayalam, Chinese, Japanese, Persian, Old Russian, Ottoman Turkish, Irish, and Welsh, to mention but a few languages. Some researchers, such as Joshua A, Fishman, have even deemed a very specialized case of bilingualism to be diglossia. He affirms that the H and L varieties in Paraguay are Spanish and Guaraní respectively (Fishman 1971, p. 75, originally formulated in Fishman 1968). Furthermore, Fishman (1971, p. 74) has also claimed that the use of any two varieties of a language in different situations constitutes diglossia. We may refer to this as 'extended' diglossia which, in essence, leads to labeling all speech communities diglossic. At the very heart of the term is really the matter of degree, which is why the notion of the continuum is so useful in the analysis being presented in this essay. Diglossia in Arabic is a different phenomenon from diglossia in English—quantitatively more than qualitatively—especially when one notes the extreme, all-encompassing pervasiveness of the Arabic H-L dichotomy vs. the limited extent of formal vs. informal English stylistic variation. With this in mind, it appears safe to assert that diglossia is holding steady or is on the increase in the English-speaking realm, but declining in Arab countries such as Egypt, where ECA is becoming increasingly more acceptable in written form (e.g., in advertisements) and in some formal oral situations, such as certain political or religious contexts (e.g., the speeches of Abdul Nasser or the Koranic commentary by Sheikh Shagrawi). Egypt is the most populous Arab country, and the one which has the greatest tendency to use its dialect for cultural identification and nationalistic purposes in situations bordering on the unthinkable in other Arab states.

It is important to keep in mind that diglossia was slow to evolve. In the case of Arabic, Blau (1977, p. 190) is of the opinion that diglossia is not pre-Islamic, but began as the Arab armies spread out of Arabia conquering foreign lands such as Egypt in 640 AD. This is a controversial view not shared by all Arabists. Be that as it may, the Koran was instrumental in preserving the classical language in a frozen state, while its contemporary spoken dialects continued to change, like all living languages. It is generally agreed that the most classical (read: 'most elegant' or 'best' variety of H) Arabic today is, as has always been the case, the language of the Koran.

1. *Function*

Ferguson (1959) noted that H is apropos for sermons, all sorts of letters, speeches, university lectures, news broadcasts, and poetry, whereas L is appropriate when talking to servants, waiters, clerks, and workmen, conversing with family, colleagues, and friends, and in soap operas, captions on political cartoons, and folk literature. Thus, it is inconceivable that a husband would tell his wife that he loved her using anything other than L. In a similar vein, a parent scolding a child (or two children conversing) would use L. However, a professor giving a lecture would be using MSA, although there might be some L interspersed (especially in Egypt).

2. *Acquisition*

Modern linguistics distinguishes between language acquisition and language learning. Thus, it is axiomatic that native languages are acquired, whereas superposed varieties (and foreign languages taught to adults in schools) are formally learned. Every Arab grows up speaking his/her native dialect, and is formally taught MSA, given the opportunity. No one speaks MSA as his or her mother tongue. Exposure to MSA has been on the increase throughout the Arab world in the twentieth century, although a few peripheral Arabic-speaking communities have had little or no exposure to it, thus preventing the development of diglossia.

3. *Grammar*

One of the major characteristics of H is a more involved grammar. Ferguson (Hymes 1964, p. 435) calls H 'grammatically more complex.' Basically, MSA may be viewed as a marked system, and colloquial Arabic as unmarked (see Kaye 1972 for details). That is to say, MSA marks many more categories of grammar: nominative, genitive, and accusative cases, duality in the pronoun, verb, and adjective, and so on. No Arabic dialect has retained these grammatical categories, which have been lost over time.

Let us now consider a simple sentence: 'I saw the man going to his house.'

MSA: *raʾaytu rrajula ʾaahiban ilaa baytih.*

ECA: *šuftʾirṛaagil ṛaayiħ beetu.*

In addition to the different lexemes for 'see' and 'go,' MSA marks the noun 'man' with *-a* 'accusative masculine singular,' also observable in the accusative *-an* in the following active participle. Moreover, the preposition *ʾilaa*, absent in ECA, governs the genitive case of the following noun, which would, in its non-pausal form, be *baytihi* (the form *baytih* is pausal, since it occurs in final position, i.e., before pause).

4. Phonology

It is well known that the MSA voiceless uvular plosive corresponds to a glottal stop in ECA, Syro-Palestinian dialects, etc. (Kaye and Rosenhouse 1997 for the details of cross-dialectical comparisons). However, a native knows that *alqur'aan* 'Koran' is to be pronounced only with /q/. Ferguson correctly concluded that the L phonology is thus the basic system (Hymes 1964, p. 435). Thus, it is of great importance to realize that MSA pronunciation is not uniform throughout the Arab world. This is one of the reasons for my claiming that MSA is ill-defined, while ECA and all colloquials are well-defined (Kaye 1972). The most important factor determining MSA phonetics is the nature of the L underlying input (assuming a solid background of schooling in the language). Thus, ECA speakers, such as President Hosni Mubarak of Egypt, pronounce the letter *jiim* as *giim* (a voiced velar stop for the voiced palato-alveolar affricate) because this is the ECA reflex of the *jiim*. There are ECA stress patterns which are carried over to MSA as used in Egypt; e.g., *tajannábataa* 'they (f.) both avoided' (Mitchell 1990, p. 103). As Mitchell succinctly points out: 'Vernacular influenced' is nowhere more clearly in evidence than in the matter of accentuation' (Mitchell 1990).

5. Conclusion

Kaye (1972) concluded that MSA is, to a large extent, unpredictable, and thus ill-defined. There are so many varying microscopic details, since MSA is used in so many different countries by so many people with so many different educational backgrounds. Hary (1996, p. 84) refers to this state of affairs when he affirms: 'In the middle (between H and L: ASK), the mesolect, one finds almost countless variation, or lects, used by native speakers, on different occasions and under various circumstances.'

A. S. Kaye

Dimensionality of Tests: Methodology

A critical concern underlying the claims for validity argument relates to ensuring appropriate representation of the construct to be assessed. It is critical to ensure that the construct is neither over- nor under-

represented, and that the assumption of unidimensionality is not violated (Ackerman 1987, Luecht and Miller 1991, Messick 1989, Tam 1992). This unidimensionality assumption specifies that a score can only have meaning if the set of items measures only one attribute. If the measuring instrument has a number of items that measure differing attributes it is difficult to interpret a total score from this set of items, to make psychological sense when relating variables to this total score, or to make comments about individual differences. For example, if there are 10 spelling and 10 mathematics items in a test then it is not clear what the total score for any individual could mean. For example, two students scoring 50 percent are not comparable as it could be that one student scored correctly on the spelling and the other scored correctly on the mathematic items. Test scores only have meaning when the items measure a single attribute (for a more complete and earlier review see Hattie 1985).

The concept of unidimensionality is a specific instance of the principle of local independence—that is, the existence of one latent trait underlying the data. The principle of local independence requires that responses to different items are uncorrelated when θ (the person's ability) is fixed, although it does not require that items be uncorrelated over groups in which θ varies. Lord and Novick (1968) gave the definition of local independence more substantive meaning by writing that:

> an individual's performance depends on a single underlying trait if, given his value on that trait, nothing further can be learned from him that can contribute to the explanation of his performance. The proposition is that the latent trait is the only important factor and, once a person's value on the trait is determined, the behavior is random, in the sense of statistical independence (p. 538).

A set of items can be said to be unidimensional when it is possible to find a vector of values $\theta = (\theta_i)$ such that the probability of correctly answering an item k is $\pi_{ik} = f_k(\theta_i)$ and local independence holds for each value of θ. This definition is not equating unidimensionality with local independence, because it can further require that it is necessary to condition only on one θ dimension and that the probabilities p_{ik} can be expressed in terms on only one θ dimension.

McDonald (1981) outlined ways in which it is possible to weaken the strong principle of local independence. The strong principle implies that not only are the partial correlations of the test items zero when the latent traits are partialled out, but also the distinct items are then mutually statistically independent and their higher joint moments are products of their univariate moments. A weaker form is to ignore moments beyond the second order and test the dimensionality of test scores by assessing whether the residual covariances are zero (see also Lord and Novick 1968, pp. 225, 544–5). Under the assumption of multivariate normality, the weaker form of the principle implies the strong form, as well as conversely. McDonald (1979, 1981) argued that this weakening of the principle does not create any important change in anything that can be said about the latent traits, though strictly it weakens their definition.

1. *Stout's Evaluation of Essential Unidimensionality*

Stout (1987, 1990) also used this weaker form to develop his arguments for 'essential unidimensionality.' He devised a statistical index based on the fundamental principle that local independence should hold approximately when sampling from a subpopulation of examinees of approximately equal ability. He defined essential unidimensionality as: a test $(U_1,\ldots, U_N)$ of length N is said to be essentially unidimensional if there exists a latent variable θ such that for all values of θ,

$$\frac{1}{N(N-1)} \sum_{1 < i \neq j < N} |Cov(U_i, U_j|\theta)| \approx 0.$$

That is, on average, the conditional covariances over all item pairs must be small in magnitude (for more detail regarding the theoretical developments see Junker 1990, 1991, 1992, Nandakumar 1994, Nandakumar and Stout 1993, Stout 1990). Essential unidimensionality thus replaces local independence and is based on assessing only the dominant dimensions. Stout has developed an empirical notion of unidimensionality to match his weaker form (Stouts T-index). There are many applications of Stout's procedures (Nandakumar 1994, Nandakumar et al., 1998), and simulation studies that have supported the value of his statistic (Hattie et al. 1996). Zhang and Stout (1999a, 1999b) have generalized the Stout procedure via the DETECT method (Dimensionality evaluation to enumerate contributing traits). This method simultaneously assesses the latent dimensionality structure and determines the degrees of multidimensionality present in test data. This procedure has been extended by Kim et al. (Douglas et al. 1998, Stout et al. 1996) to identify that partition P of the available k items into disjoint and exhaustive subsets that best represents the underlying dimensionality structure. The best partition is detected by $\text{DETECT}_{\max}$, and thus is a measure of the amount of departure from unidimensionality. The methods have been generalized to polytomous items (Nandakumar et al. 1998).

Thus, there are many methods for assessing unidimensionality, such as nonlinear factor analysis (NOHARM), full information item factor analysis (TESTFACT), confirmatory factor analysis via struc-

tural equations programs such as LISREL, AMOS, and testing essential dimensionality with DIMTEST, and detection of simple structure multidimensionality (DETECT).

2. The Concept of Unidimensionality

It is critical to note that the assumption of unidimensionality underlying most measurement models does not necessarily imply that only these models can assess the most simple of tasks. The concept of unidimensionality can be considered at various levels of analysis. At the first-order level we can construe of a set of items being combined (by appropriate weighting) to form a total unidimensional score (such as a collection of addition items leading to a total addition score). At the second-order level we can also construe of a set of first-order scores being combined to form a total undimensional score (such as a collection of addition, subtraction, multiplication, and division totals being combined to form a total arithmetic score). In both cases we can conceive of a single underlying trait.

In a different context, we could imagine a single set of items all requiring a similar cognitive process (e.g., successive or simultaneous processing) and a total score being formed—and we could consider this a unidimensional total score—even if the items were across many content domains. All too often, the notion of unidimensional has been conceived in terms of a narrowly defined set of items. The key issue is that the methods outlined to assess unidimensionality do not lead to identifying what the total score represents—this requires other validity methods (such as judgmental analyses). Identifying a unidimensional set of items is not the same as naming it.

3. Constructing Multidimensional Data

One of the problematic issues when assessing dimensionality is that there are differing ways that the dimensions can relate to the construct of interest. Coombs (1954) defined three methods of constructing multidimensional data: the conjunctive model, whereby an excess of one ability, no matter how large, does not compensate for lower ability in other dimensions; the disjunctive model, whereby an examinee will pass an item if he/she is dominant over the item in any one dimension and will fail only if the item dominates him/her in all dimension; and the compensatory model, whereby an examinee's response to an item is a function of a weighted sum of underlying abilities. Other researchers (notably Ackerman 1987, 1992, Ansley and Forsyth 1985, Reckase et al. 1986, Wang 1987, 1988) have demonstrated that with compensatory multidimensional models the univariate calibration of two-dimensional response data can be explained in terms of the interaction between the multidimensional test information and the distribution of the two-dimensional abilities, and various interpretations of the multidimensional item difficulty, multidimensional discrimination, and multidimensional item information have been suggested.

Sympson (1978) proposed a partially compensatory model where a decrease in one ability could only be offset by a large increase in the other ability (this model has often been erroneously called a noncompensatory model). Outside of a relatively narrow ability range, the probability of passing reduces to zero regardless of the value of the stronger ability (see Lord 1984). The probability of a correct response is simply the product of probabilities for each dimension (but see Coughlan 1974, Jannarone 1986).

4. Concluding Comments

A major need is for a clear explication of the concept of dimensionality. Within the item response literature there has been much agreement about its meaning, although it has often been (falsely) assumed that only tests consisting of 'simple' attributes could lead to a unidimensional test. Certainly there are cognitive processing models, whereby it may be possible for a student to solve an item using differing cognitive strategies, thus adding another meaning to the notion of undimensional; the unidimensionality of processes or strategies. Much of the discussion about newer models of item and test analyses is oriented around such notions (Mislevy and Gitomer 1995).

It is critical to ensure that any set of items map the construct of interest, and if this construct is inherently multidimensional than so too should there be multiple unidimensional subtests. At this test score level, we may desire 'lumpy' items (such as reading comprehension, or mathematical problem solving), and thus the items may assess multiple dimensions while the total test still aims to assess a single 'over all' dimension. As Dorans and Lawrence (1999) have demonstrated, it is possible to conceive of situations where analysis at the test score level would reveal a single common factor, while analysis at the subscore level would uncover a few distinct subscore factors. Similarly, Reckase et al. (1988) have demonstrated that sets of items can meet the unidimensionality assumption even though they require more than one proficient for a correct response.

At present, the Stout procedures seem worth pursuing, as they are based on clear theoretical developments, are easy to use, dependably provide indications of the dimensionality, are reasonably robust, and provide a reasonably clear and practical demarcation between one and many dimensions. Further, there is need for further research on developing multidimensional models that allow for differing ways in which items or test scores can be combined, and we need

better diagnostics to understand the complexity of the dimensions involved in item and test scores. There are already many useful heuristics available to interpret multidimensional data using unidimensional calibration methods (Ackerman 1992, Carlson 1987, Junker 1991, 1992, Luecht and Miller 1991, McKinley and Reckase 1989, Reckase et al. 1986, 1988). It is certain that discussion will continue about the concept of unidimensionality, the best forms to assess whether items are essentially unidimensional, and the importance of diagnostics to aid in constructing better unidimensional assessments.

Diplomacy

Diplomacy is the art of obtaining agreement between countries who need one another's cooperation to create or maintain a situation in which each of them has an interest. The needed cooperation may involve refraining from certain kinds of behavior as well as changing the location or condition of people, goods, structures, military deployments, and other assets. The premise of diplomacy is that these behaviors would not occur automatically: they require the positive or negative stimuli of deliberate international (usually intergovernmental) interaction among those with the power to bring about the desired results. It is not diplomacy, for example, when the immigration officials of a country bar a group of refugees from coming into the country, nor when the supporters of the refugees voice their outrage; diplomacy transpires when officials of the affected countries interact with one another to clarify or modify the rules and procedures each of them will be applying to deal with the situation.

1. *The Essential Characteristics of Diplomacy*

Conventionally equated with negotiations to resolve international conflict, diplomacy is widely regarded as an alternative to war—and war as a failure of diplomacy. But diplomacy can also be the essential process in a nonadversarial interaction of friendly countries attempting to obtain the best allocation of costs and benefits in a commonly sought project. The term 'diplomatic' has been imported from the international into the domestic realm, where it is commonly applied to relations among groups or individuals in which polite interaction is artfully employed to avoid otherwise tense confrontations; however, the discussion here will be confined to the characteristics and role of diplomacy in the international realm.

Diplomacy, so defined, refers mainly to agreement-seeking behavior on the part of national governments. Diplomats are the officials who do the actual negotiation. But not all diplomats are engaged in negotiations; some merely represent their governments in foreign lands or international forums, conveying information about their home countries, and reporting back on conditions at their posts. Bargaining and informational diplomacy are practiced as well by international actors other than nation states—namely, the United Nations, the European Union, numerous specialized intergovernmental organizations, and, increasingly, various nongovernmental organizations, particularly those that are accorded quasi-official status in certain international forums.

Although the most important and characteristic aspect of diplomacy is face-to-face bargaining among officials of governments, such bargaining is also frequently conducted through unilateral pronouncements by officials of what they will or will not accept. Diplomacy's principal medium is verbal communication—spoken, written, often electronically transmitted—and therefore is itself basically nonviolent; but the words may threaten, or be delivered simultaneously with coercive action, even massive military attacks, to alter an adversary's assessment of the costs and benefits of accepting or rejecting particular arrangements. Diplomacy's attribute resides in its purpose—international agreement; as such it requires a modicum of nonviolent interaction, even when that interaction is coerced (as in the imposition of surrender terms at the end of a war by the victors on the vanquished). Diplomatic undertakings may fail, in that agreement is not obtained; but, succeed or fail, as long as the purpose of the international interaction is agreement, it is still diplomacy. Without any interaction, however—in particular, verbal interaction to at least explore possibilities for agreement—there can be no diplomacy.

2. *Diplomacy as a Reflection of World Politics*

The rules and rituals of international diplomacy have never been a self-contained system. The picture of the diplomat as an impeccably mannered aristocrat exchanging toasts, repartee, and subtle threats with his counterparts is a caricature derived from the Parisian scene in the court of Louis XIV. Rather, the protocols of diplomacy have always been a subsystem of the more comprehensive system of political relationships prevailing during a particular era among various sets of countries and international organizations. Thus, as world politics have evolved, so have the rituals, forms, and objectives of diplomacy, even though its most basic function—to forge agreements among international actors—has persisted.

2.1 *The Evolution of Diplomacy*

The evolution of diplomacy parallels and reflects the transformation of international relations from a system of maneuvering and secretive deal-making by

kings and their emissaries to the contemporary practice of conducting foreign policy as a continuation of domestic politics through public speech-making and media manipulation. While late twentieth-century diplomacy is unique in many respects, some of its prominent features are inherited from past international systems.

The most significant legacy from previous international systems are the norms that were codified in the Westphalian peace treaties ending the wars of religion in 1648 and which became the cardinal principles of statecraft—at least for Western Europe. No longer regarding their rivals as agents of the devil, the Protestant and Catholic monarchs, re-established the ancient imperial rituals of polite dialogue among governments, their high officials, and plenipotentiaries, even when threatening or engaging in war against one another. Most important, they pledged respect for state sovereignty and the principle of noninterference in one another's domestic affairs. This structurally anarchic yet mutually respectful society of states prevailing in Western Europe from the last half of the seventeenth century to the last quarter of the eighteenth century is often referred to by diplomatic historians as the 'classical' system. The so-called Classical Balance of Power denotes the presumably self-equilibrating characteristic of the system, featuring short-term and shifting alliances through which states, big and small, preserved their sovereignty through balancing one another's military power.

The classical power-balancing diplomacy could work as long as the games of maneuver and alliance making could be played by elites who did not have to answer to the people within their jurisdictions. But as the countries of Europe (and America) evolved into nation–states in which major governmental undertakings required broad cooperation from their commercial, industrial, and intellectual classes, often in the form of parliamentary approval, the conditions allowing for flexible and shifting alliance commitments began to erode. Following the American and French Revolutions, war—now to be fought by citizen armies and industrially produced arsenals, rather than lightly armed mercenary troops—could no longer be credibly threatened or sustained without the consent of the governed. And such support would not be forthcoming unless the nation as a whole could be convinced that the country's vital interests and way of life were at stake. Accordingly, as became evident in World War I, military hostilities once begun became more difficult to stop. War, previously regarded as an instrument of diplomacy, was becoming its antithesis, at least for the democracies. The democratic aversion to war's disruptions of normal life was one of the reasons why Hitler and the Japanese militarists were able to bully the world as much as they did before a balance of power could be mobilized against them. The development and use of nuclear weapons at the end of World War II reinforced these trends.

For many statespersons and citizens, the highest imperative of diplomacy has become to manage international conflicts *without* resorting to war. But for others, the threat or actual use of military force, even the new weapons of mass destruction, would continue to be an instrument of diplomacy. Moreover, the expanding and deepening interdependence of the world's peoples has, paradoxically, moved the issue of military intervention to the top of the world's diplomatic agendas.

2.2 *The New Diplomacy*

The new diplomacy, generated by the events and forces since World War II that have transformed the world polity—the Cold War, decolonization and self-determination movements, the human rights ideology, terrorism, economic globalization, and threats to the planet's ecologies—involves an expansion of the ends and means of foreign policy, and of the functions of international organizations. Political, economic, and environmental conditions in the majority of the world's countries have become the world's business. Accordingly, the new diplomacy features efforts by governments and nongovernmental actors to affect conditions *within* other countries, not only to adjust relations between countries.

Guardians of traditional statecraft are concerned that the norms and structures that have sustained the 'anarchical society' of mutually respectful sovereign countries are being undermined by the new interventionist diplomacy. They worry that the new diplomacy is lending support, whether purposefully or inadvertently, to the forces subverting the capacity of governments to protect their national polities and cultures, and is giving license to unaccountable actors to impose their will on others. The anarchical international *society* is in danger of degenerating into an uncontrolled anarchy in which only the most aggressive thrive. Yet, realistically, there is no going back to the traditional Westphalian system, for the technology-driven mobility of people, things, and information that has been eroding the sovereignty of the territorially-defined nation state is irreversible. At the most, defenders of the authority and power of nation states can attempt to slow the process through protectionist economic measures to control access into their markets and through restrictions on immigration. National governments will still retain their role, into the foreseeable future, as the main authorities for assuring that people remain accountable to larger community standards for how they treat one another, and how they manage the natural environment. But, increasingly, the national government will need to share this role with supranational and subnational authorities. And these political entities, as they assume more responsibility for determining who gets what, when, and how in world

society, will themselves need to engage in diplomatic interaction with the existing nation states and with each other.

3. The Requisites of Effective Diplomacy

Diplomacy in the world polity, like legislation in domestic polities, is directed toward getting parties to agree on a particular course of action (or inaction), so they will not have to be physically forced to accept it. But unlike the domestic legislative process, in which it is sufficient to obtain agreement among a controlling majority for the course of action to take place, in international diplomacy each participating state normally has the recognized unilateral right to accept or refuse what even a substantial majority of the states have agreed upon. (The major exception to this norm is the UN Security Council's authority, in situations threatening international peace and security, to order all states to obey its resolution.) Thus, diplomatic strategies must always be targeted specifically on each state whose adherence to an agreement is sought. Each state must be convinced that its own interests will be better served by agreeing to the arrangements under discussion than in refusing to agree.

Effective diplomacy, accordingly, requires the ability to induce agreement from states that may initially be opposed to a contemplated arrangement, but whose acquiescence is essential for its realization. Skillful diplomats are able to secure favorable terms for their countries by persuasively outlining the benefits and costs their counterparts can expect from alternative arrangements. This requires a detailed and accurate understanding of both the material conditions and the political circumstances (domestic and international) of the countries involved in a particular diplomatic encounter.

States with the material resources to affect their counterparts' preferences for alternative outcomes by credibly offering to provide valued objects ('carrots') or threatening to apply uncomfortable or painful sanctions ('sticks') have traditionally enjoyed an enormous advantage in the arenas of international diplomacy. But increasingly, states, international organizations, and political movements, deficient in the relevant material assets are able to redress such resource–power imbalances through artful appeal to, and manipulation of, the cultural and political values of the parties to a negotiation, other governments, and implicated transnational and subnational groups. Success in regional and global coalition-building (what used to be called 'balance of power' politics), now penetrating beyond the crust of state sovereignty, has become the most important requisite of effective diplomacy, especially the new diplomacy.

Disability, Demography of

There are two definitions of 'disability' that have wide acceptance in demographic studies. The first, developed by the World Health Organization, conceives of disability as a restriction or lack of ability to perform an activity normally, as a result of the impact of disease. The second definition, developed by Saad Nagi and adapted by the US Institute of Medicine, is similar, but emphasizes the relevance of disease impact to the ability to perform social roles. This latter definition allows for the possibility of intervention to minimize restriction of social roles, despite disease and consequent physical impairment (Verbrugge and Jette 1994). It has gained in popularity as a framework for thinking about the needs of the world's aging population. More recently, this framework has been applied to understand disability among children, persons entering the labor force, and working-age adults, with an emphasis on supportive services, such as home health and physical therapy, to improve or maintain physical functioning and other aspects of quality of life, and elimination of environmental barriers.

1. History of Disability Measurement

1.1 Work Limitation

Traditionally, demographers relied on census data on the number and characteristics of people, combined with information on death from vital statistical sys-

tems, to project the working age population. A table of working life added age-specific data on labor force participation (Wolfbein 1949). This system proved unworkable, as many persons of working age are limited in their labor force participation and others retire voluntarily. While these causes of being out of the labor force could be handled with multiple decrement life tables, the recognition that people in these situations often re-entered the work force reduced the value of this working life table approach (Schoen and Woodrow 1980).

Despite these practical problems, nations found it essential to be able to project the numbers of workers by age, sex, and educational levels, the numbers of these workers who will be employed under current and alternative projections of the demand for workers, the number of working-age persons who are disabled or limited in labor force participation, and the retired population who would draw on pension systems. This necessitated an individual level of analysis in which more direct data on factors in labor force participation (including health and disability) can be collected, and the use of methods for event history data to identify the demographic social variables involved.

To estimate the scope of disability within countries, scientists have devoted substantial effort to the development of valid measures. Health interview surveys in Europe and the USA collected data on disability in large populations as early as the late 1800s and the early 1900s. Disability was measured as the prevalence of days of sickness per 1,000 persons and the number of people who were sick and unable to work on the day of interview, thus introducing a measurement approach still in use in current large-scale surveys. In addition, measures of labor force participation were expanded to include persons who report they are not working because of disability.

1.2 Activities of Daily Living

In 1949, the Commission on Chronic Illness was established in recognition of the high prevalence of chronic illness in the USA. The Commission called for a classification of difficulty in the performance of activities of daily living in order to measure the disabling impact of chronic illnesses and conditions on people's lives. A number of scales of this type emerged in the 1950s. Among the most valid and replicable is the Index of Activities of Daily Living (ADLs), constructed on the basis of empirical observations of patients' recovery of ability to perform necessary daily tasks after hip fracture (Katz et al. 1963). Standard ADLs include bathing, dressing, toileting, transferring in and out of bed and chairs, eating, and getting around inside the house. Measures more indicative of cognitive than physical impairment, e.g., using the telephone and managing medications, are often included also. This scale and its many hybrids have been in use since it was developed, both to monitor the decline and recovery processes in individuals, and also to measure levels of disability in populations.

Given that ADL scales tap levels of disability most relevant to the very frail, Lawton and Brody (1969) devised the Instrumental Activities of Daily Living (IADL) Scale, designed to measure competence at a more complex level than the basic ADL scale. This scale includes activities more typically problematic for people with chronic conditions who live in the community, such as shopping, housework, and the ability to handle finances. Unlike ADLs, which are mainly applicable to people in long-term care institutions, IADLs are particularly useful in capturing variation in physical functioning among community-dwelling populations. Severity of disability at the population level is typically measured by counts of activity limitations, e.g., the proportion of the population with one or two ADL limitations versus three or more. While in general limitations in ADLs are indicative of a more severe disability than IADLs, empirical research has not identified a strict hierarchical order. Nevertheless, estimates of disability are often framed in terms of the proportion of the population with (any) ADL limitations, and separately, with (any) IADL limitations. More recently, it has become common to ask survey respondents who indicate difficulty in activity performance whether they need help, and whether needed help is received; thus generating estimates of unmet need for services.

In specialized studies of disability during the 1990s these scales have been supplemented by questions that tap a variety of physical impairments, including a series of questions developed by Saad Nagi to measure mobility and flexibility, e.g., ability to walk a quarter mile (Nagi 1979). Such studies generally include measures of sensory impairments as well, including the ability to see, hear, and communicate. The strategy to use measures of daily activity, ability to perform basic tasks, and participation in age and gender-appropriate roles and functional capacities is widely applicable over the life span, in developed nations, and among different socioeconomic and cultural groups. Such measures provide an indication of level of need for medical and supportive services and equipment within given populations. For persons not covered by old age medical insurance plans, information on access to and cost coverage for services for potentially disabling health conditions is essential. In the USA both cost restrictions and lack of access to appropriate services are factors sometimes preventing appropriate medical care and support services for both children and adults.

2. Considerations and Cautions in Disability Measurement

While still in widespread use, the applicability of measurement of limitation in major activities (i.e., work, housekeeping, and going to school) is limited

and interpretation is difficult. Limitation in ability to work is very much determined by what one does for a living, for example. Two people with similar health profiles may report limitation in major activity quite differently if one is a construction worker and the other a teacher. Furthermore, it is often difficult to define one's major activity, particularly for people of retirement age. Thus, while this measure may be helpful in estimating attrition from the work force due to disabling health conditions, it is not a precise measure of the prevalence or severity of disability in populations. Limitation in 'any' or 'other' activities presents even greater challenges to interpretation.

Use of measurement of limitations in ADLs/IADLs has far wider application as a measure of disability in populations, although such measures do have problems too. Differences in question wording, the specific activities included in measurement, and differences in study design can result in variation in estimates of ADL variation across surveys of community dwelling populations.

While ADLs such as bathing and dressing have universal meaning, IADLs such as shopping and cooking have a strong gender role component, which can result in substantial underestimates of disability for men. Thus, ADL measures are more 'pure' measures of physical function than IADLs, while assessment of IADL disability has a greater subjective component.

Other confounding influences in measurement of ability to perform daily living activities include the measurement of capability ('Can you ...') versus actual performance ('Do you ...'), ascertainment of difficulty ('Do you have difficulty with ...') versus dependency ('Do you receive help with ...'), inclusion versus exclusion of human help and/or special equipment in ascertaining difficulty ('Even with help and/or use of special equipment, do you have difficulty ...'), and use of proxy vs. self-reporting. The necessarily subjective nature of disability measurement presents challenges for researchers to achieve comparability across studies within countries. Nuances in languages present even greater challenges to assessing the scope of disability across nations.

3. *Demographic Methods for the Study of Disability*

The recognition that disability is a phenomenon best measured at the individual level has led to great advances in the demographic study of disability. Crucial to this new approach is the recognition of disability as a dynamic process characterized by entries and exits and competing risks. Thus studies of labor force participation among older workers have been designed to take into account potentially disabling medical conditions, type of job and work disability, shift to alternative jobs where the condition is not disabling, and the competing state of retirement, as well as movements into and out of these statuses. Both multidimensional life tables and methods for event history analysis have proved useful (Manton et al. 1992). The use of event history methods has proved to be of particular value because of their ability to incorporate demographic or socioeconomic covariates that affect these processes. The greatest advances have come in the study of the elderly, but these methodologies should prove powerful in the study of disability among children, the transition from adolescence to adulthood, and the situations of adults who have not reached old age. A shortcoming of this research approach as currently practiced is that it tends to focus exclusively on the individual instead of an individual within an environment that may present obstacles or provide assistance, though extension to include contextual variables is possible.

4. *Current Trends in Disability*

4.1 *Activity and Work Limitations*

Worldwide concerns about population aging and the likely increase in rates of disability associated with lengthening life expectancies have escalated research interest in the measurement of population disability trends. In the USA, a variety of cross-sectional and longitudinal national surveys are available to determine current disability rates as well as disability trends over the past several decades. Overall, annual estimates of disability (measured as activity and work limitations) available from the National Health Interview Survey since 1970 indicate that the proportion of the US population with disabilities has increased during that time period.

When disability rates are calculated by age group, it is clear that the elderly experience disability at approximately twice the rate of people between ages 45 and 64, and at four times the rate of the younger working age group (aged 18–44). Thus, the increase in the proportion of the population who are elderly contributes to the increase in rates of disability in the larger population, although actual rates of activity limitations among persons 65 and older remained relatively constant from the early 1980s to 1994, estimated at about 38 percent for men, and 39 percent for women (Kaye et al. 1996).

Activity limitation rates have also remained constant among the older working age group (ages 45–64) since the early 1980s, at about 22 percent for men, and 23 percent for women. Work disability is relatively constant in this population, with 11 percent unable to work and 7 percent limited in amount and/or kind of work. In contrast, disability has increased somewhat among people under 45 years of age, particularly in the early 1990s. From 1990 to 1994, activity limitations among younger men (aged 18–44) increased from 8.7

percent to 10.2 percent, and among younger women from 8.9 percent to 10.3 percent. During the same time period, the proportion of this subgroup that is unable to work increased from 2.9 percent to 3.7 percent.

Similarly, activity limitations among children have increased in the early 1990s, from 5.6 percent to 7.9 percent among boys, and from 4.2 percent to 5.6 percent among girls. These increases are reflected in an increase in the prevalence of asthma and cognitive disorders such as Attention Deficit Disorder and learning disabilities. Thus, increases in disability among younger adults and children, combined with an increase in the proportion of the population who is elderly, are largely responsible for the trend toward higher disability levels in the overall US population (Kaye et al. 1996).

4.2 ADL/IADL Disability Trends

There is a growing consensus that while rates of certain chronic diseases have increased in recent decades, both in the USA and in other countries, rates of disability in daily living activities have actually decreased within the elderly population. Early reports of this decrease were met with skepticism, with some researchers attributing apparent decline to an artifact of question wording or survey design. However, increasing consistency in findings across several longitudinal US surveys provide reliable evidence that disability, has decreased from the early 1980s until the early 1990s particularly in IADLs (Manton et al. 1998). Findings regarding improvement in ADL disability are less consistent.

Researchers have begun to focus their work on identifying factors that account for observed decline. Advances in medical technology and disease management as well as improved access to medical and support services and technical aids that may reduce difficulty in task performance have been credited with at least some of the reduction in measured disability levels. However, recent evidence suggests that education is the most important factor associated with disability decline in the US population, as a less educated cohort of elderly persons is being replaced by a cohort of people raised in more prosperous times. Attribution of disability decline to increases in educational levels suggests that observed decline may continue, albeit at a reduced rate (Freedman and Martin 1999).

The Global Burden of Disease Project has undertaken the massive task of estimating the incidence and prevalence of disability for world regions, for men and women across the lifespan (Murray and Lopez 1996). In this work the expectation of life at birth is divided into years of life without disability and with disability. In the established market economies males can expect a life at birth of 73.4 years, of which 8.1 percent will be spent in disability. Women's expectation of life at birth is 80.5 years, of which 8.3 percent will be spent in disability. While women spend more time than men in the disabled state because of their longer life span, that longer life span itself does not lead to an inevitable increase in the percentage of years in disability. Indeed, in those regions with an expectation of life at birth of less than 60 years, more person years are spent in disability than in nations with lower mortality, with 12 percent or higher of the lifespan lost due to disability. Similar observations apply to calculations for the population at age 60 as well. The best strategy for relieving disability over the lifespan is to begin promoting health among younger adults in order to reduce disability in later middle age and old age.

Disability, Geography of

The sociospatial causes and consequences of disability, that is, of being socially constructed as negatively different on the basis of mental or physical bodily impairment, has become a significant focus of geographic inquiry. The assumption that only able-bodied women and men occupy and negotiate social space has impoverished our understanding of society and space. Differences in mental and physical abilities affect patterns and degrees of access to urban public spaces, services, and employment opportunities, and help to determine who is most affected by urban and regional changes such as rising poverty and loss of affordable housing. Differences in bodily ability find expression in the geography of cities and regions: in the spatial concentration of disabled persons in poor inner city neighborhoods with a concentration of social services, for instance.

Critical geographers view disablement as a sociospatial process that marks mentally and/or physically impaired bodies as negatively 'other' and works to marginalize disabled persons within social space. Geographies of disability are, thus, as much about ableism as a regime of power based on able-bodied privilege and the sociospatial practices that sustain it, as about disabled persons' experiences of trying to negotiate environments that physically and/or socially exclude and oppress them.

1. *Why a Critical Geography of Disability?*

The recent shift toward critical geographies of disability is a response to changing conditions within society, and new perspectives on the differences disabilities make in how people are situated in society and space (e.g., in terms of access to basic necessities and acceptance in urban spaces). An increasingly vocal disability rights movement, particularly in the West, but also internationally, aging populations with higher incidence of disability, cutbacks in social programs for the disabled, and problems such as grinding poverty and inaccessible cities, have helped to encourage such research. New perspectives on disability issues have also been influential. The growth of disability studies has challenged conventional biomedical models of disability with 'social constructionist' ones, and offered significant insights into what it is like to be disabled in various spaces of everyday life (e.g., Oliver 1990, Morris 1991). These society-centered perspectives view disability as the outcome of social processes such as the economic devaluation of the disabled through lack of employment and low wages, and cultural representations of disabled people as inferior. Disability is thus a social rather than individual condition. This does not necessarily mean that disablement is entirely socially produced. Bodily impairments affect experiences of disablement. Visual impairment may result in difficulty moving within spaces such as sports arenas and negative reactions to such visible differences may help to make disabled persons feel 'out of place.' Similarly, chronic pain sufferers often find it difficult to negotiate spaces of daily life and interact with others. Scholars continue to debate how best to incorporate such bodily realities within conceptualizations of social processes of disablement.

Changes in the discipline have also encouraged critical geographies of disability. These include: greater use of critical social theory, feminist geographic studies of social differences (e.g., gender and sexuality) and marginalization in urban space, recognition of multiple bases of oppression in society and space, and desires to use geographic knowledge to help empower disadvantaged groups. Critical geographers studying disability have promoted related changes in the discipline: such as making conferences more accessible and promoting research through an international network of scholars (i.e., Disability and Geography International). They have challenged the invisibility of disabled women and men in the geographic literature; emphasizing disablement as a sociospatial form of oppression, exclusionary practices within spaces of academia, and the need to put gendered experiences of disability on Geography's research map (e.g., Chouinard and Grant 1995).

What do critical geographies of disability offer? They offer the possibility of geographic research that empowers persons with disabilities (building on the legacy of radical geography). They promise more balanced accounts of the sociospatial production of disability as a place-specific condition of life, not a natural outcome of bodily impairment. They can help us understand how ableist social relations and practices are sustained over space and time, and how more enabling environments might be created. They can shed light on why resistance to ableism varies among places: of the significance, for example, of national differences in human rights law for disability activism. By providing critical causal explanations of the sociospatial production of disabling environments and of resistance to disablement, these geographies can help us create more enabling societies and spaces.

2. *Research Topics and Directions*

Some studies focus on how disability transforms experiences of personal space and individuals' capacities to negotiate private and public spaces. Others examine the sociospatial production of disabling environments through analyses of the recursive relationship between regulatory institutions (e.g., the state and health care system) and disabled persons' access to and experiences of urban space. Other studies investigate exclusionary attitudes and practices that help to isolate, stigmatize, and segregate disabled persons from others through, for instance, neighborhood opposition to group homes. Underlying much of

this research is a concern with how and why inequalities in power give rise to social spaces that disadvantage and exclude disabled persons. This critical stance toward past and present social orders distinguishes contemporary geographies of disability.

Most studies to date emphasize how ableism shapes disabled persons' lives and life spaces. Butler (1999) examines how the importance of visual cues in lesbian women's negotiations of different life spaces disadvantages visually impaired lesbian women. Valentine (1999) discusses how masculine identity may be threatened by acquired physical impairment. Studies of the links between divisions of power within particular social orders, and sociospatial forms of disablement are relatively rare. Gleeson (1999), however, attempts to show how changing class relations and divisions of labor in the transition from feudal to industrial capitalist societies excerbated the sociospatial marginalization of physically impaired people. In a different vein, Chouinard (1999) suggests that phenomena such as sociospatial barriers to effective political action by disabled women can be understood as outcomes of a patriarchal corporeal class system that systematically devalues disabled persons in general and disabled women in particular, marginalizes and exploits bodies (especially women's) which differ from Western racialized norms, and helps to sustain intolerance toward bodily diversity and regional disparities in resources and well-being.

Contemporary geographies of disability vary in analytic approach and geographic scale. Studies of disablement within personal life spaces emphasize the 'micro' scale of everyday life. They tend to be descriptive and use personal narratives to illustrate changing geographies of daily life. Golledge's work on vision-impaired populations, wayfinding and navigational systems for the vision-impaired (1993) adopts a behavioral conceptualization of disability as an individual condition which can be compensated for through assistive devices and environmental design. Recently, Gollege's work has taken a more critical turn; reflecting on the barriers, such as print, which he and other vision-impaired professors face in academic environments (Golledge 1997).

The differences disability makes in women's abilities to negotiate individual life spaces has been the focus of Dyck's (1995) research on women, chronic illness, and healthcare. Dyck has shown how chronic illnesses such as multiple sclerosis translate into shrinking lifeworlds and sociospatial isolation. Her work examines how professional services, practices, and evaluation procedures, particularly in healthcare, affect chronically ill women's capacities to negotiate spaces of daily life. Her recent research investigates how racial and cultural differences affect women's access to medical knowledge and care, and capacities to negotiate spaces outside the home (Dyck 1997a, 1997b).

Feminist theories of the body have helped to inspire geographic research on cultural codings, readings of and responses to disabled bodies in various life spaces. Butler and Bowlby (1997) examine the disciplining of visually impaired bodies in public spaces through practices such as misinterpreting awkward bodily movements as inappropriate behavior in public space (e.g., intoxication). Complementing geographic studies of experiences of disability are studies of how discriminatory practices within the state and design professions, for instance, perpetuate disabling environments. Some also consider disabled persons' resistance to such practices. An early example is Dear's (1981) analysis of the role of bureaucratic power and practices in the sociospatial segregation of the mentally ill within urban areas. Wolch and Dear's (1993) work on homelessness in the United States and Canada shows how policies of deinstitutionalization, community care, and urban renewal resulted in growing problems of homelessness, the ghettoization of social services and service-dependent populations in central cities, and the loss of affordable housing to gentrification and redevelopment. They examine local geographies of homelessness; for example, the fragile support networks that homeless women establish along daily life paths. Imrie (1996) has examined how urban planning and design practices in Britain and the US have contributed to inaccessible urban built-environments. He argues that architects and planners largely have failed to address the access needs of disabled persons and that attempts to legislate more accessible urban and building designs have had limited success. Historical geographic studies of the development of asylums for the mentally ill and challenged (Philo 1989, Parr and Philo 1996), and contemporary studies of psychiatric survivors' struggles to challenge mental health services that are organizationally and spatially fragmented and unresponsive to needs (Parr 1997), have advanced our understanding of changing geographies of care, discipline, disablement, and resistance in institutional and community settings. Interest in disablement in academic environments is increasing, but has yet to receive systematic attention.

Cultural aspects of sociospatial exclusion are addressed in studies of community attitudes toward persons with disabilities and related geographic phenomena such as NIMBY (Not in My Backyard syndrome). Dear et al. (1997) examine how hierarchically structured attitudes of acceptance and rejection influence levels of community opposition to the siting of group homes in US urban neighborhoods. They find that attitudes toward disabled persons labeled as mentally ill, homeless, or AIDS sufferers are especially negative, and result in stronger desires for spatial separation from and greater community opposition to group homes for these persons.

Exciting directions are emerging in recent critical geographies of disability. Cultural codings of public space as able-bodied and ways of contesting such inscriptions is one emerging theme. Kitchin (1999)

examines British disability activists' use of confrontational tactics, such as chaining themselves to inaccessible public transit vehicles, to draw attention to the denial of disabled citizens' rights to mobility within cities. Stanley (1999) is investigating how the use of sports wheelchairs challenges negative cultural images of disability by associating users with athletic identities and activity spaces. Dorn's (1997) historical geographic study of a nineteenth-century medical practitioner examines medical professionals' roles in defining disability (including the moral causes of conditions such as alcoholism) and shaping healthcare practices in the Western US. Stables and Smith's (1997) study of media portrayals of and public attitudes toward disabled parents who rely on their children for care raises issues of cultural representations of disability within the home. They find that, in Britain, people demonize disabled parents who have child care-givers; regarding this arrangement as exploitative and even unnatural. Their work raises interesting questions about how outsiders and the media read departures from normal (i.e., able-bodied) parental and child care-giving relations in the home. In light of drastic changes in social programs for disabled persons, it is surprising that the impacts of state restructuring on disabled women and men has not received greater attention in the critical geographic literature. Few studies consider the interactive effects of multiple social policy changes on disabled persons' lives and life spaces. Systematic studies are needed which will explain related changes in disabled peoples' status as citizens and dependents of the state, and their capacities to struggle for enabling environments from local to global scale. Disabled peoples' access to recreation spaces is another topic in need of critical geographic research. Methodological and ethical issues in studies of disability and space are another emerging theme Researchers are exploring questions such as how the disabled might be empowered through geographic research, how efforts to make research inclusionary are complicated by the places in which research is conducted (Dyck 1997b), and whether ethical aims such as full disclosure of study objectives should be compromised in situations where this furthers the political objectives of the disabled (Wilton 2000).

3. *Future Challenges and Directions*

Where should geographies of disability go from here? One important challenge is explaining how the uneven development and dynamics of global patriarchal capitalism perpetuates social and spatial exclusion of the disabled. Systematic studies of how sociospatial restructuring of state institutions and programs is shaping the geographic boundaries and conditions of disabled peoples' lives in different places, and how different ways of organizing workplaces and labor processes (e.g., differences in accommodating special needs) affect disabled persons' access to paid employment, would help to address such challenges. Geographic variations in the design, production, availability, and consumption of disability aids, and their impacts on disabled peoples' abilities to negotiate life spaces is another topic for future research. Studies of the sociospatial production of disabling conditions; examining, for instance, how unsafe, stressful conditions of work and the hyperexploitation of female labor in places such as export zones influence the incidence and severity of different disabilities, would also help to address this challenge.

Another challenge is understanding the differences that cultural practices and images make in disabled persons' lives. Do negative images of disabled parents restrict their own or child care-givers' access to spaces outside the home? How do conditions of life in particular places influence ideas about where disabled people do and don't belong? Are urban neighborhoods with a history of disability activism less likely to view the disabled as nonproductive and hence out of place in local labor markets? Future studies could explore geographic variations in the political culture of disability struggles. Why do activists in some places adopt radical, confrontational strategies demanding collective rights, while others favor actions such as sponsoring stage appearances by famous disabled 'heroes'; events which reinforce cultural notions that only exceptional disabled persons succeed?

Theoretical challenges include developing dynamic, deeply geographic conceptions of the regulation of bodily differences in space; conceptions which allow for multiple, diverse bases and processes of oppression as disabled women and men move through space and time. How do shifting bases of exclusion, for instance, sexist discrimination within the disability movement and ableism, homophobia, and class differences within the women's movement, constrain disabled women's abilities to promote collective action on issues such as reproductive rights? How important are such processes of exclusion in the lives of disabled women in the Third World; where inabilities to walk to distant paid employment, to farm, or to care for family members often translates into dependency and isolation within the home? We have only just begun to tap the feminist theories of bodily oppression that can help us to understand such geographic processes of disablement.

Methodological challenges include gathering data on neglected aspects of disability such as spatial variations in employment and accommodation practices in workplaces, and developing accessible research formats. Ethical and political challenges include ensuring that research empowers disabled persons.

Perhaps the key challenge is promoting restless geographic imaginations about disabling environments. Such imaginations will be open to surprise about patterns and processes of disablement over space and time, and willing to learn from disabled peoples' knowledges. With creativity and commit-

ment, future geographies of disability can help to create environments that enable all members of society.

Disability: Psychological and Social Aspects

Disability can be conceptualized as activity limitations resulting from pathological and biomedical factors such as inflammation of the joint, brain lesion, age, or sensory impairment. However, there is evidence that psychological and social factors can predict and possibly influence disability unexplained by underlying pathophysiology. In addition to the definition, prevalence, and measurement of disability, this article examines explanatory models, psychological and social predictors and consequences of disability, as well as the possibility of reducing disability and its effects through psychological interventions.

1. The Term 'Disability'

Disability is defined by the World Health Organization (WHO) in their International Classification of Impairment, Disability and Handicap (ICIDH) model as 'any restriction or lack of ability to perform an activity in the manner or within the range considered normal for a human being' (WHO 1980). The ICIDH model proposes that disability is the result of impairment and that disability may result in handicap. Impairment is 'any loss, abnormality or failure of psychological, physiological, or anatomical structure or function' and is the direct result of an underlying disease or disorder. Handicap is 'a disadvantage resulting from impairment or disability, that limits or prevents the fulfillment of a role that is normal for that individual' (WHO 1980, pp. 27–9). So, for example, an individual who experienced a stroke (disorder) might have

restricted leg functioning (impairment), resulting in limitations in mobility (disability), and therefore be unable to continue to work (handicap).

However, *disability* is a widely used term both in everyday speech and by individuals in academic and applied disciplines, in addition to medicine, including psychology, sociology, physiotherapy, occupational therapy, health economics, and health services research. The common use of the construct suggests that there are varying underlying representations of the content and cause of disability (Johnston 1997). The term 'disability' has been used to refer to the WHO concepts of either impairment or handicap or a combination of disability and handicap. In some countries, the term disability may simply refer to the conditions that attract welfare support so that an assessment of 100 percent disability would mean that someone is entitled to the maximum benefit rather than being totally disabled.

2. *Prevalence of Disability*

Estimates of the prevalence of disability vary according to the definition or types of disability as well as the threshold of severity that is chosen for inclusion in a study. In the UK, the Office of Population Censuses and Surveys (OPCS) 1988 survey of disability found that 14 percent of adults living in private households have at least one disability ranging from slight to very severe (Martin et al. 1988). Disabling diseases vary in their effects on life expectancy and this also has implications for considering incidence and prevalence data. The most common disabilities in the 1988 survey were locomotion followed by hearing and personal care (for example, dressing or toileting). The most commonly cited causes of disability were musculoskeletal complaints (e.g., arthritis), ear complaints, eye complaints, diseases of the circulatory system, and nervous system complaints (e.g., stroke). Disabilities may arise from genetic disorders, from birth injuries, as a result of accidents, as well as due to disease. Martin et al. (1988) found the overall rate of disability rose with age, with almost 70 percent of disabled adults aged over 60. Of the most severely disabled adults, 64 percent were aged 70 or over. There were more disabled women then men. Even allowing for differing numbers of men and women in the population, the rate of disability among those aged 75 or over was still higher for women than for men, indicating that elderly women were more likely to be disabled than elderly men. Martin et al. (1988) found no evidence of ethnic differences in prevalence of disability.

3. *How Disability is Measured*

A disability rating serves as a key indicator of care requirements, ability to remain independent in the community, and the nature and extent of participation in society. Disability is typically measured based on self-report or observers' ratings of behavior, frequently the level of performance of basic and instrumental activities of daily living (ADL), such as eating, toileting, dressing, bathing, walking, doing housework, and shopping. However, the selection of items, the method of assessing performance, and the scaling of items to give an overall score, show immense diversity. Most measures involve self-report of either what one 'can do' or of what one has actually done. Some assessments require observing an activity to rate the 'normality' of performance. Others concentrate on whether the activity was achieved, rather than the manner of its accomplishment. Measures that elicit performance of movements assume that the disability is a constant, inherent aspect of the individual that can reliably be produced on demand. By contrast, measures of achievement of ADL use reports or performance under ordinary rather than assessment conditions. Recently, mobility limitations have been directly assessed using ambulatory monitoring techniques.

There have been considerable problems in identifying appropriate items and methods of scoring and scaling and variability in the rigor of measures used. Most measures use additive scaling, indicating a concept of equivalence of activities. In these measures, failure on feeding, self-care, or mobility would contribute in a similar manner to the overall score. Other measures use weighted additive scores, where failure on some items counts for more than failure on other items. For example, in the Sickness Impact Profile (Bergner et al. 1981), difficulties in walking a long distance count for less than difficulties in walking a short distance. In developing the OPCS scales, Martin et al. (1988) used a Thurstone scaling approach to create a set of scales for each area of disability, such as locomotion, dexterity, and personal care. For each scale, the value of each item was determined by judges' ratings. The method of combining disabilities was also empirically derived to reflect the judgment of expert raters. It is heavily weighted by the individual's most severe disabilities. This contrasts with averaging or additive measures which carry the implication that many mild disabilities, such as walking more slowly, being unable to walk half a mile, and being unable to climb stairs, may be equivalent to one severe disability; for example, being unable to walk at all. This diversity in the measurement of disability reflects the wide variation in views about the nature of disability.

4. *Explanatory Models*

The three main explanatory models of the nature of disability are the medical model, the social model, and the psychological model. The ICIDH model is a *medical model* since it conceptualizes disability within a predominantly pathological framework, explaining disability as a consequence of an underlying disease or

Health condition

Any alteration or attribute of health status which may lead to distress, interference with daily activities, or contact with health services, e.g., disease (acute or chronic), disorder, injury, trauma, pregnancy, aging, stress, congenital anomaly, or genetic predisposition.

Impairment

Loss/abnormality of body structure or of physiological or psychological function.

Activity

Nature and extent of functioning at the level of the person. Activity limitation (formerly disability) is the limitation in the performance of the activity that derives totally from the person. Limitations can be in duration and quality.

Participation

Nature and extent of a person's involvement in life situations in relationship to impairment, activities, health conditions, and contextual factors.

Contextual factors

This is the complete background to the person's life and living. *Environmental factors* are composed of components of the natural environment (weather or terrain), the human-made environment (tools, furnishing, the built environment, social attitudes, customs, rules, institutions, and other individuals). *Personal factors* are composed of features of the person that are not parts of a health condition or disablement, including age, race, gender, education, personality, character style, experiences, aptitudes, other health conditions, fitness, lifestyle, habits, upbringing, social background, profession, and past and current experiences.

Figure 1
International Classification of Impairments, Disabilities and Handicaps (ICIDH-2; WHO 1998)

disorder. However, a *social model* of disability conceptualizes disability in terms of limitations placed on the individual due to constraints in the social and physical environment and proposes that functional limitations are determined as much socially as biologically, for example, by the presence, attitudes, and actions of others (e.g., Oliver 1993). *Psychological models* conceptualize disability as a behavioral construct (e.g., Johnston 1996). These models suggest that disability is determined by psychological factors that influence behavior, for example, the individual's beliefs, emotions, skills, and habits.

Medical, social, and psychological models are not necessarily in conflict. Although some level of disability experienced by an individual may be related to their degree of impairment, there is considerable evidence that much of the variance in disability experienced by an individual remains unexplained by underlying pathology or impairment (Johnston and Pollard 2001). For example, McFarlane and Brooks (1988) found that in people with rheumatoid arthritis, psychological factors predicted more variance in ADL three years later than impairment and disease severity measures. Cognitive and emotional manipulations have also influenced the level of disability experienced by individuals under conditions where impairment was not affected. Additionally, the major task of rehabilitation therapists is to enable patients to overcome disabilities, often without resolution of underlying impairments. Moreover, many social factors are likely to operate via psychological mechanisms to alter the relationship between the components of the ICIDH model; for example, an environment with barriers to mobility or an overprotective social environment may reduce the individual's confidence with the result that their activities become even more limited. An explanatory model of disability which combines medical, psychological, and social factors would appear to be needed.

Indeed, the ICIDH model was recently modified to allow for the possibility that disability may be influenced by factors other than structure and function (WHO 1998). The revisions added complexity by proposing reverse causality, so that impairment may both result in, and result from, limitations in activity which may in turn determine, or be determined by, lack of social participation. It also introduced the possibility that contextual factors, both environmental and personal, can explain the level of disability experienced by an individual. In addition, the use of the terms 'disability' and 'handicap' were dropped in order to 'avoid deprecation, stigmatization and undue connotations' (WHO 1998, p. 19). Disability and handicap were redefined and renamed activity and participation. Activity is defined as the nature and extent of functioning at the level of the person and disability as the activity limitations of the individual person, whereas participation is defined in relation to the social context as the 'nature and extent of a person's involvement in life situations in relationship to impairment, activities, health conditions, and contextual factors.' This amended model of the consequences of disease is depicted in Fig. 1.

While consistent with previous research which has shown a meager relationship between impairment and disability, and that changes in disability have occurred without concurrent changes in impairment, the ICIDH (WHO 1998) model is nevertheless vague about exactly which psychological and social factors contribute to explaining, and thereby predicting, disability.

5. *What Predicts Disability?*

Many studies, including investigations where the effects of impairment have been controlled statistically, and randomized controlled trials where impairment was equally distributed in the control and intervention groups, have shown disability to be predicted and influenced by emotional, cognitive, behavioral, and social factors.

5.1 *Emotional Factors*

How people feel may influence their level of disability. Patients' emotional state is determined partly by their disposition and partly by situational factors such as the threats associated with their condition and treatment. Psychologists have often noted the association between disability and low mood or emotional disorder, and this is usually interpreted as emotional consequences of disability. However, most studies which examine the influence of emotional factors on disability are cross-sectional and observational in design, and it is therefore difficult to disentangle cause and effect. It seems likely that complex feedback loops occur. For example, while disability results in depression, depressed individuals are likely to be more disabled given comparable levels of impairment. Since emotional states are accompanied by physiological changes in the neuroendocrine, immune, and cardiovascular systems, it is also possible that negative emotions may influence disability by exacerbating impairments.

Nevertheless, there is evidence from longitudinal, prospective studies that emotional states, such as anxiety or depression, may influence the level of disability itself. For example, in a longitudinal study of middle-aged and older community residents, Meeks et al. (2000) found that depression predicted functional disability more strongly than disability predicted depression. In addition, changing emotions can have an immediate effect on disability levels. Fisher and Johnston (see Johnston 1997) used mood induction techniques to either increase or decrease anxiety (by asking about good or upsetting events) in two ran-

domly allocated groups of patients with chronic pain. Patients' disability was assessed by a lifting task before and after the experimental procedure, and results demonstrated that mood enhancement was associated with reduced levels of disability, while mood depression resulted in greater disability. It appears that emotional state can influence the level of disability independently of impairment.

5.2 *Cognitive Factors: Attitudes and Beliefs*

What people think or believe may influence their level of disability, particularly their beliefs about how much control they have over behaviors assessed as disability. Control cognitions are part of many theoretical frameworks constructed to predict and explain behavior. Two control cognitions, perceived personal control and self-efficacy, have been particularly associated with disability (see *Control Beliefs: Health Perspectives*).

Perceived personal control or internal locus of control refers to the degree to which persons expect that an outcome is contingent upon their own behavior. It can be contrasted with beliefs in external control, i.e., the degree to which persons expect that the outcome is not under their control, but under the control of powerful others, or is unpredictable. The evidence suggests that patients with high perceived personal control beliefs have better outcomes. For example, patients suffering from a stroke or wrist fracture were found to have greater recovery of function if they had higher beliefs in personal control over their recovery, even allowing for initial levels of disability—a finding which has been replicated in a larger sample of stroke patients six months after discharge from hospital (see Johnston et al. 1999). Härkäpää et al. (1996) found that patients in a back pain program showed greater improvement in functional activity if they had weaker beliefs in control by powerful others. In an experimental study, Fisher and Johnston (1996) manipulated the control cognitions of chronic pain patients by asking them to recall occasions when they had achieved or failed to retain control. They found that increasing perceived control resulted in reduced disability, assessed by the observed performance on a lifting task before and after the manipulation, while decreasing perceived control resulted in increased disability. Given that these were immediate effects, it is clear that the results were not due to changes in impairment, suggesting that control cognitions may play a causal role in activity limitations.

Self-efficacy relates to individuals' confidence in their ability to perform critical behaviors (see *Self-efficacy and Health*). Bandura (1997) proposes that there are four sources of information which are used as a basis for self-efficacy judgments: performance attainments, vicarious experience, verbal persuasion, and physiological state. It has been shown that successful performance leads to increased self-efficacy, whereas repeated failures result in lower self-efficacy. People with high self-efficacy beliefs are more likely to perform the behavior. Kaplan et al. (1984) examined exercise maintenance and found that changes in self-efficacy were associated with changes in walking activity in patients with chronic obstructive pulmonary disease. Changes in self-efficacy have also been associated with changes in disability among participants in arthritis self-management courses (Lorig et al. 1989), in low back pain patients, in patients with fibromyalgia, and in coronary bypass patients (see *Coronary Heart Disease (CHD), Coping with*).

5.3 *Coping Behavior*

What people do in order to cope with the stress imposed by their condition and the practical problems which arise from physical disability may affect their level of disability. For example, adherence to medication, diet, and rehabilitation regimens all may impact on disability. Coping refers to the procedures adopted to minimize stress and may or may not constitute effective management. Coping responses can be problem-focused or emotion-focused. Problem-focused coping includes attempts to modify or eliminate the sources of stress through one's own behavior, i.e., solving the problem. Emotion-focused coping includes attempts to manage the emotional consequences of stressors and to maintain emotional equilibrium. A coping model that has frequently been applied in studies of patients with chronic disease is Leventhal's Self-Regulation Model (see Brownlee et al. 2000). According to this model, the individual develops mental representations of their impairments which in turn determines what they do to cope (see *Stressful Medical Procedures*, *Coping with*). Dominant mental representations which determine coping behavior are: (a) identity of the condition: what they think it is; (b) timeline: the pattern over time (e.g., acute, chronic, or cyclical/remitting); (c) cause: what caused their condition (e.g., if it was due to their own behavior or character); (d) control/cure: if they perceive their condition can be controlled by their own or health professionals' actions; and (e) consequences: what they believe they have experienced as a result of their condition and what they expect the outcome to be. These mental representations are proposed to influence coping with both the objective condition and the emotional reaction to the condition.

However, while some predictive studies have found coping associated with activity limitations (e.g., Evers et al. 1998), other studies have not. For example, Revenson and Felton (1989) found that coping did not predict change in disability in a six-month prospective study of patients with rheumatoid arthritis. Similarly, others have found that coping did not predict and

therefore did not influence disability in people with chronic fatigue. It is possible that these findings are specific to these clinical conditions, where there is no clear action an individual can take to affect outcomes. Nevertheless, it is also possible that coping strategies are the result rather than the cause of disability.

5.4 Social Factors

Disability may be influenced by social factors such as stigmatizing reactions from others, overprotection by immediate family members, or carers' social reinforcement of activity limitations. Evidence of social influences comes from comparisons of disability assessments by different health professionals. For example, nurses rated patients as more disabled than rehabilitation therapists over a 24-hour period (Johnston 1996). While differences in ratings are obviously not due to changes in impairment, they may be due to the different social demands on the patients in the two care contexts: nurses assist patients in achieving tasks, while rehabilitation therapists enable patients to perform the tasks themselves.

Disability may also be influenced by the level and type of formal or informal support available (see *Social Support and Recovery from Disease and Medical Procedures*). While most informal support is provided by spouses—primarily for household assistance (Melzer et al. 1999), a social support network includes all members of the individual's household, family and friends living nearby, as well as more distant contacts. In patients with rheumatoid arthritis, a small network soon after diagnosis predicted a greater decrease in mobility over the following year (Evers et al. 1998). The support can be *practical*, e.g., tangible help and assistance with information, or *emotional*, e.g., that makes the individual feel esteemed and valued. Both have been related to health outcomes and behavior. For example, Weinberger et al. (1986) found that biweekly telephone calls to people with osteoarthritis led to improved functional status six months later and attributed the gains to the effects of enhanced emotional social support.

6. Consequences of Disability

Disability has a wide range of social and emotional consequences. For example, disability can impact on the person's social functioning. Newsom and Schulz (1996) report that older people with impairments have fewer family and friendship contacts and less perceived belonging and perceived tangible aid. Johnston and Pollard (2001) found that disability predicted social participation (handicap) in stroke patients, with greater disability associated with lower social participation.

Disability also has consequences for emotional functioning (e.g., Meeks et al. 2000). Perhaps the most frequently used models in psychological studies of disability explore the impact of disability on emotional functioning. These models include: (a) mental health models where rates of disorder are assessed; (b) life-event models where the emotional response to the life event precipitating in the impairment/disability is examined; and (c) stress models where the disability is seen as a stressor which elicits the strain evident as high levels of distress.

The nature of the underlying pathology, for example, whether a disease has static, fluctuating, or deteriorating patterns, is likely to temper the consequences of disability. Age at onset is also likely to be crucial, with earlier onset affecting education, family, housing, work, and leisure.

There is also evidence that disability has consequences for the people supporting the disabled person, impacting on their social and emotional functioning, as well as their health (see the review by Shulz and Quittner 1998). The effect of disability on caregivers may have further implications for the health outcomes of patients. For example, Elliott et al. (1999) found that the risk of disability and secondary complications increases for care recipients when carers have difficulty in adjusting to their new role demands.

The impact of disability is found to relate more closely to cognitive appraisals of functional limitations and coping resources than to objective indices of impairment and disability. For example, Schulz et al. (1994) proposed a model of the impact of impairment and disability, suggesting that negative affect is primarily due to the perceived loss of control rather then directly from impairment and disability.

7. Interventions

Interventions can be directed at reducing the disability or the impact of disability or both. Interventions directed at reducing the impact are similar to other cognitive behavioral programs that aim to reduce emotional and social consequences of life-events and difficulties: they concentrate on cognitive reframing and stress-management skills. Given the evidence that the individual's perception of limitations, social support, and control appear to be predictors of emotional and quality-of-life outcomes, there is clearly potential to improve these outcomes without reducing impairment.

Interventions directed at reducing disability *per se* are more akin to other programs that aim to achieve behavioral change. These include stress management techniques or elements designed to enhance self-efficacy in order to increase motivation and to develop skills and habits required to achieve the performance of activities. Kaplan et al. (1984) showed improvements in disability for patients with chronic obstructive pulmonary disease following cognitive and behavioral exercise programs. Lorig and col-

leagues have shown similar benefits from arthritis self-management programs designed to enhance self-efficacy (Lorig et al. 1989). Behavioral programs in which social attention is contingent on successful performance rather than on limitations have also been shown to decrease disability, especially in chronic pain patients.

Disability: Sociological Aspects

Disability has captured the public's attention globally, stimulated sociological inquiry, and emerged as an urgent priority for policy makers. This is due to the increased prevalence of functional limitations in society as a result of an aging population, impairments caused by war and landmines, technological innovations that prolong the lives of persons with disabling chronic illnesses, unhealthy lifestyles, and broadened definitions of disability.

The social and economic costs of disability continue to rise as exemplified in contentious national debates in most industrialized countries over the solvency and future of social welfare systems. The uneven dis-

tribution of the global burden of disability within and between countries is recognized by the World Bank and the World Health Organization as a major threat to development in the Third World and a cause of inequality in developed countries (Murray and Lopez 1996). The Institute of Medicine (1997) has emphasized that control of disability-generating infectious and chronic diseases is of vital concern to economic stability, social justice, and world peace. The salience of the problem is highlighted by the growing visibility of disabled persons in public spaces as a result of legislation such as the Americans With Disabilities Act of 1990 (ADA) and intense media coverage of wars, landmine accidents, unhealthy working conditions, and natural disasters in countries around the world. Increasingly accessible environments, personal experience with family members, co-workers, and friends who experience the impact of disability on their lives and the public activism of the disability community also contribute to a public awareness of disability.

1. *Definitions, Concepts, and Meanings of Disability*

Disability is defined by a person's difficulty in performing a task or activity due to an underlying physical or mental dysfunction. However, the specific features of a particular disability are varied, and the ways of identifying and evaluating them are diverse as well. While the disability concept has gained general acceptance by researchers, policy makers, and the public, specific applications and interpretations of the concept vary considerably depending on ideology, cultural context, and intended use (Albrecht and Verbrugge 1999).

Early definitions of disability focused on abnormality, deviance, and inability of individuals to fit into society or perform their expected roles. Disability was a defining master status often coincident with being poor, marginal, sick, and jobless. As modern medicine emerged in the nineteenth century to exert power over the definitions of health and illness, disability was conceived as a personal characteristic residing inside the individual due to some organic abnormality resulting from genetics, disease, or injury. According to this medical model, acceptable disabilities were spinal cord injury, blindness, deafness, schizophrenia, and severe depression. Increasing dissatisfaction with a strictly medical view of disability occurred as people increasingly became aware that disability often resulted from, or was compounded by, physical and social isolation. New definitions consequently emphasize the power of forces external to the individual in defining disability and shaping disabled peoples' lives (Albrecht 1992, Usten 1997).

Regardless of conceptual preference, real-world programs and policies operate on predominantly medical terms. Medical professionals concentrate on the organic base of disability in their diagnoses and treatment, assessing disability in terms of functional limitations such as independence in activities of daily living such as walking, bathing, working, and thinking. Governments generally base social welfare programs on medical definitions of disability, but they modify their definitions depending on the intent of the specific program. For example, the definition of disability embodied in the ADA emphasizes impairments that limit a person's ability to perform activities of daily living while the US Internal Revenue code stresses impairments which limit the individual's ability to work. In sum, the US government has 49 separate definitions of disability. This pattern is typical in other nations as well.

2. *Distribution and Causes of Disability*

Recent worldwide assessments indicate that, depending on how disability is measured, about 12–15 percent of the world's population is disabled. This means, with an estimated world population of six billion people in the year 2000, approximately 846 million were disabled. This disability burden is experienced unequally between less developed and more developed countries. In the year 2000, for example, 4.82 billion people (80.4 percent of the world's population) lived in the less developed countries of Asia, India, China, Africa, Latin America, the Middle East, and the Caribbean and Pacific Islands, but included 89.3 percent (755 million) of the world's disabled people. By contrast, the more developed countries of North America, Europe, and Australia, comprising 19.6 percent of the world's population, had only 11.7 percent (91 million) of the world's disabled people. The impact of this unequal distribution of disability on the health and development of less developed nations is amplified by the fact that only 10 percent of the health care dollars in the world are spent in less developed countries, where almost 90 percent of the disability is found.

Disability differs in type and distribution within and between countries (Murray and Lopez 1996). In developed countries, the major causes of disability are ischemic heart disease, cerebrovascular disease, and physical inactivity. In poorer nations, nearly half of the disability is due to infectious and childhood diseases and injuries. Disability is increasingly exported from developed to Third World nations in the form of high-risk work such as that found in chemical plants and the low-cost, high-volume labor businesses such as garment making and athletic shoe assembly. Across the entire world, the leading causes of disability are respiratory infections, diarrheal diseases, and conditions arising in the perinatal period. In the year 2020, they are projected to be cerebral vascular disease, depression, and road traffic accidents. In all circumstances, disability is disproportionately experienced

by the poor and disenfranchised, but will be experienced increasingly by those more privileged as they live longer with chronic diseases.

3. Models for Analyzing Disability

There are three major theoretical models used to analyze disability: (a) the disability as deviance model, (b) the medical model, and (c) the social model. The disability as deviance model arose from an effort to differentiate between who was normal and therefore accepted in society, and who was abnormal and to be treated as different. This distinction underlies current analyses of inclusion and exclusion in society. The distinction is historically based on appearance, gender, race, ethnicity, age, and nationality, as well as the moral stigma attached to the condition (Stiker 1982). This theoretical approach underscores that disability is a physical and/or mental condition interpreted in a historical, social, and moral context.

The medical model gives power to the physician whose task it is to diagnose and treat disability based on organic abnormalities and function identified through scientific procedures. According to this model, disability is regarded as a medical problem residing in the individual and best tackled through medical treatment. The social model of disability switches emphasis from the physician to disabled persons, and from individuals to the social and physical environment in which they live (Shakespeare 1998). Much of the work on the social model of disability was generated by disabled people themselves, who took an activist stance in embracing a minority group approach to disability (Barnes 1991). They de-emphasize the significance of impairments such as paralysis and low vision, and focus instead on socially constructed barriers such as exclusion and discrimination based on ideology and social values.

Disability studies is an emerging field of study based on the social model of disability (Albrecht et al. 2001). It is being developed by a multidisciplinary group of researchers, academics, government officials, and activists intent on shifting emphasis away from a prevention–treatment–rehabilitation paradigm to a social–cultural–political paradigm. This refocusing effort underscores the agency of disabled persons in defining and shaping their own environment by becoming involved in research, political action, and policy making. The intent is to redefine traditional power relationships between disabled persons and other stakeholders.

4. Disability as a Social and Cultural Product

Recent attention has been given to disability as a symbol and vehicle in art, literature, and film. The representation of disability reflects social and cultural values and presents images that shape public opinion. The key questions are: what does disability signify? and what does disability tell us about a culture or group? An analysis of art and literature reveals that disabled people are often portrayed across history as cripples, lunatics, mendicants, and misfits symbolizing their deviancy and marginality. Yet, when Goya painted maimed veterans, he pointed to the heroism of soldiers in combat and devastation of war, questioning the cost of sovereign power. Likewise, the many Vietnam movies such as *The Deerhunter* use disability to symbolize the divisions in society over ambiguous wars and conflicting values.

On inspection, great literature is filled with disabled figures: Shakespeare's mad King Lear, Hugo's Hunchback of Notre Dame, and the Japanese novelist Oe's autistic son. These characters tell us about the conception of disabilities in diverse societies, but also suggest universal themes warranting further investigation. Disability is the consequence of foolish or heroic action. Disability is a lonely yet public and community experience. Disabled people are portrayed in the roles of fools or as impotent, yet they have produced some of the world's great music and art. For example, Beethoven wrote his Ninth Symphony while deaf, and Monet painted his landscapes at Giverny while losing his vision. Disability is an acknowledged part of most cultures, and helps to define the meaning of life, value of the individual, and nature of society.

5. Societal Responses to Disability

The values of a group can be ascertained by the way the community treats its women, children, elderly, and disabled members. As the populations of Western nations become older, and disability is recognized as a major problem inhibiting development in Third World countries, governments are concentrating increased resources on the prevention and management of disability. In many countries of the world, disabled people have been excluded from public affairs by physical barriers which prevent their mobility, and social discrimination which makes school and work difficult at best. For much of the world, out of sight has meant out of mind. Disabled people are often cared for in their homes by their families, or they live on the street as beggars and homeless (Castel 1995). Western European countries have a strong community ethos and social welfare tradition, so disability is addressed through strong social welfare programs focused on keeping people in the community. While there are well-established disability benefits programs in the USA, the emphasis is aimed more at the individual, and institutionalization is a more frequently invoked solution. In either case, disability is becoming an enormously expensive enterprise, testing

the values and taxing the resources of many nations. Conservatives argue for limiting benefits and sharply controlling the numbers of people on the disability rolls while liberals maintain that government has a direct obligation to see that disabled people have the minimum resources to live their lives empowered and in dignity. Funding for these programs will necessarily come at the expense of the military and other social programs or through increased taxes. Ultimately, the inclusion or exclusion of disabled people in society will depend on available resources, national values, and the political activism of disabled people.

6. *Future Trends*

Because of the tremendous cost of providing benefits to an aging population, increased efforts will be made to prevent and better manage disability. Citizens will be encouraged to live with disability in their homes and communities rather than in institutions. While medical technology promises remarkable help in dealing with disability, equal attention will be given to the subjective experience of illness, because people's experience shapes their lives and those of their families. Finally, there is a growing awareness of the role of spirituality, in the broadest sense of the word, in accepting and managing life with a disability.

Disasters, Coping with

Natural disasters and catastrophic failures of technological systems require considerable adjustment by both primary victims and rescue personnel. Uncertainty, loss, threat to life, exposure to the grotesque, hazardous working conditions, and breakdowns in social support networks are just some of the consequences of exposure to disasters. Coping and adjustment can be a protracted process because disasters continue to affect people long after their initial impact. Stress associated with these disasters and their aftermath affect mental and physical health, but successful coping may have an impact on distress and other symptoms. Distinctions among coping with natural and technological disasters, coping in emergency personnel and primary victims of disasters, measurement of coping, and relationships between coping and health have been important research topics in this area.

1. *Types of Disasters*

Perhaps it is easier to call to mind examples of disasters than it is to precisely define the term 'disaster.' The 1999 earthquake in Turkey was a disaster, as was the crash of two Norwegian trains in early 2000. In the United States, a catastrophic event officially qualifies as a disaster based on the amount of damage done and the amount of assistance required. The strength of the event alone is not sufficient; a powerful earthquake in a remote area of a California desert may not be considered a disaster, whereas an earthquake of the same magnitude in the city of San Francisco would qualify because considerable damage would result. In addition to damage sustained, substantial disruption to people's lives can also be a feature in the definition of 'disaster.' Further components of what constitutes a disaster are explained when two types of disasters, natural and technological, are contrasted.

1.1 *Coping With Natural Disasters*

Natural disasters are caused by intense and powerful natural events such as hurricanes, tornadoes, earthquakes, and floods. They can also occur because of drought and famine. These and other cataclysmic

events are some of the most threatening situations a person can experience. In a sudden and uncontrollable manner, natural forces can take lives and dramatically alter the environment.

Natural disasters vary widely in predictability and impact. Earthquakes are virtually unpredictable, whereas hurricanes can be tracked for days before they hit land. However, consequences such as the extent of physical destruction and disruption of daily life often take victims by surprise, even after the more predictable types of events. Months of cleaning and rebuilding can follow initial rescue work and recovery of human remains. Moreover, drawn-out and complicated insurance, litigation, and financial issues may compound adjustment difficulties following disasters (Green et al. 1990).

Cataclysmic natural phenomena are widespread, and long-term psychological effects of natural disasters are being studied in the realm of trauma research. Reactions to trauma vary among individuals, and research has focused on documenting the effects of disasters by comparing groups who had different degrees of exposure to the event and predicting who copes well and who does not. Adjustment to natural disasters has been studied in response to hurricanes, tornadoes, earthquakes, and floods. Severe and long-lasting consequences of natural disasters may be exacerbated by characteristics of their onset. For example, sudden disasters with lack of warning are especially devastating. Disaster characteristics such as duration and intensity also influence how people cope with such events. Even events of short duration, such as an earthquake, may cause disruption and threat that last months beyond the acute phase of the disaster. Other characteristics of the disaster experience include threat to one's life, witnessing the death of others, injury to oneself or others, loss of social cohesion and resources of the community, loss of possessions and finances, and separation from family.

Anticipation, acute experience, and aftermath of natural disasters all require coping, as does the period of rebuilding. Coping includes strategies or behavior that reduce threat and may take many forms. Direct action involves reducing exposure to the stressor or directly altering the stressor so that it becomes less threatening. For example, evacuating an area where a hurricane is likely to hit can reduce immediate threat to one's life. Information seeking is another form of coping. Keeping track of a hurricane's path and windspeed, for example, may increase a sense of predictability over an impending disaster. Palliative coping includes efforts at reappraising the stressor or reinterpreting the situation to reduce threat. For example, a volcanic eruption could be seen as a way of nature reclaiming land, or a forest fire may be seen as a part of a natural cycle that is necessary for continued growth and differentiation of the forest. Emphasizing the positive aspects of the postdisaster experience, such as increased appreciation for one's health and family, is yet another way of reappraising the situation.

Seeking emotional and practical assistance from others is another common way of recovering from natural disasters (Smith et al. 1986). Community responses directed at restoring the environment are important in regaining control and coping emotionally. Unfortunately, some cataclysmic events cause social support networks to deteriorate at the time they are most needed. Social support is important in both a practical and an emotional manner (see *Social Support and Stress*). Physical assistance in recovery is often necessary for individuals to cope effectively, and emotional assistance is an important factor in recovering from the trauma. However, disasters often weaken or destroy social ties and cause social disruption that makes the kinds of social support that are so helpful in recovery more difficult to obtain. Disaster disrupts both social support and the ability to perform one's role in the family (Kaniasty and Norris 1993) and increased demand for support may be stressful for those providing it. Denial, use of alcohol and other drugs, as well as learning to live with the stressor are additional ways in which people cope with cataclysmic events like natural disasters (Lazarus and Folkman 1984).

1.2 Coping With Technological Disasters

Like natural disasters, technological disasters are caused by events that can be intense and sudden. Examples include bridge collapses, dam failures, and industrial, maritime, and aviation accidents. They also include more drawn-out events resulting from breakdown in technology in which highly toxic substances are used or stored. Such situations would include leaking toxic waste dumps, such as Love Canal, or accidents involving release of radiation, such as the Three Mile Island nuclear disaster. With increasingly widespread prevalence of technological systems there will inevitably be an increase in the potential for loss of control over these systems.

An important difference between natural and technological disasters is that natural disasters often have a 'low point' at which it seems that the worst is over. In contrast to this situation, many technological disasters do not have a low point, a situation that can contribute to prolonged distress (Baum et al. 1983). The visible damage that a natural disaster such as flooding leaves behind can serve as a reminder that the event has passed, perhaps allowing a starting point for recovery. It also provides a focus for postdisaster recovery emphasizing constructive responses associated with rebuilding. The 'low point' may actually be psychologically beneficial because victims know where they stand in relation to the disaster.

For example, once maximum velocity winds of a hurricane have passed, the worst is probably over.

When disasters do not have a low point, these 'safety' signals are not available. The exceptions, of course, include situations like airplane crashes and maritime disasters. Catastrophic breakdowns of technology that result in toxic contamination do not necessarily have a point at which the worst is over. Those exposed can wonder and worry for years about the extent of their exposure and its possible consequences.

As Green (1998) noted, it can be difficult to compare disasters because each one is unique. She suggested a continuum of intent as a means of conceptualizing disasters. Natural disasters would be placed on the low end of intent, technological disasters in the middle, and hijacking and other purposeful acts of violence would be placed at the high end of the continuum. In the case of technological disasters, an implicit social contract between citizens and corporations is violated. The assumption is that corporations will not harm their customers, workers, or members of the community where they make their products. When this contract is violated, anger and rage are added to the range of emotional responses to disasters.

Disasters have also been categorized with respect to perceived control. Natural disasters reflect a lack of control over the environment, but technological disasters reflect a *loss* of control of what was once under control (Baum et al. 1983). A major assumption underlying reliance on technological systems is that they won't break down. That is, ships are not supposed to sink, and toxic substances are not supposed to leak into the environment. Violations of this implicit assumption can contribute to the distress felt by victims and witnesses of this type of disaster.

Like natural disasters, the onset of technological disaster may be sudden or drawn-out. When the Buffalo Creek dam in West Virginia failed in 1979, there was little if any warning of the impending disaster. Very powerful and overwhelming destruction followed, resulting in hundreds of deaths. While it is possible to gain a semblance of control over disasters like this with regular inspection and evacuation plans, the fact remains that technology was not built to fail and it is extremely difficult to predict when it will. Because this disaster was a failure of a human-made dam, the flood that resulted was less predictable than naturally caused floods.

Research on reactions to the Buffalo Creek disaster identified characteristics that contributed to long-lasting mental health consequences (Green et al. 1990). One of these characteristics was that a mining company was considered responsible for the flooding. Anger, rage, and scapegoating of people and agencies that were not directly involved were some repercussions of the flooding being human-caused. In natural disasters, there is rarely someone to blame. Another factor contributing to the impact was the unusual severity of the flood, which was compounded by the isolated location of the community in a valley. Survivors remained homeless sometimes for weeks because removal of debris was delayed and prolonged. In addition, when temporary housing was arranged, it was not conducive to maintaining social support networks among family and friends, an important component of post-trauma recovery.

2. *Types of Victims*

Important distinctions exist among victims of disasters. Some are affected directly because they were present during a disaster event and experienced threat or loss as a result. Others are affected less directly; people who live in an area hit by a tornado, for example, may not have been there when it hit but may have lost property or had family members injured. Another type of victim, the rescue worker, may be exposed to a variety of extreme stressors including hazardous and fatiguing working conditions.

2.1 *Coping in Primary Victims*

Research on disasters and their effects on mental health have identified a range of outcomes associated with this kind of victimization. Predictors of a disaster's effect on people and what factors may reduce or modify this impact have also been studied. As a result, advances in understanding and treating post-traumatic syndromes have been made based on studies of victims of natural and technological disasters. For many years this research was focused on the primary victims of disasters. Differences in the extent of threat experienced during the disaster contribute to differences in their postdisaster response. Research after a wide variety of disasters has suggested that loss of resources, perceived control, adaptational demand, and life threat influence the intensity and duration of distress and stress responding in primary victims. This variation in response, together with the fact that the majority of disaster victims appear to cope effectively, suggests that situational and individual factors work together to produce long-term reactions to disasters.

The study of victims of large-scale traumas started with the documentation of responses to war trauma. Wars can be construed as human-made disasters. After the American Civil War and World War I, descriptions of 'shell shock' and 'battle fatigue' characterized extreme reactions to this type of stress. Following World War II, studies were conducted on the long-term effects of concentration camps and other traumas of war such as the devastation of Hiroshima. Disasters unrelated to war began to be studied intensively in the 1970s. Currently, a wide variety of disasters ranging from earthquakes to nuclear catastrophes are studied with respect to how victims cope over time.

Symptoms of distress following a disaster experience can include shaking, hyperventilation, palpitations,

sleep disturbances, intrusive memories, shortness of breath, sweating, and gastrointestinal reactions. Many of these anxiety symptoms are also associated with exposure to toxic substances, which can escalate panic in individuals in proximity of industrial accidents. The considerable variation in the range of responses and the ways in which people cope with their distress over time underscores the complexity of the factors which constitute the severity of postdisaster stress (Baum 1987). Some people report only a minimal emotional response to a disaster, but typically postdisaster effects include anxiety, depression, helplessness, numbness, anger, guilt, and relief. Most disasters appear to have some impact on the mental health of witnesses and victims, and sometimes these negative effects last for years. The profound effect disasters can have on people is evidenced by many studies on post-traumatic stress disorder (PTSD) in victims of a wide variety of disasters. For example, survivors of the Buffalo Creek disaster exhibited anxiety, depression, withdrawal, numbness, anger, nightmares, and other stress-related physical symptoms for years after the accident (Gleser et al. 1981).

Coping behavior is an important part of the stress response (see *Stress and Coping Theories*). Coping responses to disasters consist of attempts to remove the source of stress or insulate oneself from its effects. If coping is successful, the person returns to normal physiological and psychological arousal as the threat is eliminated or minimized. The victim can adapt cognitively by reducing awareness of the stressor or by changing their perception of threat. The individual can also cope behaviorally by removing or reducing the threat. People may have particular coping styles or habitual ways of responding to stress. For example, people may use problem-focused coping, or do wishful thinking about a stressful situation, or they may seek and use social support, avoid thoughts about the stressor, or use self-blame coping to different degrees.

Lazarus and Folkman (1984) proposed that stress responses can take manipulative or accommodative forms. They may include direct action responses, where the individual tries directly to manipulate or alter his or her relationship to the stressful situation. Changing the stressor by direct action would include solving a problem that was creating distress or leaving the scene. Flexible coping styles, where the person tailors their strategy to the situation and can manipulate and change their coping, can be especially effective in a changing environment following disasters.

Chronic stress following disasters may affect how primary victims cope with additional stressors, and these acutely stressful events may in turn feed into and maintain the chronically stressed state. Schaeffer and Baum (1984) studied stress-related consequences of living near Three Mile Island (TMI), site of a nuclear accident in the United States in 1979. Uncertainty involving the long latency of radiation's effects on the body, the potential for cancer, uncertain locations of safe and unsafe areas and amount of exposure, and the lack of scientific information on the effects of low-level exposure were all characteristics making this disaster chronically stressful. In fact, higher blood pressure and higher levels of stress hormones were observed in residents of TMI compared with a control sample living 80 miles from the site. Major stressors like the TMI disaster can have negative effects on health (Baum 1987) but relatively little systematic and long-term investigation of health-related variables in disasters have been reported. Evidence of blood pressure, hormonal, and changes in immune system functioning that could be considered intermediate to health effects has been found, and sustained changes in these functions could predispose people to illnesses.

2.2 *Coping in Rescue Workers*

Major aspects of disaster-related trauma include threat to life, witnessing death and injury, and making difficult choices like risking one's own life to save that of another. Other stressors operating during disasters include high levels of uncertainty, lack of clear leadership, and lack of control. Lack of warning also contributes to long lasting effects of those exposed, regardless of whether they were primary victims or rescue personnel. There are qualities of responding to disasters that are more specific or unique to rescue workers, however. Emergency personnel respond to a wide range of events, including large-scale catastrophes like earthquakes and airplane crashes. They must search for and help survivors as well as recover human remains and personal effects. These workers face long hours, unpleasant or gruesome working conditions, and exposure to body fluids and other hazardous materials. Exposure to dead or mutilated bodies from a disaster is a potent stressor (Ursano and McCarroll 1994). Studies have investigated emergency workers and their reactions to the stress of body handling and victim identification. These studies agree that disaster workers experience considerable distress but methods and measures used have been different across studies, resulting in findings of varying stress duration and intensity. Rescue and clean-up activities following natural and technological disasters have been associated with symptoms of PTSD, including recurrent intrusive thoughts and distressing dreams. However, it is difficult to predict long-lasting psychological consequences because many rescue workers exposed to trauma do not experience lasting distress.

Predicting long-term distress is difficult partly because of variability in rescue workers' responses. Some studies have reported consistent negative effects of disaster work, and others have failed to find long-lasting distress in rescue workers. After the 1988 Piper Alpha oil rig disaster, Alexander and Wells (1991)

found no differences in distress when comparing police officers with more or less previous experience dealing with human remains. Anxiety was actually reduced after body handling, reflecting that many of the officers found the anticipation to be more distressing than the actual body handling. Other studies using different rescue workers and disasters did in fact find differences in distress depending on prior experience. In a situation that involved extensive body handling, rescue workers who recovered human remains after the crash of Flight 427 showed persistent symptoms of chronic stress and intrusive thoughts related to their experience at the crash scene. Workers who did not expect to see remains but who did in fact come into contact with them were more distressed than those prepared for the recovery activities (Delahanty et al. 1997).

In studies on coping in rescue workers, talking about their experiences to other workers was found to be beneficial for dealing with distressing thoughts and feelings. Following the 1981 Hyatt-Regency skywalk collapse where 144 people were killed and 188 were injured, rescue workers' distress scores were consistently higher but not significantly different from the controls (Miles et al. 1984). Sharing stories as well as the experience of identifying with the dead were forms of coping commonly endorsed by these workers. Less healthy forms of coping included increased use of tobacco, caffeine, and alcohol. In a review of the literature on handling the dead after disasters, Ursano and McCarroll (1994) highlighted the aspects of disaster work that may contribute to stress or help rescue workers cope with stress. They discussed rescue and recovery work in terms of phases, including anticipation, active duty, and postduty experiences. Preparation of workers so that they know what to expect at the disaster site is beneficial. Identification with the victims, personalization, and emotional involvement heighten the trauma and increase perceived threat, however. As a consequence of this type of research, intervention efforts and critical incident debriefing sessions have been started for rescue workers responding to a variety of disasters. However, research on the effectiveness and specific mechanisms behind such intervention efforts is in its beginning stages.

3. *Summary and Conclusions*

Disasters can be defined by their origins as well as their consequences. Interactions among the nature of the stressor, degree of exposure, types of victims, and coping result in the individual's experience of traumatic stress. Natural disasters such as floods and technological disasters such as nuclear accidents and plane crashes are unpredictable and powerful threats that affect generally all of those touched by them. As a threat to life, property, and assumptions people hold about the world, disasters can cause substantial life changes. Cataclysmic events and disasters can have a sudden, powerful impact and almost universally elicit a stress response. These events usually require a great deal of effort for effective coping. Although evidence suggests that disaster stress varies according to the type of disaster experienced, research has shown that responses to disasters in primary victims and rescue workers can share a relatively predictable trajectory. Early shock and anxiety are often followed by combinations of anger, depression, distress, and post-traumatic stress. Coping is part of the stress response and is involved in changing the perceived level of threat from the stressor. Consequently, recovery from the disaster experience is intimately tied to the coping process.

Disasters, Sociology of

Disasters are nonroutine events in societies or their larger subsystems (e.g., regions and communities) that involve conjunctions of physical conditions with social definitions of human harm and social disruption. The sociological study of disasters requires attention to their special character as social problems (Fritz 1961, Hewitt 1983, Stallings 1995, Kreps and Drabek 1996, and Quarantelli 1998). The development of knowledge about disasters before, when, and after they occur (see summaries of the disaster literature by Barton 1969, Dynes 1970, Quarantelli and Dynes 1977, Kreps 1984, Drabek 1986 and Mileti 1999) necessarily draws on theories of social process and structure (see *Action, Collective*; *Action, Theories of Social*; *Functionalism in Sociology*; *Structure: Social*).

1. Sociological Meaning of the Term Disaster

As defined above, disasters are both physical and sociological events and, as such, inherent to all social systems. The phrase 'nonroutine events' distinguishes disasters as unusual and dramatic happenings from everyday issues and concerns. The dual reference to 'physical conditions' and 'social definitions' means that *each* is individually necessary and *both* are collectively sufficient for disasters to occur in social time and space. The designation 'societies or their larger subsystems' means that human harm and social disruption must have relevance for larger social systems (see *System: Social*). The death of an individual and its impact on his or her family, therefore, is not a disaster unless a rare sequence of actions is triggered that has broader societal impact (e.g., consequences of the assassination of a political elite in an unstable nation). Similarly, the fact that thousands of people die on a nation's highways in any given year does not mean that a disaster has occurred. But the explosion of a terrorist bomb in the heart of a city, even if the number killed was significantly lower than the annual highway death toll, would be consistent with the above definition of disaster. The 1979 nuclear power plant accident in the United States (Three Mile Island) was an emergency and certainly a potential disaster. Potentiality became reality in 1986 at the Chernobyl plant in the former Soviet Union. Poverty, hunger, disease, and social conflict are chronic societal concerns. Economic depressions, famines, epidemics, and wars are disasters as defined above. Global warming and ozone depletion are defined objectively and subjectively as environmental hazards or risks (see *Risk, Sociology and Politics of*). The possible disastrous consequences of these hazards, including secondary effects such as sea-level rises in the oceans, remain matters of scientific and public debate. A nuclear attack is a disaster for which there are historical precedents. A nuclear war is a possibility that heretofore has only been simulated (Kreps and Drabek 1996).

The above, precise sociological definition of disaster is important for three reasons. First, the term itself is common parlance (e.g., 'my day was a disaster') and, as such, much too inclusive to be useful. But despite this inclusiveness, the term is part of the nomenclature of those having responsibility for dealing with actual or potential events. These same events are also of interest to sociologists. Because 'disaster' has bureaucratic as well as popular meaning (e.g., disaster declarations), its usage necessarily is central to the mix of social definitions and physical conditions that sociologists must consider. Second, while all concepts in science are nominal (see *Positivism: Sociological*), consensus about objects of inquiry (in this case, what disasters are) is essential to the development of systematic knowledge about them. Third, disaster research emerged as a post-World War II research specialty within the social problems literature in sociology. That literature was and remains very broad (e.g., see *Alienation, Sociology of*; *Crime, Sociology of*). Identifying the special features of disasters is important for examining a broad range of environmental, technological, and sociopolitical events on their own terms and for comparing collective action related to these events with those of social problems generally (Erikson 1976, 1994). Disasters are no more or less important than other social problems, but they are different, and their uniqueness is of substantial importance theoretically.

2. The Special Character of Disasters as Social Problems

A core theoretical issue in the social problems literature (Spector and Kitsuse 1977) is to account for how social problems are constructed through *claims-making activities* (i.e., collective action that asserts the existence of conditions and defines them as problems), and then how their life histories are determined by *response activities* (i.e., collective action directed to addressing these socially constructed problems). The

life histories of disasters can be compared with other social problems because this social structure of claims-making and response activities is the core object of study. However, crime, poverty, hunger, disease, violence, and many other social problems that are studied have an open-ended quality in social time and space. Disasters do not. Indeed, disasters have a special feature that facilitates their analysis as social problems: *the theoretical centrality of a specific event*. Reference to a specific event is critical because, first, any disaster can be demarcated specifically in social time and space, and second, distinctions can be made among pre-, trans-, and postevent claims-making and response activities at the community, regional, national, or international levels.

The fact that disasters are nonroutine events makes them strategic research sites for their analysis as social problems. Prior to an event, claims-making and response activities within localities (as opposed to nation states) focus on future events for which the probabilities of occurrence are small. With the exception of hazards managers and selected others, disaster prevention and mitigation activities at this systemic level have low salience to government officials, economic and political elites, and the public at large. In a sense, this is a rational response (see *Rational Choice Theory in Sociology*) because the annual probability that a disaster will affect given individuals or localities directly and severely is, indeed, quite low. This does not mean that individuals in harms way are insensitive to hazards that threaten them. But it does suggest that they are preoccupied with more immediate problems and concerns of daily living, and that there are any number of disincentives to being proactive (Turner et al. 1986). The resulting social structure of claims-making and response activities about putative events tends to be subtle and is often contentious. Even at societal levels, where annual probabilities of events and aggregated losses are higher, the prominence of disasters relative to other issues can never be assumed.

However, a major transformation occurs when threats are perceived as imminent, or actual events occur. In effect, nonissues become focal public concerns. The more severe the impacts, the more massive the formal and informal mobilization that follows at local, regional, national, and international levels. Existing groups and organizations restructure everyday routines, and emergent structures of various types are socially created. Claims-making and response activities by a panorama of interlocking structural forms are directed to demands that are both objectively and subjectively labeled as acute. Thus, disasters are nonroutine problems because social processes related to them change dramatically, depending on what stage of their life histories is being considered. But whatever the stage (pre-, trans-, or postevent), disasters are catalysts of collective action at smaller to more inclusive systemic levels.

Prior to their occurrence, disasters are socially constructed as *hazards* or *risks* of various types (Clarke and Short 1993). Claims-making and response activities are directed to defining the magnitude of possible impacts and taking specific steps to prevent, mitigate, or prepare for these impacts. As noted above, these steps are constrained by social processes that are as likely to generate organized opposition as support. When disasters occur, terms such as *emergencies*, *crises* or *catastrophes* are used to capture increasing levels of severity. Claims-making activities are no longer at issue—i.e., there is a conjunction of physical conditions and social definitions—and response activities are directed to dealing with the immediate consequences of physical impact and social disruption. After disasters occur, the events become relevant to the evolution of impacted social systems. It must be recognized, however, that any social changes that follow must be interpreted in light of already existing trends (Bates and Peacock 1993, Peacock et al. 1997). Collective action is directed to long-term reconstruction of physical structures and infrastructures and restoration of the social order.

Unraveling the drama of disaster events requires reliance on basic sociological concepts. Thus, past research has drawn heavily on collective behavior theory (see *Collective Behavior, Sociology of*), organizational theory (see *Organizations, Sociology of*; *Networks: Social*), the integration of collective behavior and organizational theories, role theory (see *Status and Role: Structural Aspects*; *Status and Role, Social Psychology of*), and the integration of collective behavior, organizational, and role theories (Barton 1969, Weller and Quarantelli 1973, Perrow 1984, Kreps and Bosworth 1993, Dynes and Tierney 1994, and Webb 1998). The field clearly has become multidisciplinary in more recent decades, with strong intersections among the natural, social, and policy sciences. There remains, however, a very strong sociological core within ongoing research. That core characterizes both major research emphases within mainstream American sociology and a growing body of disaster research internationally.

3. *Disaster Research*

The origins of disaster research can most readily be traced to the US Strategic Bombing Surveys of World War II (Quarantelli 1994). In this historical context, the prototypical hazards or risks were weapons, ultimately nuclear weapons. The prototypical events studied were war-time bombings of cities and regions (primarily in Germany and Japan). The historical context within which these bombings took place was a global war of unprecedented proportions. In general, the war-time studies showed that civilian populations were remarkably resilient in the face of sustained bombing attacks. But with a rapidly developing

nuclear arms race, there was a very practical rationale for the subsequent funding of research on peacetime disasters—to study preparedness for and response to events that parallel war-time situations (i.e., acute impacts of considerable magnitude and scope). Prior to World War II, there was no systematic program of disaster research in sociology. Following the war, the above rationale supported the development of disaster research in the United States during the next 25 years, allowing the field to become an established research specialty within sociology. With funding from defense-related government agencies, studies at the University of Chicago (National Opinion Research Center) and two other state universities (Maryland and Oklahoma) were initiated in the late 1940s and early 1950s. These were followed by a series of studies under the auspices of the National Academy of Sciences—National Research Council from the early 1950s to the mid-1960s. Then in 1963, the Disaster Research Center was established and has been in continuous operation ever since. This Center was located for over 20 years at the Ohio State University (1963–85), and it presently resides at the University of Delaware (1985–present). Disaster research became an established specialty within sociology primarily because a critical mass of professionally trained sociologists in the above and other universities completed most of the studies undertaken prior to the late 1960s. While a public policy rationale was important to those funding the work, the interests of university researchers and the students they trained were theoretical as well. The contemporary attention to systemic structures and processes continues to be grounded in the earlier studies, although considerations of possible war-time applications (Perry 1982) have been supplanted by concerns about a much broader range of societal hazards and risks.

Like the strategic bombing studies, the early to more recent research on peacetime disasters have highlighted the remarkable absorptive capacities of social systems, contradicting conventional notions that during a disaster victims will panic (see *Panic, Sociology of*), that those expected to respond will abandon occupational roles, that community structure will break down, and that antisocial behavior will be rampant. Having systematically debunked such myths about disaster behavior, the more interesting questions to sociologists have related to describing and explaining structural continuity and change before, during, and after an event. The earlier reference to claims-making and response activities of social systems provides a very useful way of framing these questions. Where the majority of studies prior to the 1970s focused on collective action during the immediate emergency period, contemporary research gives more balanced attention to disaster prevention, mitigation, preparedness, and long-term recovery.

Sociology no longer dominates disaster research. There has been growing attention since the late 1960s to studying an expanded range of peacetime hazards and disasters on their own terms. There has been growing involvement of other social sciences (geography, economics, psychology, political science, anthropology, public policy, and public administration) in studying these hazards and disasters. It has become increasingly necessary to wed social science research and findings with those of natural sciences and engineering specialties (seismology, meteorology, structural engineering, and many others). In effect, disaster research has become a multidisciplinary, applied field that seeks practical solutions to putative or agreed upon problems posed by actual or potential events. Sociologists pursuing their own applied or basic research interests cannot do so in an intellectual vacuum.

4. *The International Context of Disaster Research in Sociology*

Just as disaster research has become a multidisciplinary applied field in the United States and internationally, ironically, fundamental sociological questions are being emphasized by scholars outside of the United States (Lars Clausen, Wolf R. Dombrowski, John K. Schorr from Germany; Kitao Abe, Hirotada Hiros, Ritsuo Akimoto from Japan; Tom Horlick-Jones, Barry Turner, Nicholas Pidgeon from England; Charles Chandessais, Claude Gilbert from France; Carlo Pelanda, Bruna De Marchi from Italy; Kenneth Hewitt, Joseph Scanlon from Canada; Boris Porfiriev, Konstantin Popov from Russia; Neil R. Britton from Australia and New Zealand; Uriel Rosenthal from The Netherlands; and many others from both industrialized and developing societies). The involvement of these scholars has been very beneficial. They are raising important theoretical issues about social structure and disaster. They are questioning the dominance of one country (United States) or a single paradigm (see *Functionalism in Sociology* on the evolution of the field. They are concerned about the historical preoccupation with a narrow range of events (rapid as opposed to slow onset disasters). Such issues merit serious attention.

Perhaps the most fundamental issue that continues to be discussed internationally became the title of a recent book edited by a pioneer disaster researcher (Quarantelli 1998): *What is a Disaster?* This volume essentially culminates a multiyear dialogue among social scientists from the United States and other countries on defining the core subject matter for sociology and, hopefully, disaster research as a whole. Despite the wealth of alternative issues and perspectives that have been presented, the precise definition used in this article captures the substantial underlying agreement that exists internationally. Explicitly or implicitly, this agreement is based on two factors. First, there is a strong commitment to using

the tools of science to conceptualize and measure disaster as a sociological construct. Second, there is an effort to extract general knowledge about the relationship between social structure and disaster from studies of particular historical and cultural contexts. The international character of disaster studies therefore provides the comparative approach that is essential for defining the limits to which extant theoretical relationships and models can be generalized. To that end, it is advantageous to maintain the broad range of environmental, technological, and sociopolitical events subsumed by the characterization of disasters as nonroutine social problems.

Disciplines, History of, in the Social Sciences

1. Social Science and Disciplinary History

The social nature of human beings means that there have always been rules regulating the life of a community. Tacit social knowledge exists in any human community. The whole of human history is filled with examples of efforts to give guidance to rulers, sometimes written down in books or manuals. Some contemporary social scientists try to trace a lineage of reasoning reaching back hundreds, if not thousands, of years. Thus political scientists often portray Plato and Aristotle as early representatives of their discipline. Economists and educational researchers may point to the perennial nature of the aspects of human life that constitute their scholarly domains. In the case of legal scholarship a tradition, if only in a weak sense of the word, may be said to obtain from at least the twelfth and thirteenth centuries. The emergence of this tradition is in fact coterminous with the creation of European universities (Kelley 1990). Examples of this kind are interesting in their own right. However none of them amounts to a disciplinary social science history in any real sense of the word. This is so for three reasons (which provide the rationale for the structure of this article).

First, the concept of social science appears only in the 1790s and its use presupposes a meaningful conceptualization of something called a society. This does not occur before the second half of the eighteenth century.

Second, in none of these cases can we talk of a discipline in the sense of a relatively coherent and

delimited program of research and teaching that is consolidated and consistently reproduced in a university environment. This presupposes the existence of a university, but also that the university is seen as a primary vehicle for research activities. However, the research-orientated university does not emerge as a key societal institution until the second half of the nineteenth century.

Third, in none of the cases mentioned above is there an unbroken scholarly tradition that links these early efforts to present-day activities in university settings. Such intellectual and institutional continuities presuppose a degree of disciplinary consolidation that does not occur on a more general level until the early twentieth century. In this respect, developments in the 1930s are crucial although limited to Europe and the Americas. Elsewhere, disciplinary consolidation does not occur until after World War II.

2. *The Rise of the Social Sciences: From Moral and Political Philosophy to Social Science*

The first recorded uses of 'social science' appear in France in the 1790s. Ever since then, these new forms of knowledge have been characterized by an effort to understand the world of modernity. They have tended to describe key features of this new world in terms of processes of industrialization, urbanization, and political upheaval, originating at the northwestern edge of the Eurasian landmass but eventually having global repercussions. In the self-understanding of the social sciences, accordingly, there is a longstanding and predominant view about the formation of modernity, which highlights transformations in the late eighteenth and early nineteenth centuries. It sees these transformations as a conjunction of a technological and a political transformation—the industrial and the democratic revolutions, respectively. This traditional interpretation, however, radically underestimates the deep-seated epistemic transformation that occurred in the same period.

In fact, in this period there is a fundamental transition from earlier forms of moral and political philosophy into social science. This transition is linked to an institutional restructuring not only in forms of political order but also in the forms in which human knowledge is brought forth and claims to validity are ascertained. One feature of this institutional transition is the emergence of a public sphere that gradually replaces arenas of a more closed nature such as aristocratic literary salons (see *Civil Society/Public Sphere, History of the Concept*). Another is the rise of new or reformed public higher education and research institutions that come to replace both the laboratories of wealthy amateurs and the academies under royal patronage and partial control (see *Universities, in the History of the Social Sciences*).

The rise of the social science disciplines must then be cast in terms of the fundamental transformation of European societies that the formation of modernity entailed. One intellectual and cultural transformation in this period pertains precisely to the concepts of society and history and to the new awareness of the structural and constraining nature of societal life. Pierre Manent has put forward the notion that society is a 'postrevolutionary discovery' (Manent 1998, p. 51). It is true that the term 'society' underwent a long conceptual development in the French context in the course of the seventeenth and eighteenth centuries (see Baker 1994)—with a dramatic increase in the utilization of the term in the mid-eighteenth century. However, even if there was a long process of gestation for the modern concept of society, the unique event of revolutionary upheaval requires that discursive controversy and political practice become joined in the formation of a distinctly modern era.

The late eighteenth century witnessed the creation of a political project encompassing the whole world and shattering the existing absolutist order. In this process horizons of expectation to use Koselleck's term opened up that were previously unknown. This sense of openness and contingency also served as a forceful impetus to an examination of the structural conditions of the political body and entailed a passage from political and moral philosophy to social science. This transition required that four key problematics—which today are more acutely open to reinterpretation than they have been for decades—be formulated or at least fundamentally reformulated and enter into the new social-science discourse.

First, the role of historical inquiry becomes crucial. Historical reasoning becomes an integral part of the intellectual transition, and even abstract reason itself becomes historicized in early nineteenth-century philosophy. However, the moral and political sciences break up into a variety of new discourses that in the course of the nineteenth century coalesce and are reduced to a number of disciplines. This means that the stage is set for the divergence between a professionalized historical discipline and the other social and human sciences, a divergence that we still today experience as a major intellectual divide.

Second, interest in language and linguistic analysis enters into all domains of the human and social sciences. One outflow of this is the constitution of textual and hermeneutic modes of analysis. There is also an effort to historicize language and linguistic development itself, thereby providing a crucial link with the historic construction of the notion of different peoples.

This leads to a third problematic: that of constituting new collective identities. Membership in a collectivity could no longer be taken for granted in the life experiences of the inhabitants of a certain village or region. Nor could a relationship of obligation and loyalty between the princely ruler and his subjects

continue to constitute the unquestionable core of the body politic. That, however, meant that even the most basic categories of societal existence were open to doubt. In the western part of Europe, categories such as 'citizen' and 'compatriot' came to play an even more important role at the turn of the eighteenth century.

Fourth, assumptions about what prompts human beings to act and how to interpret their actions within a broader framework are at the very core of any scholarly program in the social and human sciences. At the turn of the eighteenth and nineteenth centuries, the fundamental categories that we still largely draw upon were elaborated and proposed. We might describe these categories as follows:

(a) *Economic-rationalistic*, with a corresponding view of society as a form of compositional collective;

(b) *Statistical-inductive*, with a view of society as a systemic aggregate;

(c) *Structural-constraining*, with a view of society in terms of an organic totality; and

(d) *Linguistic-interpretative*, with a conceptualization of society as an emergent totality.

The transition from a discourse of moral and political philosophy to a social science entailed a decisive shift from an agential—some would say voluntaristic—view of society to one that emphasized structural conditions. In economic theorizing this also entailed a shift away from a concern with moral agency. During the nineteenth century, the context of 'average economic man' became a web of structural properties and dynamic regularities rather than a moral universe of individual action.

Thus, fundamental categories of agency and society that came to be elaborated and refined during much of the rest of the nineteenth and twentieth centuries can be discerned in rudimentary form already during the great transition. So too, however, can some of the features that came to affect these endeavors.

One such tacit but crucial feature concerns the abandonment of the truly universal heritage of the Enlightenment project in favor of forms of representation and endowment of rights based on territoriality or membership in a linguistically and historically constituted and constructed community. Another feature was an emerging and growing chasm between moral discourse and other forms of reasoning about society. Thus, an earlier encompassing conception of the moral and political sciences was gradually replaced by social sciences that marginalized moral reasoning or consigned it to the specialized discipline of philosophy. Third, historical reasoning, which had been at the core of the intellectual transformation at the end of the eighteenth century, became a separate discipline and, toward the end of the nineteenth century, a permanent divide emerged between history and the social sciences.

The end of the eighteenth century was a formative period in the rise of the social sciences in conceptual terms. It is possible to discern, across all confrontations and divergences, a fundamental acknowledgement of the idea that agency, reflexivity, and historical consciousness might help construct a new set of institutions but that this takes place within a complex web of interactions that jointly constitute a society. Thus, there existed a limited number of thematic foci underlying the cultural constitution of a new set of societal macroinstitutions.

3. The Institutionalization of the Social Sciences: The Social Question, the Research University, and the New Nation-states

Relatively early in the nineteenth century, economics (or rather political economy) became differentiated from moral philosophy. It is also in this period that history emerges as a scholarly field with its own canon of rules, but the full disciplinary formation of history is a highly extended process.

However, social science as an institutionalized scholarly activity performed within a series of disciplines is largely a phenomenon of the late nineteenth and early twentieth centuries. It is an activity that directly and indirectly reflects concerns about the wide-ranging effects of the new industrial and urban civilization that was rapidly changing living and working conditions for ever-larger parts of the population in many European nations during the nineteenth century. These changes, often collectively referred to as 'the social question' (*die soziale Frage*), were gradually forcing themselves upon the agendas of parliamentary bodies, governmental commissions, and private reform-minded and scholarly societies (see *Social Question: Impact on Social Thought*). Often the impetus for the search for new knowledge came from modernizing political and social groupings that favored industrialization but advocated more or less far-reaching social reforms. These groupings gradually came to embrace the notion that political action to alleviate 'the social question' should be based on extensive, systematic, empirical analysis of the underlying social problems. In country after country, the political agenda of the nineteenth century was being formed by two macro-projects: the search for a solution to 'the social question' and to the question of national identity and nationhood within new or reformed nation states (Rueschemeyer and Skocpol 1996, Wagner et al. 1991a, 1991b).

Between 1870 and the turn of the century, all signs seemed to indicate that new social science approaches would gain access to the scientific institutions. The thinking of their proponents was widely diffused among the intellectual and political elites. This occurred at a time when traditional liberal economics was undergoing a crisis. Thus traditional political economy was seen to be unable to deal with the 'social question' and the widespread deterioration of living

and working conditions due to urbanization and industrialization.

However, another important, and indeed competing, field of study and training, whose concerns overlapped those of the new social sciences, was that of the legal sciences. The strength of the legal scholar's position in continental Europe arose from two factors. First, the training function of the universities for the state service produced officials and judges. This meant that legal scholarship came to exert a considerable impact on the general outlook of the servants of the state. Second, legal scholars sought to provide a doctrine, a body of concepts that was based on elaborate technical distinctions and would enable lawyers and judges to act with promptness and precision, clarify the deliberations of the law-maker, and bring coherence and order into the legal system (Dyson 1980, p. 112). This doctrine was legal positivism, which was first developed for private law and later for public law (in the latter case known as the legal theory of the state). Legal scholarship remained an important alternative to social science and, in fact, strengthened its position towards the end of the nineteenth century. Thus, the so-called 'state sciences' in the German and Nordic states did not really develop into anything that might be labeled 'political science.' Rather they became increasingly embedded in the legal constitutional scholarship that was expanding in Germany in the wake of German political unification. Conversely, in the Nordic countries a similar tradition of 'state sciences' in the late nineteenth century was characterized by a dual legacy of constitutional legal scholarship and, as in Britain, of studies of philosophy and political history.

By and large, approaches to a social and political science did not succeed in institutionalizing themselves in European academia. In some cases, they tried but failed. In other cases, they did not perceive the relevance of academic institutionalization, but blossomed during a passing period of a favorable political climate and decayed with the changing societal situation. For example, the term 'sociology' had been coined early in the nineteenth century, but the key sociologists of the late nineteenth century (Weber, Durkheim, and Pareto) remained broad social science generalists. Their contributions and professional allegiances traversed a range of fields, including politics, economics, education, history and religion, and the term sociology often referred to a broad historical-comparative study of society. However, it was a type of study that saw itself as scientific and separate from reform-orientated activities of a more general nature.

In the United States, social science research originally had the same characteristics of associational organization and ameliorative orientation as in Europe. For example, the American Social Science Association (created in 1865) embraced the notion that the social scientist was a model citizen helping to improve the life of the community, not a professional, disinterested, disciplinary researcher. During the final cades of the nineteenth century, however, this model was gradually replaced by the emerging disciplinary associations such as the American Economic Association (1885), the American Political Science Association (1903), and the American Sociological Society (1905) (Furner 1975, Haskell 1977, Manicas 1987, Ross 1991). They did not have to face the kind of entrenched opposition or ideologically motivated hostility that many similar efforts in Europe met with (even though it would be misleading to portray these processes as the harmonious unfolding of disciplinary consolidation).

By the turn of the century, a particular pattern of differentiation and professionalization had emerged in the US and proved to be compatible with an active role in government service early on. Economists and psychologists were, for instance, able to play a role in government service as early as World War I, just as demographers were able to do through the Bureau of the Census. At the same time, disciplinary and professional recognition was being achieved within the setting of American universities which started to become ever more orientated towards research undertakings (Geiger 1986, Rothblatt and Wittrock 1993)

This process of successful disciplinary consolidation marked the beginning of a divergence between American and continental European social science. Late nineteenth century American social scientists, many of them German-trained, defined their intellectual projects in a society undergoing a process of rapid transformation: industrialization, urbanization, and concomitantly emerging massive social and political problems. As social scientists with a professional legitimacy, they tried to mark out their own scientific territory and establish their own systems of accreditation. These ambitions entailed the establishment of separate social science disciplines (Manicas 1987). In Europe, on the other hand, the professorate often already had an established position; one writer (Ringer 1969) even uses the term 'a Mandarin class' to describe the situation of the leading German academics at the turn of the nineteenth century. The situation in some other countries, such as Sweden and Norway, was no different.

The social sciences emerged as forms of knowledge about societies undergoing fast and deep societal transformations. The relative success of given research programs largely depended on the intellectual coherence and viability of these programs. The cases of Max Weber and Emile Durkheim are exemplary in this respect, but so is the ability of marginalist economics programs to assert themselves even under political conditions which may have appeared as far from advantageous. However, the institutionalization of the social sciences was also clearly related to two other forms of institutional processes.

First, the late nineteenth century was the period when the idea of the university as a key vehicle for

research became predominant in a number of countries across the globe, from California in the west to Japan in the east. This process created the possibility for the new social sciences, if in a highly uneven way, to find a relatively stable basis for continued research and training.

Second, the late nineteenth century was also a period of deep institutional change in the political and administrative order in a number of countries. Administrative reforms were undertaken and new objectives assigned to the state. Furthermore demands for wider political representation meant that institutional reforms of the state, not least the demand for a culturally coherent nation-state, created demands upon the social and historical sciences to contribute to these reform processes. The particular forms of interaction between research programs, efforts to deal with the social question, and the relationship of that question to the restructuring of universities and of the state, differed greatly across countries. However, in a number of cases, opportunities arose for the successful institutionalization of some of the social science disciplines in ways that came to structure disciplinary developments in these countries for many decades.

4. *Research Programs in the Interwar World*

The end of World War I saw the triumph of liberal democracy and the reorganization of the political order across the European continent as well as a decisive weakening, if not the end, of European global predominance. Soon it became evident that the triumph of democracy was being replaced by its crisis and the emergence of new forms of political and social order with claims to represent the future of humankind in Europe and beyond. It was in this period that preeminent representatives of a range of social science disciplines engaged in a self-critical reflection on the history of their own disciplines. Based on such historical reflection, however, they were able to formulate research programs that came to serve as focal points for scholarly endeavors for decades to come.

Within just a few years in the middle of the 1930s a range of pathbreaking programmatic formulations occurred. At this time economists, most notably Keynes in England but also Gunnar Myrdal and the other members of the so-called Stockholm school in Sweden, took stock of the historical experience of their discipline and formulated a coherent long-term research program. In sociology, Parsons' *The Structure of Social Action* was equally historically and programmatically orientated. Its influence extended far beyond the domain of disciplinary sociology and came to affect developments in a number of other fields, including political science and social anthropology. In statistics, Fisher was able to achieve an encompassing synthesis that became a landmark. In political science and sociology, scholars at Chicago and Columbia opened up new areas of empirical research. In Europe, the early work on electoral geography by André Siegfried in France was complemented by sociological and sociopsychological studies by Paul Lazarsfeld and his collaborators in Austria, and by Tingsten's and Wold's minor classic, *The Study of Political Behaviour* (1937).

The comprehensive philosophical programs outlined by the Continental logical empiricists and their Anglo-Saxon counterparts, despite their relative numerical weakness, came to set agendas for years to come. In this respect, Alfred Jules Ayer's polemical and programmatic volume on *Language, Truth and Logic* (1934) became one of the most noted examples, as did Otto Neurath's *Empirische Soziologie* published at roughly the same time. Meanwhile the French Annales School charted a completely new terrain of research that forever changed scholarly efforts in the historical and the social sciences. This was also the period when the first edition of the *International Encylopedia of the Social Sciences* appeared, as a further testimony to need for reflection, for stocktaking but also for the setting of new scholarly agendas.

Furthermore, research programs emerged in the 1930s that positioned themselves in conscious opposition to disciplinary developments in the social sciences and the humanities. One prominent example of this was the broad synthetic program associated with the so-called Frankfurt school. A very different one was the effort of philosophical phenomenologists, most prominently Husserl and Heidegger, to elaborate a conceptualization of human activity from a point of view at odds with that of both analytical philosophy and dominant forms of empirical social research.

Many of these efforts proved to be of lasting importance. However, in institutional terms, the devastating effects of the European political landscape in these years and the ravages of World War II mean that it is difficult to discern clear institutional continuities in the continental European case. Many of the developments in the interwar years were followed by deep ruptures sometimes tended to make the social sciences after World War II appear as a new phenomenon.

5. *The Internationalization of the Social Sciences: The Age of International Associations, Public Policies, and Mass Higher Education*

The full-blown institutionalization of the social science disciplines on a global scale is largely a phenomenon of the era after World War II. One manifestation of this was the establishment, originally under the auspices of *UNESCO*, of the *International Political Science Association (IPSA)* and the *International Sociological Association (ISA)* in 1949. A process of

professionalization was set in motion and came to exert a truly profound influence worldwide in the wake of the expansion of higher education systems in a range of countries in the 1960s and early 1970s.

The 1960s saw a dramatic expansion of higher education systems across Western Europe and North America but in many other parts of the world as well. In the same countries, sweeping processes of administrative reform also occurred, which often coincided with the coming to power of new political majorities. Major new public policy programs were launched across the board in these countries. In this context, the social sciences came to be finally and firmly entrenched as academic disciplines in university settings. In this same age of great public policy programs, disciplines such as political science and sociology were able to secure a firm basis in a series of European countries, in some cases for the first time; in others (as in Britain, Germany, Sweden, and Italy) in a renewed and greatly expanded form. This expansion was paralleled by a growth of the social science disciplines on a global level that for the first time tended to make the international associations truly international.

On all continents, the full array of disciplines and subdisciplines appeared. There was also an impressive expansion of research methods being utilized. Thus a previously predominant concern for institutions and processes on a national level was gradually complemented by a stronger research orientation towards the study and management of clearly quantifiable processes. In terms of research methods, the 1960s were the period of the breakthrough of the behavioral revolution; a revolution which had been largely foreshadowed by European scholarly efforts in the interwar period. No longer could historical, juridical, and philosophical reasoning alone or in combination be considered sufficient for the analysis of social and political phenomena. Methods and techniques previously elaborated in statistics, sociology, psychology, and economics were now being tapped by social scientists on a vast scale.

This shift in research methodology coincided with the numerical expansion of the social science disciplines and in Europe was often complemented by the introduction of more formalized graduate education programs, normally with compulsory courses in research methodology. At the same time it became possible to see the emergence of an informal 'invisible college' of younger scholars in Europe and in other continents as well, in marked contrast to the much more national orientation of scholars of older generations. In those universities and countries where this shift was most decisively pushed through, there were certainly instances where the older juridical, historical, and philosophical competence was either partially lost or could at least not be developed on a par with the new approaches. Thus it became gradually antiquated and lost touch with what had been the rationale for the use of these traditional methods in the first place.

Apart from external political-societal reasons for this pattern of disciplinary development, a fundamental fact of a long period after World War II was that only in the United States did the social sciences have sufficient size and scope to make widespread international emulation appear feasible. Thus, for example, the American Political Science Association had more than five thousand members in the early 1950s, when corresponding figures for European nations were generally only on a scale of 1 percent or less of that number. Even in the early 1990s, the combined enrolment of West European political science associations was only a third of that of the American association.

Furthermore, only the American version of a science of society and of politics could present a clear institutional lineage dating back to the late nineteenth and early twentieth centuries. In this perspective, the history of the social sciences in a number of European countries constitutes exceptions to this general tendency only in a weak sense of the word. This is perhaps particularly clear in the case of political science. There has been a persistent notion that political science is intimately linked to the particular intellectual and institutional history of the United States. This can be discerned as early as 1923, in Charles Merriam's presidential address to the American Political Science Association. The same theme recurred 30 years later in the presidential address of Pendelton Herring, and again in the one delivered by Samuel Huntington another quarter of a century later. Political science is then seen to constitute an originally American-conceived science that has successfully spread to a range of nations that (by virtue of their effective, if belated, acceptance of a pluralistic political system) had come to qualify as proper recipients of this intellectual heritage.

Even if such a perspective is understandable, it rests on a misperception. It identifies political science inquiry with one particular form of such inquiry—related to the concerns of liberal individualism. In this and many similar cases, a lack of historical perspective threatens to unduly narrow both the range of problems addressed and the theoretical traditions explored and advanced.

6. *Continuities and Reassessments*

Three key features stand out in the development of the social sciences in the late twentieth century. First, their professional consolidation has proceeded. Their institutional position in the modern mass higher education systems seems relatively secure. Never before have there been so many social scientists in the world, and never before have they been so well organized in

professional terms, well trained in technical terms, and internationally linked through journals, networks, and research conferences. Many social science disciplines—political science, sociology, educational research, business administration studies, and public policy research—have to a large extent emerged and evolved as confederations of different practices. They have been held together by a common concern with broad substantive themes rather than by a core of theoretical assumptions.

Second, however, it is remarkable to what an extent truly innovative research contributions have resulted from work in scholarly settings outside of the structure of regular disciplinary university departments. Three types of such environments seem to have been particularly important to the intellectual advancement of the social sciences. First, especially in the major American research universities, the system of so-called organized research units has been of great importance in providing settings outside of the departmental structure designed to be hospitable to research of a transdisciplinary nature. Second, research institutes, also normally of a transdisciplinary nature, have been created both outside and inside of the structure of regular universities. In Germany, the institutes of the Max Planck Society have played a crucial role in this respect. Third, the important role of so-called institutes for advanced study has been steadily increasing during the second half of the twentieth century. Such institutes allow scholars, free from the normal concerns of a university department and coming from a variety of disciplines, to focus on their own research efforts during a limited period, normally one academic year. Whereas initially such institutes tended to be international in their scholarly orientation and national in their own organizational structure, there has recently been an increase in the number of such institutes set up within individual universities. The so-called humanities centers now found in a large number of American universities provide one example of this trend. The recommendation of the Gulbenkian Commission (Wallerstein 1996) that every university create a transdisciplinary institute for advanced study is another indication, a recommendation that now slowly seems to correspond to an emerging institutional reality.

Third, the demands upon the social sciences, from politicians, administrators, and the public at large, to demonstrate the usefulness of their contributions, do not seem to have subsided but if anything to have increased. Sometimes these demands have even resulted in the creation of new proto-disciplines such as social work, criminology, and migration research.

The foremost social scientists of the late nineteenth century had to demonstrate the intellectual and institutional legitimacy of their activities relative to competing forms of scholarship in law, economics, and philosophy. These competitors remain but have been complemented by management consultants, computer experts, and representatives of new transdisciplinary fields such as that of the cognitive sciences.

There is no reason to believe that the social sciences will not be able to defend their current position. It is important, though, to recognize that advances in these sciences depend upon intellectual integrity in the face of an array of demands for immediate usefulness. At the same time, any truly innovative social science inquiry has to be contextually and historically sensitive. This also means that a search for a solution to most of the essential problems of the social sciences has to proceed with a high degree of openness to the contributions from outside of the field of a single discipline. This, however, should be seen as an asset rather than as a liability. In this situation, historical reflection is a necessary component of serious research efforts. Clearly, a number of assumptions concerning our deepest cultural and national identities and their relationship to the basic forms of political and social organization have to be examined anew with the same openness for foundational inquiry as social scientists have shown in earlier periods of fundamental change. In fact, social science scholarship may be crucially important to the possibility of a civilized community of human beings.

Discourse and Identity

The human being is inextricably tied to language. As soon as children are born, a biologically rooted, built-in discourse-developing mechanism is activated enabling them to become communicatively competent, to interact with the world and, as will be discussed in this article, to become aware of their role and specificity in society; that is, of their identity. However, not all discursive sources of identity have the same quality and strength. In general, three major discursive sources of identity may be schematized as an inverted triangle in which a broad section at the top represents 'inherited' sources such as nationality, sex, and race/ethnicity. A narrower section in the middle of the triangle would represent 'optional' identity sources, mainly social groups to which the human being chooses to belong. Finally, a very narrow section at the bottom of the inverted triangle would represent the human self as it is developed and shaped through everyday face-to-face conversations.

In the following three sections these three major identity sources will be discussed. A fourth section will deal with contemporary, transnational communication through the Internet, which actually *inverts the inverted triangle*, providing surprising sources of identity.

1. 'Inherited' Sources of Identity

When a child is born, it inherits several distinctive discursive features such as belonging to a community (e.g., a nation), being male or female, and having distinctive racial or ethnic features. All of these inherited qualities have closely related discursive features (consolidated as the child grows up) ranging from living in a speech community to particular sex- or race-related features.

The role which discourse plays in the community (i.e., the nation in a broad sense) as a source of identity varies depending on its current sociopolitical state, but in all cases it is one of the clearest sources of social identification: experiences within our culture(s) and our community shape human beings and their role in society (see Lanehart 1996). This level of identity relates to Turner's (1987, p. 45) intermediate level of *ingroup–outgroup categorizations* between the broad superordinate level of *being human* and the subordinate level of *personal attributes*.

Needless to say, the sense of *belonging* to a community and *sharing* the same language, a major source of identity, goes beyond the political lines as drawn on maps. This is why the speech community, defined as 'any human aggregate characterized by regular and frequent interaction by means of a shared body of verbal signs and set off from similar aggregates by significant differences in language use' (Gumperz 1971, p. 114) is a much better term, since it goes beyond the reductionist view of society as a clear-cut physical space with members speaking the very same language.

On the other hand, places in which a shared language is embraced as part of a broader resistance against other imposed languages, as is the case of Quebec in Canada or Catalonia in Spain, tend to originate very tight links between discourse and identity, whereas in more politically stable linguistic

areas this source of identity may not be felt so explicitly.

Another major identity marker is sex. There is now a huge amount of bibliography dealing with (non)-verbal speech differences of men and women in same-sex and cross-sex conversational interactions. To a certain extent, fitting the expected discursive attributes of one's sex may reinforce personal identity as a *sense of belonging to a social group* (see West and Zimmerman 1985 for a general overview of the topic). General areas of research include vocabulary differences (including the traditional coining of male-connoted words) and the analysis of conversational *genderlects* (systems of linguistic features linked to one of the sexes).

Finally, the relationship between race, discourse, and identity is important since one's race may be a strong link to society as a multifaceted experience covering such aspects as the recognition of biological origins and, on some occasions, also a deep reinforcement of personality against oppressive, racist attitudes. A related issue has to do with (inherited) ethnic differences within the same community. A clear example is the United Kingdom, in which we can find a great deal of variation between standard and nonstandard forms of the English language, several indigenous languages (Welsh, Scots, Gaelic), and non-English languages brought to Britain by immigrants mainly from countries in the Commonwealth. In all cases, language is raised to a basic source of personal specificity against 'default' speaking correctness.

2. *'Optional' Sources of Identity*

Next in the inverted triangle of identity sources, a middle section of optional sources may be isolated. As human beings grow up, they tend to get together in medium-sized social groups providing an essential sense of belonging and often involving particular discursive features which work as inherent sources of intragroup identity and also as intergroup differentiation (the so-called jargons). A typical example is scientific discourse. Adolescents also display explicitly narrow codes of vocabulary choices and nonstandard pronunciations only available to those 'in the gang' or the group of peers.

Furthermore, laughing is considered to be an important source of identity display in this age group through reducing the 'others' to some laughable characterization that makes them different to us (Boxer and Cortés-Conde 1997, p. 283), normally to enhance a deeper bonding between group members. Finally, in adolescence the strict code of group membership is extended to other codes such as clothing, so that very fixed combinations define 'urban tribes' and provide a supplementive visual channel of intragroup identity.

An important term in this medium-sized area of optional group membership is social network (Milroy 1978), a way of representing people's social transactions within a speech community. This term is essential for understanding the role that discourse plays in the shaping and developing of one's identity. For example, a key issue in the theory of networks is that social groups with tight links of solidarity (*tight-knit networks*) favor the preservation of their vernacular language, a major identity source as commented upon above. In this sense, it should be stressed that there is a difference between vernacular languages, which are learned at home (thus belonging to the broad 'inherited' source of identity) and argots or special parlances, learned after childhood and typically used on those occasions in which group membership is worth stressing. Closely related to this issue are Le Page's (1986) *acts of identity*, a term which stresses the individual's tendency to try and resemble the linguistic attributes of those groups of people which he or she aims to identify with: 'when we talk we project the universe as we see it on to others as on to a cinema screen in our own images, expressed in the language we consider appropriate at that moment, and we invite others by these acts to share our universe' (p. 23).

3. *Discourse, Identity, and the Self*

The speaker's interactional *self* would be placed at the bottom vertex of the inverted triangle which has been suggested to describe different-sized discursive sources of identity. In this case we refer to the person's identity as shaped and modified by daily and ordinary conversational interactions. It is commonly assumed in research on the pragmatics of language use that interlocutors continuously realign their conversational role and either explicitly display their identity or negotiate a *relational identity* with and through others (Boxer and Cortés-Conde 1997, p. 282). Consequently, one's current (and past) conversational exchanges will shape or affect the relationship between participants and speakers' relational self-identity.

Analysis of the self as developed and affirmed through daily interactions goes back as far as the 1950s, with analyses by researchers of the social attributes of exchanges, the so-called *interactional sociolinguists* (Schiffrin 1994), with Goffman (1959) as one of the main contributors to this trend of research. Goffman argues that the self is a social construction (specifically, an *interactive construction*). This is clearly exemplified by the identity-related notion of *face*, defined as the social value that speakers effectively claim for themselves in the course of a conversational interaction. What Goffman focuses on is the social value of conversational involvement, the way different social and conversational settings involve specific expectations and display of this involvement, which

normally entails the use of certain ritualized forms of address. Schiffrin (1994) also includes Gumperz in the label of interactional sociolinguistics because of his view of language as a culturally constructed system and which can be used either in order to reflect macrolevel social meanings or to create microsocial meanings at the level of ordinary conversational exchanges.

Another trend of research which focuses on the social implications of daily conversational interactions is *ethnomethodology*, with Garfinkel as one of its main representatives. This trend focuses on the cognitive rules by which members of a society assess the significance of actions in everyday life. People's previous experience and their knowledge of the institutions and practices of the world around them act to constrain their interpretations of what they see and hear, in somewhat the same way that grammatical rules constrain their perception of sound sequences (Gumperz 1972, p. 215). It is clear that daily interactions play an important role in the shaping of personal identities within a social background. Under ethnomethodology, conversational scenes acquire an essential importance in the display and shaping of self-identities, which are only knowable through the understandings displayed by the interlocutors themselves: 'membership of a category is ascribed (and rejected), avowed (and disavowed), displayed (and ignored) in local places and at certain times, and it does these things as part of the interactional work that constitutes people's lives' (Antaki and Widdicombe 1998, p. 1).

The main conclusion of this research is that people's self-identity is not a fixed feature of their lives, but a dynamic attribute continuously under negotiation, reshaping, transformation, as people engage in daily ordinary communication with others. When some social or cultural aspects are continuously brought into conversations, they tend to become attached to the identity of interlocutors as part of their background of group membership. For example, Georgakopolou (1999) focuses on identities of the young and how *peer networks* are created in the conversational repetition of specific elements in the discursive (sub)culture of the young. As mentioned above, for young people, symbolic cultural associations such as dress styles and others such as music preferences, activity patterns, etc. are firmly located in their conversational interactions, especially in the unfolding of conversational narratives.

On the other hand, self-identity is not only achieved through the *blending* with others through conversational interactions, but also in the feeling of personal specificity when contrasted with others in the course of a conversation. In this case, Davies and Harre's (1990) term *positioning* as 'discursive production of selves' is very interesting. They agree on the interactive formation of self-identity, and that self-identity is not fixed but constituted and reconstituted through the various discursive practices in which people participate. They symbolize this by saying that the human being is an open question with a shifting answer depending on the positions made available by one's own and others' discursive practices and within those practices. Positioning would be the discursive process through or within which people's selves are foregrounded in conversations as observably and subjectively coherent participants in jointly produced story lines. There can be *interactive positioning* in the sense that what one person says positions another, and there can also be *reflexive positioning* when one simply positions oneself.

Markus and Nurius' (1986) theory of *possible selves* also deals with the way people acquire a sense of self-identity through the conversational interactions in which they participate. These possible selves represent the picture that all interactants have about what they are and what they would like to become. In this sense, possible selves influence people's future behavior and are a constant evaluation of people's current state of their self-identity. People's social and cultural contexts play an important role in this shaping, since the range of possible selves derives not only from people's personal experiences (e.g., prior conversational interactions), but also from categories which acquire prominence in a specific sociocultural and historic context, together with images and symbols provided by (highly influential) media discourses constraining the personal choices of self-identity (Lanehart 1996, p. 323).

4. *Inverting the Inverted: Discourse and Identity on the Internet*

So far, three sources of links between discourse and identity have been isolated and represented as an inverted triangle: at the broad top, macrosocial issues such as the speech community, one's sex, and race provide general inherited factors shaping identity from childhood. A middle section of the triangle dealt with optional linguistic groups whose special argots, parlances, and jargons act as a major source of intragroup identification. Finally, the vertex at the bottom of the triangle addressed the personal self as acquiring identity through conversational interactions.

However, these are far from clear-cut, stable features of human identity, but are subject to constant change depending on the current state of sociopolitical relations among people. Specifically, we are now in a *global village* dominated by an increasing quantity and quality of international communications which affect the way the self is viewed and located in an interconnected (i.e., networked) world beyond physical or political boundaries. Castells (1997) specifically deals with this *self/net* dichotomy and how it influences personal identity. The network is inherent to modern, economically advanced societies. The self is a symbol of human activities oriented towards the reaffirmation

of identities in a world like today's, subject to the constant change and instability of networks. In this environment, identity is viewed as 'the process of construction of meaning on the basis of cultural attribute, or related set of cultural attributes, that is/are given priority over other sources of meaning' (Castells 1997, p. 6). The important conclusion is that people tend to react by reaffirming their historical, cultural, ethnic, and religious roots as a reaction against networked globalization.

The most paradigmatic example of a communicative network is the Internet. It is a centerless network linking people from all over the world by an intricate system of (mostly telephonic) wires. It was initially used for military purposes and exploited by academic researchers, but nowadays is has become an inherent source of identity for millions of people. Actually, due to the ubiquity of the Internet, a tendency towards *inverting the inverted triangle* can be observed nowadays.

First, the formerly broad section of inherited attributes at the top of the triangle is narrowed as a consequence of increasing transnational communication and depersonalization of networked transactions. Nowadays, it is easy to exchange messages with people in different parts of the world simultaneously, and therefore national attributes may become blurred and their identity-shaping effect be weakened or invalidated. Other inherited features such as race and sex may be suppressed from daily communicative exchanges through the Internet and may no longer affect the way people are viewed and shaped as interactants in the network. As Meyrowitz (1985, pp. 143–4) points out, 'many categories of people… were once 'naturally' restricted from much social information by being isolated in particular places. The identity and cohesion of many groupings and associations were fostered by the fact that members were 'isolated together' in the same or similar locations…. Now, however, electronic messages…democratize and homogenize places by allowing people to experience and interact with others in spite of physical isolation. As a result, physical location now creates only one type of information system, only one type of shared but special group experience.'

Second, the middle section of optional sources of identity, mainly through self-socialization in groups shaped by specific linguistic patterns, remains more or less in the same medium-sized section of the triangle. On the Internet, these specific discourse groups with their limited-access jargons are reproduced in parallel forms of organization: the so-called *discussion forums* and *distribution lists* via e-mail, which also exploit the same sense of group-membership language specificity that we can find in real-life social instances. The sense of sharing in this type of community also requires that the participants agree on the ideas around which the group is based; even if they disagree, there needs to be some fundamental common ground. Trust in the shared motivations and beliefs of the other participants—in other words, their social identity—is essential to the sense of community (Donath 1999).

Third, the former narrow vertex of personal self in the inverted triangle has now become very broad due to the multiplicity of selves (often anonymous) that may be used in conversational exchanges through various forms of Internet communication such as *chats* or *multiuser domains* (see Turkle 1995). In the physical world the body provides explicit (and stable) clues of inherited and personal qualities shaping the person's identity. On the Internet, however, these attributes are not explicitly conveyed, and one can have as many electronic identities and selves as one is willing and/or able to create, all of which are presented with no corporeality. As Mitchell (1995) correctly states, the process of mutual construction of identities on the Internet usually gives very little away. Because communication takes place without bodily presence or the sound of users' voices, others who 'know' a user quite well may not realize how he or she looks, and thus may be unable to make the usual inferences from that. On the Internet people can very easily conceal, leave carefully ambiguous, or falsely signal gender, race, age, body shape, and economic status. 'People's representation on the Net is not an inevitability of biology, birth, and social circumstance, but a highly manipulable, completely disembodied intellectual fabrication' (Mitchell 1995).

In some cases, real-life and virtual-life selves may overlap, creating, in extreme cases, problems of self-identity when one is unable to dissociate the physical and the virtual. In normal circumstances, though, our on-line selves become just one more series of selves in our everyday lives that we create in order to deal with a variety of situations. The difference between a cyberspace persona and an ordinary workplace persona is that, unlike a workplace persona, the cyberspace persona does not exist in a direct relationship to survival on any level. It is a *surplus personality* (Newitz 1995) but which might occasionally take over from our real-life self.

The medium of identity construction on the Internet is a special kind of text, a hybrid between the permanence and fixed quality of written texts, and the spontaneity and ephemeral status of oral utterances (Baron 2000, Tella 1992). Beyond the evident problems that text-based interlocutors face in the course of a conversation due to the lack of contextual support, the increasing appeal that *chats* and other interactive online phenomena have nowadays should make us think twice before claiming that the oral medium is undoubtedly superior to the written medium. The profusion of written messages that people exchange through mobile phones nowadays, for instance, is a clue suggesting that, perhaps, people are still willing to construct and communicate identities through language, but perhaps not so much through face-to-face encounters.

Discourse, Anthropology of

Anthropology has been shaped at various points by what has often been referred to as a 'linguistic turn,' reliance on models of language for theories of culture and society. Franz Boas, for example, used phonetics as a model for cultural processes; he suggested that just as each language selected a small range of sounds from a practically unlimited array and arranged them in unique ways, so culture mapped the infinitely varied range of personal experience onto a limited range of categories. This line of reasoning was extended by Edward Sapir and Benjamin Lee Whorf. In the 1960s and 1970s, Claude Lévi-Strauss drew on Roman Jakobson's and Morris Halle's distinctive feature model of phonology in creating a variety of structuralism that revolutionized anthropology, literary criticism, and other fields.

At first glance, the centrality of the concept of 'discourse' to the work of many anthropologists and other scholars in the 1980s and 1990s might seem to represent another linguistic turn, a new convergence of linguistic and social/cultural models. Nevertheless, the situation, at least until recently, has been the opposite. Practitioners influenced by poststructuralist and postmodern theories have generally followed Michel Foucault in 'treating discourse [not] as groups of signs … but as practices that systematically form the objects of which they speak' (1972, p. 49). Invoking the term thus signaled rejecting semiotic and structuralist analyses that identified formal patterns immanent in cultural codes in favor of discerning the power relations that shaped them. Many linguists, on the other hand, were trying to overcome the formalism of structuralism by seeking a more rigorous empiricism, and the concept of discourse was appealing as a rallying cry for going beyond decontextualized analysis of isolated signs to the analysis of communicative acts as they are embodied in concrete contexts. Although the latter practitioners defined discourse—generally implicitly—in a variety of ways, most associated the term with particular texts, conversations, and electronically mediated messages, and analyses generally focused on details of form, content, and context. The result has been the creation of divergent bodies of literature, both of which carry the banner of discourse, that have had relatively little to say to one another until recently.

This article outlines these opposing approaches at the same time that it points to recent research trends that are not only narrowing the gap between the two

types of perspectives but leading to critical reconceptualizations of discourse, language, culture, and other key concepts and producing new insights into social and political life.

1. Discourse in Poststructuralist and Postmodern Perspective

A number of writers turned scholarship on its head in the 1960s and 1970s. Academics had claimed an epistemologically superordinate position, framing their analytic concepts and methods as privileged devices that were not subject to the political and empirical constraints of the phenomena they illuminated. Poststructuralism challenged such claims, placing scholarship squarely into the middle of the politics of social life. Having played a key role—along with transformations in social and material relations—in the creation of modernity, philosophical and academic texts became central objects of analysis. Jacques Derrida suggested that concepts of language, culture, aesthetics, and so forth were in need of 'deconstruction,' of playful and irreverent analyses that unraveled the powerful illusions that imbue dominant frameworks with authority. While Lévi-Strauss characterized culture as based upon unconscious oppositions, Derrida revealed the magical acts that he and other scholars used in creating these sorts of dichotomies and making them seem real.

The influential writings of Michel Foucault (1972) brought the term 'discourse' and a scholarly practice known as 'discourse analysis' or 'the archaeology of knowledge' to the fore in a wide range of disciplines. He suggests that we must examine how 'effects of power circulate among scientific statements, what constitutes, as it were, their internal régime of power' (1980, p. 112). Foucault does not identify discourse with particular utterances or texts, and he argues that it is not possible to grasp the power of discourse when it is seen as rooted in a particular context, viewed as an isolated and self-sufficient totality. He rather suggests that 'a statement always belongs to a series or a whole, always plays a role among other statements, deriving support from them and distinguishing itself from them' (1972, p. 99). One of his major contributions is demonstrating that institutions form key loci for the production and legitimization of discourses, and he identifies the way they are embodied in 'political technologies' that create schemes of surveillance and regulation in such settings as prisons, clinics, and asylums.

Foucault's work has been criticized for its focus on dominant texts, thereby reproducing the marginalization of contributions by women, people of color, and populations outside of Europe. Particularly in his early work, Foucault seems to go against his disavowal of structuralism and his call to look beyond the dispersion and mutability of elements of discourse in favor of finding of 'a unity … [that] resides, well anterior to their formation, in the system that makes possible and governs' (1972, p. 72). Foucault's archeological approach ultimately construes discursive practices as constituting an autonomous sphere that is epistemologically privileged and possesses causal efficacy.

A complementary point of departure was provided by attempts to reverse the marginalization of rhetoric, a step long advocated by Kenneth Burke. In the course of analyzing narrative emplotment, Hayden White suggests that the way historians construct the past involves two steps—an act of imagination that creates a vision of the social world and a subsequent act of rhetorical magic that renders the imaginary real, convincing audiences that that is just the way it happened. Attending to issues of both rhetoric and power, practitioners have critically examined how anthropology similarly contributes to the imagination of what Michel-Rolph Trouillot (1991) refers to as the 'savage slot,' the continual reproduction of modernity's Others. James Clifford and George Marcus (1986) and other writers dissect 'the poetics and politics' of anthropological texts, the rhetorical strategies ethnographers use in imagining 'the field' and imbuing their constructions with authority and authenticity. When viewed critically as power-laden discourse, ethnography became suspect, particularly in the eyes of scholars in cultural and ethnic studies. Unfortunately, classic deconstructions by scholars of color of the rhetorics adopted by ethnographies that stereotyped racialized minorities (see Paredes 1977) were seldom cited as precedents.

Anthropologists have also detailed the way that complex, multifaceted, and contested relations were discursively transformed into seemingly simple dichotomies, such as savage vs. civilized and traditional vs. modern, through colonial discourses. By revealing the complicity of ethnography in colonial regimes and the colonial underpinnings of contemporary anthropology, practitioners have deepened the critique of fundamental concepts and practices within the discipline. Michael Taussig (1987) draws on the work of the Frankfurt School in revealing the way that the production of racialized images went hand-in-hand with the violent oppression of indigenous Latin Americans. Students of colonialism and others have turned to theorists who come from outside the Euro-American orbit, including the Subaltern Studies group in India (Guha and Spivak 1988) and such Latin American theorists as Néstor García Canclini (1995 [1989]) for points of departure.

Finally, a number of scholars have responded to analyses of the 'free floating' character of postmodern discourse by experimenting with techniques of ethnographic analysis and writing. Anthropologists have sought to disrupt dominant rhetorical strategies and political positions by creating ethnographic and other texts that draw on surreal, fictional, and other tech-

niques. The idea that both culture and ethnography are dialogic, which can be traced to M. M. Bakhtin's conception of discourse and Dennis Tedlock's work on narrative, has influenced many of these innovations. Concern with cultural discourses has thus been translated into attempts to transform anthropologists' own discourses of culture.

2. *Linguistic Approaches to Discourse*

Other scholars have used the concept of discourse to grapple with limitations in existing approaches to language. Structural linguists largely followed Ferdinand de Saussure in constructing languages as closed systems of context-independent signs that stand apart from politics, history, and social differences between speakers. Noam Chomsky pushed many linguists toward even more formal, abstract approaches and further marginalized the study of social heterogeneity by positing an ideal speaker–listener as the model of the subject that should be adopted by linguists. An orientation toward discourse promised to free practitioners from focusing exclusively referential relations as encoded in small, decontextualized units in favor of studying the way that texts, conversations, and entire genres were embedded in social life. Rather than seeking to circumvent 'positivistic' concerns with concrete, empirical data, as was the case with many poststructuralist and postmodern scholars, the concept of discourse was seen by linguistic anthropologists and other scholars as a means of achieving greater empirical scope and depth.

Beginning early in the twentieth century, 'Russian Formalists' focused on such discursive units as stories or poems, detailing how writers played with linguistic forms apart from their semantic content (see Jakobson 1960). The Prague School developed a dynamic approach that emphasized expressive, appellative, and aesthetic functions in addition to the referential function and examined how they intersected in different genres. Russian V. N. Volosinov took on Saussure directly, drawing attention to the capacity of signs to link multiple contexts, voices, and texts and detailing the special role of reporting the words of others in creating this diversity. M. M. Bakhtin (1981) characterized discourse as heteroglossic, suggesting that languages are not closed, stable systems but points of intersection between competing structures, styles, genres, and perspectives. Rather than the sources of social consensus—and national unity—that Saussure had envisioned, languages became sites of struggle. British philosopher J. L. Austin (1962) transformed received understandings of the relationship between word and world by arguing that utterances are performative—that they do not simply refer to real world events but create them; saying, in short, is a form of doing. Linguists have mapped the grammatical and 'discourse level' features of texts and genres and tied them to communicative functions, as in Michael Halliday's systemic-functional approach.

In the 1960s and 1970s, American scholars drew on these insights in challenging dominant structuralist and transformational (Chomskyian) approaches. Dell Hymes (1974) called for an ethnography of speaking that documents cultural patterning of language in its social context. While Saussure and Chomsky banished linguistic variation, the way that forms and meanings vary between speakers and contexts, from serious linguistic study, Hymes and other scholars placed it at the center of an emerging sociolinguistics. A generation of practitioners who obtained their Ph.D.'s in the 1960s and early 1970s conducted ethnographies of speaking that focused on such issues as gender, political and religious ritual, rank and status, and expressive genres (see Bauman and Sherzer 1974). Richard Bauman and other writers have illustrated how this approach can be used as a tool for historical analysis. This ethnographic approach was linked directly to a concern with esthetic and performative dimensions of language in a focus on performances, speech events that are marked by special forms of authority, and formal elaboration (Bauman 1977, Hymes 1975). At the same time, Joshua Fishman (1972), John Gumperz (1982), and William Labov (1972) drew attention to the linguistic and political importance of relationships between dialects, languages, and discourse strategies. The frameworks they presented helped to focus attention on linguistic diversity and language policies in contemporary nation-states, presaging later interest in discursive dimensions of nationalism, power, conflict, and social inequality. Michael Silverstein (1976) drew on the work of Charles S Peirce and Roman Jakobson in developing a 'metapragmatic' approach that complements the study of semantics with rigorous attention to the centrality of indexes that anchor discourse in existing social contexts—and create new contextual parameters. All of these approaches placed questions of communicative functions—the multiple roles of language in shaping social life—alongside those of structure at the center of inquiry.

Other scholars working in the United States sought to draw the study of discourse away from the study of types, rules, norms, and functions; they defined discourse as—and limited objects of analysis to—particular stretches of talk. Sociologists Harold Garfinkel and Erving Goffman argued that discourse should be studied not as an end in itself but as a window on social interaction. Garfinkel's concern with everyday, mundane encounters was placed at the center of the field of conversation analysis, which proclaimed 'an insistence on the use of materials collected from *naturally occurring* occasions of everyday interaction by means of audio- and video-recording equipment or film' (Heritage and Atkinson 1984, p. 2; emphasis in original). Eschewing reference to contextual information that does not appear in the

recording itself, conversation analysts scrutinize transcripts for regularities in the sequencing of conversational features. Many practitioners now focus on institutional contexts, detailing the role of interaction in shaping what takes place in courtrooms, schools, clinics, and other settings. Joel Sherzer proposes a 'discourse-centered' framework that similarly privileges 'naturally occurring and recorded speech' (1983, p. 10) at the same time that he calls for systematic attention to broader social and cultural contexts. These approaches represent an opposite pole from poststructuralist frameworks in that they view discourse in maximally empirical terms and focus on minute analysis of recorded talk.

3. *Converging Paths: The Politics of Discourse*

In recent years, many anthropologists and other scholars have focused on the role of discourse in shaping power and the politics of difference, resulting in a number of important intersections between practitioners who formerly held opposing views of discourse.

Pierre Bourdieu (1991) placed sociolinguistic concepts into a framework that defined types of linguistic competence as 'symbolic capital' in seeking to reveal the role of discourse in processes of 'symbolic domination.' He redefined the concept of communicative competence in such a way as to draw attention to the barriers of class and race that limit access to sites in which such competence can be acquired. Aaron Cicourel, Charles Briggs, Elliot Mishler, and others have focused on interviews as social as well as communicative events, detailing how formal and contextual features shape and are shaped by power asymmetries, thereby creating discourses that scholars use in imagining social life and imbuing their texts with authority and authenticity.

Building on Silverstein's (1979) foundational work, linguistic anthropologists have explored the role of language ideologies, socially situated conceptions of the nature and functions of language, speech, and communication, in shaping both linguistic structure and social life (see Schieffelin et al. 1988). Challenging the notion that linguistics provides a privileged and at least ideally objective understanding of language, investigations of language by linguists, philosophers, missionaries, and others come to be seen as being just as socially situated and politically interested as other social constructions. Bauman and Briggs (2000) argue that language ideologies have played a key role in shaping modernity, having been used in constructing and naturalizing political ideologies and institutions since the seventeenth century. Such ideologies are tied in crucial ways to metadiscursive practices that provide the means for attempting to control the production, circulation, legitimization, and reception of discourse (see Silverstein and Urban 1996).

Anthropologists responded to Jurgen Habermas's work on the construction of a 'public sphere' in which citizens debate discourses that shape social life and political institutions by detailing the way that dominant forms and arenas are contested by resistant voices and counterpublics. Such investigations have helped to illuminate the processes by which limits are imposed on what sorts of things can be said and who can say them. Research on multilingualism and language policy similarly have provided crucial insights into the way that efforts to legislate the dominance of national languages and standard dialects provide politically palatable means of legitimizing forms of social inequality based on class, race, and immigration status (see Hill 1998, Zentella 1997). Work by US based linguists parallels European critical discourse analysis (Wodak and Reisigl 1999) and British concern with language and power, which have also scrutinized the discursive foundations of racism, anti-immigrant rhetorics, and other ideologies of inequality. Approaches have similarly converged in analyzing the discursive underpinnings of science and public health. At the same time that this work has helped to transform Foucault's call to scrutinize how discourses 'systematically form the objects of which they speak,' it has provided tools used by specialists in cultural, ethnic, women's, and science studies in revealing how structures of subordination and marginalization are produced and maintained.

The study of discourse has come under attack of late. Martha Nussbaum criticizes Judith Butler (1997), for example, for 'turning from the material side of life, toward a type of verbal and symbolic politics that makes only the flimsiest of connections with the real situation of real women' (Nussbaum 1999, p. 38). Such criticisms seek to reduce these many types of discourse analysis to explorations of ideological—and therefore ultimately inconsequential—dimensions of social life, thereby suggesting that such approaches cannot illuminate inequalities of power and material resources. Responding effectively to such criticisms will require new syntheses of sociopolitical and linguistic approaches in demonstrating the materiality of discourse and the way it, along with other symbolic (including material) forms, shapes social life.

Discovery Learning, Cognitive Psychology of

1. Discovery Learning

Like most of the terms and catchphrases that provoke controversy in education, 'discovery learning' is marvelously vague. A plausible one-sentence definition would simply elaborate on the name itself to produce something like the following: discovery learning is a philosophy of education in which students discover ideas and knowledge via exploration, projects, activities, problem solving, and play. As such, discovery learning is usually contrasted with a style of education which might (depending on the background or predilections of the person doing the contrasting) be referred to as instructionist, regimented, orderly, traditional, or efficient—i.e., a style of education focusing on the transfer of knowledge via lessons, textbooks, lectures, and direct instruction.

More realistically, the phrase 'discovery learning' denotes, as much as anything, a style or aesthetic of education. Broadly speaking, advocates of discovery learning tend to invoke visual images of children learning in playgrounds, gardens, laboratories, workshops, and studios; the opposing visual images are those of children seated at rows of desks, listening to a teacher, reciting in unison, or writing in lockstep. These contrasting visual images are important because they encapsulate the concerns, and anticipate the rhetoric, of both the proponents and opponents of discovery learning. Proponents focus on notions such as motivation, depth and authenticity of experience, and respect for individual learning styles; opponents focus on notions such as rapid skill acquisition,

efficiency of learning, and quantitative assessment of learning outcomes. The arguments between the two camps, then, are in large part rooted in a strong division between two venerable notions of education—one which focuses on the cultivation of deep individual interests, and one which focuses on mastering fundamental skills as the basis for productive citizenship.

This article focuses on discovery learning as an object of study in cognitive science. As such it does not, and could not, resolve the philosophical debate over the value of discovery learning; to do so would be to resolve far deeper questions about what the essential purpose of education might be. Nonetheless, a cognitive science perspective can inform this ongoing debate in several ways: in particular, cognitive theory suggests where the strengths or pitfalls of discovery learning may lie, whether there are settings and domains for which it might best be suited, or what sorts of research and development efforts might improve its practice. The following sections explore these issues. By way of preface, Sect. 2 begins by describing the role of discovery learning in the history of science and mathematics education. Section. 3 then focuses on those particular issues for discovery learning that are highlighted by cognitive science research; and Sect. 4 discusses the role of educational technology in the practice (both current and future) of discovery learning.

2. *Discovery Learning in Science Education: From Ancient History to Recent Debates*

Images of discovery learning have an ancient pedigree in educational writing. Indeed, one could argue that Socrates' mathematics lesson in Plato's *Meno*—perhaps the quintessential classical portrait of pedagogical success—is an instance of 'guided discovery learning' in that the slave boy (student) is brought to understand a special case of the Pythagorean theorem through his own responses rather than direct instruction. (Undoubtedly, this instance of discovery learning is very energetically guided.) Elements of discovery learning can be found in the writings of the seventeenth-century Czech religious educator John Comenius:

> Men must, as far as possible, be taught to become wise by studying the heavens, the earth, oaks, and beeches, but not by studying books; that is to say, they must learn to know and investigate the things themselves … (N)o information should be imparted on the grounds of bookish authority, but should be authorised by actual demonstration for the senses and to the intellect. (Rusk 1967, p. 97)

A century later, Jean-Jacques Rousseau's educational classic *Emile* includes similar passages: 'Teach your scholar to observe the phenomena of nature … Put the problems before him and let him solve them himself. Let him know nothing because you have told him, but because he has learnt it for himself. Let him not be taught science, let him discover it' (Rousseau 1992, p. 131). Rousseau's ideas were taken up in the nineteenth century by the Swiss educator Johann Pestalozzi, and by Friedrich Froebel, the innovative German educator famous for his development of the idea of a 'kindergarten' (Brosterman 1997, pp. 18–22, 30–5).

In the past century, the central images of discovery learning are prominently found in the writings of Dewey, particularly in his descriptions of science education (cf. Dewey 1916, pp. 266–76). Piaget's work is likewise often cited as providing a theoretical foundation in cognitive psychology for discovery learning: the Piagetian child is one who (in the apt summary of Gardner et al. 1996, p. 28) 'would first learn about the world directly through spontaneous and natural actions upon the physical world; then, acquiring a set of more complex cognitive structures in a preordained fashion, that child could perform "mental operations" of increasing abstraction and power on the representations that she had constructed.' Perhaps the most eloquent advocate for the role of discovery in education is Bruner, whose essay 'The act of discovery' (Bruner 1979) may be read as a sort of manifesto for the entire discovery learning enterprise. In this essay, Bruner hypothesizes four broad benefits that a student might derive from learning via discovery: an increase in intellectual potency (i.e., development of stronger techniques for problem solving); a shift from extrinsic to intrinsic rewards (i.e., a shift to motivation derived from the act of discovery itself); learning of heuristics of discovering; and improved memory for learned material (since that material was learned in a rich context developed by the student themselves).

After centuries of such energetic and passionate advocacy, one might expect that discovery learning would be a relatively uncontroversial notion in education; but the history of education shows that uncontroversial notions are few and far between. A representative critique of discovery learning may be found in Hirsch (1996, p. 250), who presents a skeptical one-paragraph definition of the concept, noting that '(T)here are two serious drawbacks to preponderant or exclusive reliance on discovery learning. First, students do not always make on their own the discoveries that they are supposed to make … Second, discovery learning has proved to be very inefficient.' This theme of the pedagogical uncertainty of the method is described as well by Driver (1994, p. 42): '(T)he connections that are apparent to a scientist may be far from obvious to a pupil.' Even among educators sympathetic to discovery learning, pitfalls are noted. Papert (1993, p. 16), for example, sounds the important theme of context: 'It is simply double-talk to ask children to take charge of their own learning and at the

same time order them to 'discover' something that can have no role in helping them understand anything they care about or are interested in or curious about.'

3. *Discovery Learning and Cognitive Science*

The preceding paragraphs leave us with a frustrating problem. On the one hand, learning via discovery would seem to be desirable on affective and intellectual grounds; on the other hand, the difficulties of practical implementation of discovery learning are widely acknowledged. One question that we might begin with, then, would be whether there is evidence that children (as opposed to, say, professional scientists) are indeed capable of effective learning via discovery.

One body of relevant evidence comes from recent work in infant cognition. The tasks with which babies are confronted—to learn the grammar of their natural language, to learn the behaviors of objects in the world, to learn about their own and other people's minds—seem, upon examination, to be approached by persistent and at least somewhat systematic inquiry. Gopnik et al. (1999, p. 86) summarize this research, writing:

> Human children in the first three years of life are consumed by a desire to explore and experiment with objects. In fact, we take this for granted as a sometimes exhausting fact of parenting … (F)or our species the dangers of exploration are offset by the benefits of learning. The rapid and profound changes in children's understanding of the world seem related to the ways they explore and experiment.

It appears, then, that successful discovery learning does occur, given the right conditions. But note that infant cognition may be special in a number of respects: first, the domains in which discovery takes place for infants (language, object recognition) are most likely domains in which a great deal of inborn cognitive and perhaps neurological structure already exists prior to exploration. Second, as Gopnik et al. point out, the infant's environment is interestingly poised to reward infant experimentation in the form of adult behavior: adults, for example, ease the learning of language through the use of 'motherese,' with its short, simple sentences and affectionate intonations (Gopnik et al. 1999, pp. 128–32).

The problems with discovery learning in science—the most typical classroom domain—are more pointed, and form an interesting contrast to the successful learning scenarios of infant cognition. Children (and adults) come to scientific learning with many misconceptions, some of them arguably derived from the very same natural explorations they performed as infants (e.g., the notion that inanimate moving objects inevitably 'run down,' Driver et al. 1985). Our everyday environment is not especially well suited to disclosing phenomena that occur in the absence of friction (such as Newtonian mechanics), or over long periods of time (such as evolution), or at high speeds (such as relativistic effects) or small scales (such as quantum effects), making scientific subjects difficult to teach and understand, even for adults. Moreover, as discussed by Kuhn et al. (1988, p. 220), key aspects of sustained scientific inquiry (e.g., maintaining a conscious distinction between evidence and theory) are difficult for both children and adults.

4. *Directions for Discovery Learning*

Despite the difficulties involved in getting it right, the benefits that accrue from providing students with opportunities for discovery seem profound, not least on the affective dimension. Csikszentmihalyi, who has done extensive empirical work on motivation and creativity, writes:

> When people are asked to choose from a list the best description of how they feel when doing whatever they enjoy doing most—reading, climbing mountains, playing chess, whatever—the answer most frequently chosen is 'designing or discovering something new.' … (U)nless enough people are motivated by the enjoyment that comes from confronting challenges, by discovering new ways of being and doing, there is no evolution of culture, no progress in thought or feeling. (Csikszentmihalyi 1996, pp. 108–10)

Csikszentmihalyi's admonition suggests that one promising direction of research in discovery learning is to make it more motivating and enjoyable for students, perhaps by looking to the sorts of factors that encourage discovery and exploration in infants and toddlers. These factors include increased attention to (a) the nature of students' preexisting theories and to their skills and predilections for theory building; (b) the arrangement of learning environments, both physical and social, conducive to enjoyable discovery; and (c) the design of novel artifacts whose purpose is to encourage and reward sustained periods of exploration and discovery.

Many provocative recent examples of research in this last direction may be found in the development of new technologies for education. The advent of numerous computer 'microworlds' (Papert 1980), in which simulations or experimentation can take place under conditions difficult to achieve in the 'real' world of objects, is one notable development in the past two decades. More recent developments in the integration of physical and computational elements to produce (for example) new types of 'digital manipulatives' (Resnick et al. 1998, Eisenberg and Eisenberg 1999) suggest new and uncharted vistas for creating 'discovery-friendly environments.' Such environments, to be pedagogically successful, will need to be designed with an eye both toward cognitive research in students' scientific understanding, and toward supportive social structures (e.g., for adult mentoring, for apprenticeship, for collaboration). Nonetheless, despite the practical obstacles, there is still life in the centuries-old dream of learning via discovery.

Discovery: Legal Aspects

Discovery is the legal process for compelling production of information relevant to disputed factual issues in litigation. While discovery can take place in both civil and criminal cases, this article will focus on the civil side. This article briefly outlines the purposes of pretrial discovery. It then describes the basic regimes of pretrial civil discovery in the United States and England, the two leading common law jurisdictions, reviews some data on their performance, and contrasts their approach with analogous civil law institutions.

1. The Aims of Discovery

In common law systems, discovery is viewed as too complex and costly for small claims and ordinarily is unavailable in those settings. In larger cases, discovery normally occurs after the parties have filed their initial pleadings, which make clear the general character of the dispute and, in some cases, the main points of contention. If a claim or defense is legally invalid on its face, the court can resolve the dispute at that point. But if the dispute concerns an issue of fact, the pleadings will not suffice. The ultimate test of disputed facts is a trial, but trials are expensive both for the parties and for the legal system.

Discovery can improve the handling of factual disputes by making each party disclose, before trial, the evidence it plans to offer. Such disclosures can make trial more efficient by clarifying disputed issues, permitting the parties to edit out irrelevant or redundant evidence, and reducing unfair surprise and consequent mistrials or adjournments.

Discovery can also make trials more accurate by compelling production of information that otherwise would not be presented because it is harmful or embarrassing to the person who controls it. Greater accuracy might appear noncontroversial, since it benefits right-doers and harms wrong-doers. But if a class of plaintiffs or defendants tend to control a disproportionate share of relevant information, accuracy-promoting discovery may enable new types of claims and defenses that otherwise would fail outright. For example, although price fixing schemes are unlawful, it may be difficult to prove their existence without compelled discovery of defendants' business records (James et al. 1992, p. 236).

Discovery may also improve the quality of public and private decisions about whether there should be a trial. It may demonstrate that a factual contention is doomed to fail at trial and can be dismissed summarily. The additional information disclosed (and the costs of disclosure) may also influence the likelihood and terms of settlement.

2. The Law of Discovery

The United States and England differ in their approach to pretrial discovery. For ease of exposition, the discussion of American law is based exclusively on the Federal Rules of Civil Procedure, which apply only in federal trial courts but have heavily influenced state court practice. The discussion of English law is based exclusively on the Civil Procedure Rules and Practice Directions, which apply in the High Court and county courts.

2.1 Scope and Limitations

A discovery system which aimed only at preventing surprise could limit its scope to evidence that the

parties intend to present at trial. For example, with respect to testimonial evidence, English law requires only that parties prepare and submit statements for each witness whom they intend to call at trial summarizing the proposed testimony. (Civil Procedure Rules, Part 32.4). A system that aims for improved accuracy needs a broader principle. England adopts such a principle for documentary evidence, setting the scope of discovery as materials 'relating to the matters in question in the action,' which are then defined in terms of their tendency to prove or disprove the claim of any party. (Civil Procedure Rules, Part 31.6.) American discovery extends even further. It reaches 'any matter … relevant to the claim or defense of any party.' But unlike English law, the information sought need not have probative weight, provided it 'appears reasonably calculated to lead to the discovery of admissible evidence' (Federal Rules of Civil Procedure 26 (b) (1)). Thus, under American law, discovery can be used to identify and pursue investigative leads. In England and all other common law jurisdictions, such discovery is rejected as an improper 'fishing expedition' (Jolowicz 2000, pp. 41–5).

Under both English and American law, some relevant information is shielded from discovery. Information within a recognized evidentiary privilege (such as the attorney–client privilege) is immune. Both systems recognize a complete or qualified privilege for materials prepared by attorneys and others in anticipation of litigation. Finally, each system has recently adopted a principle holding roughly that the scope and costs of discovery should be in proportion to the value of the information to be produced. Concerns about commercial confidentiality and invasion of privacy, though frequently raised, rarely operate as a complete bar to otherwise proper disclosure. Instead they are addressed through restrictions on access to and use of the information disclosed.

2.2 *Mechanisms for Obtaining Discovery*

The only significant form of discovery in English law is disclosure of documents. In cases valued at more than £5,000, each party is routinely ordered to provide a list of all relevant documents in its possession, custody, or control. The party must then produce listed documents on request unless the document is privileged or the burden of producing it would be disproportionate. A party may also file a request with the court for additional document discovery either from another party or from a nonparty. The party seeking discovery must specify the documents sought, demonstrate that they are relevant, and show how their discovery will advance the case. Discovery with respect to witnesses is ordinarily limited to the provision of the summaries of testimony noted above. The deposition, an interview of a witness, taken under oath and stenographically recorded, is not available for discovery, but only to preserve the testimony of a witness who cannot attend trial (Civil Procedure Rules, Part 34).

In United States courts, the obligation to make discovery was traditionally contingent upon receipt of a proper demand. But recent amendments oblige each party to provide certain information without request at the outset of the action. A party must identify each person likely to have 'discoverable information that the disclosing party may use to support its claims or defenses.' They must also provide copies or descriptions of documents and other tangible things in its possession, custody, or control that it may use for that purpose. Prior to trial parties must identify trial witnesses and exhibits (Federal Rule of Civil Procedure 26 (a)).

Discovery beyond the initial disclosures can be pursued through multiple devices. Broadly framed document demands and depositions both may be used, without leave of court, to seek any information falling within the scope of discovery against any party. Even more striking, if the document or deposition discovery is properly joined with a subpoena (which is also available without leave of court), these devices may be used against any nonparty as well. Other discovery devices, including interrogatories, court-ordered physical examinations, and requests for admission, are available only against parties. The most important in practice are interrogatories, written questions which must be answered in writing and under oath. Because the response must include all information available through reasonable investigation, preparing an answer may involve significant data gathering activities.

2.3 *Costs*

The costs involved in discovery include lawyers' fees, the time of the responding parties and witnesses, and intangible costs from invasions of privacy and the frictions of adversary litigation. On the public side, costs include judicial time spent in supervising discovery. For out-of-pocket costs such as attorneys' fees, both the English and American systems have generally followed the standard cost allocation rules applicable for civil litigation. In England that involves awarding the winner's reasonable costs of discovery against the loser. In America, costs are normally borne by the party who incurred them, with certain exceptions for costs that result from a party's improper use of, or improper opposition to, a discovery request.

2.4 *Sanctions and Judicial Supervision*

Discovery can fail in various ways. Deliberate withholding of properly requested information and inten-

tional use of discovery to inflict financial or emotional harm are illegal. But separating intentional misconduct from the assertion of legitimate legal rights is difficult. There are often nonfrivolous legal justifications for discovery conduct that deprives the tribunal of critical information or imposes costs on an opponent, and taking incidental advantage of an opponent's lack of perspicacity or resources is a well-accepted feature of adversarial ethics. The resulting strategic interaction may lead to underproduction of information or to an escalating cycle of demands, resistance, and disputes (Brazil 1979). The scope of American discovery has made these issues urgent in the United States.

For much of its modern history, discovery has been largely party initiated and controlled. The judge was to be involved only in the event of a dispute concerning the propriety of a request or the adequacy of a response. Compliance was to be assured by the professionalism of the lawyers involved and the threat of judicial sanctions. Available sanctions included monetary penalties, contempt, orders deeming certain matters to have been established against the offending party, and default judgments.

Many American lawyers and judges have come to believe that this essentially reactive enforcement model allows too much abuse and waste. Changes in the legal profession have reduced the potential for easy cooperation between counsel (Gilson and Mnookin 1994). Judges feel they have more important work than to master the details of discovery disputes. Sanctions are an imperfect tool, not draconian enough to eliminate temptations to withhold critical evidence in high stakes cases, but too cumbersome to address the routine tactical jostling that characterizes much discovery.

These concerns have led to reforms designed to cut back on the scope of discovery and to increase judicial control over its initiation. In both England and the United States, reforms have narrowed discovery's scope, placed renewed emphasis on the concept of proportionality between benefits and costs, and, in England, eliminated some types of discovery altogether. In both countries, the occasions on which advance judicial approval must be sought have been broadened. Finally, in both countries there is an increased emphasis on proactive judicial supervision and participation in the discovery planning process (Marcus 1999, Wolff 1998, Jolowicz 2000).

3. *Effectiveness of Discovery*

For many years there was a widespread view, based largely on anecdotal accounts, that American-style discovery generally tends to be unduly costly in proportion to its social benefits. Repeated empirical studies have demonstrated that this view is at best overly simple (Willging et al. 1998, Kakalik et al. 1998, McKenna and Wiggins 1998). Those studies show that even in the categories of civil litigation where discovery is available and in common use, a substantial minority, approaching 40 percent, of filed cases are resolved without any formal discovery, typically through abandonment or settlement. In cases where formal discovery occurs, it typically involves only a few discovery events and moderate costs (measured primarily in terms of lawyer time expended). Finally, in a small percentage of cases, typically involving greater factual complexity and higher stakes, there are more discovery events and much higher discovery costs. Even in this class of cases, costs remain roughly proportional to the amount in controversy. Lawyers believe that in most cases the discovery process works tolerably well, generating about the right amount of information given the needs of the case and at a level of expenditure that is about right in relation to the stakes (Willging et al. 1998, pp. 550–2).

Within this overall pattern, however, there are more or less severe problems of withholding, delay, or waste in a substantial proportion of cases where formal discovery occurs. By some estimates, nearly 20 percent of discovery costs are attributable to such problems (Willging et al. 1998). Some evidence suggests that problems are disproportionately encountered in high stakes, complex, and contentious litigation (Brazil 1980a, 1980b). But others argue that the higher incidence of reported problems in such cases may reflect the larger number of discovery events and the higher proportion of litigation expenditures devoted to discovery, rather than any underlying pathology (Willging et al. 1998). Attempts to moderate the costs of discovery in such cases through judicial management have thus far met with very limited success (Kakalik et al. 1998).

While these studies show that broad discovery is not clearly a failure, they do not demonstrate its success, for several reasons. First, their focus on lawyer time as the measure of cost leaves out costs to clients, nonparty witnesses, and the court system itself. Second, the focus on formal discovery overstates some marginal effects of the discovery rules and omits others. Some information exchanged in formal discovery would be shared voluntarily even if there were no discovery rules, simply to persuade the opponent to abandon its claim or settle (Hay 1994). Neither the production of this information nor the costs of producing it are due to the discovery rules. On the omission side, the studies ignore effects that *prospective* application of the discovery rules may have on filed and unfiled claims resolved without formal discovery but 'in the shadow' of those rules.

Third, current studies say little about how the marginal effects of discovery rules actually influence litigation outcomes and behavior. Are outcomes more accurate? Or are they less accurate, for example because the prospective costs of discovery discourage prosecution or defense of some claims? (Brazil 1980a,

at 225). What is discovery's impact on the likelihood of settlement and how does it generate that impact? On this issue, the theoretical literature suggests several possibilities (Cooter and Rubinfeld 1994, Hay 1994), but the empirical literature is silent.

Finally, the studies do not explore discovery's impact on real world conduct. The benefits of more accurate adjudication may differ dramatically for different types of cases, and they may be very imperfectly correlated with the practicing lawyer's conventional measures of a dispute's importance, such as the amount in controversy (Hay 1994, Kaplow 1994, Bundy 1994).

4. *Comparison to Civil Law Approaches*

Civil law jurisdictions have much less discovery. The German system is a helpful example, since it is not atypical and has heavily influenced other systems, including Japan, Korea, and Brazil. In the German system, a judge or panel of judges acts as the trier of fact. Party requests for information occur during what amounts to an ongoing hearing and are directed, not to the opposing party, but to the trial judge (Langbein 1985).

German hearings proceed primarily on the basis of the witnesses and documents identified in the parties' preliminary submissions, which generally do not identify much information harmful to a party's case. A party can ask the judge to require the production of additional evidence only within limited categories. A party is entitled to all documents referred to in the opposing party's submissions and to documents to which he has a right of access under the substantive law (typically because of a contract or fiduciary relationship between the parties) (Gerber 1986). Even within these categories, the party must make a stronger demonstration of relevance than in American law: the information must be reasonably likely to influence the court's determination of a disputed factual issue and described with reasonable particularity. Beyond these categories of information, there is no discovery.

Differences in discovery regimes have produced significant conflict between the United States and foreign states with more restrictive discovery practices. Most of the issues have arisen from efforts to take extensive American-style discovery from defendants who are located in civil law jurisdictions. Some of these issues are now the subject of international agreements, such as the Hague Convention on the Taking of Evidence (Hazard 1998).

Differences between common law and civil law discovery reflect contrasting arrangements for trial, conceptions of adjudication, and commitments to party control of litigation. The common law's concern for preventing surprise is not matched in civil law systems, whose professional triers of fact exercise greater control over the presentation of evidence, are less likely to be influenced by surprise, and can more readily adjourn to permit rebuttal evidence (Langbein 1985). American discovery came of age when civil litigation was increasingly seen as a law enforcement device, in which 'private attorneys general' play an important role (Scott 1975). Conversely, civil law's 'relative indifference to the completeness of the evidentiary material submitted to the court' (Damaska 1997, p. 114) sees adjudication more as resolving disputes on the parties' terms. Finally, in America, party initiation and control of discovery at least initially sidestepped the steep administrative and political costs of an intrusive judge-directed inquiry into private conduct. In civil law systems, the expectation that expanded discovery would be channeled through overworked career judges—while consistent with civil law traditions—certainly makes it unattractive on both administrative and political grounds.

Discrete Mathematics

Some of the most important problems of the social and behavioral sciences are concerned with arrangements, designs, patterns, sequences, schedules, and assignments. These are among the fundamental notions dealt with by discrete mathematics (dm). This article describes some of the tools of dm—digraphs, graphs, signed and marked graphs, partial orders, rankings, combinatorics—and their applications.

1. *What is Discrete Mathematics?*

John Kemeny made the following distinction. Many problems of science deal with quantities so large that it is natural to assume that they are dense, continuously distributed, and that all real numbers can be used to measure them. Centuries of development of 'continuous mathematics' have given us extremely powerful tools for handling these kinds of problems. Other problems are so small that we can deal with all the possible cases by hand. These are truly 'finite' problems. Some of the most important problems, however, fall in between: not big enough to assume density, continuity, etc., but not small enough to allow us to consider all cases. These are, for the most part, the problems with which discrete mathematics (DM) deals. Because increasingly powerful computers are allowing us to replace computations by hand, it is becoming increasingly feasible to deal with problems of DM. This explains, in part, why DM has become perhaps the fastest growing field of modern mathematics.

Many of the basic problems of the physical sciences, dealing with time, mass, velocity, etc., are of the first kind. So are many problems in the biological sciences. However, many problems of the social and behavioral sciences fall in the middle ground described by Kemeny. The tools of DM are especially relevant here. For an elementary introduction to DM, see Kolman et al. (1999) and Roberts (1984).

2. *Digraphs*

A *digraph* is a pair (V, A) where V is a set called the set of *vertices* and A is a set of ordered pairs from V called the set of *arcs*. *Throughout, we shall assume that V is a finite set*. Usually, arcs (x, x), known as *loops*, are not permitted or disregarded, and we shall disregard them. Typically, we represent a digraph geometrically by letting the vertices be points and including a directed line from x to y if (x, y) is in A. The arcs in a digraph are used in social and behavioral science models to represent relations among the vertices. Thus, $(x, y) \in A$ can mean that x is preferred to y, x is louder than y, x influences y, etc.

Suppose (V, A) is a digraph with arcs representing 'preferred to.' Then an *ordinal utility function* can be thought of as a function f that assigns a real number $f(x)$ to each x in V so that for all $x, y \in V$,

$$(x, y) \in A \leftrightarrow f(x) > f(y). \tag{1}$$

Similarly, if arcs represent 'louder than,' then a function satisfying Eqn. (1) might measure loudness. If a function satisfying Eqn. (1) exists, then the digraph is *asymmetric* in the sense that if there is an arc from x to y, then there is no arc from y to x, and *transitive* in the sense that if there are arcs from x to y and y to z, then there is an arc from x to z. It is also *negatively transitive* in the sense that if there is no arc from x to y and no arc from y to z, then there is no arc from x to z. It turns out that asymmetry and negative transitivity of the digraph are together sufficient for the existence of a function satisfying Eqn. 1 (see Roberts 1976). An asymmetric, negatively transitive digraph is called a *strict weak order*.

Digraphs provide precise mathematical language for expressing concepts in the social and behavioral sciences. For instance, let us say that vertex y is *reachable* from vertex x if there is a sequence of vertices $x_1, x_2, \ldots, x_t$ so that

$$(x, x_1), (x_1, x_2), \ldots, (x_{t-1}, x_t), (x_t, y)$$

are arcs. The notion of reachability is important in sociology in the study of *communication networks*. If an arc in the digraph means that x can communicate directly with y (not necessarily a *symmetric* relationship in the sense that $(x, y) \in A \rightarrow (y, x) \in A$), then

reachability means that it is possible for x to initiate a message to y. There is then interest in minimum-size sets of vertices that can reach all others (so-called *vertex bases*). In large digraphs, it is often very important to represent them geometrically in such a way that their structural properties become clear. We might wish to find another digraph on the same vertex set with the same reachability properties and a minimum number of arcs. This idea arises in the area of data analysis called *interpretive structural modeling* (see Warfield 1976). The drawing of digraphs so as to visualize the information they contain in useful ways has become a major research field known as *graph drawing*.

Understanding the structure of communication networks is aided by considering *strong components*, maximal sets of vertices each two of which are reachable from each other. Many large social networks have some huge strong components. This is the case in *telephone call digraphs* where the vertices are telephone numbers and arcs correspond to calls between them, and in *scientific collaboration digraphs* where an arc means that x collaborates with y (a symmetric relationship). Similar results are being found for pages on the World Wide Web, with arcs corresponding to references from one page to another, and the results seem to suggest that totally new models are needed to explain how large social networks are formed. (For a basic introduction to such digraph concepts as reachability, vertex basis, strong component, etc., see Harary et al. 1965 and Roberts 1976. For more on social networks, see Degenne and Forse 1999.)

3. Partial Orders

If (V, A) is a digraph, its *symmetric complement* is the digraph (V, B) where

$$(x, y) \in [B \leftrightarrow (x, y) \notin A \quad \& \quad (y, x) \notin A]$$

If there is an f satisfying Eqn. (1), then the digraph (V, B) is transitive. If A corresponds to preference, then B corresponds to indifference. Arguments against the transitivity of indifference were made by the economist Armstrong in the 1930s and even earlier by Karl Menger in the nineteenth century. Similarly, in *psychophysics*, if A corresponds to 'louder than,' then B corresponds to 'equally loud' and this might not be transitive. Arguments against transitivity of B often involve *thresholds*: x and y might be within threshold and so sound equally loud, y and z might be within threshold and so sound equally loud, but x and z might not be within threshold.

This kind of argument led Luce in 1956 to introduce a different model for utility of loudness judgments:

$$(x, y) \in A \leftrightarrow f(x) > f(y) + \delta \tag{2}$$

where δ is a fixed positive constant measuring threshold or *just noticeable difference*. Luce and also Scott (1958) and Suppes gave necessary and sufficient conditions for a digraph to have a function f satisfying Eqn. (2), conditions defining a *semiorder*. Semiorders are transitive digraphs. They are also very important examples of a second fundamental concept of DM, a partial order, an asymmetric, transitive digraph. (Sometimes this is called a *strict partial order* and the term *partial order* is reserved for the digraphs that are transitive, *reflexive* $[(x, x) \in A$ for all $x]$, and *antisymmetric* $[(x, y) \in A \ \& \ (y, x) \in A \leftrightarrow x = y]$.) Partial orders arise in numerous applications in the social and behavioral sciences (see *Partial Orders*).

If f satisfies Eqn. (2), then consider the real interval $J(x) = [f(x) - \delta/2, f(x) + \delta/2]$. Suppose that when J and J' are two real intervals, $J \succ J'$ means that every point of J is to the right of every point of J'. Then Eqn. (2) can be rewritten as

$$(x, y) \in A \leftrightarrow J(x) \succ J'(y) \tag{3}$$

We can think of $J(x)$ as a range of fuzziness about $f(x)$. If these intervals have different lengths, then the digraphs defined by Eqn. (3) are called *interval orders*, another important class of partial orders. The term interval order is due to Fishburn in 1970, but the concept was anticipated by Norbert Wiener in 1914. For more about semiorders, interval orders, and a variety of partial orders, see Fishburn 1985 and Trotter 1992.

4. Graphs

If a digraph (V, A) is symmetric, we call it a *graph*. Replacing each pair of arcs (x, y) and (y, x) by an unordered pair $\{x, y\}$, we can think of a graph as a pair (V, E) where E is a set of unordered pairs from V. Elements of E are called *edges*. Geometrically, the vertices are represented as points and if $\{x, y\} \in E$, then we connect x and y by an undirected line. The symmetric complement of a digraph, of course, is a graph. The symmetric complement of a semiorder is called an *indifference graph* or a *unit interval graph*. The name comes from the case where A corresponds to preference. The symmetric complement of an interval order is called an *interval graph*. Interval graphs have a huge number of applications in archaeological seriation, developmental psychology, ecology, molecular biology, data retrieval, scheduling, etc. (see Roberts 1976).

Indifference graphs and interval graphs are special cases of *intersection graphs*, graphs whose vertices correspond to sets and which have an edge between two vertices if and only if the corresponding sets have a nonempty intersection. There are many important open research questions concerning intersection graphs. For example, characterizing intersection graphs where the sets are unit squares in the plane, a long-standing open problem, is relevant to judgments of indifference when there are two dimensions to the alternatives being compared.

Social networks are often graphs since the underlying relation defining the arcs is often symmetric. In this case, the strong components are simply called *components*. The components often consist of sets of vertices each two of which are joined by an edge. Such a set of vertices is called a *clique*; if an edge between x and y means that they are friends, then a clique is a set of individuals each two of which are friends. Surprisingly enough, it is computationally difficult to find the largest clique in a graph.

If (V, E) is a graph, its *complement* is the graph (V, F) where $\{x, y\} \in F \leftrightarrow \{x, y\} \notin E$. We often seek to partition the vertices of a social network into cliques. In the complement, this problem corresponds to partitioning the vertices into sets with no edges joining vertices within the same set. Such sets are called *independent sets*. The problem of partitioning the vertices of a graph into independent sets is equivalent to one of the most important problems in graph theory, the *graph coloring problem*. A *coloring* of a graph is a function f that assigns a color $f(x)$ to each vertex x so that $\{x, y\} \in E \rightarrow f(x) \neq f(y)$. The sets of vertices of a given color form independent sets. Graph coloring has many important applications. In a typical application, individuals who dislike each other must be assigned to different tasks or time schedules or groups. Disliking defines the edges while the colors correspond to the tasks, schedules, or groups. The theory of *role assignments* in sociology, sometimes known as the theory of *role colorings*, is closely related. While the subject of graph coloring is an old one, going back to the famous 'four color problem' of the nineteenth century, it is a very lively area of research today with important modern variations on graph colorings motivated by practical applications. An example is the *list coloring problem*, where a list of acceptable colors (tasks, time schedules, groups) is given at each vertex and the color assigned to a vertex must be chosen from its list (see Roberts 1984 for an introduction to graph coloring and Kratochvíl et al. 1999 for the list coloring problem).

5. Signed and Marked Graphs

In some applications of graph theory, it is useful to classify edges as + or –. We then speak of a *signed graph*. One of the most fascinating applications of signed graphs is as a model of *balance* in small group sociology. A group of people is called balanced if it works well together, lacks tension, etc. Cartwright and Harary (1956) and Harary (1954) made this concept precise as follows. Let the vertices of a graph be individuals in the group, an edge mean they have a strong relationship, and the sign distinguish between a positive relationship (such as likes, associates with, agrees with, stimulates) and a negative relationship (such as dislikes, avoids, disagrees with, inhibits). If (V, E) is a (signed) graph, a *circuit* or *cycle* is a sequence $x_1, x_2, \ldots, x_t$ of distinct vertices so that $t \geqslant 3$, $\{x_t, x_1)$ is in E and for $i = 1, \ldots, t-1$, $\{x_i, x_{i+1}\}$ is in E. There is a lot of evidence to show that a small group is balanced if and only if in the corresponding signed graph, every circuit has an even number of – signs. If the latter holds, we call the signed graph *balanced*. The same notion was introduced into the economics literature by Morishima in 1952. Characterization of balanced signed graphs was first given by a 'structure theorem' by Harary (1954). Later, Maybee and Maybee, Harary and Kabell, and Hansen gave linear time algorithms for determining whether a signed graph is balanced. Notions of balance theory have found applications in a variety of areas, including the study of 'social justice,' social inequalities, international relations, and the analysis of multiparty political systems. Since not all systems are totally balanced or totally unbalanced, ways to measure the degree of balance are important and remain a subject of research today (for an introduction to balance theory, see Taylor 1970 or Roberts 1976).

In some applications, it is useful to put signs on the vertices of a graph rather than on the arcs. Such *marked graphs* arise in the study of social networks, where we think of vertices as individuals who either tell the truth (+ sign) or lie (– sign), and where we trace messages through the network. Beineke and Harary called a marked graph *consistent* if every circuit has an even number of – signs, a concept analogous to balance in signed graphs. Surprisingly, it is mathematically very difficult to characterize consistent marked graphs. In spite of a lot of work on this subject, a complete understanding of what marked graphs are consistent remains elusive.

6. Rankings and Combinatorics

Strict weak orders, that is, asymmetric, negatively transitive digraphs, are sometimes called *rankings*. We can rank the vertices from top to bottom, with ties allowed. Rankings arise in the theory of voting, group consensus, and social welfare. There are situations where just knowing a voter's first choice candidate does not give us enough information to find an appropriate winning candidate. It can be useful to have each voter provide a ranking of the candidates. Then we need a rule that provides a winning ranking. If such a rule is defined for every possible combination of rankings, we call it a *group consensus function* or *social welfare function* (SWF).

The theory of SWFs goes back at least to the eighteenth century (in the work of Marie Jean Antoine Nicolas Caritat, Marquis de Condorcet, and of Jean-Charles de Borda), but had its modern impetus in the economic modeling of Kenneth Arrow. Arrow listed some reasonable axioms we might require of an SWF and showed that there was no function satisfying these axioms. *Arrow's Impossibility Theorem* has been modified, replicated, and applied in a myriad of ways since then. A few general references on group con-

sensus are Campbell 1992, Kelly 1988, and Roberts 1976, 1989.

Modern applications of SWFs and notions of group consensus put a great deal of emphasis on computational tractability of rules for determining the winning consensus. Bartholdi, Tovey, and Trick, Wakabayashi, and others showed that there are voting rules that are *computationally intractable*, that is, where it is extremely difficult to compute the winner of an election (see Roberts 1989). They also pointed out that sometimes computational intractability is useful, as when we wish to make it difficult to manipulate the outcome of an election such as by adding voters, declaring candidates ineligible, etc. Computational tractability becomes an issue when there are large numbers of voters or candidates. This is the case in applications of theories of group consensus to *metasearch* on the Internet, that is, combining the results of different search engines, and to such e-commerce applications as *collaborative filtering* where the rankings of different individuals among alternative movies, books, or restaurants are combined to produce an automated ranking as a recommendation to a given user of a system. Important open questions about SWFs arise in such applications, including issues of learning and adapting through repetition.

If a ranking does not allow ties, we sometimes talk about a *strict simple order* or a *permutation*. Strict simple orders are also important in applications such as models of power in voting situations. Suppose different 'players' (such as states in the US Electoral College or owners of shares in a company) have different numbers of votes. Imagine adding players to a 'coalition' one at a time until enough votes are obtained to 'win.' The player whose votes throw a coalition over from losing to winning is called *pivotal*. One measure of the 'power' of a player in such a situation is the probability that the player is pivotal if a coalition is formed at random. This is known as the *Shapley value*. There are a variety of other interesting power measures that, like this one, have come out of the theory of cooperative games (see Fudenberg and Tirole 1991 and Roberts 1976). The Shapley value can be calculated by counting the number of permutations of the players in which a given player is pivotal and then dividing by the number of permutations of the players. In large games, this becomes a computationally intractable problem. To solve it in special cases, one has to solve counting problems.

The *counting problem*, involving finding the number of permutations, combinations, and other mathematical objects, is a fundamental problem of the branch of DM known as *combinatorics*. The Shapley value has been calculated for various governmental bodies such as different legislatures, the UN Security Council, and the US Electoral College. Yet, new computational procedures for calculating it are very much required. This is especially important in light of the many uses of the Shapley value in cost allocation problems such as fairly sharing the cost of telephone systems, airports, libraries, and multicast transmissions of movies.

In conclusion, discrete mathematics is finding many new and unexpected applications in the social and behavioral sciences. At the same time, the social and behavioral sciences are one of the important stimuli for the development of this rapidly growing field of mathematics.

Discrete State Models of Information Processing

Around the middle of the twentieth century, experimental psychology shifted from a behavioristic to a cognitive perspective, where unobservable mental processes were allowed as theoretical explanations of behavioral data. A dominant type of theoretical explanation analyzed the mind analogously to a computer in the sense that it performs operations like inputting, storing, organizing, maintaining, comparing, and retrieving information. This approach came to be known as information processing (IP) psychology. At about the same time, formal probabilistic IP models were advanced in mathematical psychology in such areas as choice theory, concept identification, learning, memory, and signal detection (see Batchelder 2000, for a review). Many of these formal models fall into the category of discrete state information processing models, the subject of this article. Discrete state models of an IP task assume that manifest (observable) responses in the task are generated probabilistically from one of a finite, and usually small, set of latent (unobservable) cognitive states. The input stimulus of the IP task probabilistically triggers a sequence of one or more cognitive states, that in turn probabilistically generates the response output. In this article, the focus will be on parametric, discrete state models that yield *categorical data*, that is, observations that fall into a discrete set of nonoverlapping response categories.

1. Introduction

In the early history of IP modeling, most discrete state models were of two varieties, signal detection models and *Markov models* for learning tasks. Sections 2 and 3, respectively, will describe these two areas. Section 4 will describe the family of multinomial processing tree models (MPT) in some detail because the family has a well worked out statistical theory and it subsumes most discrete state models for categorical data, as well as the two earlier varieties. Suppose an experimental subject's response to a stimulus must fall into exactly one of a discrete system of categories, say $C_1, C_2, \ldots, C_J$. If there are M different stimulus conditions, then under repeatable and homogeneous conditions, there are theoretically M different observable probability distributions, $p_m = (p_{1m}, \ldots, p_{Jm})$, one for each stimulus condition, $1 \leqslant m \leqslant M$. This situation is typical of many IP tasks, for example, identification, categorization, and yes–no signal detection. In an identification task, there are J different stimuli, and the subject's task is to identify the presented stimulus. The data consist of a $J \times J$, row stochastic *confusion matrix*, whose ijth term is Pr $(R_j | S_i)$, the probability that stimulus i is identified as stimulus j, $1 \leqslant i, j \leqslant J$. In categorization, each stimulus belongs to a particular response category, however, unlike the identification task, several stimuli belong to the same category, so $M > J$. Yes–no signal detection is described in the next section. Many discrete models exist for these and other IP tasks.

2. Signal Detection Models

One of the earliest applications of discrete state models was the development of threshold models for the yes–no signal detection task. The task involves exposing observers to a series of items, some of which satisfy a task definition of 'signal items' (s_1) and the others are 'noise' (s_2) items. Examples include whether or not an acoustic event includes a particular sound signal in an auditory signal detection experiment, whether or not a tested item was on a previously studied list in a recognition memory experiment, or whether or not an x-ray exhibits a particular type of tumor in a medical diagnosis setting. The observer's task is to say 'yes' (r_1) to all items that satisfy the definition of signal, and otherwise say 'no' (r_2).

Discrete state models for the yes–no detection paradigm are characterized by the assumption that observers set detection thresholds. One example is the general high threshold model. The model is motivated by the assumption that the observer sets a threshold for detecting a signal item and another one for detecting a noise item. Both thresholds are set sufficiently high that the observer never detects the wrong type of item; however, if no detection occurs (neither threshold is reached), the observer must guess.

The model postulates three latent states, D_1, D_2 and D_0 for detect signal, detect noise, and detect neither, respectively. The parametric representation of the model is easy to present in terms of two matrices, one giving the probability that the stimulus triggers the various discrete states, and the second the probability distributions over the responses for each discrete state. The stimulus input matrix is given by

$$I(\theta) = \begin{bmatrix} 1-d_1 & d_1 & 0 \\ 1-d_2 & 0 & d_2 \end{bmatrix} \tag{1}$$

where the ijth term is $\Pr(D_j | s_i)$, i = 1, 2 and $j = 0, 1, 2$, and the response matrix is given by

$$R(\theta) = \begin{bmatrix} g & 1-g \\ 1 & 0 \\ 0 & 1 \end{bmatrix} \tag{2}$$

where the jkth term is $\Pr(r_k | D_j)$, $j = 0, 1, 2$ and $k = 1, 2$, and where $\theta = (d_1, d_2, g)$ is the parameter vector with parameter space $\Omega = [0, 1]^3$.

Equation (2) gives the three probability distributions over the two response categories, r_1 and r_2, and the output distributions for each item type are easily computed by matrix multiplication as follows:

$$M(\theta) = I(\theta) \cdot R(\theta) = \begin{bmatrix} d_1 + (1-d_1)g & (1-d_1)(1-g) \\ (1-d_2)g & d_2 + (1-d_2)(1-g) \end{bmatrix} \quad (3)$$

Note that Eqn. (3) is in the form of a 2×2 row stochastic matrix, with two degrees of freedom. However, there are three parameters so the model is not useful in analyzing data without further restrictions. For example, if $d_1 = d_2$, the model is known as the double high threshold model, and if $d_2 = 0$, the single high threshold model results. Both models are discussed in Macmillan and Creelman (1991).

Most theorists in perception and memory have rejected these two models because they fail to account for the shape of experimental *receiver operator characteristics* (ROC), sometimes called relative operating characteristics, e.g., Swets (1996). The data for an ROC come from a set of experimental conditions wherein the detection processes are held constant and the response bias processes are allowed to vary. The ROC then becomes a plot of the hit rate, $H = \Pr(r_1 | s_1)$, as a function of the false alarm rate, $F = \Pr(r_1 | s_2)$, where each experimental condition x yields a pair $(F(x), H(x))$. Such plots are obtained experimentally in a variety of ways (see *Signal Detection Theory*).

The general high threshold model implies a linear ROC given by

$$H(x) = d_1 + \left(\frac{1-d_1}{1-d_2} \right) F(x) \quad (4)$$

where x indexes conditions leading to variations in g but not in d_1 and d_2. Experimental evidence is strongly against a linear ROC, and therefore most theorists have abandoned simple high threshold models. Nevertheless, measures of detection, such as $H-F$, consistent with the double high threshold model, are frequently seen both in empirical papers in recognition memory and as a 'correction-for-guessing' formula in psychometric models.

Discrete state models that are based on 'low thresholds' that allow an observer to detect a signal when none is present have had more appeal to theorists. One example is Luce's (1963) low-threshold theory. The theory is difficult to reject from ROC data, unless conditions lead to extreme values of the false alarm rate. There are other, more complex discrete state models in the signal detection area. One example is the *neural quantal model* (e.g., Larkin and Norman 1964). Also, Graham et al. (1987) discuss both continuous and discrete state models for multidimensional stimuli. Finally, Batchelder and Riefer (1990) develop a family of models for the so-called source monitoring paradigm, where signals come from several sources or are of several types.

3. Markov Learning Models

Markov learning models (ML) are a variety of discrete state IP models for learning and memory tasks which were especially popular in the 1960s and 1970s (see *Mathematical Learning Theory, History of*). A typical task requires a learner to acquire simple associations that involve an experimenter assigned correct response pairing to each of a set of stimulus items over a series of discrete learning trials. On each trial, learners receive a series of study events in each of which they are informed of a correct stimulus-response pairing and a series of test events in each of which they are given a stimulus item and required to produce the correct response. The task is continued for a number of learning trials until some performance criteria are met. Typically, the responses for each item are scored as errors (E) or correct responses (C), so the response categories for an item are defined in terms of the possible observable sequences of Es and Cs over trials.

Markov learning models are characterized by several assumptions. First, it is assumed that on each test trial, an item is in one of a (small) finite set of latent cognitive states, each characterizing a possible state of the to-be-learned item–response pair, e.g., an unlearned state, a short-term memory state, a long-term memory state. Second, it is assumed that associated with each state is a probability of a correct response, where this probability is constant over trials. On any trial, the item is assumed to be in exactly one of the latent states and the response is governed by the state's response probability. Third, it is assumed that the effect of study trials is to generate transitions among the learning states described dynamically by a finite state, homogeneous Markov chain. The states of the chain are the cognitive states, and the starting distribution over the states, as well as the state-to-state transition probabilities and the state-to-response probabilities, are each functions of a parameter vector, $\theta = (\theta_1, \ldots, \theta_s)$ where each component parameter taps some latent cognitive process. Technically, most ML models in the literature can be viewed as discrete trial, discrete state hidden Markov chains (e.g., Smyth 1999). The statistical inference for an ML model involves estimating the parameter vector θ from observed frequency counts over the response sequence categories. The mathematical and statistical details are presented in Wickens (1982).

Many examples of Markov learning models are reviewed in Greeno and Bjork (1973). However, Markov learning models ceased to be of major theoretical importance in learning and memory some-

time in the late 1970s, when a variety of more elaborate and detailed IP models of learning began to be introduced such as *connectionist* models (see *Connectionist Models of Concept Learning*; *Artificial Intelligence: Connectionist and Symbolic Approaches*) and global memory models (see *Memory Models: Quantitative*). Nevertheless, ML models have continued to serve as psychometric models for psychological measurement. For example, they have been applied to early development and to aging, where standardized paradigms provide learning sequences for different age groups that can be used to estimate age-related trends in latent storage and retrieval processes (reviewed in Batchelder and Riefer 1990).

4. Multinomial Processing Tree Models

Multinomial processing tree models constitute a large family of discrete state IP models for categorical data. The MPT family was developed and formalized, including its statistical inference, in Riefer and Batchelder (1988) and Hu and Batchelder (1994). Informally, the assumption is that each stimulus presentation triggers one of a number of processing sequences, each of which, in turn, terminates in an observable category. There may be more than one processing sequence that results in a particular category, so knowledge of the response category does not necessarily reveal the underlying processing sequence. Most current and past discrete state IP models, including signal detection and Markov learning models, can be parameterized to fit into a subclass of MPT models called binary MPT models, so that subclass is presented next in detail.

4.1 Definition

There are four aspects to a binary MPT model: observable categories; latent parameters; tree architecture; and computational rules. The first aspect consists of J observable categories, $C_1, C_2, \ldots, C_J$. Second, there are S functionally independent parameters, $\theta_1, \theta_2, \ldots \theta_S$, each with full range, $0 \leqslant \theta_s \leqslant 1$. Each parameter is interpreted as the probability of some latent IP event, e.g., storing an item, retrieving an item, matching an item, clustering items, making an inference, detecting a signal, discriminating between items, or guessing a response.

The tree architecture is a binary tree with a single initial node, intermediate nodes, and terminal nodes. There are two types of continuations after each nonterminal node: parametric probability links and numerical links. Each parametric probability link is associated with a particular parameter θ_s, and the two directed links from the node correspond to the success (θ_s) or failure ($1-\theta_s$) of the corresponding latent event. The numerical links are constructed similarly with a numerical probability instead of a parameter. Finally, each terminal node corresponds to one of the J categories.

The computational component of any MPT model provides the probabilities of each observable category in terms of the parameters. First, each branch in the tree is a sequence of links from the initial node into one of the categories. Branch probabilities are computed as products of link probabilities and have a special form as follows:

$$\Pr(Branch\ k) = c_k \prod_{s=1}^{S} \theta_s^{a_{ks}} (1-\theta_s)^{b_{ks}} \tag{5}$$

where c_k is the product of numerical constants on the links of branch k and a_{ks} and b_{ks} are the number of links on branch k with parameters θ_s and $(1-\theta_s)$, respectively.

Since each branch ends in a particular category, category probabilities p_j are sums of suitable branch probabilities:

$$p_j = p_j(\theta_1, \ldots, \theta_s) = \sum_{k=1}^{I_j} \Pr(Branch\ k \text{ ending in } C_j) \tag{6}$$

where I_j is the number of branches ending in category C_j. Given this structure, it is easy to show that $0 \leqslant p_j \leqslant 1$, and

$$\sum_{j=1}^{J} p_j(\theta_1, \ldots, \theta_S) = 1$$

for all $0 \leqslant \theta_s \leqslant 1, s = 1, 2, \ldots, S$. It is a consequence of the computational rules of an MPT model that if the category counts, $N_1, N_2, \ldots, N_J$, are obtained as independent and identically distributed cases, then the MPT model becomes a specially parameterized multinomial model with probability distribution

$$\Pr(N_j, \ldots, N_J) = N! \prod_{j=1}^{J} \frac{[p_j(\theta_1, \ldots, \theta_S)]^{N_j}}{N_j!} \tag{7}$$

where $N = \Sigma N_j$.

Figure 1 provides an example of an MPT model which is a representation of the general high threshold model in Eqns. (1)–(3). In the representation, there are six branches, $J = 4$ response categories, and $S = 3$ parameters. Psychological paradigms yielding categorical data usually involve more than one system of categories, wherein each category system reflects a type of item. For example, for the general high threshold model, there are two category systems, one for signal items and one for noise items. One of the purposes of the constant links in the earlier definition of MPT models is to combine separate MPT models into a single model.

Figure 1
A binary MPT representation of the general high threshold model. The quantity c represents the proportion of signal items, d_1, d_2, and g are the parameters of the model, and r_{ij} is the category of response type j to item type i (1 for signal and 2 for noise)

4.2 Statistical Inference

Hu and Batchelder (1994) provide methods for statistical inference for the entire class of globally identifiable MPT models based on the *Expectation–Maximization algorithm* (EM) (Demster et al. 1977). Global identifiability means that at most one parameter vector generates any particular probability distribution over the J categories. Thus, in principle, knowledge of the category probabilities uniquely determines the ('best fitting') underlying parameter vector θ.

The key to the application of the EM algorithm is to treat the branch frequencies as 'missing data.' Let N_{jk} be the frequency out of N counts of the occurrence of branch k terminating in category j, where $1 \leqslant k \leqslant I_j$, $1 \leqslant j \leqslant J$ and I_j is the number of branches ending in category C_j. Suppose the N_{jk} are known, then it is easy to see that the *maximum likelihood estimators* (MLEs) of the θ_s are given by

$$\hat{\theta}_s = \frac{\sum_{j=1}^{J}\sum_{k=1}^{I_j} a_{jks} N_{jk}}{\sum_{j=1}^{J}\sum_{k=1}^{I_j} (a_{jks}+b_{jks}) N_{jk}} \tag{8}$$

where the a_{jks} and b_{jks} are defined as in Eqn. (5). Thus, the maximization step of the EM algorithm yields a simple closed form expression.

There is a software package described in Hu and Phillips (1999) that enables a researcher to design an MPT model graphically, load in a data file of category frequencies, and obtain point estimates, confidence intervals, goodness-of-fit measures, do hypothesis testing within and between groups, and run Monte Carlo simulation with and without beta distributed hyperparameters.

4.3 Application Areas

It is obvious that the class of possible binary MPT models is large and that most members are uninteresting and devoid of scientific meaning. However, it is a framework where a researcher can construct and experimentally validate interpretable discrete state models. By the end of the twentieth century, many researchers have used models in the MPT class to understand data in specific cognitive paradigms (reviewed in Batchelder and Riefer 1990). They include applications to many areas of human memory including proactive and retroactive inference, associative recall, short-term memory, recognition failure, cued-then-free recall, clustering in free recall, the bizarreness effect, source monitoring, recognition memory, process dissociation, eyewitness memory, and hindsight bias. Outside of the area of human memory, there are applications of MPT models in other areas including object perception, speech perception, letter identification, propositional reasoning, interjudge reliability, social perception, social networks, and ability testing. In addition, MPT models have been developed for anthropological methodology, under the rubric cultural consensus theory (see Romney and Batchelder 1999), and for the area of clinical assessment, for example, Batchelder (1998).

The family of MPT models stands in contrast to most nondiscrete state IP models in that the latter assume much more complex cognitive architecture, more elaborate underlying processes, and in particular, continuous type variables that determine the output. In fact, many theorists view discrete state models as theoretically impoverished. Indeed, this view is common in the signal detection literature, e.g., Macmillan and Creelman (1991), as well as in other areas of cognition, e.g., Mulder et al. (1995). However, it may not be possible to rule out discrete state models on empirical grounds, e.g., Summers and Suppes (1997) or from a computational perspective, e.g., Pylyshyn (1986). In practice, however, MPT models have been most useful as simple, approximate models to measure underlying cognitive processes in particular experimental paradigms rather than providing a deep understanding of cognitive processes across a wide range of phenomena. In this sense, they provide psychometric tools for cognitive psychology.

W. H. Batchelder

Discrimination

The Oxford Dictionary defines discrimination as 'the perceiving, noting, or making a distinction or difference between things.' As modified by descriptors such as 'invidious,' the term 'discrimination' refers to the making of distinctions that ought not to be made. When the distinction is inappropriate because it distinguishes among individuals, entities, or practices that are *legally* entitled to equal treatment, 'discrimination' takes on its legal meaning.

Contemporary antidiscrimination law is predominantly (or at least most controversially) concerned with distinctions drawn (or, in some cases, inappropriately *not* drawn) on the basis of socially defined personal attributes that have been and remain the bases for adverse treatment (such as religion, race, gender, national origin, and disability). The legal concept of discrimination is not limited in its historical origins to group-based distinctions of this sort. As a concept in American constitutional rhetoric and law, the term also designates protectionist distinctions between states and countries engaged in interstate and foreign commerce. For purposes of this article, however, our focus shall be on 'discrimination' of the inter-group sort, in part because it is that form of discrimination that has most interested the social scientific community.

The development of any nation's antidiscrimination law is deeply dependent upon its own history and culture. In the field of race and ethnicity, the need for legal redress for race discrimination arises out of variable histories of immigration and its selective suppression, slavery and indentured labor, colonialism, and genocide. Social movements calling for legal and social change are culturally specific as well, although influenced by past experiences elsewhere in the world. Movements to identify and redress gender discrimination are also shaped by local settings. This is true not merely because the degree to which gender takes center stage depends in part upon whether and how the stage must be shared with the issue of race, but also because the variable social situation of women has much to do with how women will conceptualize their own equality and the spheres of activity in which they will press their legal claims. This essay will focus on efforts by the United States at the federal level, but will conclude with a discussion of leading issues from several other countries.

1. *Federal Antidiscrimination Law in the United States*

Federal antidiscrimination efforts reach a wide array of social and legal arenas. Some of the most important of these are education, employment, voting, public and private housing, public accommodations (e.g., transportation), bank lending, government contracting, marriage and parenting, and the administration of criminal justice.

In light of the American history of slavery, civil war, failed post-civil-war reconstruction of the South, and the mid twentieth-century civil rights movement aimed

at ending the pervasive segregation of African-Americans, race has been the most frequent starting point for American antidiscrimination law. The Fourteenth Amendment of the Constitution of the United States, itself a product of the Civil War experience, contains an Equal Protection Clause that serves as the primary source of federal constitutional antidiscrimination doctrine. Federal equal protection analysis generally assigns different 'levels of scrutiny' to different types of discriminatory classifications. For example, race discrimination is subject to 'strict scrutiny'; gender discrimination to 'intermediate scrutiny'; and age discrimination to 'rationality review,' the same level of review that is given to ordinary economic legislation for a general survey, see Tribe (1978). Governmental classifications rarely survive strict scrutiny and struck down rarely under rationality review, although there are some exceptions. Because the Fourteenth Amendment does not reach discrimination by purely private parties, much of the federal antidiscrimination effort in the United States has been made under the auspices of antidiscrimination statutes.

The American law of discrimination starts with high-sounding commitments in seminal statutes or Supreme Court opinions, but its development rapidly takes the form of the elaboration of highly specific structures of proof for dealing with discrimination claims arising under the various sources of law and in the various areas of social practice surveyed above. One result is that antidiscrimination law has developed a number of distinct specialities, each concerned with a separate jurisprudence of discrimination in its own field. Another result is that, in American antidiscrimination law, the devil is in the details. By shaping proof structures, and by applying civil procedure and evidence rules to discrimination cases, courts shape the likelihood that plaintiffs will succeed in their claims (Albiston 1999).

1.1. Employment

The leading federal antidiscrimination statute in the employment field, Title VII of the Civil Rights Act of 1964 (known as 'Title VII') was stimulated by the violent resistance by the South to court-ordered racial desegregation and to the 1960s civil rights movement. Title VII prohibits discrimination on the basis of race, color, sex, religion, and national origin. Although feminist activists lobbied for the inclusion of sex discrimination, the statute as originally proposed left sex discrimination out. It was included through an amendment proposed by a congressional opponent of the statute, whose confidence that including sex would block passage of the statute proved misplaced. Once enacted, however, the prohibition of sex discrimination has been a robust and creative aspect of statutory enforcement.

Employment discrimination on the basis of age and disability was subsequently addressed in the Age Discrimination in Employment Act (1967) and Americans with Disabilities Act (1993). Legally-focused civil rights movements on behalf of non-racial groups (such as the development of the disability-rights movement and its involvement in the design of the Americans with Disabilities Act) have contributed to these legal developments. Not all groups have met with success: for example, Congress has yet to enact legislation barring employment discrimination on the basis of sexual orientation.

In the early years of race discrimination litigation under Title VII, the Supreme Court developed three basic proof structures: 'individual disparate treatment,' 'pattern and practice,' and 'disparate impact.' None of these terms appear in Title VII itself, which speaks most generally in terms of discrimination 'because of' race, sex, and so forth. The 'individual disparate treatment' and 'pattern and practice' proof structures turn upon proof of the employer's discriminatory intent. The disparate impact proof structure does not. Relying instead upon proof of discriminatory effects of racially-neutral practices.

In the 'individual disparate treatment' case, intent is an inference drawn by a factfinder (judge or jury) from a variety of types of circumstantial evidence aimed at refuting the possible nondiscriminatory reasons for an adverse employment action. While this sounds relatively straightforward, the Supreme Court surprised the plaintiffs' bar in 1993 by holding that merely establishing the required prima facie case and disproving the employer's stated justification for its action does not entitle the plaintiff to a victory (Malamud 1995), and has only begun to clarify the circumstances under which doing so entitles the plaintiff to go to trial.

In 'pattern and practice' cases, plaintiffs (most often a group of plaintiffs using the procedural mechanism of the class action) rely primarily on labor market analysis and statistical evidence to create an inference of intentional discrimination. The theory underlying the use of statistics is that, absent discrimination, each employer's workforce would resemble the racial composition of the relevant labor market. Employers' defense consists chiefly of attacks on the appropriateness of the plaintiffs' labor market definition and on the accuracy of their statistical analysis. Because the pattern and practice case is so reliant on expert testimony, these cases are expensive to litigate and often push the courts beyond their level of technical expertise.

In a disparate impact case, a plaintiff or plaintiff class challenges a facially-neutral employment practice (for example, a test) on the grounds of its disparate adverse effects on members of her group. So, for example, in the case of *Griggs* v. *Duke Power Co.* (401 US 424 [1971]), markedly lower proportions of blacks and Latinos than whites in the relevant labor market

passed standardized aptitude tests and had high school diplomas, leading to diminished access to preferred jobs in the employer's workforce. Absent a showing of 'business necessity' or 'job relatedness,' the Supreme Court held, employers could not use tests and other hiring criteria that placed 'arbitrary headwinds' in the way of the progress of traditionally excluded groups. In 1988 and 1989, the Supreme Court made it markedly harder for plaintiffs to win cases under the disparate impact proof structure; legislation in 1991 rewrote the statute to eliminate some but not all of the effects of those decisions. (See Hunter and Shoben 1998, for a discussion in a comparative context.)

Even after Congress passed clarifying legislation in 1991, elements of the disparate impact proof structure remain uncertain. Because these cases involve comparison-group definitions, questions are raised in every case as to whether the reference group should be employer's existing labor force, the applicant pool, or some other definition of the relevant labor market. The current standard for showing disparity has been criticized for failing to comport with social-scientific definitions of statistical significance (See, e.g., Meier et al. 1984). The precise conceptual content of the phrases 'business necessity' and 'job relatedness' is still subject to doubt, particularly when disparate impact analysis is used to challenge employment practices other than paper-and-pencil tests (where 'job relatedness' has long been tested through psychometric techniques of test validation). In addition, while the use of disparate impact analysis is now provided for by statute in the case of Title VII and the Americans with Disabilities Act, its availability under federal age discrimination legislation is open to serious doubt.

One area in which Title VII law has been relatively stable is the law of affirmative action. Under *United Steelworkers of America* v. *Weber* (442 US 193[1979]), employers are permitted to use affirmative action (if it is consistent with standards laid out in that opinion), and the Supreme Court reiterated more recently that the employer does not need to prove that its own prior policies were discriminatory in order to do so (*Johnson* v. *Transportation Agency of Santa Clara County*, 480 US 616 [1987]). The debate among the justices in these cases was open and virulent, and yet affirmative action in employment has not provoked recent challenge (in contrast to the status of affirmative action under the constitution, discussed below). The Supreme Court's embrace of affirmative action in employment is not without limits, however, and as of 2001 there is a mismatch between current social practice and the Supreme Court's past opinions. The Supreme Court has never held that the desire for greater diversity is a permissible basis for affirmative action under Title VII but, despite that fact, diversity is the major stated justification for many affirmative action programs. In addition, the Court has never held that Title VII permits the use of affirmative action principles in making layoff decisions.

The example of American employment discrimination law shows that the true state of antidiscrimination law cannot be assessed merely by looking at the written laws themselves. One must also be aware of how the statutes are being interpreted by courts and/or relevant administrative agencies; of how generally applicable procedural and evidentiary rules are used in discrimination cases; of the expense of litigation; and of the practical availability of experts with necessary skills and experience. One must also have a sense of trajectory (is the law becoming more or less friendly to plaintiffs over time?) and of symmetry (are similar laws being interpreted in similar or dissimilar ways?).

1.2. Other Areas of American Law

In considering proof structures outside the employment discrimination field, a key factor is the unavailability of the disparate impact cause of action in constitutional cases arising under the Fourteenth Amendment. (The Supreme Courts so held in the case of *Washington* v. *Davis* 26 US 229 [1976]). Although *Washington* v. *Davis* was in fact an employment-testing case, the Court's decision was likely motivated by the wide range of government programs that might be subject to challenge under the Constitution.

Because of the lack of the disparate impact route, showing discriminatory intent is the key to constitutional antidiscrimination litigation. Needless to say, it can be quite difficult to determine the intent of a legislative body. One conspicuous example is in the field of legislative redistricting, in which a string of equal-protection reverse-discrimination suits have been brought by white voters to challenge majority–minority districts created pursuant to the Voting Rights Act. The Court has held that the Equal Protection Clause is violated (under strict scrutiny) when race becomes the predominant factor motivating the redistricting decision. The Supreme Court is still wrestling with how to characterize the intent of the state legislature when, in order to protect incumbents, it creates majority–minority districts that are less compact and/or less contiguous than ordinary districts (see Pildes and Niemi 1993).

In primary- and secondary-school desegregation litigation, close judicial scrutiny was triggered in years past by findings that boards of education were operating their schools in an intentionally discriminatory fashion. Courts retained jurisdiction to administer complex court-ordered desegregation plans, often for decades. Until such time as the districts are declared 'unitary' by the presiding court, practices that were not themselves intentionally discriminatory could be challenged as perpetuating the effects of past intentional discrimination. In recent years, however, the trend has been for courts to conclude that the school districts under their jurisdiction have achieved

'unitary' status and that any continuing inequalities within the system no longer bear an organic connection to the district's past history of intentional discrimination (Orfield and Eaton 1996).

In higher education, affirmative action has been the focus of major political and judicial attention in a variety of fields under constitutional law. The continued constitutionality of affirmative action in higher education under the Supreme Court's decision in *Regents of the State University of California* v. *Bakke* (438 US 265 [1978]) question, and challenges have been brought to affirmative action programs in the undergraduate and professional schools of several major state universities. Whether the Supreme Court will re-commit itself to affirmative action in higher education when the appropriate case comes before it remains to be seen.

Criminal justice in the United States has a significant racial dimension, one that contributes to the gap in perception of the fairness of the system between blacks and whites. Some important efforts to redress racism in criminal law enforcement have met with failure, in part because of the difficulty of persuading courts of discriminatory intent through statistical evidence. For example, in *McCleskey* v. *Kemp* (481 US 279 [1987]), the Court rejected the claim, based on extensive statistical evidence, that the death penalty as practiced by state governments is unconstitutionally discriminatory (Baldus, Pulaski, Woodworth 1983). (See *Death Penalty*.)

2. *International Developments*

As other nations and transnational entities address the discrimination in their own midsts, they learn not only from their own histories but also from the successes and the failures of the American model. A few examples must suffice.

The new constitution of South Africa expressly permits constitutional challenges to be brought under disparate impact theory, by prohibiting both direct and indirect discrimination. The Constitutional Court of South Africa is a court of great sophistication and deep commitment to comparative constitutional analysis. It will thus serve as a counterexample to the United States, which early eschewed constitutional disparate impact theory and has never looked back.

The law of free speech under the First Amendment of the United States constitution has stood in the way of pervasive hate speech regulation in the US. In contrast, out of the historical experience of Germany has grown a strong commitment in German law to prohibiting the group-hate speech exemplified by expressions of anti-Semitism (Stein 1986; see Schauer and Pildes 1999). Notwithstanding these legal prohibitions, skinhead and other white racialist groups in Germany continue to attack perceived outsiders to their idealized homogeneous ethnic German society, just as racist attacks continue to occur in the United States.

In the field of gender discrimination in employment, the theory of 'comparable worth' is an important (if still unclear) part of the gender discrimination law of the European Community and some of its member states (e.g., Ellis 1998, Libeson 1995). In comparable-worth analysis, women use the tools of job and wage analysis to demonstrate that they do not receive the same returns on effort, education, and skill as do occupants of traditionally-male jobs. In contrast comparable worth has not made significant inroads into American law (Blum 1991).

Affirmative action (under its many names) and its surrounding controversies are international phenomena. In Europe, the European Court of Justice has upheld the use of affirmative action in favor of women seeking promotion, but only when they are of 'equal suitability, competence and professional performance' and no 'reasons specific to an individual [male] candidate tip the balance in his favor.' (See Zuleeg 1999, Cox 1998). In contrast, Indian law has 'reserved' scarce positions for members of 'backward castes and classes' for decades, including legislative seats (Galanter 1984). In South Africa, the post-apartheid constitution explicitly permits affirmative action. The slowly-developing case law on the issue has met with controversy as members of the intermediate racial groups in the old apartheid system (coloreds and Indians) find themselves in competition with blacks for scarce positions (e.g., Higginbotham 1999, Adam 1997). See *Affirmative Action: Comparative Policies and Controversies*.

In surveying examples, one must not forget that in many countries, antidiscrimination law is still in its infancy. To choose one example, Japanese employment discrimination law has only recently been used to challenge the pervasive exclusion of professionally educated women from professional-level jobs (e.g., Fan 1999, Yamakawa 1999).

3. *The Role of Social Science in Antidiscrimination Legal Practice*

As should be apparent from the above survey of American antidiscrimination practice, social science has a crucial role to play in proving discrimination. Social science has also been an important reality check, by asking important empirical questions both about the efficacy of current antidiscrimination laws and the variables underlying the development of effective antidiscrimination law. Social science has played the weakest role, however, in the area where it may well have been the most helpful—that is, in developing the law's basic concepts of discrimination.

In the employment discrimination field, expert testimony from social scientists is a necessity in disparate impact and pattern and practice cases. (See

Expert Testimony). At a minimum, several types of social scientific expertise must be brought into a case. In both disparate impact and pattern and practice cases, labor market experts are necessary to formulate and to defend definitions of the relevant labor market, using census data, industry surveys, and other sources. Testing psychologists (psychometricians) play a crucial role in disparate impact cases both in designing employment screening tests in such a way as will allow them to withstand legal scrutiny, and in challenging the designs of tests in litigation. Statisticians are needed in both types of cases to ensure that appropriate data are collected through the court-administered evidence discovery process, to formulate an affirmative case from the data, and to critique the rival statistical story being told by the opposing party. Expertise from a number of disciplines is drawn upon to demonstrate or to refute the extent to which underrepresentation of groups results from their lack of interest in particular categories of jobs (e.g., Schultz 1990). Thus, disparate impact and pattern and practice cases are universally viewed as battles of the experts—which is a problem for the untrained judges and juries who must evaluate the evidence. Expert testimony has also found its way into individual disparate treatment cases. In *Price Waterhouse* v. *Hopkins* (490 US 228 [1989]), for example, expert testimony was admitted in order to demonstrate that certain statements by supervisors were based on sexual stereotypes.

While employment discrimination litigation employs the talents of psychologists, labor economists, and statisticians, the field of voting rights has brought political scientists into the expert witness role. Legislatures employ sophisticated demographic and political models when they redistrict, and the political scientists who created these models have played an important role in defending them and their results in court. Educational desegregation litigators utilize the expertise of specialists not only in education but also in demography, because patterns of housing segregation play an important role in long-term educational segregation.

Social scientists have ascertained the effectiveness of existing antidiscrimination frameworks both in the United States and elsewhere (e.g., Donohue and Heckman 1991, McCrudden et al. 1991, Edelman 1990). Social scientists have also contributed to the legal debate by re-examining legal assumptions about the mechanisms through which discrimination takes place. In the area of comparable worth, for example, US-based researchers have argued that gender wage disparities are caused by organizational practices that are not likely to be remedied by 'putting comparable worth as an overlay on existing compensation systems (Nelson and Bridges 1999). On a more theoretical level, empirical comparative studies in political science can shed light on the social and institutional circumstances that lead constitutional courts in some countries to be particularly willing to use their authority to articulate and to extend anti-discrimination norms (e.g., Epp 1998).

Where social science has played less of a role is in the development of the law's basic concepts of discrimination. Contemporary studies of prejudice in social psychology and elsewhere are critical of the intent-based model of discrimination that permeates American law. Perhaps the lack of penetration by social scientists into the conceptual core of American anti-discrimination law is a problem of origins. American antidiscrimination law grew out of the blatant intentional discrimination practiced against African Americans. In *Brown* v. *Board of Education* (347 US 483 [1954]), social scientific testimony convinced the Court that intentional segregation stigmatizes blacks; by so doing, it fostered the nation's hope that desegregation would allow blacks and whites to put ancient hatreds and mistrusts to rest. Close to fifty years of life post-*Brown* has put that optimism to the test, perhaps to a greater degree than the courts are prepared to admit. When they are not ready to admit the problem, legal actors show little willingness to turn to social science either to redefine it or to solve it.

Discrimination, Economics of

1. Discrimination

In the abstract, 'discrimination' refers to distinctions or differentiation made among objects or individuals. In economics, as in ordinary parlance, discrimination carries a pejorative connotation. The term is generally reserved for distinctions that are socially unacceptable and economically inefficient. Economic theories of discrimination usually fall into one of three broad categories: tastes and preferences of economic agents, economic power, and statistical discrimination. Unlike the world of theory, empirical documentation of discrimination is subject to much ambiguity and differences of interpretation.

2. Theories of Discrimination

2.1 Tastes and Preferences

Publication of *The Economics of Discrimination* (1957) by Gary Becker was instrumental in making discrimination a legitimate and popular topic for study by economists. The tastes and preferences approach adopted by Becker was pure neoclassical economics. This approach appeals to tastes for discrimination by utility-maximizing economic agents. Tastes for discrimination are embodied in discrimination coefficients that are susceptible to measurement by the economist's monetary yardstick. Agents' tastes for discrimination are manifested by a desire to minimize economic transactions with members of certain demographic groups. While discriminating agents may be prepared to forfeit income in order to indulge their tastes, the effects of their discriminatory behavior can lead to segregation or reduced incomes for the groups discriminated against. In addition to employer tastes for discrimination, Becker also considered the effects of tastes for discrimination by consumers and fellow workers. Under some circumstances, competitive pressures can ameliorate the effects of discriminatory behavior.

The literature provides support for Becker's contention that labor-market discrimination is lessened by product market competition. Ashenfelter and Hannan (1986) present statistical evidence that within the banking sector the employment opportunities for women are negatively related to market concentration. Peoples and Saunders (1993) show that deregulation of trucking in the USA lowered the white/black wage ratios among both union and nonunion drivers. This competitive effect was identified with the reduction of rents accruing to whites.

One avenue for exploring the effects of discrimination by fellow workers is to examine the effects of unionism on racial wage differentials. An early study by Ashenfelter (1972) showed that the average wage of black workers relative to the average wage of white workers in the USA was higher in the union sector than in the nonunion sector. In particular, Ashenfelter estimated that compared with the complete absence of unionism, the black/white wage ratio was 4.0 percent higher in the industrial union sector, and 5.0 percent lower in the craft union sector. These results suggest that the union sector is less discriminatory than the

nonunion sector, and that industrial unions are relatively more egalitarian compared with craft unions. Peoples (1994) found evidence not only that the returns to union membership are higher for blacks than for whites, but also that racial wage differentials were higher among nonunion workers in the highly concentrated industries.

2.2 Market Power

Prior to Becker, early work by economists on the topic of discrimination focused on pay differentials between men and women. Joan Robinson's (1933) classic on imperfect competition provided an early example of the economic power theory of discrimination. Robinson considered the case of a monopsonistic employer (single employer labor market) of men and women who are equally productive (perfect substitutes in production). She proved that if the labor supply elasticity (responsiveness to wages) were smaller for women, a profit-maximizing employer would equate the incremental employment costs of men and women by offering women a lower wage.

Madden (1975) explored the circumstances under which the labor-supply elasticities of women would be lower, and how male monopoly power insulates men from any monoposony power that might exist in labor markets. The key element was the existence of job segregation which reduced competition from women. It was shown that under these circumstances women would receive lower wages than men, if both worked in equally productive, but different, sets of jobs. Earlier, Bergmann (1971) advanced the occupational crowding hypothesis to explain income inequality between white male workers and otherwise equally capable nonwhite workers. Crowding nonwhites and women into a narrower range of occupations raises the incremental value of white males in their occupations and lowers the incremental value of all workers in the occupations dominated by nonwhites and women.

The ubiquity and self-reinforcement of a broad range of discriminatory behavior in society was examined in Thurow (1969). For example, discrimination in schooling opportunities has the effect of diminishing the subsequent earnings potential of minority workers. This reduces the costs to discriminating employers of paying lower wages to minority workers, as the latter will have fewer skills to begin with. Lower wages reduce the cost of housing discrimination because better housing is beyond the incomes of most minority workers.

2.3 Statistical Discrimination

Statistical discrimination is an approach that relies upon risk and information costs rather than tastes for discrimination or market power to explain income disparities among different demographic groups in society (Aigner and Cain 1977). One example is that of two groups who are equally productive on average, but the productivity signal, for example, test scores, is a noisier signal of productivity for one of the groups. A risk-averse, profit-maximizing employer might offer lower wages or less desirable positions to applicants from the demographic group with the noisier signal. Consequently, employment decisions are made on the basis of group characteristics as well as on the basis of individual characteristics.

3. Wage Decompositions

In the study of wage inequality, the most commonly used methodology for apportioning wage gaps between two demographic groups to productivity and discrimination can be traced to Blinder (1973) and Oaxaca (1973). The basic idea is quite simple. One first estimates wage equations for each of the demographic groups from a sample of workers. These wage equations are mathematical formulas relating wages to observed productivity factors such as education and experience. In the absence of direct labor-market discrimination, equity is characterized as a situation in which both demographic groups are expected to be compensated according to the same wage (salary)-determination formula. In this scenario the only reason for the existence of a wage gap would be that the two groups differ on average with respect to the observed wage (productivity)-determining characteristics. This wage gap is commonly referred to as the 'endowment' or human capital effect.

The difference between the actual wage gap and the endowment effect is often referred to as the 'unexplained gap.' Many practitioners regard the unexplained gap as an estimate of discrimination. Those who prefer the term 'unexplained gap' reason that this estimate is in the nature of a residual and as such may include the effects of productivity factors not explicitly taken into account in the wage-determination formula. Hence, the measure may be a biased estimate of discrimination. From an econometric standpoint, the bias can go in either direction. The counterargument is that there are always factors omitted from any statistical relationship and that there is no reason to suppose that these are anything but random in the present context. In addition, the same sort of methodology is very commonly used to estimate other types of wage gaps, for example union/nonunion, north/south, manufacturing/nonmanufacturing. In these contexts the term 'unexplained gap' is not used.

According to the Blinder/Oaxaca standard decomposition methodology, one of the two demographic comparison groups is designated as the reference group. If, for example, one is interested in male/female wage differentials, one might select males as the reference group. This means that the statistically estimated wage formula for males serves as the

nondiscriminatory wage structure. Operationally, one estimates the average wages for both males and females by applying the estimated male wage formulation to each group's wage-determining characteristics. The gender difference in these predicted average wages is the 'endowment' effect, since the same wage formula is applied to the characteristics of both groups. The difference between the original unadjusted wage gap and the gap attributable to the 'endowment' effect is by definition the result of different wage formulas for males and females. This residual gap is what is termed either the 'unexplained gap' or the gap attributable to direct labor-market discrimination. Therefore, the decomposition technique is a method for decomposing an observed wage gap into an endowment component and an unexplained/discriminatory component.

3.1 Identification of Individual Components of Discrimination

Apart from differences in what researchers call the 'residual gap,' there are other ambiguities in the standard decomposition technique. First, it would seem desirable to be able to identify the contribution of each wage-determination characteristic to the endowment component and the discrimination component. For example, one could identify the contribution of gender differences in a characteristic such as work experience to the overall endowment effect as the gender difference in average work experience multiplied by the pecuniary return to an additional unit of work experience estimated from the male wage equation. Or consider the case of a wage-determining characteristic defined by a set of mutually exclusive categories such as educational levels, for example, 'less than high school,' 'high school,' 'some college,' and 'college graduate.' The estimated return to each included educational category is relative to the return on an arbitrarily selected educational category variable that is omitted from the wage equation. The monetary value of gender differences in the proportion of workers in the sample who are college graduates is simply calculated as the gender difference in the proportion of college graduates weighted by the estimated value of a college education for males relative to the omitted educational category. The sum of all of these endowment valuations equals the overall endowment effect.

Unfortunately, an identification problem can arise when one attempts to estimate the contribution of each wage-determination characteristic to the discrimination component. The problem is initially described in Jones (1983) and further extended in Oaxaca and Ransom (1999). For example, weighting the average amount of work experience for females by the male–female difference in the estimated return to an additional unit of work experience would constitute a measure of the contribution of gender differences in the return to experience to the overall discrimination measure. It turns out that this computation is affected by a simple shift in the experience measure. For example, potential experience is commonly calculated as either schooling-age-five or schooling-age-six. This is a seemingly innocuous shift in the experience measure, yet it will affect the estimated contribution to discrimination of gender differences in the return to experience. Because this change in the experience measure creates an offsetting change in the intercept term in the wage equations for males and females, it does not affect the overall estimate of discrimination. Nor does this change in the experience measure have any effect on the contribution of gender differences in work experience to the endowment effect.

This arbitrariness is more manifest when attempting to estimate the contribution to discrimination of gender differences in the returns to a variable defined by mutually exclusive categories. Returning to the education example, note that the contribution to measured discrimination of the gender difference in the returns to education is calculated as the sum of the gender differences in the estimated returns for each included educational category weighted by the proportion of females who are in each included category. As it turns out, this calculation is affected by the choice of which educational category variable is to play the role of the omitted reference category. The choice of omitted reference category is of course quite arbitrary. Fortunately, the overall estimated discrimination component is not affected by which categorical variables are selected to be the omitted reference categories. Also, the choice of omitted reference group has no effect on the estimated contribution to the endowment effect of gender differences in the values of the categorical variables.

3.2 Nondiscriminatory Wage Structures

To examine a second source of ambiguity in standard wage decompositions, imagine that the choice of reference group is reversed so that female workers are designated as the reference group. Now one estimates the (nondiscriminatory) average wages for both males and females by applying the estimated female wage formulation to each group's wage-determining characteristics. An ambiguity arises in that in general estimates of the endowment and discriminatory wage effects will depend on which demographic group is serving as the reference group. This ambiguity is a manifestation of the familiar index number problem. The researcher is trying to measure 'value' using alternative base weights.

As a measure of discrimination, the estimated residual gap is subject to quite different interpretations depending on the choice of reference group. The situation is one in which the presence of discrimination is manifested as a wage gap based on the fact that in actuality men and women do not face the same wage-

determination process. This can be viewed as either that women are underpaid relative to the male wage structure or else that men are overpaid relative to the female wage structure. The interpretation and estimated magnitude of each of the two components comprising the original unadjusted wage gap depend on which group's wage structure is regarded as the nondiscriminatory standard. To further add to the ambiguity surrounding wage-decomposition analysis, there is the theoretical possibility that which group is being discriminated against depends on whose wage-determination formula is being used as the nondiscriminatory standard.

It is clear that the second type of ambiguity surrounding the standard wage decomposition analysis has to do with identifying an appropriate nondiscriminatory wage standard. Ideally, one would want the wage structure that would prevail in a nondiscriminatory world to serve as the standard by which to measure actual discrimination. Under some assumptions, such a wage structure would be the one that would exist in a world characterized by perfect competition in product markets and labor markets. One would estimate the average wages for both males and females by applying the nondiscriminatory wage formulation to each group's wage-determining characteristics. The gender difference in these predicted average wages is the endowment effect. Again, discrimination is measured by the unadjusted gender wage gap net of the endowment effect. However, it is now possible to further decompose the discriminatory wage gap because the gap is in general the sum of two distinct components. The first component is the difference between the actual average wage of the male workers, and their predicted average wage based on the nondiscriminatory structure. The second component is the difference between the predicted average wage of females based on the nondiscriminatory wage structure, and their actual average wage.

These discriminatory wage components have interesting interpretations (Neumark 1988). The first component is a measure of the male wage advantage relative to the nondiscriminatory norm. This component can be viewed as favoritism toward males. The second component is a measure of the female wage disadvantage relative to the nondiscriminatory norm. This component can be viewed as pure discrimination against female workers. This methodology, in principle, allows researchers to sort out how much of the male–female discriminatory wage gap results from overcompensation of men, and how much stems from undercompensation of women. In the light of this approach, the conventional decomposition method is seen as a special case.

While seemingly attractive as a decomposition method, there is a practical difficulty in making operational the concept of a nondiscriminatory wage structure. One notion is the wage structure that would prevail had discrimination never existed. A slightly less challenging task might be to define the non discriminatory wage structure as the structure that would emerge in the immediate aftermath of a cessation of discrimination. In general, this is not the same as the wage structure that would have prevailed had discrimination never existed. This is because of a likely path-dependence feature in which discrimination permanently alters the evolution of wage structures. While a still formidable enterprise, it is possible to reach useful approximations to a wage structure that would emerge after the cessation of discrimination.

The basic idea underlying this approach is contained in Neumark (1988) and Oaxaca and Ransom (1999). A reasonable presumption is that with the cessation of discrimination between two demographic groups, the resulting wage structure would in some way be related to the preexisting separate wage structures. A natural approximation is the wage structure that is estimated on the basis of a combined sample obtained by pooling the data on the two demographic groups. Such a common wage structure can be shown to be a matrix-weighted average of the separately estimated wage structures. The weights are related to the precision by which each group's wage-equation parameters are statistically estimated. Neumark (1988) applies this methodology to the gender wage gap.

In Oaxaca and Ransom (1994) the methodology is generalized to allow for estimation of a nondiscriminatory wage structure as any matrix-weighted average of the separately estimated wage structures. Without restrictions on the weighting matrices, any common wage structure can be rationalized as a matrix-weighted average of the separately estimated wage structures. Reimers (1983) uses simple averages of separately estimated wage structures when comparing whites, blacks, and Hispanics.

3.3 Residual Decomposition

An important aspect of the study of wage inequality is trying to understand the components of changes or trends in wage inequality. Juhn et al. (1991) introduce a method of decomposing changes in the residual wage gap between two demographic groups into the effects of changes in the average rankings of the two groups in the residual wage distribution of the dominant group, and the effects of changes in the residual wage dispersion (standard deviation) of the dominant group. This approach is referred to as the Juhn–Murphy–Pierce (JMP) decomposition. It follows the practice of interpreting the wage gap left after controlling for group differences in observed characteristics as an unexplained differential.

In Blau and Kahn (1996) the JMP decomposition is adapted to analyzing gender wage gap differences between nine countries and the USA during the 1980s. Earnings are standardized to a full-time (40 hours) work schedule. The earnings models estimated with

G: The (unadjusted) gender wage differentials (in logs). $G–G_{us}$: The gender wage gap difference between each country and the USA. Quantities: The effects of gender differences in personal characteristics. Prices: The effects of gender differences in the returns to personal characteristics. Rankings: The effects of gender differences in percentile rankings in the wage distribution. Dispersion: The effects of international differences in wage dispersion.

microdata sets control for education, potential experience, union membership, industry, and occupation. Table 1 summarizes the Blau and Kahn findings in which the gender wage gaps in each country are compared with that of the USA. Column 2 reports the raw (log) wage differentials by country. The wage gaps range from 0.258 log points (approximately 26 percent) in Sweden to 0.4875 log points (approximately 49 percent) in the UK. Column 3 reports each country's wage gap minus that of the USA. It is this difference that is decomposed into the effects of international differences in the following: (a) gender differences in human capital characteristics (quantities); (b) the (male) returns to human capital characteristics (prices); (c) gender differences in the percentile rankings in the male wage residual distribution (rankings); and (d) differences in the (male) standard deviation of the wage residuals (dispersion). In six of the nine countries, the male human capital advantage is greater than that of the USA. Without exception, international differences in the returns to human capital and in the dispersion of wage residuals lower the gender wage gap in other countries relative to the USA. In six of the nine countries the less favorable rankings of women in the male wage residual distribution widens the gender wage gap relative to the USA. What emerges from this study is that the gender wage gap is relatively high in the USA because the greater wage residual inequality in the USA more than offsets the greater relative human capital of US women.

4. *Correcting Wage Inequities*

Although economists are presumably interested in measuring the extent to which discriminatory wage gaps represent overpayment of the dominant group versus underpayment of the subordinate group, custom and the legal environment lean more to the dominant group's wage structure as the nondiscriminatory standard. The idea is that inequities should be addressed by raising the wages of the subordinate group, as opposed to lowering the wages of the dominant group. Indeed, the US Civil Rights Act of 1964 prohibits equity wage adjustments that involve lowering any group's nominal wages. Thus, attempts to remove discrimination in the workplace in a way that would correspond to accepted economic principles of efficiency are constrained by legal and employee morale considerations.

4.1 *Econometric Modeling Approaches*

One might properly speculate about how econometric models of the wage-determination process can be used to address a salary inequity issue in the workplace. Examples from legal practice are provided in Finkelstein (1980). Oaxaca and Ransom (1999) report on several approaches on how to use statistical salary models to correct salary inequity within a firm. For illustrative purposes, the examples are in terms of gender inequity, but the methodology extends without modification to racial or ethnic salary inequity. The remedies range from simply compensating each female worker exactly according to the estimated male wage equation to constraining the salary equity adjustment process to award minimum settlements regardless of personal circumstances.

4.2 *Comparable Worth*

Comparable worth is a general policy for eradicating discriminatory wage disparities within firms. The idea

behind comparable worth is that jobs of equal value should pay equal wages. While this sounds like free market economics, at issue is how value is determined (Hill and Killingsworth 1989). Advocates of comparable worth envision a system in which points are awarded to each job based on the skills, effort, and responsibility required. Experts are responsible for evaluating a firm's jobs in a manner that does not bias wage determination against women. The objection against letting the market value the jobs is that occupational segregation dooms women to a subordinate wage position. An important question is whether or not comparable worth would provide employers with the incentives to eliminate job segregation, and whether or not women would switch among occupations that were equally compensated. Critics of comparable worth fear the massive inefficiencies that could emerge from interference with labor-market resource allocation.

5. *Self-selection in the Labor Force*

Estimation of labor-market discrimination in general is complicated by the observation that individual workers in a statistical sample generally do not constitute a random sample of the adult population. Whether or not to participate in the labor force will depend upon the individual's calculation of the net benefits of labor-force participation. While the net benefits are unobserved by researchers, the decision to participate is observed, as well as many determinants of the net benefits. For women, the presence of small children at home would likely be a factor in the decision to be in the labor market. The statistical equation corresponding to labor-force participation is known as a selection equation, since it describes a rule for individuals to select themselves in or out of the labor force.

Sample selection bias can arise when the random statistical errors in the selection equation are correlated with the random statistical errors in the wage equation that is being estimated for a self-selected sample of workers (Heckman 1979). Unless the probability of selection (which depends on the selection equation) is taken into account, the estimated parameters of the wage equation can be biased. The selection probabilities for the selected sample are controlled for in a variable known as the Inverse Mills Ratio. This variable is constructed from the variables and parameters of the selection equation.

A number of studies have attempted to correct for sample selection bias when dealing with occupational segregation or more generally labor-market discrimination (Reimers 1983, Dolton et al. 1989, Neuman and Oaxaca 1998). Neuman and Oaxaca (1998) explore alternative ways of estimating (ethnic and gender) labor-market discrimination from selectivity-corrected wage equations using a sample of Jewish professional workers drawn from the Israeli 1983 Census of Population and Housing.

6. *Progress and Future Directions*

Smith and Welch (1989) chronicle the economic progress of African-Americans over a 40-year period. Black male wages as a percent of the white male wage rose from 43.3 percent in 1940 to 72.6 percent by 1980. The documented wage gains of African-Americans were largely attributed to more and better education, migration, and general economic growth. Some evidence was found that affirmative action policies improved the employment and wage prospects of African-Americans. Data from the US Current Population Survey are consistent with the Smith and Welch findings. The median income of full-time, year-round black workers as a percent of the median income of full-time, year-round white workers rose from 68.1 percent in 1970 to 73.9 percent in 1998.

Empirical findings from gender labor-market studies are quite mixed, variable over time and across countries. Zabalza and Tzannatos (1985) examine the gender employment and wage effects of labor-market legislation in the UK on the employment and wages of women. Panel data, which contain detailed information on individuals over their working lives, have been used to study gender wage gaps in Denmark (Rosholm and Smith 1996). In a shift of emphasis from gender wage discrimination Flückiger and Silber (1999) examine both theoretically and empirically the phenomenon of gender labor market segregation with special emphasis on the Swiss labor market.

Empirical studies of racial-, ethnic-, gender-, and caste-based labor-market outcomes in developing countries may also be found (Birdsall and Sabot 1991, Psacharopolulos and Patrinos 1994). Intercountry comparisons of labor-market inequity between the developed and the developing countries will be the inevitable result of globalization. The implications of labor-market discrimination for international trade and specialization should occupy the attention of social scientists well into the twenty-first century.

Discrimination: Racial

Racial discrimination exists in straightforward actions but also in complex systems of social relations that produce racial inequities. Discrimination is not, as popularly thought, simply the accumulation of individual acts of unfairness between members of different groups. It consists as well of an elaborate web of institutional arrangements that produces group inequalities, a web that becomes racial discrimination when the groups perceive each other as separate 'races.' Studied throughout the social sciences, these inequalities can involve political power, economic resources, and cultural access.

1. Conceptual Complexities

Viewing racial discrimination as an institutional web casts a wide net but leaves room for considerable ambiguity. Disagreement about what constitutes discrimination stems from two sources—one ideological and political, the other empirical. First, because discrimination violates law and professed values in many countries, a judgment that unequal outcomes reflect discrimination is a call for unpopular change and costly remedies. Resistance to such change and

costs activates debate about the extent of discrimination. Second, deficiencies in analysis and evidence limit the ability of scientists to trace precisely the dynamic system of effects triggered by discrimination.

Consider first the political issue. The broadest definitions of discrimination assume that racial minorities have no inherent characteristics that warrant inferior social outcomes. Thus, all inequality becomes a legacy of discrimination and a social injustice to be remedied. Favored by the political left, this view appears to many as too sweeping.

By contrast, political conservatives favor a narrow definition that limits the concept's scope by including only actions intended to restrict a group's chances. Most social science specialists resist this reformulation for several reasons. An intentionality criterion returns the concept to the realm of psychology and deflects attention from restraining social structure. And the invisibility of intentions creates formidable obstacles for substantiating discrimination. Finally, the effects of discrimination are the same whether or not the causal institutional mechanisms were intended to produce group inequalities.

This rejection of the intentionality criterion leads to an important distinction between direct and indirect discrimination (Pettigrew 1985). Direct discrimination occurs at points where inequality is generated, often intentionally. When decisions are based explicitly on race, discrimination is direct. Indirect discrimination occurs when the inequitable results of direct discrimination serve as a basis for later decisions. Hence, discrimination is indirect when an ostensibly nonracial criterion becomes a proxy for race in determining social outcomes. Indirect discrimination perpetuates or magnifies the original injury.

Wage discrimination illustrates the distinction. Direct racial discrimination exists when employers pay equally qualified members of two races different rates for the same work. Indirect discrimination exists when the employers pay the two groups unequally because prior discrimination in employment, education, or housing created apparent differences in qualifications or channeled the groups into better- and worse-paying jobs. This direct/indirect distinction resembles the distinction often made by legal systems between disparate treatment and disparate impact. While intentional direct discrimination may have triggered the causal chain, the original injury is perpetuated and magnified by largely unwitting accomplices.

2. *Empirical Ambiguities*

This conceptual complexity carries over to impede the empirical study of discrimination. Apparently rigorous quantitative analyses often camouflage the crucial issues, as an examination of wage decomposition research reveals.

Assessments of racial discrimination produced by decomposing gross racial differences in social outcomes are common in sociology (Farley 1984) and economics (Gill 1989). This approach first assigns one segment of the gross racial differential to 'qualifications' and other factors deemed legitimate determinants of social rewards. The residual segment not demonstrably linked to 'legitimate' determinants of the outcomes often is presented as the estimate of discrimination. However, without better information than usually available and closer agreement on what constitutes discrimination, no unique estimate of discrimination is possible. The choice of control variables to index 'legitimate' determinants of social outcomes shapes the answers. Any appearance of scientific certitude is an illusion. Not surprisingly, discrimination estimates from this approach vary enormously.

Empirical research on group discrimination must mirror the phenomenon in its variety and complexity. The regression decomposition approach is useful but limited. Regression analyses could provide more pertinent information if based on more homogeneous job groups (Conway and Roberts 1994) and on structural equation models that test reciprocal causation. Most important, if the aim is to guide policy, a framework far more complex than the dichotomous discrimination-or-not approach is required. Research that traces the actual processes of institutional discrimination is essential (Braddock and McPartland 1987). Also needed is attention to victims' perceptions of discrimination and to the changes generated by anti-discrimination efforts.

3. *Racial Discrimination in the United States and Western Europe*

Both direct and indirect forms of racial discrimination can be found throughout the world. Most of the available research, however, focuses on the long-festering racial problems of the United States. In such long-term situations, injuries of indirect discrimination often are more extensive than those of direct discrimination. This conclusion does not imply that direct discrimination no longer exists. Employment complaint records reveal the continued operation of direct forms of discrimination. US women and minorities have filed 1.5 million job discrimination complaints since 1965. Not all such complaints reflect genuine discrimination, but analysts believe that false complaints are minimal in comparison with the amount of actual discrimination that goes unreported and thus undetected. Many major corporations have been found guilty of direct racial discrimination in the 1990s. And employment audits using paired, equally qualified applicants reveal widespread direct discrimination (Reskin 1998). Employers have admitted to interviewers that their stereotypes of minorities, par-

ticularly of innercity black men, lead them to avoid minority hiring (Neckerman and Kirschenman 1991).

Along with direct employment discrimination, indirect discrimination is pervasive. Many employers rely on word-of-mouth recruiting of new employees, especially for unskilled jobs. Thus the current workforce, often disproportionately white, reproduces existing racial inequalities in employment by bringing in white friends and relatives as the next generation of workers. This is just one aspect of 'business as usual' that represents indirect discrimination. Although word-of-mouth recruiting appears to be color blind, it serves to perpetuate racial inequalities (Reskin 1998).

Recent analyses of indirect discrimination in the USA have focused on wealth. Racial inequalities in assets dwarf disparities in other social outcomes. Although the magnitude of inequality in home equity is grave, racial inequality in liquid assets is even more marked. The average white family has been estimated to hold liquid assets 14 times greater than those of the average black family (Conley 1999).

The racial gap in assets results from a history of direct and indirect discrimination. Prohibitions against black self-employment and land ownership in the American South were an early part of the picture. More recently, occupations to which blacks were confined, agricultural and domestic work, were excluded from Social Security provisions. Direct and indirect discrimination by federal housing agencies, banks, realtors, and white homeowners have limited black Americans' opportunity to accrue wealth through home ownership (Conley 1999, Massey and Denton 1993, Oliver and Shapiro 1995).

The cumulation of disadvantage is particularly acute when the focus is assets. Since wealth reproduces itself exponentially, the racial gap in assets in the USA has continued to grow. And assets have important implications for other social outcomes such as education and labor market success. Where parents do not have the means to live in higher status neighborhoods, children do not have access to good public schools. And for most students, attendance at the best colleges and universities depends on parents' ability to provide tens of thousands of dollars per year to cover tuition and expenses. Labor market outcomes reflect educational disadvantage, but assets have other indirect effects as well. Access to networks of information crucial to job-seekers, proximity to lucrative employment, automobile transportation to work—all these are a function of assets, and black Americans are at a pronounced disadvantage (Conley 1999). Innovative strategies for intervention must be devised to break into the spiraling disadvantage produced by black Americans' deficits in wealth.

Analogous dynamics afflict the minorities of other nations. And a research literature on the subject is now emerging in Western Europe. Discrimination against the region's new immigrant racial minorities is pervasive (Castles 1984, MacEwen 1995, Pettigrew 1998). And both direct and indirect discrimination are involved, though the indirect forms are largely unrecognized in Europe.

Investigators have repeatedly uncovered direct discrimination in the UK (Amin et al. 1988). Controlled tests reveal the full litany of discriminatory forms involving employment, public accommodations, housing, the courts, insurance, and banks. Employment discrimination poses the most serious problem. In every European Union nation, minorities have markedly higher unemployment rates than natives.

As in the US, there are many reasons for minority unemployment disparities. The 'last-in, first-out' principle selectively affects the younger minority workers. Typically less skilled, they are more affected by job upgrading. Minorities also are more likely to be in older, declining industries. These patterns are not accidental. Planners put minorities into these industries for cheaper labor precisely because of their decline. Yet these multiple factors offer insufficient explanations for the greater unemployment of minorities. Veenman and Roelandt (1990) found that education, age, sex, region, and employment level explained only a small portion of the differential unemployment rates in The Netherlands.

Indirect discrimination arises from the inability to obtain citizenship. It restricts immigrants' ability to get suitable housing, employment, and schooling. In short, the lives of Europe's noncitizens are severely circumscribed. Castles (1984) contends that the guestworker system that brought many of the immigrants to Europe was itself a state-controlled system of institutional discrimination. It established the newcomers as a stigmatized outgroup suitable for low-status jobs but not citizenship. And racial prejudices add to this stigma. Widespread indirect discrimination, then, was inevitable for these victims of direct discrimination.

4. *Remedies for Racial Discrimination*

The most elaborate array of remedial measures is found in North America. Both Canada and the United States have instituted a battery of laws against many types of racial and other forms of discrimination. Court rulings in the two nations also have proven decisive. The effects of these legal actions are magnified by class action suits—the ability of single litigants to sue for remedy for their entire 'class' or group. Further remedies have involved various forms of 'affirmative action' in which special efforts are made to close group disparities caused by discrimination. All these approaches have led to narrowing racial disparities in social outcomes. But sharp racial inequities remain in both countries, and majority resistance has hardened against the most successful remedies.

Antidiscrimination remedies have been largely ineffective in Europe. Germany guarantees basic rights

only to citizens. So, the disadvantages of noncitizenship include the inability to combat discrimination. There is extensive German legislation to combat anti-Semitism and Nazi ideology, but these laws have proved ineffective in protecting noncitizens. The German constitution explicitly forbids discrimination on the basis of origin, race, language, beliefs, or religion—but not citizenship. Indeed, the Federal Constitutional Court has ruled that differential treatment based on citizenship is constitutional if there is a reasonable basis for it and if it is not wholly arbitrary. And restaurants can refuse service to Turks and others on the grounds that their entry might lead to intergroup disturbances (Layton-Henry and Wilpert 1994).

Few means of combatting discrimination are available in France either. Commentators often view discrimination as 'natural' and universally triggered when a 'threshold of tolerance' (*seuil de tolerance*) is surpassed (MacMaster 1991). Without supporting evidence, this rationalization supports quotas and dispersal policies that restrict minority access to suitable housing.

The Netherlands, United Kingdom, and Sweden have enacted antidiscrimination legislation that specifically applies to the new immigrant minorities. And the Dutch have instituted modest affirmative action programs for women and minorities. Yet this legislation has been largely ineffective for two interrelated reasons. First, European legal systems do not allow class action suits—a forceful North American weapon to combat discrimination. Second, European efforts rely heavily on individual complaints rather than systemic remedies. The UK's 1976 Act gave the Commission for Racial Equality power to cast a broad net, but individual complaints remain the chief tool (MacEwen 1995).

Individual efforts are unlikely to alter discrimination, because they are nonstrategic. Minorities bring few charges against the worst discriminatory firms, because they avoid applying to them. Complaints about job promotion are common, but they are made against employers who hire minorities. Effective anti-discrimination laws must provide broad powers to an enforcement agency to initiate strategic, institution-wide actions that uproot the structural foundations of discrimination.

5. *Two Summary Propositions*

The long-lasting character of racial discrimination means that the effects typically outlive the initiators of discriminatory practices. Discrimination is fundamentally normative; its structural web operates in large part independent of the dominant group's present attitudes or awareness. Hence, models based primarily on individual prejudice or 'rationality,' whether psychological or economic, will uniformly understate and oversimplify the phenomenon.

Discrimination feeds upon itself; it is typically cumulative and self-perpetuating. An array of research on African Americans has shown that neighborhood racial segregation leads to educational disadvantages, then 'to occupational disadvantage, and thus to income deficits, (Pettigrew 1985). To be effective, structural remedies must reverse this 'vicious circle' of discrimination.

Seen in this perspective, discrimination is far more intricate and entrenched than commonly thought. The complexity of discrimination presents major challenges to social scientific attempts to trace its impact. This complexity also precludes any simple correspondence between perpetration and responsibility for remedy. Broad social programs will be necessary if the full legacy of direct and indirect racial discrimination is finally to be erased.

Disgust, Psychology of

Disgust appears in virtually every discussion of basic emotions, including ancient Hindu texts and Darwin's *The Expression of the Emotions in Man and Animals* (Darwin 1965). Darwin defined disgust as referring to 'something revolting, primarily in relation to the sense of taste, as actually perceived or vividly imagined; and secondarily to anything which causes a similar feeling, through the sense of smell, touch, and even of eyesight' (p. 253). In the classic psychoanalytic treatment of disgust, Andras Angyal (1941, p. 395) claimed that 'disgust is a specific reaction towards the waste products of the human and animal body' (p. 395). Angyal related the strength of disgust to the degree of intimacy of contact, with the mouth as the most sensitive focus. Sylvan Tomkins (1963) has offered the more general contention that disgust is 'recruited to defend the self against psychic incorporation or any increase in intimacy with a repellent object' (p. 233). Derivative of Angyal's definition, Rozin and Fallon (1987, p. 23) expand on Angyal's definition, and define disgust as: 'Revulsion at the prospect of (oral) incorporation of an offensive object. The offensive objects are contaminants; that is, if they even briefly contact an acceptable food, they tend to render that food unacceptable.' Disgust is related to pollution, as used in the anthropological literature. In particular, Mary Douglas' (1966) view of polluting, meaning matter out of place, has direct relevance to disgust.

Most scholars recognize a special relation between disgust and ingestion; the facial expression of disgust represents an oral and nasal 'rejection,' the word 'disgust' in English and some other languages means 'bad taste,' and nausea, the physiological signature of disgust, is directly related to, and inhibitory of, ingestion.

However, it is also clear that, cross culturally, the emotion of disgust is elicited by a wide range of elicitors, most of which have nothing to do with food (Miller 1997, Rozin et al. 1993). In certain respects, disgust can be thought of as the emotion of civilization. The history and trajectory of disgust, from a food-related emotion to a much more general emotion, is the central concern of this entry.

1. *Disgust as an Emotion*

Disgust is the only basic emotion that is specifically related to a motivation (hunger) and to a particular bodily location (mouth). Along with other basic emotions, as described by Paul Ekman (Ekman 1992, Scherer and Wallbott 1994), disgust has a characteristic behavior (withdrawal), physiological state (nausea), and facial expression. The facial expression of disgust has received most attention from Ekman (Ekman and Friesen 1975), Izard (1971), and Rozin (Rozin et al. 1994). The expression centers on the mouth and nose, and is characterized principally by a wrinkling of the nose, a raising of the upper lip, and a gape. The mental or feeling component of disgust is often described as revulsion; it is typically of shorter duration than most other.

2. *The Meaning of Disgust*

Rozin et al. (1993), based on surveys in Japan and the United States, designate nine domains of disgust: certain foods or potential foods, body products, animals, sexual behaviors, contact with death or corpses, violations of the exterior envelope of the body (including gore and deformity), poor hygiene, interpersonal contamination (direct or indirect contact with unsavory human beings) and certain moral offenses. Disgust has to do with offensive elicitors which are wide in range, but exclude many other types of negative events, such as pain, and those that elicit the emotions of fear, sadness, and anger.

Rozin et al. (1993) propose that disgust originated in animals as a response to distasteful food. These authors hold that in cultural evolution, the output side of disgust (expression, physiology, behavior) remained relatively constant, but the range of elicitors and meanings expanded dramatically. Disgust came to mean offensiveness to the self or soul, rather than bad taste, its origin. Indeed, it was proposed that, in humans, distasteful items do not elicit the full emotion of disgust. The expansion of elicitors and meanings in cultural evolution was attributed to the process of preadaptation; use of a mechanism evolved in one system for a novel use in another system. For example, the mouth, and in particular the teeth and tongue,

evolved for processing food, but these structures were co-opted in human evolution for use in speech articulation. The expansion of the meanings of disgust is proposed to have occurred in four stages (Rozin et al. 1993).

2.1 Core Disgust

The initial form of disgust, that appears first in children, has to do with food, but primarily the nature and origin of the food, rather than its taste (Rozin and Fallon 1987). Core disgust has three components: (a) a sense of oral incorporation (and hence a linkage with food or eating), (b) a sense of offensiveness, and (c) contamination potency. The mouth is the principal route of entry of material things into the body; such things may be essential for life, but may also be very harmful. Disgust has to do with the harmful side, the risks of ingestion. The threat of oral incorporation is illustrated by a widespread belief that 'You are what you eat.'

Almost all elicitors of core disgust are whole animals, or animal body parts or body products. The great majority of food taboos concern animals and their products, and in most cultures the great majority of animals as potential foods are considered disgusting.

The contamination response (e.g., the rejection of a potential food if it even briefly contacted a disgusting entity) appears to be powerful and universal among adults, and is a defining feature of disgust. It is an example of the sympathetic magical law of contagion, which essentially holds that 'once in contact, always in contact' (Rozin and Nemeroff 1990).

2.2 Animal Nature Disgust

Common elicitors of disgust include inappropriate sex, poor hygiene, death, and violations of the ideal body envelope (e.g., gore, deformity, obesity). Contact with death and the odor of death (decay) are potent elicitors of disgust. Individuals who score high on disgust sensitivity also score higher on a fear of death scale (Haidt et al. 1994).

The centrality of death in disgust suggests a more general construal of disgust. While Freud (1953) conceived of disgust as a defense against culturally unacceptable sexual or coprophilic urges, disgust may be better understood as a defense against a universal fear of death. Ernest Becker (1973) has argued that the most important threat to the psyche is the certainty of death. Human beings are the only organisms that know they will die. Disgust, as a withdrawal system, may help to suppress thoughts or experiences that suggest human mortality.

More generally, anything that reminds us that we are animals elicits disgust (Rozin and Fallon 1987); eating, excretion, sex, soiling of the body surface, soft viscera within the body envelope, and death are all properties that humans share with animals. Cultures typically have extensive rules about these matters, including a wide range of prohibitions, in an attempt to humanize or deny our animal bodies. People who ignore these prescriptions are reviled as disgusting and animal-like (Rozin et al. 1993, see also Miller 1997 for a related conception). This conception of disgust links it to the concern of humans, frequently cited by anthropologists, to distinguish themselves from animals.

2.3 Interpersonal and Moral Disgust

Across cultures, there is a sense of disgust at touching most people who are not intimates, of making indirect contact with them, such as by wearing their clothing. Most other persons are contaminating, in this sense, and this sensitivity can serve to reinforce social boundaries. Cultures differ in degree of this sensitivity; it is particularly high in Hindu India, where it serves as an important means of maintaining caste distinctions.

In many, if not all languages, the word for 'disgust' is applied to certain moral violations. And the contamination property of disgust is also extended to the perpetrators of such immoral acts. It is possible that disgust functions, along with anger and contempt, as a basic moral emotion involved in expressing moral outrage at the actions of another (Rozin et al. 1999). Richard Shweder and his colleagues (Shweder et al. 1997) identify three types of moral codes that occur in cultures around the world. Violation of the community code, having to do with issues of hierarchy and duty, may map on to the emotion of contempt. Violations of the autonomy code deal with rights and justice, and may be associated with anger. The third code, divinity, focuses on the self as a spiritual entity and seeks to protect that entity from degrading or polluting acts. Disgust may be the emotion that is evoked when the divinity code is violated (Rozin et al. 1999).

3. Development of Disgust

Distaste, the origin of disgust, is present at birth, as in the innate rejection by neonates of bitter substances. Disgust first appears in North American children between the ages of 4 and 8 years, with the appearance of the contamination response, and rejection of foods because of their nature or origin. Disgust, as opposed to distaste, seems to be uniquely human, and is a product of culture. The contamination response, also uniquely human, is probably, in origin, a means of

protection from microbial contamination; however, it is acquired. Even feces, surely a source of such contamination, and a universal disgust substance among human adults, is not rejected by infants. Toilet training may well be the first disgust-generating experience for humans, but the means by which strong negative affect becomes associated with feces is unknown, as is the way that disgust 'spreads' to a wider range of elicitors.

Presumably parental reactions to disgusting things play a central role in the development of disgust. There is evidence for family resemblance in disgust sensitivity.

4. Disgust, History and Culture

Across cultures and history, the expression of disgust seems to vary rather little, while the elicitors and meanings vary widely. It seems that disgust was relatively infrequent and limited to a narrow range of elicitors in medieval Europe. The full scope of disgust in Western history, and its flowering as both an emotion of sensibility to the animal nature of humans, and a marker of immorality, is presented in William Miller's *Anatomy of Disgust* (Miller 1997).

Many cultures show specific attractions to entities that most other cultures find disgusting. For example, particular spoiled foods (e.g., cheese for the French, fermented fish sauce for Southeast Asians) are highly desired in particular cultures, and there are major differences in the sexual practices and contact with the dead across cultures.

The largest historical and cultural variation in disgust is probably associated with interpersonal and moral disgust. For example, disgust seems to center more on interpersonal and moral matters for Hindu Indians than it does for Americans.

5. Individual Differences

Results from a standardized test of disgust sensitivity, applied in Japan and the United States, indicate that sensitivity is somewhat higher in females and people of lesser education or lower social class (Haidt et al. 1994). As well, disgust has been implicated in two clinical phenomena: phobias and obsessive compulsive disorder.

6. Neural Correlates of Disgust

Very recent work by Sprengelmeyer, Young, Phillips, and others, in Germany and England, has established a link between disgust and the basal ganglia; in particular, damage to the basal ganglia, as in Huntington's disease, is associated with a sharply defined inability to recognize expressions of the emotion of disgust. These patients do not seem to have major deficits in disgust other than in the recognition of its expression.

7. Disgust and Related Emotions

Fear and disgust share a behavioral component, withdrawal based on a threat. Anger and sociomoral disgust share the appraisal of moral condemnation, and the common facial gesture of raised upper lip. Contempt shares the appraisal that someone is base and inferior to oneself, but has a complex and rich set of connotations, as described by Miller (1997). Shame has been described as disgust turned inward, a judgment that the self is disgusting. It is not clear what emotion is 'opposite' to disgust, but perhaps love is the closest opposite.

8. Disgust and the Arts

Disgusting images appear frequently in visual art. Disgust is also a focus of humor, at least in Western culture, and plays a particularly central role in children's humor. Disgust appears to be attractive in situations where it is contained and not too threatening; in this regard, our enjoyment of disgust may be related to our enjoyment of horror movies, sad movies, and amusement park rides. All of these proclivities seem to be uniquely human. In general, disgust plays a major role in socialization, and the sensibilities it promotes are at the heart of what it means to be human and to be civilized.

Dispute Resolution in Economics

Negotiation is common in many settings. A common feature of all negotiation is an understanding by the parties to the negotiation about the process that will be used to resolve a dispute in the event that the parties fail to reach agreement. Disputes between labor unions and employers can end in a strike, or can be resolved by arbitration. Disagreement over contracts or tort damages can result in civil litigation and a decision by a judge or jury. Disagreement between nations can result in military disputes. The dispute settlement process defines the expectations that the parties have about what will happen in the event that no agreement is reached. And this process, in turn, determines negotiator behavior.

There are two fundamental types of dispute settlement mechanism. The first is the systematic imposition of costs on each side. Strikes and military disputes are examples of this type of mechanism. No determinate end to the dispute is implied, but presumably one or both parties concedes sufficiently to make an agreement possible and end the dispute. The second mechanism is the mandating of a settlement by a third party. Arbitration of labor and commercial disputes, and litigation of civil disputes, are examples of this type of mechanism.

Both types of mechanism (strikes and arbitration) are used in the resolution of labor disputes, and the discussion here focuses on that area. This discussion is necessarily selective and is meant to provide a brief introduction to important concepts and issues. See Hirsch and Addison (1986) for a more extensive survey.

1. *Strikes*

A difficult problem in the economics of labor unions is the modeling of strikes. The difficulty arises because strikes appear to be non-equilibrium phenomena. Both sides would have been better off if they had been able to agree on whatever the outcome was without bearing the costs of a strike. In other words, strikes are Pareto-dominated by the same bargaining outcome without a strike. While research on strikes in the United States has diminished with the level of strike activity in the USA since the mid-1980s, there was an active empirical literature in the 1970s and 1980s.

Ashenfelter and Johnson (1969) developed a non-equilibrium model of strike activity by attributing to the union an arbitrary concession schedule positing an inverse relationship between the minimum acceptable wage and the length of strike. The firm selects the point on this schedule that maximizes profits, the tradeoff being longer strikes involving larger up-front strike losses, but lower labor costs into the future. Ashenfelter and Johnson used this model to motivate an empirical analysis of the aggregate level of strike activity in the United States. Farber (1978) used the same theoretical framework to estimate a structural model of the joint determination of wage changes and strike length using data on the outcomes of a time-series of cross-sections of negotiations for large US corporations.

Tracy (1986) developed an equilibrium model of strikes based on learning in a model of asymmetric information (Fudenberg and Tirole 1981, Sobel and Takahashi 1983). The model is based on the idea that the union does not know the profitability of the firm. The union would like to extract a high wage from high-profit firms and a lower wage from low-profit firms. The key is that high-profit firms have a high cost of bearing strikes relative to low-profit firms. In this case, the union can make a high initial wage demand. High-profit firms will prefer to pay this wage immediately rather than to lose profits during a strike. Low-profit firms will prefer to lose their lower profits during the strike in exchange for a lower wage into the future.

Tracy (1986) used this model to generate the empirical implication that there will be more strikes where there is more uncertainty about the firm's

profitability. He then implemented this model using data on a large number of negotiations and using the volatility of daily stock returns as his measure of uncertainty about profitability. He finds evidence that uncertainty is correlated positively with strike activity. A final point is that the declining concession schedule in the Ashenfelter–Johnson model can be interpreted as a reduced-form expression of the union learning function. As the strike goes on, the union is willing to accept a lower wage as they learn that the firm is lower-profit.

It is quite possible that strikes are not equilibrium phenomena, and that the insistence in the economics literature, both theoretical and empirical, on equilibrium explanations, is inappropriate. Strikes can result from miscalculation. In particular, the parties may be relatively optimistic about the outcome after a strike. For example, the union may expect a wage settlement of \$20/hour after a strike, while the firm expects to pay only \$18/hour after the same strike. If the cost of a strike is \$0.50/hour to each side, then the union will accept no less than \$19.50 to avert the strike, while the firm will be willing to offer no more than \$18.50. The result will be a strike. Of course, the expectations of both sides cannot be accurate, *ex post*. This relative optimism can have a variety of sources. One possibility with a long history in the industrial relations literature, is that the parties selectively overweight arguments that are favorable to their side (Walton and McKersie 1965, Neale and Bazerman 1991). However, relative optimism can be generated even with appropriate weighting of available information. If each side is getting independent (and accurate in expectation) information on the likely uncertain outcome, for some fraction of the time the information will lead to relatively optimistic expectations sufficient to outweigh the costs of a strike. Strikes will occur in these cases.

2. *Arbitration*

In the United States, arbitration is used commonly to determine the terms of labor contracts in the public sector in cases where the parties cannot agree on their own. In conventional arbitration, the arbitrators are free to impose whatever settlements they deem appropriate. A common alternative is final-offer arbitration, where the arbitrator must select one of the final offers submitted by the parties and cannot compromise.

2.1 *Conventional Arbitration*

Consider the following simple model of the negotiation process where conventional arbitration is the dispute settlement mechanism (Farber and Katz 1979). Suppose the parties are negotiating over the split of a pie of size one. The share of the pie going to the union is Y, and the share going to the firm is $(1-Y)$. The arbitrator will impose a settlement of Y_a, and each party has a prior distribution on Y_a. Let Y_a^u and Y_a^f represent the prior expected value to the union and firm, respectively, of the arbitration award. Finally, let C_u and C_f represent the cost to the union and the firm of using arbitration (denominated in pie shares). Assume further that the parties are risk neutral, so that the union will prefer any negotiated share for itself (Y_n) such that $Y_n > Y_a^u - C_u$ and the firm will prefer any negotiated share for itself such that $1-Y_n > 1-Y_a^u - C_f$. These are the reservation values of the parties in negotiation. The result is a *contract zone* of settlements preferred by both sides to arbitration that consists of all shares that fall in the range:

$$Y_a^u - C_u < Y_n < Y_a^f + C_f \tag{1}$$

The size of the contract zone is:

$$CZ = Y_a^f - Y_a^u + C_u + C_f \tag{2}$$

In the simplest model, there will be a negotiated settlement whenever $CZ \geqslant 0$, and there will be an arbitrated outcome whenever $CZ < 0$.

This model provides an important insight into when one might expect a dispute. Relative optimism about the likely arbitration award $(Y_a^u > Y_a^f)$ can be a reason for a dispute. If the relative optimism is sufficiently great to outweigh the total costs of arbitration $(C_u + C_f)$, then there will be no contract zone, and arbitration will be required. Thus, relative optimism is a cause of disputes. Clearly, higher total costs of arbitration imply a larger contract zone. Larger costs make it less likely that any degree of relative optimism will cause there to be no contract zone. Thus, larger total costs of disputing reduce the likelihood of disputes. This latter property is implied by any reasonable model of disputes.

The model also demonstrates how the dispute settlement mechanism determines fundamentally negotiated outcomes. Consider the case where the parties have identical expectations about the arbitration award of $Y_e = Y_a^u = Y_a^f$. The size of the contract zone in this case is determined entirely by the costs of arbitration (Eqn. 2), and there will be no dispute. The negotiated settlement will lie in the range defined by:

$$Y_e - C_u < Y_n < Y_e + C_f \tag{3}$$

In other words, the negotiated settlement will lie in some range around the common expectation of the arbitration award.

One criticism of conventional arbitration as a dispute settlement mechanism in labor disputes is that arbitrators appear to split the difference between the

demands of the parties, resulting in an arbitration award that is close to the average of the demands. However, Eqn. 3 makes it clear that the opposite is likely to be true: The negotiated settlement is likely to lie between the reservation values of the parties. Mnookin and Kornhauser (1979) and Farber (1981) present analyses that make this point.

2.2 Final-offer Arbitration

The perception that arbitrators split the difference in conventional arbitration led to the belief that conventional arbitration 'chilled' bargaining by providing the parties with an incentive to maintain extreme demands. This led to the development of final-offer arbitration, which prevented the arbitrator from compromising (Stevens, 1966). Farber (1980) developed a simple model of final-offer arbitration where arbitrators select the offer closest to what they would have imposed in conventional arbitration (Y_a). In this model, the probability that the union's offer is selected is:

$$P_u = Pr\left(Y_a > \frac{Y_u + Y_f}{2}\right) = 1 - F\left(\frac{Y_u + Y_f}{2}\right) \tag{4}$$

where Y_u and Y_f represent the final offers of the union and the firm respectively and $F(\cdot)$ represents the cumulative distribution function of the parties' common prior on Y_a.

Assuming risk-neutrality, the expected payoff to the union from final-offer arbitration is:

$$V_u = P_u Y_u + (1 - P_u) Y_f \tag{5}$$

and the expected payoff to the firm is:

$$V_f = 1 - [P_u Y_u + (1 - P_u) Y_f] \tag{6}$$

The Nash equilibrium final offers of the parties are the offers such that (a) Y_u maximizes V_u conditional on Y_f, and (b) Y_f maximizes V_f conditional on Y_u. These offers have the property that neither party will desire to change its offer.

Since the parties are uncertain about Y_a, the Nash equilibrium final offers reflect a tradeoff between the value to the party of its offer if its offer is selected, and the probability that its offer is selected. A more extreme offer yields a higher payoff to the party if its offer is selected by the arbitrator, but it lowers the probability that the offer will be selected.

A key implication of this model is that final offer arbitration may not encourage more convergence in negotiation than conventional arbitration because of the desire to present optimal final offers to the arbitrator that may be extreme.

2.3 Empirical Evidence

Ashenfelter and Bloom (1984) present evidence from arbitration of contract disputes for public sector employees in New Jersey, where both conventional and final-offer arbitration are used, consistent with the general model of arbitrator behavior outlined here. They find that arbitrators use a common underlying notion of Y_a to make awards in both conventional and final-offer arbitration. Their evidence is consistent with the arbitrators' decision in final-offer arbitration being to select the offer closest to Y_a. Bazerman and Farber (1986) reach similar conclusions based on evidence from arbitration awards, both conventional and final-offer, made by professional arbitrators in hypothetical cases.

Convincing evidence is scarce on whether final-offer arbitration leads to more settlements and reduces reliance on arbitration. Ashenfelter et al. (1992) present experimental evidence that does not show higher rates of agreement in final-offer arbitration than in conventional arbitration.

Disputes, Social Construction and Transformation of

The 'social construction' of disputes refers to the process by which people perceive a wrong or an injustice, articulate a claim against the offending party, and assert that claim publicly before a third party. Disputes are not concrete entities or objective events, but are instead social constructs, the results of subjective feelings and perceptions, and expressed through language and actions. 'Transformation of disputes' refers to the change in form or content of disputes as other participants become involved in the disputing process and add their own perceptions and interests to those of the original parties.

1. *Law and Disputing*

Empirical research on dispute transformation developed in the late 1970s and early 1980s as a result of trends in several social science fields and in law. Anthropologists showed how a focus on 'trouble cases' could provide a useful framework for comparative study of law in different societies. Research reported in Nader and Todd (1978), for example, explored the factors behind parties' choices of different methods for pursuing, or attempting to resolve, disputes in diverse societies. Relations between disputants, the location of the dispute, and the nature of the problem, along with the range of disputing alternatives, could all explain the construction and handling of disputes. The interest of anthropologists in disputant choice and the availability of different alternatives for dispute resolution overlapped with the interest of legal scholars in access to justice.

Expansion of legal services for litigants in civil cases and concern for the role of civil courts in society led analysts to examine the legal needs of citizens. What kinds of cases and what groups of citizens are not being served by the civil justice system? How can access to justice be improved? Questions such as these spurred efforts to describe and count 'unmet legal needs.' It is easy to count cases in court, but counting cases that have not been filed proves more problematic. The problems center on what kinds of cases should be in court, are there too many court cases, are they the wrong ones, and what populations do the courts serve? Through such questions, the very nature of what constitutes a civil court case is called into debate. Comparative studies of legal caseloads in different societies also fueled an interest in improving understanding of the relation between individual and social conflicts and court cases. Such concerns led scholars to focus explicitly on the social construction of disputes and their emergence in court.

Recognition that courts provide only one way to resolve conflicts, and a costly way at that, led some observers to propose alternative processes for dispute resolution. Interest in alternatives to court also led to research on dispute transformation as scholars. Interest in alternatives to court also led to research on dispute transformation as scholars explored the impact of different institutional mechanisms on disputes. Alternative dispute resolution (ADR) provides new processes such as mediation and arbitration as alternatives to adjudication in the courtroom. Those who favor ADR praise its informality, lower cost, speed, and case outcomes particularized to the needs of the disputants. ADR opponents worry about a two-tier legal system with courts reserved for wealther litigants and alternatives for others, and about the lack of legal norms guiding the resolution of disputes outside of court. Scholars on both sides of the debate have sought to bolster their positions by gathering information on how disputes are transformed through negotiation, mediation, arbitration, or adjudication.

Other interest in dispute transformation comes from sociologists studying case processing in the criminal justice system, from psychologists examining conflict resolution, and from political scientists concerned with the role of courts in resolving political issues. Criminal justice officials negotiate the meaning of events and identities of suspects as in the process of plea bargaining. Crimes are defined according to their normal situational and social features, as well as by legal codes. Sociological research shows that criminal defendants, for example, are sometimes offered a plea bargain to a lesser offense in the process of narrowing their cases into conventional categories of crime. Psychological study of negotiation in conflict resolution involves attention not only to how players try to maximize their interests, but also how they seek actively to define the nature of the issues and the scope of their conflict.

Finally, political scientists study dispute transformation as a means of understanding legal mobilization and the role of courts in society. Test case litigation involves the construction of individual lawsuits as vehicles for articulating and advocating collective political interests. In successful litigation, disputants may become important creators of law, and their lawyers are spokespersons for a cause. Court trials may be confined to the individual facts and issues in dispute, or broadened to address the normative implications and legal meaning of the dispute. As a consequence of cause lawyering, interest group activity, or media attention, political trials may result from such broadening of issues in dispute. Parties in

litigation, their lawyers, and court officials may each seek to transform disputes in different ways, for different political ends.

For detailed treatment of these topics and for further references see *Law, Mobilization of*; *Public Interest Law*; *Class Actions: Legal*; *Parties: Litigants and Claimants*; *Legal Culture and Legal Consciousness*; *Mediation, Arbitration, and Alternative Dispute Resolution (ADR)*; *Law and Everyday Life*; *Law as Constitutive*.

2. *The Emergence and Transformation of Disputes*

A hypothetical sexual harassment case can illustrate some of the central issues in the emergence and transformation of disputes. The sections that follow this example elaborate on some of the key contributions of dispute transformation research: the perception of a grievance; the disputing pyramid; the lawyer's role in transformation; the role of language; how courts and institutions shape dispute transformation; and the relation between dispute transformation, politics, and law.

2.1 *Sexual Harassment as an Example*

Consider the situation in which a manager makes sexual overtures toward his secretary. He frequently tells crude jokes, embarrasses her with comments about her looks and dress, and invites her for after-hours dates. She is not attracted to him, but she likes her job. What would be her response? She might simply brush him off and try to live with his unpleasant behavior ('lump it'); she might seek advice from co-workers, neighbors, friends; she might leave her job and seek work elsewhere ('exit'); she might pursue an internal complaint within her place of work, or seek legal counsel outside the job and file a claim of sexual harassment. This suggests how the secretary's dispute with her manager is not a discrete event, but is instead socially constructed by her perceptions, by others, and by her disputing alternatives. The conflict may or may not lead to a legal case.

The emergence of a dispute depends first on recognizing and identifying a problem. For many women employees in the United States until the 1990s—and still for many worldwide—the occasional lecherous boss was part of a normal working environment. Cultural and political changes led to women's recognition of their grievances and the language of federal law introduced a new name for their grievance: 'sexual harassment.' Supporters of an employee—such as co-workers, a women's group, or employees, union—could broaden the scope of the conflict to transform her individual dispute with the offending manager into a larger protest over sexist working conditions. Additional issues could be added to the dispute, such as discrepancies in pay and working conditions between men and women employees. Advice from a civil rights lawyer could lead to a class action lawsuit, which would further broaden the scope of the conflict and add new parties to the case. Alternatively, internal processes of dispute resolution within the organization could depoliticize the dispute, remove any aspect of sex discrimination or sexual harassment, and transform it into a personality conflict between the two parties. In short, both the meaning and the course of the dispute are contingent. They depend on the perceptions, actions, and interests of various parties, and on the alternatives provided by language and institutions. Furthermore, the way in which the dispute is defined—and whether it is even seen as a dispute or not—reinforces certain power relations and ideas, and links law to everyday life. (See *Sexual Harassment: Legal Perspectives*.)

2.2 *The Disputing Pyramid*

Why are some grievances ignored but others become disputes? And why do some disputes in American society end up as court cases but the vast majority do not? There is a 'disputing pyramid,' or 'legal iceberg,' with vast numbers of grievances at the bottom, fewer disputes in the middle, still fewer legal claims toward the top, and only small number of actual cases in court (Galanter 1974, Miller and Sarat 1981). The emergence of disputes depends first on perceiving an injury or problem ('naming'), then attributing the problem to the fault of another ('blaming'), and finally confronting the opposing party and seeking some kind of remedy ('claiming') (Felstiner et al. 1981). Many injuries are never perceived as such, and still others are not acknowledged because of cultural ideas, institutional barriers, or the lack of social support. Not all grievances become claims and not all claims become lawsuits in court. Movement of grievances to the top of the disputing pyramid depends in part on structual characteristics of the dispute, such as the relationship between the parties, the type of claim, and the relation parties have to the legal system. The disputing pyramid is shaped differently for various kinds of cases but demographic characteristics of the parties (e.g., class, education) may not be as significant for disputing as is commonly thought (Miller and Sarat 1981). Institutionalized procedures and remedies for handling conflicts may encourage claiming by lowering costs and making the disputing process more accessible and predictable.

In addition to social and institutional factors affecting dispute transformation, psychological factors play a role. Individuals vary in their claims consciousness and in their propensity to assert claims or pursue legal

rights. This variation is associated with preferences for different modes of conflict resolution and with self-described personality attributes, but appears to be independent of demographic status (Vidmar and Schuller 1987).

Dispute transformation helps to explain not only where disputes end up in the disputing pyramid but also how changes occur in the very nature of disputes. Both the object of the dispute and the normative framework for handling it are matters to be negotiated (Mather and Yngvesson 1981). To succeed in establishing what the dispute is about can go a long way toward resolving it. Changing the normative framework for viewing events or relationships can transform disputes over them. Viewing interpersonal conflict as a cognitive bargaining process has led psychologists to pursue research on conflict frames, that is, on disputants' cognitive interpretations of conflict. Cognitive framing influences both the process and outcomes of disputes, as well as disputant satisfaction (Pinkley and Northcraft 1994).

2.3 The Lawyer's Role in Dispute Transformation

Lawyers play a major role in constructing and transforming disputes. Exactly what the nature of that role is, however, is a matter of considerable controversy. In one view, lawyers escalate conflict, urging their clients to pursue adversarial formal legal solutions to problems that might be more appropriately resolved informally. Thus, lawyers are said to encourage clients to take their claims higher on the disputing pyramid in order to vindicate legal rights and obtain greater compensation. Of course, such vigorous legal advocacy could also enrich the lawyer, through enhanced fees or a percentage of a larger settlement. Although this view has wide currency in the popular press, it has mixed support in empirical research on lawyers and clients.

Studies of lawyer/client interaction, particularly in the areas of divorce, personal injury, and criminal law, suggest that lawyers more frequently dampen conflict than escalate it. Financial incentives discourage lawyers from pursuing extensive formal legal action and encourage quick, informal settlements of cases. Where clients have the resources to support it, it is they—not their lawyers—who may insist on extended legal combat. Thus, O. J. Simpson spared no expense for his defense lawyer, but the vast majority of criminal defendants lack such resources and plead guilty.

In divorce, some of the most bitter and highly contested trials occur between very wealthy spouses who can underwrite the fees of their attorneys. But in most divorces in the United States only one spouse can afford a lawyer and the other is *pro se* or else neither party is represented by counsel. Even in two-lawyer divorces, attorneys typically seek to cool out their clients, to protect the children, and to preserve the long-term relationship between ex-spouses, because cooperative settlement is seen to be cost-effective, or because the law encourages equitable division of property and shared parenting.

An important question about lawyers' interactions with clients is the extent to which clients' stories and objectives are heard by counsel. One thing that lawyers clearly do is translate clients' problems into legal language. Lawyers rephrase auto accidents into torts, domestic violence into assaults, and racist actions into civil rights violations. In lawyers' offices, clients may want to pour out stories in their full social and personal context. But details that clients see as highly relevant are dismissed by counsel as not germane to the legal case. Lawyers are trained to focus on particular issues, leading to frustration in clients (who are not being 'heard') and possibly to overlooking key details. Variation in the lawyers' role in dispute transformation by different areas of law and by different types of lawyers and clients remains a crucial topic for further study.

2.4 Language and Dispute Transformation

As social constructs, disputes depend upon the language used to describe them. Yet language is not neutral. It orders 'facts' and invokes 'norms' in ways that reflect the interests of the parties, or that anticipate the reactions of others (Mather and Yngvesson 1981). By including or excluding certain facts, or by selecting particular words, parties are situating their conflict in a certain normative framework. For example, in a case of sexual harassment, the word '*harassment*' itself invokes a different normative meaning than, say, '*flirting*' or '*being friendly*.' Struggles over language involve negotiation over which framework to apply, and such negotiations are integral to the disputing process. How a dispute is defined has consequences for the identity and relations between the parties, and for whether and how a dispute is resolved. Working-class Americans seeking to obtain legal redress in court often have their disputes redirected away from a legal framework and into a therapeutic framework of mental health or social welfare concerns (Merry 1990).

An analytic framework that examines language and disputing not only applies in modern legal systems, but also to smaller societies and even ancient ones. For instance, research on litigation in ancient Athens has produced powerful insights about Athenian law and democracy. The rhetoric and procedures of litigation there were used to transform broad conflicts into two-party disputes, impose specialized roles and identities, create new political resources, and foreclose other options—thus effecting the reproduction of Athenian democracy (Johnstone 1999).

Anthropological studies in different cultural settings also reveal how particular linguistic definitions of

conflict affect individual disputes and reinforce patterns of social order. Narratives in a Fiji Indian community, for example, aid in the management of social conflict by constructing identities, transforming personal experiences, and constituting knowledge. By 'telling troubles' to various different audiences, the Indian villagers construct their social relationships, privileging some accounts over others (Brenneis 1996).

2.5 How Courts and Other Institutions Shape Dispute Transformation

Institutional structures influence disputing by channeling the ways in which conflicts can be transformed. Courts, for example, often have strict rules of evidence that limit what kinds of information may be included in the construction of a case during trial. But informal negotiations outside of court, such as plea bargaining or settlement talks, have few such limits. When informal plea negotiations over disposition of a first-time drug defendant include discussions of the defendant's social background, family situation, and employment, lawyers may lean toward lenient treatment. But none of this material might be admitted in adjudication and the resulting sentence could be much harsher after conviction at trial. Different institutional procedures transform cases in different ways, producing variation in case outcomes.

In theory, a distinguishing feature of mediation—in contrast to adjudication—is the ability of mediators to range widely over different issues in a conflict. Whereas judges are supposed to narrow their focus to particular legal elements of a case, mediators (who are not bound by law) may encourage the emergence of new issues in their effort to formulate an agreement that is acceptable to both parties. Divorce mediators sometimes comment on the 'strange-looking agreements' that result from such wide-open mediation sessions. Some observers believe that the individualized agreements produced by mediation are more effective in resolving specific issues in dispute and also lead to increased compliance with the outcome. But critics of mediation worry that the agreements come at a high price—that is, through possibly overpowering the weaker party or through the lack of legal norms shaping the final agreement.

Mediators may have more in common with judges than with other mediators in terms of how they actually handle cases, and negotiation is frequently intertwined with adjudication. Instead of assuming differences across processes, a more productive focus centers instead on how processes influence dispute transformation—for example, through specialized or general language, through closed or open dispute hearings, or through linkages between dispute processes and other organizations in society (Ynvgesson and Mather 1983).

One response of large corporations to increased legal regulation of employment in the United States has been to create internal processes of dispute resolution. As a condition of employment, workers may even be prohibited from using courts for their disputes in order to favor internal organizational complaint procedures and avoid external legal liability for the employer. The result of such policies is the transformation of civil rights in the workplace from an issue of public law to an issue of private employee relations (Edelman et al. 1993). The object of dispute shifts from the working conditions provided by the employer to the personal relations among employees. Institutional mechanisms for resolving problems influence the ability of disputants to negotiate over issues and set limits on how legal norms penetrate everyday disputes. Conflict in organizations is increasingly handled by procedures that more closely resemble the imposition of authority than third party facilitation of dispute resolution (Kolb and Putnam 1992).

2.6 Dispute Transformation, Public Order and Law

A focus on the normative framework and definitions of a dispute reveals the political aspects of disputing and links the routine disputing processes to broader questions of power, order, and law. Dispute transformation thus bridges consideration of individual agency and social structure. When a secretary pursues a harassment claim against her supervisor, she is pursuing an individual dispute while simultaneously her case is reproducing the social structure of gender relations in the workplace. By providing the language of law and certain institutions for handling disputes, the social structure makes resources available to challenge and change that very structure. Those resources, however, are then countered by others (e.g., internal complaint mechanisms) that may sustain existing power relationships.

Most disputes are narrowed or rephrased in established categories of discourse. But, on occasion, new meanings are given to disputes. When a dispute is *expanded*—rephrased in terms of a new normative framework—it challenges the prevailing order. 'Expansion of individual disputes is one way that social change is linked to legal change' (Mather and Yngvesson 1981, p. 779). Agents of dispute expansion include the parties themselves, lawyers (especially cause lawyers), interest groups or supporters, third parties, or the audience to the dispute. Judges, or other third parties, may expand disputes in order to further their own political interests. In appellate court decisions, judges sometimes introduce new legal rules or ways of interpreting conflicts. For example, a dispute over obscenity in the lower courts became the famous *Mapp v. Ohio* case of illegal police behavior in the appellate court.

Litigation against tobacco manufacturers illustrates both dispute narrowing and dispute expansion. When ill cigarette smokers initially filed claims against the cigarette industry, their cases were *narrowed* into

established normative frameworks that insulated the industry from attack. Smokers were said to have 'assumed the risks' of tobacco harm, and were thereby responsible for their own illnesses. With the release of damaging internal evidence from the tobacco industry, and with the introduction of new normative frameworks (of fraud, consumer protection, or Medicaid reimbursement), there was some change in cases against tobacco manufacturers. Through dispute *expansion* anti-tobacco lawyers succeeded in transferring responsibility for smoking-related injuries back to tobacco manufacturers. With sizable jury verdicts the normative claims of anti-tobacco advocates assumed greater strength (Mather 1998). Indeed, through litigation and other forms of disputing, the meaning and scope of law are actively constructed in the process of defining individual disputes.

3. *Problems and Prospects for Studying Dispute Transformation*

The dispute transformation perspective can be faulted for its overemphasis on process to the exclusion of dispute outcome, a failure to examine the political significance of disputing, its individualistic focus, the methodological difficulty of identifying or measuring transformations, and its insufficient concern for institutions. By addressing these issues, however, researchers have redefined their work to include data that allows a more complete picture of disputing and law. The concept of dispute transformation is inherently interdisciplinary. Insights and methodological advances, from for example, anthropological linguistics, organizational studies, social network theory, psychology of negotiation, legal mobilization, and judicial decision making have broadened the application of the transformation perspective.

Viewing how disputes emerge and are transformed contributes to understanding both the micropolitics of dispute resolution and the macropolitics of disputing in society. The transformation perspective is useful crossculturally, and across different historical periods, and helps to explain how law is created and maintained.

Dissolution of Family in Western Nations: Cultural Concerns

1. *The Question of Family Centrality*

Apprehensions about the demise of the family reach back to biblical times (Stern 1938). Social historians have amply demonstrated that eras of family change, which are endemic in Western history, are invariably accompanied by fears of family breakdown. The Industrial Revolution introduced a widespread anxiety that the family was losing its centrality—kinship was becoming less salient, elders were losing authority, and functions were being replaced by other institutions in society—although historians continue to debate whether any of these claims are valid (Goldthorpe 1987). The challenge of establishing the breakdown of the family system is complicated.

Comparisons to any period in the past are inevitably tinged with a longing for what the eminent sociologist of the family, William J. Goode, referred to as 'the classical family of Western nostalgia' (Goode 1963). It is a difficult task to sort out ideology from experience when it comes to charting trends in family dissolution.

If dissolution is described as the weakening of kinship systems, marriage, and the significance of family ties because the claims of other institutions have taken on some of the tasks previously carried on within the household, then it can hardly be doubted that the family as a social institution has experience a decline. However, following this definition, we must conclude that the strength of the family has been waning for at least several centuries, along with the church and the community. The creation of a job-based economy, the growth of nation-states, and, more recently, the development of a global economy have eroded locally based institutions. Families are less likely to be fixed in a geographical place, to control job opportunities, and hence to be able to sponsor the next generation; accordingly, they are far less inclined to support the claims of extended family members. Moreover, state welfare systems have lessened the burden of caring for the elderly and distant relatives who might have called upon family assistance in times past. (Elaborations of this general argument can be found in Burch and Matthews (1987) and Thornton and Freedman (1983).)

At the same time, in other arenas the family has taken on added importance. For example, the family has grown as a center of emotional development and perhaps of personal identity as well (see, for example, Gillis 1996). There is little evidence that might suggest that entering parenthood is less important now than it was a century or two ago. It is difficult to establish that parents feel less responsibility for their children today or take on parental duties less deliberately. Indeed, it could be argued that intensity of kinship obligations to children replaced more extensive kinship ties during the twentieth century. Parents assume a greater cost of bearing children as they provide little or no economic return in the form of household labor or care in old age (Caldwell 1982). The cost of education and training has risen and children since the middle of the twentieth century have spent a longer period as economic dependents (Watkins et al. 1987). Thus, kinship has become more concentrated within the nuclear family and close extended and collateral kin.

The rise of the so-called 'isolated nuclear family,' a system based on a strong and durable conjugal tie that is structurally independent of and equally linked to maternal and paternal kin lines, became the ideal family form in all Western nations during the latter part of the nineteenth and first half of the twentieth centuries. Family scholars debated whether this form would spread to developing countries in other regions of the world along with the free market economy. Goode (1963) argued that the functional 'fit' between an advanced industrial economy and the nuclear form would promote the transformation of family systems to Western-style families worldwide.

Clearly, the convergence has not occurred to the extent that functionalists predicted it would, although it may still be too soon to rule out the possibility that complex and varied kinship systems in Asia and Africa will wane as the economy becomes globalized (Thornton and Fricke 1987). However, provisionally, it appears that these Western-centric predictions may have underestimated the capacity of complex kinship systems to adapt to economic change and vice versa.

Moreover, the functional 'fit' of the nuclear family to the economy did not account for the revolution in gender roles that occurred in the second half of the twentieth century, or the strain placed on the conjugal relationship by what Rose Coser once labeled the 'greedy institution of work.' Paradoxically, the 'fit' between the nuclear family and a postindustrial economy worked far less well than was envisioned by social theorists of family change. Thus, the family place as 'a haven in the heartless world'—a description that was applied to the early, postindustrial family of the late nineteenth century—has continued to be an apt description of its current social definition. Indeed, a mountain of evidence from public opinion surveys shows that the family remains the central institution from which individuals derive meaning and authenticity. Individuals continue to form families although the definition of what constitutes a family has broadened beyond the nuclear unit. In large measure, this recent trend toward diversification has come about because the institution of marriage has been redefined.

2. *Reworking The Marriage Contract*

In the last third of the twentieth century, divorce and nonmarital childbearing rose throughout the West, with the exception of a few countries in southern Europe which remained more dependent on local agriculture, such as Italy and Greece. Generally, when sociologists and social critics argue that the family is declining, they mean that the notion of conjugal permanence has diminished and that marriage expectations have changed. Indisputably, the marriage contract has been radically altered since the 1950s (Bumpass 1990). In virtually all Western societies, individuals have been granted more autonomy in choosing marriage partners; parents' ability to influence marriage decisions has all but disappeared. Over the past several decades, partners enter marriage expecting relative equality in decision making. The authority of males has declined as a cultural expectation even when it is still maintained in practice by marriage partners. This transformation was brought about in part because of the erosion in the gender-based division of labor within the family. This shift, in turn, can be traced to the growth of a high-skills labor

market in which women are, more or less, on an equal footing with men. The growth of gender equality has also been linked to education, political activism by feminists, and legislative changes resulting in growing economic and political equity among men and women. These changes have altered the cultural context in which marriage takes place. Marriage ceremonies are less likely to include the pledge of obedience—a symbolic shift that suggests that equality among marriage partners has become the ideal.

3. *Changing Marriage Practices*

The change in the marriage contract has generated considerable strains in the matrimonial institution: both men and women have been forced to adhere to a new set of rules governing everyday household practices. Women are now expected to work outside the home and men to assume a greater share of the domestic chores. This renegotiation of gender roles has been accepted more quickly as an ideal among the better educated. Whether it has been put into practice among more educated couples has been questioned by some researchers (Hochschild 1989), but the preponderance of the evidence suggests that this change in gender roles has been dramatic in the past several decades. At least in childcare, men are assuming more responsibility than they did in previous generations, and the normative support for paternal involvement has grown at a phenomenal pace. Still, it is unusual in most countries to find stay-at-home fathers, with the exception of the Scandinavian countries, Norway and Sweden most notably, where public policies have promoted paternal leave, partly to signal men's equal responsibility to childcare.

No doubt the decline of the gender-based division of labor is partially responsible for the remarkable increase in marital dissolution during the latter third of the twentieth century. It may also be linked to the growing practice of cohabitation and the rise of nonmarital childbearing. Marriage is widely viewed as a more problematic and less permanent arrangement than at any time in the recent past, perhaps especially by women. This wariness about wedlock is both a consequence and a cause of higher levels of marital instability. Couples are inclined to enter marriage more cautiously and deliberately than they did in the 1950s. For example, no longer is premarital pregnancy a cause for marriage as it was in the mid-twentieth century. As couples have become more discerning and planful about entering marriage, they have relied on cohabitation as a way of hedging their bets. Some researchers have argued that cohabitation establishes a pattern of leaving relationships that are not good enough.

What constitutes a 'good enough' marriage has become more exacting as well. Whereas in earlier times couples remained wed even if they were discontent with the relationship, today they are more inclined to leave the relationship unless they are content. A rising standard of marital expectations can be inflationary, creating ever higher standards for couples.

This search for greater contentment also plays out in the sexual dimension of marriage. The more open attitude about sexuality and the greater level of premarital experience places greater demands on achieving sexual satisfaction within marriage. Whereas in earlier times couples might have put up with minimal gratification, it is less likely that they are willing to do so today. Increasingly, then, we have seen a shift from a companionate marriage to an intimate marriage as the standard of success.

Another and perhaps more important source of marital instability derives from women's ability to live independently, albeit generally at an economic lower standard. Economic independence permits women to leave relationships that are deemed to be unsatisfactory and men to justify dissolving unhappy partnerships more easily. The turnover of relationships means that marriage is exposed to norms of the market place. The conditional marriage contract itself contributes to the inflationary expectations for marital contentment, driving individuals to be ever more wary and to keep an eye on their options. In some sense, this process resembles the inflation of political expectations that Tocqueville describes in explaining why revolutions breed discontent.

4. *Marital Dissolution and Children's Welfare*

How these changes in the institution of marriage have affected children's welfare is a matter of considerable discussion and a certain amount of debate among researchers (Cherlin 1981). Yet the range of scholarly disagreement seems to be narrowing. Almost everyone agrees that divorce and nonmarital childbearing leave children with fewer resources owing to the facts that women who earn less than men are typically awarded primary custody and that marriage generally provides more than a single income. Only in Sweden do children from single-parent families retain the same standard of living as children in two-parent families through welfare benefits; in all other countries, the income gap is at least modest and more often extreme as is the case in the Anglo-speaking countries which provide less generous support for single parents. In general, parental marital status is strongly associated with family income and appears to account for a substantial portion of the 'divorce effect' on children (Garfinkel and McLanahan 1986).

It is also widely accepted now that some portion of the difference in the well-being of children in two-parent and lone-parent families results from social selection. Couples who divorce have less human and

social capital and are probably less resourceful, skilled, and committed to maintaining a stable union. In other words, children in such families would presumably not do as well even if their parents maintained a stable union while they were being raised owing to a host of conditions related to the probability of marital discontentment and divorce as well as perhaps parenting practices and the ability of parents to manage their children's success.

Still, most scholars agree that marital instability, or family instability of any type, is associated with developmental disadvantages over and above the costs of growing up with fewer resources or social selection. Children profit from stable, secure family situations where they receive attention, support, monitoring, and sponsorship from parent figures, and two such individuals (in a working collaboration) are surely better than one. A mounting number of studies show that, on average, children do better both in the short-term and as adults when they are raised continuously by their biological parents. Remarriage does not appear to confer similar benefits to children apart from the obvious economic benefits, though much of the research on remarriage fails to distinguish the effects of divorce from the impact of remarriage.

It is still an unsettled question whether parents who provide a stable union to children need to be the biological progenitors and whether formal marriage offers any benefits over informal, contractual unions. These issues are especially thorny ones to examine, for they introduce difficult issues of social selection. Provisional evidence suggests that it is the quality of the partnership and the ability of parents to collaborate successfully that seem to matter more than the gender of parents or whether the union was sanctified by the state or church.

5. *Societal Consequences of Marital Dissolution*

The continuing high levels of nonmarital childbearing and union instability in all Western countries has placed added demands on extended kin, especially in segments of the population where remarriage rates are low. Grandparents, especially, are called upon to lend assistance to divorced or unmarried parents and their children. And even prior to family formation, parents may incur greater obligations as their adult children forestall marriage. In many countries, the postponement of marriage has meant that adult children remain in the home well into their twenties and return to reside with their parents in the event of divorce or nonmarital childbearing.

The pressure on parents at mid-life to maintain responsibilities to their children and grandchildren has certainly increased over several decades. Similarly, adults at mid-life frequently face growing obligations to care for their elderly parents who are surviving in greater numbers. In these respects, the extended family is alive and well. The flow of assistance to children is increasingly downward through the generations, at least until parents are no longer able to provide care for their offspring and support for their grandchildren. In contrast to the past, parents of mature children appear to provide more assistance to their offspring than is given to them.

The ways in which divorce and remarriage have affected the provision of support among close kin has received growing attention by scholars. Evidence is accumulating that divorce seriously disrupts the exchange of support from fathers to their children and from the extended patrilineal kin to their former in-laws and their offspring. Whether the reverse is true when fathers retain custody has not been documented. To a remarkable degree, fathers' contact with their children tends to slacken off after marital dissolution. It is possible that this pattern of attrition in paternal contact and support may be less marked today than it was in the 1970s and 1980s. Men, it seems, shift allegiance to new households, and custodial mothers may actively discourage their former mate's involvement with the children when they acquire new partners. Despite the strong legal support for the maintenance of biological ties, the practical implications of creating harmonious relationships across households of formerly and currently married couples is formidable. Consequently, the cumulative impact of divorce (and nonmarital childbearing, where fathers are even less likely to be an active presence in the child's life) has been to give the kinship system a matrilineal tilt.

Remarriage partially restores the bilateral pattern of the family system by reintroducing paternal kin into the family. However, stepparents do not generally create the same strong kinship ties as biological parents, owing perhaps to the fact that kinship ties are often cemented during childhood. Stepkin may also divide their allegiance to former and current marriage partners and their offspring. Nonetheless, the creation of 'remarriage chains' that link former and current kin is a growing source of connection in Western family systems with high rates of conjugal succession. There is some evidence suggesting that the network of in-laws may expand with remarriage as some relatives from the first (or second) union are retained along with the acquisition of kin from the second (or third).

Possibly, too, the pattern of growing involvement of formerly married men in the lives of their children may also help to maintain kinship ties between children and their paternal kin. The attrition of family bonds between men and their children appears to have lessened in recent years as men have become more involved in childcare both after marriage and divorce. The growing pattern of joint legal, if not physical, custody may encourage continued contact between fathers and their children. If this happens, it is likely that the kin of divorced fathers will also play a more active role in children's lives.

The growing complexity and diversity of kinship networks are likely to be a feature of family life in the twenty-first century. It seems unlikely that life-long monogamy will be a prominent feature of the family as it was, at least for a time, in the previous century. If this prediction proves to be right, then public policy is likely to focus on how to deal with the problems of family life created by marital fragility.

6. *Public Policy Considerations*

Current public policy in the USA and Europe has weighed heavily in favor of promoting paternal involvement, especially in the form of material support. A series of legislative acts in the USA, beginning with the Child Support Act of 1988, have been designed to increase the level of child support payments. This legislation has had modest effects in increasing payments, but has also provided normative pressure on men to retain their paternal responsibilities. Fathers Rights groups have become advocates for more even-handed custody policies, to the dismay of some feminists who believe that children will suffer from an increase in conflict created between custodial and noncustodial parents when joint custody is imposed. It is still too early to draw firm conclusions about the consequences of the new policies promoting greater paternal involvement. However, judging from recent information collected by the Census Bureau on Child Support Payments, it seems unlikely that change in postdivorce family relationships is likely to be dramatic. A substantial minority of fathers are still unwilling or unable to pay the mandated child support, although these official figures do not always reveal informal payments that are passed from fathers to mothers and children. Even taking 'under the table' support into account, these results suggest a high degree of recalcitrance on the part of men to undertake support of their children or, alternatively, that men are giving a greater priority to supporting their current households than their former ones.

The largest segment of nonpaying parents is unmarried fathers whose ties with their children appear to become especially tenuous over time. This is also the fastest growing portion of childbearing couples who do not reside together. In most European countries, the growth of nonmarital childbearing has not implied the absence of cohabitation as it does in many of the Anglo-speaking countries, especially the USA. Although *de facto* marriages are ultimately less stable than *de jure* unions, they appear to share most of the features of nuclear families.

In contrast to most of the Western nations, the characteristic pattern of nonmarital childbearing in the USA is matrifocal, putting the father in a more marginal and tenuous position. This family form, especially common among low-income couples and minority populations, may be linked to economic and social marginality in the larger society. One of the most intriguing questions facing social demographers and household economists is whether a sustained economic boom will reverse this alternative pattern of family formation by making marriage more affordable. It seems that for less privileged segments of the population marriage has been considered a luxury item.

In the USA, and to a lesser degree in other Anglo-speaking countries, concern about family dissolution has generated considerable public discussion about the link between family change and the welfare of the next generation. Americans, particularly, are culturally committed to what might be called a highly 'privatized' family system, in which the State and family are seen as antagonists rather than allies. In countries where the opposite is the case, such as Scandinavia and northern European nations, the family and State are viewed as isomorphic. The State is expected to sustain and support the family, and parents are accustomed to receiving benefits for assuming parental responsibilities.

Some scholars have raised the question of whether the relationship between family and State has implications for the overall welfare of children. In short, are children better off when the State is held at arm's length, or when the State is granted more leeway in allocating resources and mandating requirements? The paucity of cross-national data and studies precludes an answer to this question. Rather little research has been undertaken that compares State and family arrangements or examines the institutions that mediate between the two, such as schools, community organizations, voluntary groups, and the like. Such research provides a fertile ground for understanding both the determinants and consequences of change in kinship systems and the resulting consequences for the welfare of children.

Distance Education

1. *History: From Correspondence Education to Distance Education*

The beginning of what today we call 'distance education' is to be found in the concept of correspondence courses starting in the middle of the nineteenth century, with surface-mail corrections of assignments in, for example, shorthand courses or language-learning courses. Printed material as instructional provision was enriched by tutorial interaction via the mail.

The university extension movement, which enabled students in the colonies to prepare for a final examination, is another root of distance education. Elements such as written assignments and corrections, as well as instructions following the prescribed curriculum of an institution, could be more and more elaborated and diversified as the quality and ease of mail services all over the world developed.

Wherever the mail service was unreliable or wherever socialization processes were predominant, alternative forms of higher education evolved. An example is the former USSR, where until the middle of the twentieth century correspondence education was developed as a special form of higher education for the workforce, with personal contacts, seminars, and examinations offered on the premises of classical education institutions at times when the regular students were on vacation (e.g., in summer periods). Adult education with evening courses and correspondence education with vacation courses increased the efficiency of higher-education institutions: more than one-third of all higher-education examinations in the former USSR came from this kind of correspondence education.

There is also a tradition of distance education in rural regions (where geographic distances have to be overcome) and even for secondary schooling, for example in Australia. Some governments provide their staff and families with opportunities for distance education during stays abroad. During World War II, for example, the US government had a large department of distance education for the military.

As basic communication systems gradually changed in the middle of the twentieth century from surface mail to electronic systems, a gradual change from correspondence education to distance education took place. There was more and more dependency on the efficiency of modern media, leading to today's situation, in which even final examinations in some universities may take place as video conferences.

2. *Definition*

Distance education is an organizational form of education in which instructional provisions, tutorial interactions, monitoring of practice, as well as individual control of learning may take place via media which make the simultaneous personal presence of tutors and students avoidable.

3. *Theory*

The characteristic feature of distance education is the planned and controlled two-way interaction which differentiates it from all self-instructional methods. For a long time distance education was regarded as an inferior form of higher education, lacking all the possibilities of socializing students in an academic tradition.

Meanwhile the large institutions for distance education increase their leading role in national higher-education provision. Sir John Daniel (1996) of the British Open University speaks of 'mega-universities' regularly enrolling more than 100,000 students a year. In Europe at the end of the twentieth century more than 2.2 million students were enrolled in formal systems of distance education—in France alone the Centre National d'Education à Distance, founded in 1939, offers distance education as a form of continuing education for the public services to more than 400,000 students. With the decline of government-controlled higher education in the former socialist regions of Europe, there is also a growing 'private market' selling distance education courses to half a million people in Eastern European countries. Enrolments of more than 100,000 students each year are also reported from China and Korea.

The above-mentioned sense of distance education as inferior is fading away not only because of its success in terms of enrolment numbers but also because of the insight that the processes of planning or better 'designing' instruction, foreseeing instances for communication, including regular assessment possibilities for self-paced learning, and the necessity for constant quality control all have a long tradition in distance education and are seen to be the key factors of modern higher education.

3.1 Dropout Rates

One of the major problems of all distance education institutions is the fact that they have to report dropout rates of mostly more than 50 percent. The reason for such dropout figures is the heterogeneity of the students attracted by this form of higher education.

Many students drop out because they:

(a) just want to own course material for reference to keep up with the development in their subject area (nonstarter);

(b) try to work through the material and decide that the course does not meet their expectations (drawback);

(c) worked through the material, participating in regular assessment, but stopped when saturated (dropout); or

(d) worked through the whole course but decided not to sit for an examination (no-show).

It is clear that for adult learners none of these decisions can be associated easily with academic failure. Only in one of the categories, whenever 'dropout' students fail to meet their own goals, can we speak of 'dropout' in the usual sense of failure. Therefore the dropout rates do not give information about the didactic quality of the program but rather about bureaucratic problems of handling different types of customers with different types of interests.

3.2 Microdidactics for Megasystems

For a long time educational systems have been organized as representing a static concept of learning. Curricula with a plethora of old and new elements recommended as being useful for life or jobs were prescribed for young people—with initiation rites at the end of schooling (Vertecchi 1998). The clearer it became that learning will never end in one's lifetime, the faster and more regularly industry and changing administrations needed new qualifications, the faster educational systems had to adapt to these changing scenarios. One of these modern scenarios is distance education. In the middle of the twentieth century the striking analogy between distance education and the processes and pitfalls of early industrialization was presented by Peters (1983), who coined the expression

Figure 1
Structure of distance education

'DE as an industrialized form of teaching and learning,' mass production and specialization of the workforce in the production process being the characteristic features of large distance-education institutions. This subsequently led to the discussion of Fordism and labour-market theories in distance education (Rumble 1995). At the turn of the millennium observations in so-called virtual seminars led back to the microdidactic features of distance education in proving that characteristics of school learning would also take place in virtual settings (Fritsch 1997).

The discussions of quality control in the field of education at the turn of the twenty-first century showed that distance education institutions are much more at ease with the requirement of institutional evaluation than traditional institutions, where didactical situations are beyond control of the management because the door of the classroom is usually closed.

3.3 Media as Method

The didactic dimensions of the field of education are also valid for modern higher education using modern media:

(a) The pitfalls of misunderstanding media can easily be traced to the assumption that some areas of interest (content and goals) are easier to transmit via modern media than others.

(b) Media for instruction, especially increasing the number of possible students by mass production of teaching material (and thus the functions and characteristics of teachers), are the reason why distance education has suffered from an inferiority complex: virtual teaching situations are considered less valid than real world ones.

(c) There is a misunderstanding that media must be a separate element (what is the most convenient way of doing this?) in the dimensions of education. In fact, it is the method of teaching which forms this element, not the media. Consequently the didactic field has not changed in its basic structure.

Where media have a role to play in all fields is with regard to the question of interactions between didactic functions: 'qualifying, counselling, instructing, interacting, controlling and certifying.' Many interactions between didactic elements (see Fig. 1)—goals–content,

teacher–student, and practice–society—can also be realized using modern media. 'Non-contiguous forms' (Holmberg 1989) of interaction (transcending the limitations of time and place) in the educational process are in the foreground of distance-education theory.

For example: whenever a university uses campus TV or satellite TV to 'broaden' the scope of its audience, this should not yet be called distance education because the didactical setup remains dependent upon the simultaneous presence of student and teacher at defined places. Instead, this setup belongs to the concept of 'distributed learning' (Bates 1995). However, when a 'lecture' is integrated (e.g., as a video) into a defined setting of didactical considerations it might very well be part of a distance-education program, because the necessity for individuals to attend a certain place simultaneously is no longer a given. This argument does not mean that distance education will never provide face-to-face contact: most distance-education organizations do have provisions for social interaction or tutorial help. The question is which predefined didactical function can be best met by which medium.

3.4 Error-oriented Tutoring

Mass production of teaching material on the one hand is counterbalanced by the need to tutor large numbers of students on the other—as long as tutoring and individual help are carried out in the same way as in regular educational settings, distance education will not have a big economic effect on educational systems. But the possibility of designing tutorial help, via modern media, to include systems of automatic tutorial help makes distance education economically much more efficient. In classroom situations teachers know there are certain points in the learning process at which students always have similar difficulties. Good teachers not only indicate that an error has been made, but give assistance in the form of explanations, additional assignments, etc. Such error-oriented comments, explanations, and additional assignments can be geared automatically to the student exactly when an error occurs—just in time. In the early days of distance education the Open University, for example, had two different forms of assignments: tutor-marked assignments (TMA) and computer-marked assignments (CMA). It is more costly to have many TMAs and the turnaround time of CMAs can be far more effective (even more so if transferred to the World Wide Web for instant control). Fern University at Hagen, Germany, has developed a system of CMAs which provide the student with comments on typical errors made. Empirical research has shown that a very high percentage of previewable errors can be handled in this way. In projects of language learning, too, instant correction of previewed errors has proven to be a very important didactical feature in the use of modern media.

3.5 Transformation

In many cases concentrating on the element of instructional provision and transforming it into modern media is misunderstood as a way of attempting to transform the whole system of education, and neglecting other elements of teaching (tutorial interactions, monitoring of practice, and individual control of learning).

It is much easier to transfer existing courses of distance education to the World Wide Web, if they have been prepared in a way that is typical for high-quality education of this type, with:

(a) learning goals explicitly formulated;
(b) structured curriculum decisions according to individual interests;
(c) instances for monitored practice and tutorial help;
(d) control of learning outcomes; and
(e) evaluation of the system of teaching and learning.

4. State of the Art

Many large universities have found a new market in courses for continuing education and have installed departments for distance education, especially because of the need to cater for students who belong to the regular workforce or live far away and cannot be asked to come to campus for lectures or seminars. These universities are called 'dual-mode universities' because their academic position in the hierarchy of higher-education institutions has been thought to depend on the classical structure of also being a 'regular' university. Even the earliest forms of distance education institutions, such as the University of South Africa, are regarded as dual-mode universities. It was the British Open University which was the first to enter the higher-education sector as a purely single-mode distance-education university, and it has influenced the development of dozens of other universities worldwide. It is the impact of new technologies on both systems, traditional and distance education, which is forcing higher-education institutions to think about their specific potential. The distinction between campus-based and distance learning becomes more and more irrelevant as both learner groups use modes of distributed teaching. Asynchronous communicative acts for learning are no longer specific to the distance-education sector. The boundaries of campus have lost their relevance with the advent of the World Wide Web. Whether distance education will survive in future

depends on whether classical higher-education institutions are prepared to enter into a continuous dialog with each individual learner.

5. *Distance Education Institutions Developing into Virtual Universities*

There has been an explosion of distance-education courses made available through the Web—at the end of the 1990s linked Web descriptions of more than 15,000 different courses could be traced—and this comprises just the major institutions of English-speaking countries, which have a longer tradition in distance education. Global universities (http://www.global-learning.de/g-learn/aktuell/index.html), Globewide Network Academy (http://www.gnacademy.org), and World Lecture Hall (http://www.utexas.edu/world/lecture) are the main addresses of these initiatives. This booming advance has been made possible by the fact that *customers* want to know what they will 'get' for their participation, and internationally accepted credits are the key to this development. Without a functioning credit transfer system like the one students are familiar with in the USA, this development will halt at the borders of traditional tertiary education. As a result the development of a European Credit Transfer System has become a major topic in the European Union. But the time that elapses before such a European-wide system is introduced and accepted will show that this form of education is big business; people interested in continuing education are more interested in 'just-in-time' courses, taken when they need them, than in following a prescribed curriculum. Consequently, one of the goals of the International Council for Distance Education (ICDE), the worldwide association of major institutions acknowledged by UNESCO, which runs biannual conferences (http://www.icde.org), is to provide databases with information about all the courses available. This goal is also being pursued by the International Centre for Distance Learning (ICDL) at the Open University in Milton Keynes, which has produced a structured bibliography of distance learning (http://www.icdl.open.ac.uk/bib/toc.htm).

Distributions, Statistical: Approximations

Every random variable has its own particular distribution. It is, however, very useful if one can use a well-studied distribution as an approximation. This article describes a set of situations in which a random variable with a complicated probability distribution can be approximated well by another, better understood and the studied probability distribution. The first example is the normal distribution which approximates the distribution of many random variables arising in nature. This approximation is based on the central limit theorem. Generalizations of this theorem provide a second set of approximations called the stable laws. A third example arises when one is considering extremes, or the maximum of a set of random variables. Here, the family of extreme value distributions is shown to provide accurate approximations. Moreover, the excesses over a high level can be approximated by a generalized Pareto distribution. The final example involves the distribution of the times between events, such as system failures. Under certain conditions, these times can be well approximated by an exponential distribution. Consequently, the corresponding point process (or event history) can be approximated by a Poisson process.

1. *Normal Approximations*

The normal or Gaussian distribution has a probability density function (p.d.f.) given by

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right) \qquad -\infty < x < +\infty$$

where the parameter μ is the mean or median and σ is the standard deviation. The standard normal distribution corresponds to the special case in which $\mu = 0$ and $\sigma = 1$, for which the p.d.f. is given by

$$f(x) = \frac{1}{\sqrt{2\pi}} \exp(-\tfrac{1}{2}x^2), \quad -\infty < x < +\infty$$

The normal distribution serves as an excellent approximation to many random variables that arise in nature. The reason for this lies in the central limit theorem, the simplest version of which states:

Theorem (Central limit theorem)
Suppose $\{X_r\}_{n=1}^{\infty}$ is a sequence of independent identically distributed (i.i.d.) random variables with cumulative distribution function F, mean μ, and variance $\sigma^2 < \infty$. Then

$$Z_n = \frac{\Sigma_{i=1}^{n}(X_i - \mu)}{\sigma\sqrt{n}} \Rightarrow \Phi$$

where Φ represents the c.d.f. of a standard normal distribution and $\Rightarrow$ denotes weak convergence.

This theorem says that the standardized partial sums of the $\{X_n\}_{n=1}^{\infty}$ sequence converge weakly to a standard normal distribution.

This theorem has many generalizations which allow for the $\{X_n\}_{n=1}^{\infty}$ to have different distributions (so long as each random variable has finite variance and contributes only a small part to the sum) and to have a dependency structure (so long as the correlation among the variables diminishes rapidly enough). The reader should consult *Distributions*, *Statistical*: *Special and Continuous* for additional information about the normal distribution. The textbook by DeGroot (1986) offers examples of the application of the central limit theorem, some extensions of the basic theorem, and discussions of weak convergence, also known as convergence in distribution. The reader should consult the text by Billingsley (1995) for the precisely stated theorems.

The central limit theorem indicates that suitably standardized sums of independent random variables will have an approximate normal distribution. Thus, any random variable which arises as the sum of a sufficiently large number of small random components can be modeled accurately by a normal distribution. This is especially appropriate for error distributions, where the error term is the sum of a number of different sources of error. The question of how large n must be for the approximation to be accurate depends on two factors: (a) the degree of accuracy required; and (b) the underlying distribution F. A common 'rule of thumb' is that the normal approximation can be safely used when $n \geqslant 30$ as long as F is not highly skewed and a high degree of accuracy is not required. The normal distribution is commonly used as a model for many statistical problems especially in linear models; see *Linear Hypothesis* and *Linear Hypothesis*: *Regression* (*Basics*) for details.

2. *Stable Distributions*

In this section, we present an extension of the central limit theorem. When $\{X_n\}_{n=1}^{\infty}$ is a sequence of i.i.d. random variables, each having a finite variance, then the partial sums of these variables can be normalized to converge weakly to a normal distribution. When the underlying random variables do not have a finite variance, then normalization of the partial sums can still lead to weak convergence to a nondegenerate limiting distribution; however, the limiting distribution will no longer be normal, but will instead be a *stable* distribution.

Definition (Stable distributions)
A distribution F is stable if given any three i.i.d. random variables, X_1, X_2, X_3, with distribution F and any constants c_1, c_2, there exists constants a and b (depending upon c_1, c_2) such that $c_1X_1 + c_2X_2$ has the same distribution as $a + bX_3$. If $a = 0$, the F is *symmetric stable*.

This means that any linear combination of two i.i.d. random variables with a common stable distribution can be transformed linearly to have the same stable distribution. This definition can be used to prove that if $\{X_i\}_{i=1}^{n}$ are i.i.d. with a stable distribution F, then there exist constants a_n, b_n such that $\frac{\Sigma_{i=1}^{n} X_i - a_n}{b_n}$ also has c.d.f. F. The symmetric stable distributions are most easily described by their characteristic functions.

Theorem (Characteristic function of a symmetric stable law)
A standard symmetric stable distribution has characteristic function $\phi(s) = e^{-|s|^{\alpha}}$ for $0 < \alpha \leqslant 2$.

Two special cases are the normal (0,1) distribution ($\alpha = 2$) and the standard Cauchy distribution ($\alpha = 1$). The following theorem indicates that the non-degenerate stable laws represent all possible limiting distributions for sums of i.i.d. random variables.

Theorem
Suppose $\{X_n\}_{n=1}^{\infty}$ is a sequence of i.i.d. random variables with cumulative distribution function F, and suppose that there are sequences of constants, $\{a_n\}_{n=1}^{\infty}$ and $\{b_n\}_{n=1}^{\infty}$ for which $\frac{\Sigma_{i=1}^{n} X_i - a_n}{b_n} \Rightarrow G$, a nondegenerate limiting c.d.f. Then G is a nondegenerate stable law.

The family of stable distributions represents a wider class of possible limits of sums of i.i.d. random

variables. The distributions other than the normal have heavier tails than the normal distribution. Informally, a symmetric distribution with exponent $\alpha < 2$ has finite moments of order less than α. For example, the Cauchy distribution ($\alpha = 1$) does not have a first moment, but all moments less than 1 are finite. The stable distributions have been used to model certain economic variables and the return of financial assets such as stocks or currency exchange rates. See *Distributions, Statistical: Special and Continuous* for additional information on the Cauchy distribution. The reader should consult Billingsley (1995), Embrechts et al. (1997), or Lamperti (1966) for more detailed information on stable distributions and the theorems underlying this more general central limit problem.

3. Extreme Value Distributions

Another type of approximation occurs when one is studying the maximum of a set of random variables. This situation is particularly relevant in the casualty insurance industry, where interest centers on the largest claims. These situations also arise in engineering and environmental problems, where a structure such as a dam or building must withstand all forces, including the largest. Suppose $\{X_n\}_{n=1}^{\infty}$ is a sequence of i.i.d. random variables with common distribution function F. Suppose that x^* denotes the rightmost support point of F, the smallest x for which $F(x) = 1$, or $+\infty$ if no such x exists. We consider $\{M_n\}_{n=1}^{\infty}$ where $M_n = \max_{\{1 < i < n\}} X_i$, the largest among the first n random variables in the sequence. Fisher and Tippett (1928), a classic paper, showed that if there are sequences of constants $\{a_n\}_{n=1}^{\infty}$ and $\{b_n\}_{n=1}^{\infty}$ for which $\frac{M_n - a_n}{b_n} \Rightarrow H$, a nondegenerate limiting c.d.f., then H takes on one of three possible forms:

(a) The Gumbel distribution:

$$H(x) = \exp(-e^{-x}), \quad -\infty < x < +\infty$$

This limiting form arises when $x^* = \infty$ and the underlying distribution F has a right-hand tail which decreases at an exponential rate. Specifically, if there exists a constant $b > 0$ for which $\lim_{x \to \infty} \exp(x)(1 - F(x)) \to b$, then $M_n - \log(nb)$ converges to the Gumbel distribution as $n \to \infty$.

(b) The Fréchet distribution

$$H(x) = \begin{cases} \exp(-x^{-\alpha}) & \text{if } x > 0 \\ 0 & \text{if } x \leqslant 0 \end{cases}$$

where $\alpha > 0$. This limiting form arises when $x^* = \infty$ and the right tail of the underlying distribution F has a tail which decays at a polynomial rate. Specifically, if $\lim_{x \to \infty} x^{\alpha}(1 - F(x)) \to b$, for some constant $b > 0$ and $\alpha > 0$, then $M_n/(bn)^{1/\alpha}$ converges to the Fréchet distribution as $n \to \infty$.

(c) The Weibull distribution

$$H(x) = \begin{cases} \exp(-(-x)^{\alpha}) & \text{if } x \leqslant 0 \\ 1 & \text{if } x \geqslant 0 \end{cases}$$

where $\alpha > 0$. The above distribution is concentrated on $(-\infty, 0)$, and it is the negative of the traditional Weibull distribution. This limiting form arises when $x^* < \infty$, i.e., the underlying distribution F is bounded above by a constant. Specifically, assume $\lim_{x \to x^*} (x^* - x)^{-\alpha}(1 - F(x)) \to b$ for some constants $b > 0$ and $\alpha > 0$, then $(nb)^{1/\alpha}(M_n - x^*)$ converges to the Weibull distribution defined above as $n \to \infty$. The reader should consult *Distributions, Statistical: Special and Continuous* for additional information on the Weibull distribution.

Fisher and Tippett (1928) proved that these are the only possible limiting forms. It is, however, important to point out that, for some underlying F, there may be no set of constants $\{a_n\}_{n=1}^{\infty}$ and $\{b_n\}_{n=1}^{\infty}$ for which $\frac{M_n - a_n}{b_n} \Rightarrow H$. The conditions under which this convergence occurs are complicated, and the interested reader is referred to Embrechts et al. (1997). Lamperti (1966) also provides a nice treatment of extreme value theory.

The three extreme value distributions given above describe the limiting of the maximum of a random sample. There is a second random quantity that is related to the maximum and is interesting in it own right. Suppose we begin with a random variable X with c.d.f. F and consider the conditional excess distribution of X, $X - u$, given that it exceeds u. Specifically, consider $F_u(x) = P(X - u \leqslant | X > u)$. One could also consider the expected excess, conditional on the random variable exceeding u, $e(u) = E(X - u | X > u)$. This distribution and expectation arise in engineering and insurance problems, where the quantity above a certain high limit is of concern, such as the insurance claim above a large deductible amount.

The standard generalized Pareto distribution is a family of c.d.f.s indexed by a parameter $\theta \in (-\infty, +\infty)$ given by

For $\theta < 0$,

$$G_{\theta}(x) = \begin{cases} 0 & \text{if } x < 0 \\ 1 - (1 + \theta x)^{-1/\theta} & \text{if } 0 \leqslant x \leqslant -1/\theta \\ 1 & \text{if } x \geqslant -1/\theta \end{cases}$$

For $\theta = 0$,

$$G_0(x) = \begin{cases} 0 & \text{if } x < 0 \\ 1 - e^{-x} & \text{if } x \geqslant 0 \end{cases}$$

For $\theta > 0$,

$$G_{\theta}(x) = \begin{cases} 0 & \text{if } x < 0 \\ 1 - (1 + \theta x)^{-1/\theta} & \text{if } x \geqslant 0 \end{cases}$$

The family can be enlarged by adding a location and scale parameter.

For a given value of θ, the probability distribution of F_u approaches that of a generalized Pareto distribution as $u \to x^*$. Thus, the generalized Pareto distribution can be used to approximate the probability distribution of excesses over a high limit. The mean excesses can also be modeled using a generalized Pareto distribution.

The reader should consult Embrechts et al. (1997), a comprehensive treatment of extreme value theory and for exact conditions and statements of these approximation results.

4. *Times Between Events in a Point Process*

A random point process is a sequence of events (or points) that occur in time. Common examples of point processes are event histories, the failure times of systems, arrivals of customers to a service facility or the firing of neurons in the human nervous system. Clearly, modeling such point process phenomena can be very complicated and detailed. There is, however, an approximate result that is widely useful in such modeling. Specifically, for an important class of point processes, a reasonable approximation is that the times between events are i.i.d. random variables with an exponential distribution, a p.d.f. given by:

$$f(x) = \begin{cases} \lambda e^{-\lambda x} & \text{if } x \geqslant 0 \\ 0 & \text{if } x < 0 \end{cases}$$

with $\lambda > 0$. The parameter λ measures the rate at which the events occur and is measured in units of events per unit time. Such a point process is called a Poisson (λ) process. Poisson processes have three important properties: (a) the number of events in an interval of length L is a random variable with a Poisson (λL) distribution; (b) the number of events in non-overlapping time intervals are independent random variables; and (c) the probability of exactly one event in an interval of length h, divided by h, converges to λ as $h \to 0$. Hence events cannot occur simultaneously in a Poisson process. See *Distributions, Statistical: Special and Continuous* for additional information on the exponential distribution.

Now, suppose that the point process is composed of the superposition of a large number of independent point processes, each individually with insignificant intensity function. Then the superposed (aggregated) point process converges (as the number of components superposed increases) to a Poisson process. The reader should consult the text by Karlin and Taylor (1975) for a precise statement of this theorem. This situation is very realistic for system failures in which the system is composed of many different parts, the failure of any one of which leads to system failure. Each component has its own failure distribution, and the time to the next failure will be the minimum of these failure times, which will converge to an exponential distribution as the number of components increases. A similar situation occurs with aggregate customer arrival processes, where the aggregate process is the superposition of a large number of different arrival processes. As the number of different arrival sources increases, the limiting aggregate arrival process will become Poisson. The reader should consult *Queues* to learn about the use of the exponential distribution, and the Poisson process as a model for customer arrival processes.

5. *Further Reading*

The reader should consult a basic textbook on probability such as DeGroot (1986) for information on many of the distributions mentioned in this article, for a description of the basic central limit theorem and examples of its use, and for some more general results. Billingsley (1995) provides a more comprehensive and technically detailed treatment of the central limit theorem, the stable laws and the extreme value distributions. Finally, the book by Embrechts et al. (1997) gives a comprehensive treatment of the extreme value distributions and associated approximation theorems.

Distributions, Statistical: Special and Continuous

Continuous probability distributions are used widely in probability and statistics when the underlying random phenomenon is measured on a continuous scale. Common examples include the time until an

event occurs, such as the failure time of a component or system, or most human physical dimensions such as height or weight. In some cases, the underlying random quantity has a discrete set of possible values. If that set is large, it may be possible to rescale those values and treat them as continuous. Continuous distributions arise frequently in the social sciences, for example in IQ or educational testing settings in which the scale is designed to yield a normal distribution of performance. Economic measurements such as income levels are often modeled using continuous distributions. Many observed distributions do not fit any of the standard distributions presented in this article (for example, they may be skewed when compared with the normal distribution); however, it may be possible to apply a transformation to the variable in question to make it fit one of the standard distributions better. In this article, we begin by describing univariate probability distributions, then specialize to the absolutely continuous case. The concept of a failure rate function as an alternative way to describe an absolutely continuous distribution is also introduced. The next section introduces special continuous distributions, including the uniform, beta, normal, exponential, gamma, Weibull, Chi-square, Student t, F, and Pareto. The entry concludes with a definition of multivariate distributions, and the bivariate normal distribution is presented.

1. Definitions and General Properties

A univariate random variable X has a probability distribution which is defined by its cumulative distribution function (c.d.f.),

$$F(x) = P(X \leqslant x), \quad -\infty < x < +\infty$$

A c.d.f. has several properties:

(a) $F(x)$ is non-decreasing, i.e., $F(x) \leqslant F(y)$ if $x < y$;

(b) $\lim_{x \to -\infty} = F(-\infty) = 0$;

(c) $\lim_{x \to +\infty} = F(+\infty) = 1$;

(d) F is right continuous, i.e. $\lim_{h \to 0} F(x+h) = F(x)$; and

(e) $P(a < X \leqslant b) = F(b) - F(a)$, $-\infty \leqslant a < b \leqslant +\infty$.

When the c.d.f. is a step function, $\{(x_i, p_i)\}_{i=1}^{\infty}$, with a jump of height p_i at location x_i, $1 \leqslant i < \infty$, then the associated probability distribution is called a *discrete distribution*. If the c.d.f. is a continuous function, the associated probability distribution is called a *continuous distribution*. When the c.d.f. has jumps satisfying $0 < \sum_{i=1}^{\infty} p_i < 1$, the distribution is said to be *mixed*.

For continuous distributions, we can define the derivative, $f(x) = dF(x)/dx$. The function f is called the probability density function (p.d.f.). When the c.d.f. is absolutely continuous, then one can integrate the p.d.f. to recover the c.d.f., that is,

$$F(x) = \int_{-\infty}^{x} f(u)\, \mathrm{d}u, \quad -\infty < x < \infty$$

One can calculate the probability of an event by integrating the density function; for example, if the event is an interval $[a, b]$, then

$$P(a < X < b) = \int_{a}^{b} f(x)\, dx$$

If X has a continuous probability distribution, then $P(X = x) = 0$ for any value $-\infty < x < +\infty$. The interpretation of the p.d.f. is that $P(x \leqslant X \leqslant x+h) \approx f(x)h$ for small $h > 0$. That is, the probability a random variable with an absolutely continuous probability distribution takes a value in a small interval of length h is given by the probability density times the length of the interval.

For absolutely continuous distributions, the c.d.f. F and the p.d.f. f are equivalent in that one can be derived from the other. An absolutely continuous probability distribution might also be described by its failure rate function, also known as the hazard function. This function is often denoted by $\lambda(x)$ and is defined by:

$$\lambda(x) = \frac{f(x)}{1 - F(x)}$$

The failure rate function arises naturally in specifying the reliability of a system or in mortality tables. This function gives the probability that a system will fail (person will die) in the next small interval of time conditional on it not yet having failed (died) up to the present time. The failure rate function satisfies

$$P(X \leqslant x+h \mid X \geqslant x) \approx \lambda(x)h.$$

The c.d.f., $F(x)$, can be derived from $\lambda(x)$ from the formula

$$F(x) = 1 - \exp\left(-\int_{-\infty}^{x} \lambda(u)\, du \right)$$

where $\lambda(x)$ can be any function satisfying $\lambda(x) \geqslant 0$, $\int_{-\infty}^{x} \lambda(u)\, du < \infty$, $-\infty < x < \infty$, and $\int_{-\infty}^{+\infty} \lambda(u)\, du = +\infty$. See *Survival Analysis: Overview* and *Quality Control, Statistical: Reliability and Life Testing* for additional information about the use of the failure rate function.

The c.d.f., p.d.f., or the failure rate function give complete information about the distribution of a random variable having an absolutely continuous distribution. It is, however, often useful to provide a few simple characteristics or features of the distribution. Typically, one specifies the mean and the variance of the distribution. For absolutely continuous distributions, these can be computed from the p.d.f. by

$$E(X) = \int_{-\infty}^{+\infty} xf(x)\,dx,$$

$$\mathrm{Var}\,(X) = \int_{-\infty}^{+\infty} x^2 f(x)\,dx - (E(X))^2$$

2. *Individual Continuous Distributions*

This section describes some of the most important univariate continuous distributions.

2.1 *Uniform Distribution*

This is a basic distribution with two parameters, a and b denoting the endpoints of an interval. The p.d.f. is given by:

$$f(x) = \begin{cases} \dfrac{1}{b-a} & \text{if } a \leqslant x \leqslant b, \\ 0 & \text{otherwise} \end{cases}$$

If X has a Uniform (a, b) distribution, then for any interval (c, d) satisfying $a \leqslant c < d \leqslant b$, $P(c < X < d) = (d-c)/(b-a)$. The mean and variance are given by

$$E(X) = \frac{(b+a)}{2},\ \mathrm{Var}(X) = \frac{(b-a)^2}{12}$$

The Uniform (0, 1) distribution is often referred to as the standard uniform distribution. If U is a random variable with standard uniform distribution, then $X = a+(b-a)U$ has Uniform (a, b) distribution. Thus, any uniform random variable can be constructed from a standard uniform random variable. This property of using standard uniform random variables to construct other random variables with specific distributions is quite general. The method is called the probability integral transform. Specifically, suppose X is a random variable with a c.d.f. given by F. Let $F^{-1}(p)$, $0 < p < 1$ denote the inverse of F defined by

$$F^{-1}(p) = \inf\{(y \mid F(y) \geqslant p\}$$

It can be shown that if U has Uniform (0, 1) distribution, then $X = F^{-1}(U)$ has c.d.f. given by F. This property is especially important in simulation studies in which one must generate a sequence of random variables with some prescribed probability distribution. If F^{-1} can be computed, then one need only generate a sequence of standard Uniform (0, 1) random variables, plug each of them into F^{-1}, and the result will be a sequence with the required distribution. See *Random Numbers* for more details.

2.2 *Beta* (α, β) *Distribution*

The Uniform (0, 1) distribution is a special case of a two parameter family called the Beta (α, β) distribution. It has a p.d.f. given by:

$$f(x) = \begin{cases} \dfrac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} x^{\alpha-1}(1-x)^{\beta} & \text{if } 0 \leqslant x \leqslant 1, \\ 0 & \text{otherwise} \end{cases}$$

where $\alpha > 0$, $\beta > 0$ and $\Gamma(a) = \int_0^{+\infty} x^{a-1}e^{-x}\,\mathrm{d}x$.

The Beta (1, 1) distribution is the same as the Uniform (0, 1) distribution. The mean and variance of a random variable with Beta (α, β) distribution are given by

$$E(X) = \frac{\alpha}{\alpha+\beta},\quad \mathrm{Var}(X) = \frac{\alpha\beta}{(\alpha+\beta)^2(\alpha+\beta+1)}$$

The Beta distribution offers a very flexible two parameter family of distributions for random variables taking values between 0 and 1. Consequently, it can often be used to model percentage or fractional quantities.

2.3 *Normal* (μ, σ^2) *Distribution*

One of the most important probability distributions is the normal or Gaussian distribution. Its p.d.f. is given by

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2 \right), \quad -\infty < x < +\infty$$

The parameter μ is the mean, while σ^2 is the variance. Since the p.d.f is symmetric about μ, this parameter is also the median.

The standard normal distribution corresponds to the case in which $\mu = 0$ and $\sigma = 1$. It has p.d.f. given by

$$f(x) = \frac{1}{\sqrt{2x}} \exp(-\tfrac{1}{2}x^2), \quad -\infty < x < +\infty.$$

One can construct a Normal random variable X, with mean μ and variance σ^2 from a random variable, Z, with standard normal distribution by using the relationship $X = \mu + \sigma Z$. Consequently, the calculation of

the probability of an event involving X can be reduced to a calculation involving Z. For example,

$$P(a < X < b) = P\left(\frac{a-\mu}{\sigma} < \frac{X-\mu}{\sigma} < \frac{b-\mu}{\sigma}\right)$$
$$= P\left(\frac{a-\mu}{\sigma} < Z < \frac{b-\mu}{\sigma}\right)$$
$$= \Phi\left(\frac{b-\mu}{\sigma}\right) - \Phi\left(\frac{a-\mu}{\sigma}\right)$$

where $\Phi(x)$ is the c.d.f. of the standard normal distribution. The function $\Phi(x)$ is widely tabled and is given in nearly every basic statistics textbook.

The normal distribution is of great importance, because it is an excellent approximation for the probability distribution of many random variables that arise in nature. The reason for this is based on the central limit theorem. This theorem states that if a random variable arises as the sum of a large number of independent random variables with a common probability distribution having a positive but finite variance, then the distribution of the sum has an approximate normal distribution; see *Probability: Formal* for additional details. The normal distribution is widely used in the social sciences. It is often used to model the distribution of IQ and educational testing measurements within a population. It is commonly used as the distribution of the error term in regression analysis and other linear models problems; see *Linear Hypothesis* and *Linear Hypothesis: Regression (Basics)* for details. Given the importance of this distribution as a basis for much of statistical inference, in cases for which the normal dstribution does not serve as an appropriate distribution for a random variable, one often attempts to find a transformation such that the transformed variable will have an approximate normal distribution.

2.4 *Exponential* (λ) *Distribution*

The exponential distribution arises frequently in problems involving system reliability and the times between events. This distribution is most easily described using the failure rate function, which for this distribution is constant, i.e.,

$$\lambda(x) = \begin{cases} \lambda & \text{if } x \geqslant 0, \\ 0 & \text{if } x < 0 \end{cases}$$

The constancy of the failure rate function leads to the memoryless or Markov property associated with the exponential distribution. Specifically,

$$P(X > s+t \mid X > s) = P(X > t)$$

The interpretation of the above property is easiest to understand when X represents the lifetime of a component or system. The memoryless property indicates that if the component has lasted for s units of time and is still functioning, then the probability that it will last an additional t time units is independent of s. Thus, the likelihood of an additional life of at least t time units does not depend on its current age, hence the term 'memoryless.'

The p.d.f. is given by

$$f(x) = \begin{cases} \lambda \exp(-\lambda x) & \text{if } 0 \leqslant x < +\infty, \\ 0 & \text{otherwise} \end{cases}$$

for $\lambda > 0$.

If X has an exponential (λ) distribution, then

$$E(X) = \frac{1}{\lambda}, \quad \mathrm{Var}(X) = \frac{1}{\lambda^2}$$

The exponential distribution is the basis for continuous time Markov chain models. This distribution is used to model the sojourn or holding time in a state for a continuous time chain; see *Markov Models and Social Analysis*. Moreover, the distribution is often used as a model for the time between events; for example, in modeling the arrivals of customers to a service center; see *Distributions, Statistical: Approximations* and *Queues*.

2.5 *Gamma* (α, λ) *Distribution*

The Gamma (α, λ) distribution generalizes the exponential distribution. The parameters must satisfy $\alpha > 0$ and $\lambda > 0$. The p.d.f. is given by

$$f(x) = \begin{cases} \dfrac{\lambda^\alpha x^{\alpha-1} e^{-\lambda x}}{\Gamma(\alpha)} & \text{if } 0 \leqslant x < +\infty, \\ 0 & \text{otherwise} \end{cases}$$

Thus a Gamma (1, λ) is an exponential distribution with mean $1/\lambda$. Suppose α is an integer, and $\{X_i, 1 \leqslant i \leqslant \alpha\}$ are independent random variables, each with a Gamma (m, λ) distribution, then $S = \sum_{i=1}^{\alpha} X_i$ has a Gamma (αm, λ) distribution.

If X has a Gamma (α, λ) distribution, then

$$E(X) = \frac{\alpha}{\lambda}, \quad \mathrm{Var}(X) = \frac{\alpha}{\lambda^2}$$

The Gamma distribution offers a two-parameter family of distributions of positive random variables with many possible shapes. This is particularly useful for modeling event histories in social science studies.

2.6 Weibull (A, λ) Distribution

Another probability distribution that arises in reliability and event history modeling is the Weibull (α, λ) distribution for $\alpha > 0$ and $\lambda > 0$. The p.d.f. is given by

$$f(x) = \begin{cases} \alpha\lambda^{\alpha}x^{\alpha-1}e^{-(\lambda x)^{\alpha}} & \text{if } x \geqslant 0, \\ 0 & \text{otherwise} \end{cases}$$

The failure rate function for the Weibull distribution is given by

$$\lambda(x) = \alpha\lambda^{\alpha}x^{\alpha-1}$$

If $0 < \alpha < 1$, then the failure rate function is decreasing, whereas if $\alpha > 1$ the failure rate function is increasing. The $\alpha = 1$ case results in a constant failure rate which corresponds to the exponential distribution.

If a random variable X has Weibull (α, λ) distribution, then X^{α} has an Exponential (λ^{α}) distribution. Thus, when $\alpha = 1$, this distribution becomes the Exponential (λ) distribution.

The Weibull distribution is often used in reliability or survival analysis (or life testing) studies; see *Quality Control, Statistical: Reliability and Life Testing*. The distribution can exhibit a wide range of tail behaviors, especially heavy tails. The Weibull distribution is one of the three *extreme value distributions*, distributions which arise by normalizing the maximum of a random sample from a distribution; see *Distributions, Statistical: Approximations*.

2.7 Chi-square (n) Distribution

The Chi-square distribution with n degrees of freedom has p.d.f. given by

$$f(x) = \begin{cases} \dfrac{1}{2^{n/2}\Gamma(n/2)}x^{(n/2)-1}e^{-x/2} & \text{if } x \geqslant 0, \\ 0 & \text{otherwise} \end{cases}$$

This distribution is a special case of the Gamma (α, λ) distribution with $\alpha = n/2$ and $\lambda = \frac{1}{2}$. It arises as a sum of squares of independent standard normal random variables. Specifically, suppose $\{X_i, 1 \leqslant i \leqslant n\}$ are independent standard normal random variables, then $\sum_{i=1}^{n} X_i^2$ has a Chi-square (n) distribution.

The mean and variance of a random variable having a Chi-square (n) distribution are given by

$$E(X) = n, \quad \mathrm{Var}(X) = 2n.$$

The Chi-square distribution is very widely used in statistics, especially in goodness of fit testing (see *Goodness of Fit: Overview*) and in categorical data analysis. The distribution also arises as the distribution for the sample variance estimator of an unknown variance based on a random sample from a normal distribution.

2.8 Cauchy Distribution

The standard version of the Cauchy distribution has a p.d.f. given by

$$f(x) = \frac{1}{\pi(1+x^2)}, \quad -\infty < x < +\infty.$$

This distribution is symmetric about 0; however, one can introduce both location and scale parameters which can move the center and change the concentration of the distribution.

The Cauchy distribution has a very heavy tail, comparable to the tail of the Pareto $(1, c)$ distribution. In fact, the tail is so heavy that the distribution does not have a mean value. The Cauchy distribution is a *stable distribution*, see *Distributions, Statistical: Approximations*. In particular, it can arise as a properly normalized sum of independent random variables having a suitably heavy tail. The Cauchy distribution and related stable distributions have been used to model certain economic variables, especially financial asset returns.

2.9 Student $t(n)$ Distribution

The Student t distribution with n degrees of freedom arises in statistical inference problems associated with the mean of a normal distribution when both the mean and the variance are unknown. If Z and Y are independent random variables, with Z having a standard normal distribution and Y having a Chi-square (n) distribution, then the ratio nZ/Y has Student t distribution with n degrees of freedom. It has a p.d.f. given by

$$f(x) = \frac{\Gamma((n+1)/2)}{\sqrt{n\pi}\,\Gamma(n/2)}\left(1+\frac{x^2}{n}\right)^{-(n+1)/2}, \quad -\infty < x < +\infty$$

The Student t distribution with 1 degree of freedom is the same as the Cauchy distribution. For large n, the Student t distribution is well approximated by the standard normal distribution. The Student t distribution is widely used in the formation of confidence intervals for an unknown mean of a normal distribution estimated from a sample of data from a normal distribution with both mean and variance unknown. It also arises in the formation of confidence intervals for regression parameters; see *Linear Hypothesis: Regression (Basics)*.

2.10 $F(m, n)$ Distribution

The $F(m, n)$ distribution arises in statistical inference problems associated with the normal distribution, especially in the analysis of variance to determine the significance of effects. If random variables V and W are independent, each with a Chi-square distribution

having degrees of freedom given by m and n, respectively, then the ratio $(V/m)/(W/n)$ has an $F(m, n)$ distribution. The p.d.f. is given by

$$f(x) = \begin{cases} \dfrac{\Gamma((m+n)/2)\, m^{m/2} n^{n/2}}{\Gamma(m/2)\Gamma(n/2)} \dfrac{x^{(m/2)-1}}{(mx+n)^{(m+n)/2}} & \text{if } x \geqslant 0, \\ 0 & \text{otherwise} \end{cases}$$

The F distribution is of great importance in the analysis of variance and the design of experiments. This distribution is used to determine the significance of different effects in an analysis of variance study; see *Experimental Design: Overview*; *Linear Hypothesis*; *Analysis of Variance and Generalized Linear Models*.

2.11 Pareto (α, c) Distribution

This is a two-parameter family of distributions indexed by $\alpha > 0$ and $c > 0$. The p.d.f. is given by

$$f(x) = \begin{cases} \dfrac{\alpha c^{\alpha}}{x^{\alpha+1}} \text{if } x \geqslant c, \\ 0 \quad \text{otherwise} \end{cases}$$

This distribution has a relatively heavy tail which decreases at only a polynomial rate. Consequently, only moments of order less than α exist. In particular, if X has a Pareto (α, c) distribution, then

$$E(X) = \frac{\alpha}{\alpha-1} c, \quad \text{if } a > 1$$

and

$$\mathrm{Var}(X) = \frac{\alpha}{(\alpha-1)^2(\alpha-2)} c^2, \quad \text{if } a > 2$$

If X has a Pareto (α, c) distribution, then the transformed random variable $\log(X/c)$ has an Exponential (α) distribution.

The Pareto distribution arises in contexts in which the tail of the distribution is relatively heavy. This occurs especially in economics; for example, in the distribution of incomes and the returns from various financial assets. The distribution also arises as the excess of a random variable over a high limit. The excess is especially important in the casualty insurance where one is interested in the excess of a claim over a high deductible limit; see *Distributions, Statistical: Approximations*.

3. Multivariate Distributions

It often happens that it is wished to consider two or more random variables simultaneously rather than individually. If $\{X_i, 1 \leqslant i \leqslant n\}$ is a set of n random variables, then each will have its own probability distribution, F_i, $1 \leqslant i \leqslant n$. This individual or marginal information does not offer insight into the relationship among these variables. To capture these relationships, one must consider the n-dimensional random vector $(X_1,\ldots, X_n)$. To do this, one defines the higher dimensional analogs of the c.d.f. and p.d.f. Specifically, the n-dimensional c.d.f. (or joint c.d.f.) is defined by

$$F(x_1,\ldots, x_n) = P(\{X_1 \leqslant x_1\} \cap \ldots \cap \{X_n \leqslant x_n\}), \quad \text{for } -\infty < x_i < +\infty, \quad 1 \leqslant i \leqslant n$$

If the joint c.d.f. is absolutely continuous, then one can define the joint p.d.f.,

$$f(x_1,\ldots, x_n) = \frac{\partial^n}{\partial x_1 \ldots \partial x_n} F(x_1,\ldots, x_n)$$

In the absolutely continuous case, one can calculate the probability of events by integrating the joint p.d.f. over the values specified by the event. When we consider the joint distribution of two random variables, (X_1, X_2), the associated joint c.d.f. and joint p.d.f. are referred to as the bivariate c.d.f. and bivariate p.d.f. A special case of this occurs when the pair of random variables has a bivariate normal distribution. See *Multivariate Analysis: Overview* for additional detail.

3.1 Bivariate Normal $(\mu_1, \mu_2, \sigma_1^2, \sigma_2^2, \rho)$ Distribution

The bivariate normal distribution is a special joint distribution associated with two random variables, X_1 and X_2. The joint p.d.f. of (X_1, X_2) is given by

$$f(x_1, x_2) = \frac{1}{2\pi\sqrt{1-\rho^2}\sigma_1\sigma_2} \exp\left(-\frac{1}{2(1-\rho^2)} \right) \left(\frac{x_1-\mu_1}{\sigma_1} \right)^2 - 2\rho \left(\frac{x_1-\mu_1}{\sigma_1} \right) \left(\frac{x_2-\mu_2}{\sigma_2} \right) + \left(\frac{x_2-\mu_2}{\sigma_2} \right)$$

for $-\infty < x_1, x_2 < +\infty$.

The parameters μ_i, $i = 1,2$ are arbitrary; however, the other parameters must satisfy $\tau_i > 0$, $i = 1,2$ and $-1 < \rho < +1$. When $\rho = \pm 1$, the random variables X_1, X_2 are related linearly.

If a pair of random variables (X_1, X_2) has a bivariate normal distribution with the parameters given above, then each has a marginal normal distribution, i.e., X_i has a Normal(μ_i, σ_i), $i = 1,2$ distribution. The parameter ρ is the correlation coefficient of X_1 and X_2. The bivariate normal distribution has the special property that if $\rho = 0$, then X_1 and X_2 are independent random

variables. Generally, uncorrelated random variables are *not* independent.

One can represent (X_1, X_2) in terms of two independent random variables (Z_1, Z_2), each with a standard normal distribution through the relationship:

$$X_1 = \mu_1 + \sigma_1 Z_1,$$
$$X_2 = \mu_2 + \sigma_2(\rho Z_1 + \sqrt{1-\rho^2} Z_2).$$

The bivariate normal distribution arises naturally in simple regression problems, see *Linear Hypothesis: Regression (Basics)*.

4. Further Reading

A large amount of material on continuous distributions, including statistical inference for unknown parameters of the distribution, is given in the text by Johnson et al. (1994). Multivariate continuous distributions are covered extensively by Johnson and Kotz (1972). Many of the above distributions are discussed in basic probability textbooks; for e.g., the text by DeGroot (1987). Some illustrations of the use of continuous probability distributions in the social sciences are given by Handcock and Morris (1999).

Distributions, Statistical: Special and Discrete

Discrete probability distributions form the basis of much of the statistical methodology for modeling, analyzing, and making inferences about discrete data (sometimes known as count data). Usually each observation (outcome) is an integer; for example, the number of individuals in a family, or the number of telephone calls handled by a switchboard in a unit of time. This article is primarily concerned with these underlying distributions and their properties, rather than their applications. The article first discusses the general properties of univariate discrete distributions and then defines and examines a number of widely used distributions. Ways of combining distributions to form new distributions are briefly considered. Finally multivariate discrete distributions (more than one variable is measured for each outcome) are introduced and the multinomial distribution (which is involved in the analysis of contingency tables) is examined (see *Multivariate Analysis: Discrete Variables (Overview)*).

1. Definitions and General Properties

Formally, a (univariate) discrete random variable (which is used to model the observation) X can take the values $x_1, x_2, x_3, \ldots$. Usually these $\{x_i\}$ are restricted to be the nonnegative integers or some subset of them. For example, an investigator might assume that $\{1, 2, 3, \ldots, 20\}$ includes all the possible different values for family size that he might observe.

The (discrete) distribution of X associates with each possible X-value the probability p_x that it will be the observed value. The distribution must satisfy the two conditions:

$$0 \leqslant p_x \leqslant 1; \quad \sum_x p_x = 1. \tag{1}$$

i.e., the probabilities are all nonnegative real numbers lying between zero (impossibility) and unity (certainty), and their sum must be unity because it is certain that one or other of the values will be observed. It is often convenient to assume that the number of possible outcomes (values of X) is countably infinite, i.e., there is no upper bound to X.

In discrete distribution theory the p_x, are regarded as values of a mathematical function, $p(x)$, that is usually called the probability mass function (pmf). Different functional forms lead to different discrete distributions. For example:

$$p(x) = \frac{e^{-\lambda}\lambda^x}{x!} \tag{2}$$

is the pmf of the Poisson distribution, while:

$$p(x) = \frac{n!}{x!(n-x)!} p^x (1-p)^{n-x} \tag{3}$$

is the pmf of the binomial distribution. λ is the parameter of the Poisson distribution; this fact is sometimes highlighted by writing $p(x; \lambda)$ or $p(x \mid \lambda)$ instead of $p(x)$ or p_x.

There are various useful and important constants associated with a distribution. They may be used to summarize various features of the distribution. The most familiar and widely used are the moments, particularly the mean and the variance. The rth (uncorrected) moment of the distribution is defined as:

$$\mu'_r = \sum_x x^x p_x. \tag{4}$$

The mean is μ'_1, the first moment of the distribution; it is conventionally denoted by μ and is used as a measure of the location of the distribution on the X-axis.

The rth moment about the mean is defined as:

$$\mu_r = \sum_x (x-\mu)^r p_x. \tag{5}$$

The variance is μ_2, the second moment about the mean; it is conventionally denoted by σ^2 and is widely used as a measure of the spread of the distribution. μ_3 is sometimes used to form a measure of the degree of asymmetry of the distribution. There is a formula for μ_r in terms of the μ'_i, and vice versa.

There are other related sets of constants, such as the cumulants, the factorial moments, the factorial cumulants, which may be more convenient to use in some circumstances. For details of these constants, and very detailed information generally about univariate discrete distributions, see Johnson et al. (1992).

In principle all the theoretical properties of the distribution can be derived from the pmf. There are, however, several other functions from which exactly the same information can be derived. This is because the functions are all one-to-one transformations of each other, so each characterizes the distribution. One particularly useful function is the probability generating function (pgf), which is defined as

$$G(s) = \sum_x s^x p_x. \tag{6}$$

For example, the Poisson distribution has pgf:

$$G(s) = \exp[\lambda(s-1)] = e^{-\lambda}\sum_x \frac{\lambda^x}{x!}s^x = \sum_x p_x s^x. \tag{7}$$

If any function that is known to be a pgf is expanded as a power series s, then the coefficient of s^x must be p_x for the corresponding distribution. An alternative way of obtaining the probabilities is by repeated differentiation of $G(s)$ with respect to s. If the pmf of a distribution is a complicated function and there are difficulties in computing numerical values directly, it may be possible to deduce from the pgf relatively simple relationships between successive probabilities and thus compute probabilities sequentially.

During the past half-century there has been a great proliferation of univariate discrete distributions. Patil et al. (1984) listed 136 univariate and multivariate distributions; Wimmer and Altmann (1999) list about 750 univariate distributions, but estimate the total number currently known at around 1000. Whilst some are rather thinly disguised versions of others, in general there are important differences between distributions. Some structure can be imposed on this vast array by grouping distributions into families whose members share certain properties.

2. *Individual Univariate Discrete Distributions*

2.1 *Bernoulli Distribution*

This is an extremely simple and basic distribution. It arises from what is known as a Bernoulli trial: a single observation is taken where the outcome is dichotomous, e.g., success or failure, alive or dead, male or female, 0 or 1. The probability of success is usually denoted by p. The probability of failure is $1-p$ and this is often denoted by q. The distribution has pmf:

$$p_x = p^x q^{1-x}, \quad 0 < p < 1, \quad q = 1-p, \quad x = 0, 1. \tag{8}$$

The mean is p, the variance is pq, and the pgf is $(q+ps)$. The Bernoulli is a one-parameter distribution (the parameter is p). Two standard examples of a Bernoulli trial are (a) the toss of a coin, and (b) the random selection of a ball from an urn containing a white and b black balls.

2.2 *Binomial Distribution*

This two-parameter distribution describes the outcome of a sequence of n independent Bernoulli trials, each with the same probability p of success. Then the probability that success is the outcome in exactly x of the trials is:

$$p(x) = \binom{n}{x} p^x q^{n-x} = \frac{n!}{x!(n-x)!}p^x(1-p)^{n-x},$$
$$0 < p < 1, \quad q = 1-p, \quad x = 0, 1, 2, \ldots, n. \tag{9}$$

This defines the binomial distribution. In terms of the two Bernoulli trials examples above, X would be (a) the number of heads in n tosses of a coin, or (b) the number of white balls in a random sample of n balls selected sequentially, *provided* that each ball selected is returned to the urn before the next ball is selected; this is necessary in order that p remains constant and equal to a/n. This latter procedure is an example of sampling with replacement. The mean of the binomial distribution is np and the variance is npq. The pgf is $(q+ps)^n$. Note that this is the Bernoulli pgf raised to the nth power. This illustrates a very useful property of pgfs: if X and Y are two independent random variables whose distributions have pgfs $G_X(s)$ and $G_Y(s)$, then

their sum $Z = X + Y$ has a distribution with pgf $G_Z(s) = G_X(s)G_Y(s)$.

If n is large and p is small, the Poisson distribution (see Sect. 2.3) with $\lambda = np$ may be used to approximate the binomial. If n is large and p is not too close to 0 or 1, the (continuous) normal distribution may be used to construct an approximation.

The well-known chi-squared test for a 2×2 contingency table can be shown to be equivalent to a test of the difference between two binomial proportions (the proportions of 'successes' within the two classes in the table).

2.3 Poisson Distribution

This distribution occupies a central position in discrete distribution theory analogous to that occupied by the normal distribution in continuous distribution theory. It also has many practical applications. The full formal definition of the distribution is:

$$p(x) = \frac{e^{-\lambda}\lambda^x}{x!}, \quad 0 < \lambda, \quad x = 0, 1, 2, \ldots . \tag{10}$$

The pgf of the distribution has the very simple form:

$$G(s) = \exp[\lambda(s-1)]. \tag{11}$$

Both the mean and the variance of the Poisson distribution are equal to λ. For small values of λ the distribution is very skewed (asymmetric) but as λ increases it becomes less skewed and is nearly symmetric by $\lambda = 15$.

The Poisson distribution plays an important part in loglinear model theory for contingency tables; the model assumes independent Poisson distributions for each cell in the table (see *Multivariate Analysis: Discrete Variables (Loglinear Models)*). Another reason why the Poisson distribution is important is that it is the distribution of events that occur randomly and independently in space or time. A classic example is the number of particles, X, recorded by a Geiger counter in a fixed time interval. This property of the Poisson means that it can act as a reference standard when deviations from pure randomness are suspected.

2.4 Geometric Distribution

If X is the number of trials *before* the first success in a sequence of Bernoulli trials with constant p, then:

$$p_x = pq^x, \quad 0 < p < 1, \quad q = 1-p, \quad x = 0, 1, 2, \ldots . \tag{12}$$

The probabilities form a geometric progression, hence the name.

The mean is p/q, the variance is p/q^2, and the pgf is $p(1-qs)^{-1}$.

Just as the Bernoulli distribution is a special case of the binomial distribution, the geometric distribution is a special case of the negative binomial distribution (see Sect. 2.5).

Some authors define X to be the number of trials up to and *including* the first success; the pmf is then $p_x = pq^{x-1}$, X ranges over the positive integers, and the pgf is $ps(1-qs)^{-1}$.

2.5 Negative Binomial Distribution

The negative binomial distribution (NBD) is a widely used alternative to the Poisson distribution for handling count data when the variance is appreciably greater than the mean (this condition is known as overdispersion and is frequently met in practice).

The pmf of the NBD is:

$$p_x = \binom{k+x-1}{x} p^k q^x,$$

$$0 < k, \ 0 < p < 1, \ q = 1-p, \ x = 0, 1, 2, \ldots . \tag{13}$$

The mean is kq/p, the variance is kq/p^2, and the pgf is $p(1-qs)^{-k}$.

In the literature, several different parameterizations of the distribution are found. A common one uses $Q = 1/p$ and $P = q/p$. It follows that $P > 0$, $Q = 1 + P$, and:

$$p_x = \binom{k+x-1}{x} \left(1 - \frac{P}{Q}\right)^k \left(\frac{P}{Q}\right)^x. \tag{14}$$

When $k = 1$, the NBD becomes the geometric distribution. When k is a positive integer, the NBD is sometimes known as the Pascal distribution; it can then be interpreted as the distribution of the number of failures before the kth success (i.e., X is the sum of k independent geometric random variables). This kind of model is known as a waiting time distribution.

There are several other models that lead to the NBD. A classic example arises from the theory of accident proneness which was developed during and after World War I. It was assumed that the number of accidents suffered by an Individual was distributed as a Poisson distribution, but that the Poisson parameter λ (interpreted as the individual's accident proneness) varied between individuals in the population under study. If λ is assumed to follow the (continuous) gamma distribution, then the NBD is the resultant overall distribution of accidents per indi-

vidual. This model has been applied to retail purchasing, absenteeism, doctor's consultations, amongst many others. The model reflects a type of heterogeneity in the population. A different type of heterogeneity occurs when there is clustering. If it is assumed that the number of clusters is distributed as a Poisson, but the number of individuals in a cluster is distributed according to the logarithmic distribution (see Sect. 2.6), then the overall distribution is NBD.

The existence of these and other models means that the NBD is used to model many different types of data. The penalty for this ubiquity is the difficulty in inferring which underlying model applies.

2.6 Distributions Without a Zero Class

In some applications the meaningful outcomes do not include $X = 0$. Examples are the size of a family and the size of a cluster of dwellings. Such cases require distributions that start at $X = 1$. One way of achieving this is to take a distribution that is defined for $x = 0, 1, 2, \ldots$ and truncate the term $X = 0$. In order to form a valid distribution from the remaining probabilities, it is necessary to adjust them upwards by a factor of $(1-p_0)^{-1}$ so that the second condition in (1) is satisfied. For example, the zero-truncated Poisson distribution has pmf:

$$p_x = \frac{e^{-\lambda}\lambda^x}{x!(1-e^{-\lambda})}, \quad 0 < \lambda, \quad x = 1, 2, 3, \ldots . \tag{15}$$

Alternatively, there are some distributions for which the pmf is not defined for $X = 0$. One of these is the logarithmic distribution, with pmf:

$$p_x = \frac{\theta^x}{-x\log_e(1-\theta)}, \quad 0 < \theta < 1, \quad x = 1, 2, 3, \ldots . \tag{16}$$

The mean is $a\theta/(1-\theta)$ and the variance is $a\theta(1-a\theta)/(1-\theta)^2$, where $a = -1/\log_e(1-\theta)$. The pgf is:

$$G(s) = \frac{\log_e(1-\theta s)}{\log_e(1-\theta)}. \tag{17}$$

This distribution can model data distributions with very long tails.

2.7 Hypergeometric Distribution

A key feature of the binomial distribution is its representation in terms of a sequence of independent Bernoulli trials with fixed p. In many practical situations, however, p is not constant due to dependence between successive Bernoulli trials. In the derivation of the binomial using the ball in an urn model (b), each selected ball was returned immediately to the urn (sampling with replacement) so p was always equal to $a/(a+b)$. However, if each selected ball is retained and not returned, then p changes after every trial; this is sampling without replacement (see *Sample Surveys: Methods*). The resultant distribution is hypergeometric with pmf:

$$\begin{aligned} p_x &= \binom{a}{x}\binom{b}{n-x}\Big/\binom{a+b}{n} \\ &= \binom{n}{x}\binom{a+b-n}{a-x}\Big/\binom{a+b}{a}, \\ &\quad x = 0, 1, 2, \ldots, \min(n, a). \end{aligned} \tag{18}$$

The mean is $na/(a+b)$ and the variance is $nab(a+b-n)/(a+b)^2(a+b-1)$. The pfg is:

$$G(s) = \frac{{}_2F_1[-n, -a; b-n+1; s]}{{}_2F_1[-n, -a; b-n+1; 1]} \tag{19}$$

i.e., the ratio of two classical Gaussian hypergeometric functions.

An important use of the hypergeometric distribution is in the analysis of 2×2 contingency tables; the probability of a result as extreme as the observed result is given by the tail of a hypergeometric distribution. This is known as Fisher's exact test; it is frequently recommended for use instead of the chi-squared test when the smallest expected frequency is less than 5.

2.8 Beta-binomial (Negative Hypergeometric) Distribution

In Sect. 2.5 heterogeneity of the Poisson parameter λ was allowed for by assuming that λ had a gamma distribution. The resultant Poisson–gamma distribution was in fact the NBD. Analogously, when there is heterogeneity in the binomial parameter p one way of allowing for it is to assume that it follows the (continuous) beta-distribution—a flexible distribution on the interval (0, 1). The resultant beta-binomial distribution has pmf:

$$\begin{aligned} p_x &= \binom{-a}{x}\binom{-b}{n-x}\Big/\binom{-a-b}{n}, \\ &\quad 0 < a, \quad 0 < b, \quad n \text{ an intger}, \\ &= \binom{a+x-1}{x}\binom{b+n-x-1}{n-x}\Big/\binom{a+b+n-1}{n}, \\ &\quad x = 0, 1, 2, \ldots, n. \end{aligned} \tag{20}$$

The mean is $na/(a+b)$, the variance is $nab(a+b+n)/(a+b)^2(a+b+1)$, and the pgf is:

$$G(s) = \frac{{}_2F_1[-n, a; -b-n+1; s]}{{}_2F_1[-n, a; -b-n+1; 1]}. \quad (21)$$

The distribution is also known as the negative hypergeometric or inverse hypergeometric distribution. Like the NBD, it can be interpreted as a waiting time distribution.

3. Combinations of Distributions

New distributions may be created from existing ones. Two major methods have been mentioned in Sects. 2.5 and 2.8. The process of allowing the parameter of one distribution to itself be distributed (as in the derivation of the NBD by letting the Poisson parameter λ be distributed as a gamma variable) is known as mixing (in earlier literature the term compounding was commonly used). Many other mixture distributions appear in the literature.

The process exemplified by the NBD cluster model of Poissonly distributed clusters with logarithmically distributed cluster sizes has been given several names including compounding and generalizing, both of which are ambiguous; a clearer terminology that is frequently used nowadays is to call the resultant distribution a randomly stopped-sum or stopped-sum distribution. If the pgf of the distribution of clusters is $g(s)$ and that of the cluster size distribution is $h(s)$ then the pgf of the resultant distribution has the very simple structure:

$$G(s) = g(h(s)). \quad (22)$$

Various properties of the stopped-sum distribution can be deduced via this relationship.

These processes are one reason why there are so many different discrete distributions in the literature. They often arise from attempts to model processes in applications. Clearly some distributions like the NBD that are mixtures are also stopped sums, but this is not always the case. As mentioned previously, the existence of fundamentally different ways of deriving the same distribution can raise serious problems in practice when trying to make causal inferences from data.

4. Multivariate Discrete Distributions

The move from distributions of one variable to joint distributions of several variables is complicated by the existence of relationships (dependencies) between the variables. This is reflected in the complexity of the structure of the multivariate pmf and related functions. Furthermore, there may be more than one way of representing dependency; more than one bivariate version of a particular univariate distribution may be constructed. Often the multivariate pgf is one of the simpler ways of defining and characterizing a distribution, A bivariate pgf is defined as:

$$G(s_1, s_2) = \sum_{x,y} p_{x,y} s_1^x s_2^y; \quad (23)$$

the definition of a multivariate pgf is a straightforward extension.

The multinomial distribution has pgf and pmf:

$$G(s_1, s_2, \ldots, s_r) = (p_1 s_1 + p_2 s_2 + \cdots + p_r s_r)^n, \quad (24)$$

$$p(x_1, x_2, \ldots, x_r) = \frac{n!}{x_1!, x_2!, \ldots, x_r!} p_1^{x_1} p_2^{x_2} \ldots p_r^{x_r}. \quad (25)$$

When $r = 2$ it becomes the binomial distribution. All the marginal distributions of the multinomial are binomials. The conditional distribution of $(X_2, X_3, \ldots X_r)$ given X_1 is also multinomial.

One of the first reference texts to be devoted to the multivariate area was Kocherlakota and Kocherlakota (1992). They set out the general theory of bivariate discrete distributions and considered in detail the properties of bivariate versions of the major univariate distributions. Johnson et al. (1997) give a very thorough treatment of the current position in multivariate discrete distributions; the general theory is given and a wide range of distributions is examined.

Johnson et al. (1992) is the standard reference text for univariate discrete distributions; all the univariate distributions above are considered in detail, together with very many more.

Diversification and Economies of Scope

1. Introduction

Diversification refers to the process by which single product, specialist firms become multiproduct firms.

The industrial landscape in advanced industrial countries is characterized by the prevalence of firms that maintain diversified product lines. However, diversification is not a random process. On the contrary, firms tend to diversify by adding product lines that are 'close in' to their established product lines. Put differently, diversified firms diversify in ways that are coherent. Those that don't tend not to survive. This article focuses on explaining why and how firms diversify, with an eye toward explicating the successful modes of corporate diversification.

Three related research fields have much to say on corporate diversification. The 'resource-based' view of the firm draws attention to the quasi-fungible nature of the firm's assets, and postulates that diversification is a way to use excess capacity. Transaction cost economics helps explain whether and when excess capacity is better used internally (diversification) or contracted out to parties seeking to outsource services and products. Evolutionary economics helps explain how excess capacity comes about. These three intellectual wellsprings help explain the nature, timing, and pattern of observed diversification in advanced industrial nations.

It must be pointed out, however, that there is a largely discredited literature that offers an alternative view. Theories of market strength and monopoly position stress these attributes as drivers of diversification (Montgomery 1994). Studies in this genre have been actively explored empirically, but offer little to inform the diversification process. Measures such as Tobin's Q provide a framework to compare how firm (stock) market evaluation changes with added products and markets. Such measures are useful but do little to explain why firms diversify and the relationship between direction of diversification and organizational factors, such as legal structure. This line of research has provided excellent measurement and context with which to compare diversification outcomes. However, it does not illustrate satisfactorily the decision to diversify or the real constraints on diversification that managers and firms face.

We now turn to two fundamental questions: why do firms diversify, and how do they organize for diversification. The goal in the next section is to communicate the logic and strategy of diversification, motivating the subsequent discussion on organizing for diversification. We do not mean to describe these two activities as serial, but rather interactive. The decision to diversify for profit seeking firms requires them to analyze how they can secure extra profits from the process. We can conclude that successful diversification is the combination of managers making strategic choices as to lines of business and developing appropriate organizational structures to support the resulting diversification. This conclusion has implications for empirical testing, and several scholars have recently begun to undertake an effort to integrate theories of diversification (Silverman 1999).

2. *Why Firms Diversify: Corporate Diversification and the Resource-based View of the Firm*

Although the resource-based view has, since the 1980s, been applied to several areas in firm strategy, the theory has its roots in the study of firm diversification (Teece 1982). We begin by summarizing the major points, and describe the decision to add product lines as a response to the availability of underutilized assets created by prior activity. We then discuss the strategy of diversification as the choice of those areas in which to diversify that maximize the value of the unused assets. This typically results in what has been referred to as corporate coherence (Teece et al. 1994).

Note that corporate diversification issues, as discussed herein, is a superset of multiproduct firm issues. Much of our current attention focuses on multiproduct firms, with less attention on other diversification modes (new customer or geographic markets, for example). However, firm diversification in a broader context includes many of the same analyses that are applied below. That is, diversifying international markets follows much of the same logic and reasoning as adding product lines.

2.1 *The Firm as a Set of Resources*

The resource-based view seeks to understand why firms grow and diversify. The theory grew largely out of Penrose's (1959) study, in which she cites unused managerial resources as the primary driver of growth. Penrose recognized that internal managerial resources are both drivers and limits to the expansion any one firm can undertake. This stream of literature was expanded in the 1970s and early 1980s on the heels of significant diversification and firm expansion (Rubin 1973, Teece 1980, 1982).

The resource-based view advances the importance of firm-specific resources, that is, those resources that maintain value *in the context* of the given firm's markets and other resources that are difficult to replicate by other firms (Wernerfelt 1984). Such resources include managerial ability, customer relationships, brand reputation, and tacit knowledge regarding specific manufacturing process. Resources are not the same as competencies or capabilities. Rather, a firm's access to resources and ability to mobilize and combine these resources in specific ways determine the firm's competence in a given product area. As a firm gathers resources for one business, these resources will, to differing extents, be sufficiently fungible for use in other product lines or markets (Teece 1982). Some of these resources will maintain excess capacities over time, especially since the units required for operations in one area are not necessarily consistent across multiple fields.

In some cases it is knowledge which is the 'excess resource' (Teece 1982, 1986). It is this excess capacity, coupled with profit-seeking behavior, that drives decisions to diversify. Some scholars have noted that such resources are transferable in a limited sense between firms, but such endeavors require organizational interaction beyond market contracting to include acquisitions or hybrid forms of governance (Chi 1994). This point will be considered in Sect. 4.

2.2 The Logic and Coherence of Diversification

The literature on diversification includes analysis of whether specific diversification patterns are associated with improved firm performance (Chatterjee and Wernerfelt 1991). Specifically, scholars have sought to discern whether there exist performance differences between related and unrelated diversification. Many efforts have focused considerably on outcome measures that do little to inform the rationale behind diversifying. The resource-based foundation provides scholars with a motivation for examining the linkages (or 'coherence') between classes of resources within a given firm (Teece et al. 1994). Fungible resources allow for firms to apply managerial practices and reputations to other industries, as discussed in the previous section. However, these assets have varying degrees of value across industries. The resources of firms even within the same industry may not be identical. Moreover, the degree of coherence that one expects to observe among the parts of an organization at a particular point in time depends on the relationship between learning, path dependencies, the technological opportunities available to the firm, and the firm's existing complimentary assets. This suggests that seemingly homogeneous (in terms of primary product outputs) firms may exhibit radically different diversification strategies.

While empirical evidence will be examined in more detail below, existing research suggests that there exists a *logic to diversification*. As firms grow more diverse, they maintain a constant level of coherence between neighboring activities. For example, the sales, distribution, and market understanding maintained in pharmaceutical industries is relevant to a specific set of other industries, such as medical equipment and over-the-counter medicines. The latter is in turn related to candy and confectionery and other drug store items. Note that this result contrasts with the purely market power studies discussed earlier in that the focus of analysis is on firm specific assets as an input to the diversification process, rather than solely on the industries in which a firm ends up.

We now turn to the consideration of how firms organize to diversify, and consider the implications for a combined analysis of diversification strategy and underlying organizational structures.

3. How Firms Organize to Diversify: Corporate Diversification and Transaction Cost Economics

Transaction cost economics argues that economic agents organize activities so as to economize on the costs of transacting. Specifically, the probability of observing a given form of organization is a function of various features of the transaction under consideration and the influence of these features on the relative costs of alternative modes of organizing. While transaction cost theory is most noted for its use in analyzing vertical integration decisions (i.e., make-vs.-buy decisions), its logic has also been applied to issues related to diversification (Teece 1980, 1982).

Early work in this area focused on the so-called 'conglomerate' form of organization. Williamson (1975) argues that large, diversified conglomerates are best understood as a logical outgrowth of the multidivisional form (M-Form) mode for organizing complex economic transactions. Building on work by Chandler (1962), Williamson suggests that the M-form offers a number of advantages in managing separable, related lines of business, such as a group of automobile divisions. Specifically, the M-form allows for improved transaction governance in directing and monitoring the use of assets, where a unified or function-based organization would falter under information asymmetries, bounded rationality, and managerial opportunism. Recognizing these merits, he goes on to argue that the M-form may be similarly advantaged when it comes to managing less closely-related activities (Williamson 1988). While he is careful to note that the management of diverse products is not without problems, Williamson (1988) nevertheless proposes that the advantages of the M-Form of organization carry over to the case of diverse product lines. Thus, early research in organizational economics suggested that it is more efficient to administer diversification in a multidivisional corporation than in other, more centralized forms of internal organization.

More recently, the question of how to most efficiently organize for diversification has been extended to include a direct comparison of specific alternative modes of diversification. Bethel and Liebeskind (1998), for instance, employ transaction cost reasoning to account for the decision of firms to diversify by means of a 'simple corporation,' in which a single legal entity is responsible for all contracting relationships, vs. a 'corporate group' approach, in which a parent corporation owns or partially owns a series of subsidiary corporations. Firms select a particular mode of diversification to minimize a specific type of transaction cost; namely 'protection costs.' Because diversification has a differential effect on the various stakeholders within a firm, disadvantaged stakeholders may take action to protect themselves either by seeking to prevent diversification or by seeking compensation after diversification has taken place. A 'corporate group' form of organization can reduce the

costs associated with these protection measures by reducing the losses from diversification that some stakeholders would otherwise bear. However, the use of 'corporate groups' to manage diversification is not costless. Although 'corporate groups' may reduce or eliminate the negative effects of diversification, they carry with them costs: economies of scope may be lower within a 'corporate group' than within a 'simple corporation.' Managers must explicitly trade off the advantages of economies of scope with the disadvantages associated with protection efforts by corporate stakeholders.

The research in transaction cost theory related to diversification thus attempts to account of how diversification is organized by exploring the nature of the diversification taking place, as well as its impact on the relative costs of different modes of diversification. The theory predicts that the mode of organization (such as vertical integration or joint venture) chosen in a given instance will be that which minimizes the total costs of transacting. By exploring how it is that firms diversify, transaction cost theory complements the work coming out of the resource-based view. Whereas the resource-based view analyzes the direction of corporate diversification, transaction theory allows one to predict which organizational structures are necessary to support diversification efforts.

4. *Integrating Two Views of Diversification*

The above discussion highlights the theoretical similarities and complementarities between the resource-based view and transaction cost theory. Indeed, asset specificity, a key analytical frame in traditional transaction cost economics theory, is analogous to the firm-specific resources that are the engines of diversification in the resource-based view. Recently, researchers have begun to explicitly combine these two approaches.

Among these efforts is Silverman's (1999) examination of how contractual hazards affect the likelihood of corporate diversification. As was noted in Sect. 2, the resource-based view draws heavily on Penrose's view that firm growth is driven by the internal exploitation of excess resources. A result of Penrose's approach is that firms always enter new markets, but never divest. In contrast, transaction cost theory suggests that there are multiple ways in which excess assets may be utilized, including contracting these assets to outside parties and spinning them off into stand-alone enterprises (Teece 1980). The added incentive intensity associated with exploiting excess resources through markets rather than internally provides a rationale for utilizing various contracting approaches. The relevant empirical question with respect to diversification is: under what circumstances are excess resources more suitably exploited through internal diversification than through outside contracting?

Drawing on work by Teece (1986), Silverman suggests that the contractual exploitation of technological knowledge resources (e.g., licensing) is a feasible alternative to diversification except for cases where the knowledge is highly tacit or easily transferred but weakly protected. In the former case, licensing contracts are difficult to write and enforce due to the tacit nature of the resource being contracted for. In the latter case, attempts to negotiate a licensing contract are plagued by problems of appropriating the returns to technology. Silverman therefore hypothesizes that a firm is more likely to diversify into a business when contracting out its technological resources in that business is subject to high contractual hazards. His analysis of diversification decisions for firms entering new SICs between 1982 and 1985 indicates that in fact a firm is less likely to diversify into an industry when viable contractual alternatives exist to exploit its technological resources.

5. *Conclusion: The Future of Diversification Research*

The efforts by Silverman and the others cited in this article to exploit and, where possible, combine the resource-based and transaction cost approaches to diversification are useful to help elucidate the critical aspects of each theoretical approach with respect to corporate diversification. While important first steps, the research examined here by no means provides definitive resolution to the topic of firm diversification. In particular, a number of theoretical and empirical issues remain. On the theoretical side, efforts to recognize the dynamic nature of corporate diversification decisions are needed. The treatment of diversification in this chapter and in much of the existing literature treats the why and how of diversification as two distinct (and serial) activities. In practice, successful diversification is a combination of *both* choosing where to diversify and how to support a diversification strategy.

While resource-based scholars have begun developing a theoretical understanding of corporate coherence, there exist few empirical tests of these predictions. Resource-based explanations for diversification have struggled with how to operationalize the resources that are relevant in diversification decisions. That is, the lack of adequate measures for critical firm resources has limited empirical testing of the theory's predictions with respect to diversification. Finally, greater effort to explicate and test the transaction level factors that are relevant in driving how diversification efforts are organized is needed.

Diversity and Disagreement

The extraordinary variety of ethical belief and practice that is possible within and across human societies, along with the ethical disagreement to which that variety frequently gives rise, has been a rich source of philosophical reflection. Philosophers have sought to understand the nature and causes of ethical diversity and disagreement, as well as what that diversity and disagreement might reveal about the nature of ethical argument and inquiry. They have investigated the similarities and differences between ethical inquiry and other kinds of inquiry, particularly scientific inquiry, and asked what the relevant similarities and differences can tell us about the nature of rationality. They have also analyzed the implications of ethical diversity and disagreement for ethical practice, and for the foundations of social and political life.

1. *The Nature and Sources of Ethical Diversity and Disagreement*

1.1 *Philosophical Understandings of Anthropological and Sociological Evidence*

Philosophical awareness of ethical diversity is as old as philosophy itself. It is evident in the ancient Greek beginnings of Western philosophy—particularly in the ethical and political thought of Plato and Aristotle. In the early and middle *Dialogues* of Plato, for instance, exchanges between the Platonic Socrates and his interlocutors reveal many of the ethical conflicts and debates, and hence the ethical diversity and disagreement, that helped to shape the social and political life of fourth-century BC Greece. A generation later, Aristotle's sensitivity to the concrete contexts of deliberation and action, detailed in the *Nichomachean Ethics* and the *Politics*, reflected an even richer understanding of social and political diversity, and of the resultant complexity of ethical belief and practice. Neither Plato nor Aristotle believed that ethical diversity and disagreement required us to relinquish a commitment to ethical objectivity. But this stance was in marked contrast to that adopted by some of their philosophical forebears, especially fifth-century BC sophists such as Protagoras and Gorgias, to whom Plato's philosophy was in part a response. Moreover, the objectivist conceptions defended by Plato and Aristotle were met by the emergence of a powerful current of skepticism. This development culminated in the Academic skepticism of Cicero, and especially the second-century AD Pyrrhonian skepticism of Sextus Empiricus, in which ethical diversity and disagreement inevitably raised the specter of ethical relativism.

The sixteenth-century rediscovery and dissemination of Sextus' writings coincided with the beginnings, in the West, of a period of extraordinary exploration and economic expansion. Both developments were important in shaping the rise of early modern Western philosophy in the late sixteenth and early seventeenth centuries. European exploration and expansion produced a body of literature purporting to offer a richer picture of human ethical variety than anything to be found in ancient philosophical texts. These accounts had a profound effect on early modern thinkers who pondered the nature and sources of ethical variety. Thinkers such as Montaigne came to accept the indispensability to philosophy of what we would now call sociological or anthropological explanations of ethical diversity. But, deeply influenced

by the Pyrrhonian skepticism he found in Sextus, Montaigne also insisted that fully appreciating the details of human ethical diversity would always lead a reasonable person to accept ethical relativism. Montaigne thus rejected the claims of philosophers, from Plato onward, who believed that one could render the existence of ethical diversity and disagreement compatible with ethical objectivism.

In the seventeenth, eighteenth, and early nineteenth centuries, debates about the implications of ethical diversity and disagreement—based primarily on the testimony of explorers, settlers, and economic adventurers—continued to shape philosophical reflection about ethics. That reflection took one of its most interesting forms in Montesquieu's *Persian Letters* (1973), in which Montesquieu's potentially dangerous criticisms of ethical and political life in eighteenth-century France are presented to the reader as the contents of letters written home by two fictional Persian visitors. But with the rise of modern anthropology in the late nineteenth and early twentieth centuries, philosophical reflection about diversity and disagreement took on a new tone. Philosophers were gradually persuaded by the claims of anthropology to provide expert testimony—rooted in theoretically sophisticated empirical research, rather than idiosyncratic personal or economic interests—about the nature and extent of diversity and disagreement across cultures and social groups.

Yet the cultural ascendancy of anthropological claims about diversity also reinvigorated the skeptical challenge to ethical objectivism. Ruth Benedict's *Patterns of Culture* (1934) provides an instructive and influential expression of this development. Benedict claimed to have given ethical relativism a scientific foundation for the first time. Some philosophers were prepared to accept this account of the matter and to cede authority for assessing the claims of relativism to empirical social science. But, Benedict's claims of a newly 'scientific foundation' for relativism may be difficult to sustain. Her formulation and defense of relativism seem simply to reiterate Montaigne's argument that we have 'no other test of truth and reason than the example and pattern of the opinion and customs of the country we live in.' Melville Herskovits (1972) went on to argue that modern anthropology finally provided 'tough-minded' empirical support for claims about the 'ethnocentrism' of objectivist analyses of ethical disagreement. But Herskovits's efforts to defend charges of ethnocentrism do not go much beyond Montaigne's contention that 'each man calls barbarism whatever is not his own practice.' The fact that so many familiar defenses of relativism predate the rise of modern anthropology has led some philosophers to wonder whether ethical relativism is simply a reasonable inference from ethical diversity and disagreement, or a pretheoretical assumption which determines the way some theorists characterize the data of diversity.

Yet other philosophers have undertaken detailed investigation to show the value and importance of anthropological study to philosophical reflection about ethics. Some have conducted their own ethnographic studies of the ethical beliefs and practices of Native American groups, in an effort to determine the empirical reliability of anthropological accounts (Brandt 1959, Ladd 1957). Others—spurred on, in part, by the late work of Ludwig von Wittgenstein, especially by the concept of 'forms of life' in his *Philosophical Investigations* (1978)—have interrogated the theoretical underpinnings, as well as the broader philosophical implications, of the social scientist's claims about diversity and disagreement (Wilson 1970, Winch 1972). These efforts introduced important new empirical detail into philosophical discussions of the extent of cultural diversity—details drawn, most famously, from the work of E. E. Evans-Pritchard on the Azande, and from the work of Edmund Sapir and Benjamin Whorf on the conceptual variety embedded in human languages. The resulting debates raise new and controversial philosophical questions about the nature of ethical disagreement—particularly the question whether human ethical systems could ever contain wholly incommensurable ethical (or other) concepts.

Philosophical attempts to understand the origins and causes of ethical diversity and disagreement have frequently relied on generally utilitarian or consequentialist accounts of that diversity. On these accounts, ethical practices (and their associated beliefs) come into existence, and continue in existence, primarily because they serve the aims of the groups that develop them. From the eighteenth century forward, such accounts are usually linked with essentially evolutionary hypotheses about the development of ethical practices. The ethical and political thought of David Hume, for instance, attributes the rise of particular ethical practices to unconscious, or unintended, processes that are vaguely akin to natural selection. But accounts of the processes in question usually have more in common with Herbert Spencer's theory of social evolution than with Darwin's claims about the role of natural selection in biological evolution. William Graham Sumner's *Folkways* (1909)—which combined evolutionary ethics with a forceful defense of ethical relativism—contains what became one of the most influential expositions of just such a view.

1.2 Methodological Concerns about the Idea of Fundamental Disagreement

During the mid-twentieth century, many philosophers accepted the claims of relativist anthropologists that the data of comparative anthropology could firmly ground an argument for metaethical relativism: the view that there is no rational method for adjudicating between the conflicting ethical claims of different cultures. Yet, as many of their critics objected, the

mere facts of ethical diversity and disagreement within and across cultures cannot be sufficient to establish the truth of ethical relativism (in any form). The objection is that merely from the fact of cultural variability we cannot confidently conclude that any resultant ethical disagreements will necessarily be disagreements in fundamental ethical commitments between which no rational adjudication is possible; and establishing this conclusion is essential to establishing the plausibility of ethical relativism.

This objection points to a way in which ethical relativism may, in fact, be fundamentally underdetermined by all available empirical evidence. For it is at least possible, as the psychologist Karl Duncker argued, that principles of ethical valuation might remain 'invariant' across the most diverse cultures, even while the 'situational meanings' of the acts, traits, and states of affairs subject to ethical evaluation could vary dramatically across those same cultures (Duncker 1939). In short, cross-cultural ethical diversity might be properly traced not to differences in fundamental ethical principles but to cultural variation in derivative ethical principles—that is, to principles embodying local understandings of how to apply fundamental ethical principles to particular actions, character traits, and states of affairs. Thinkers who claim to identify fundamental ethical disagreement must, therefore, be able to show that they have identified a conflict between genuinely fundamental ethical principles or beliefs, and not between derivative principles or beliefs intended to apply the more fundamental principles or beliefs. Further, as the philosopher R. B. Brandt once noted, it is very difficult to find two cultures, or even two individual people, who can be shown attribute identical non-moral properties to some action, trait, or state of affairs and who nonetheless give the relevant action, trait, or state of affairs different ethical valuations (Brandt 1959, 1967).

Identifying these difficulties does not prove that it is impossible to find convincing evidence of genuinely fundamental ethical disagreement. Brandt, himself, claimed to have found at least one such disagreement, in spite of the methodological difficulties he believed to attend any effort to do so (Brandt 1959). Moreover, the demand for conceptual clarity in defining a disagreement as 'fundamental,' rather than 'derivative,' is difficult to meet, since distinguishing fundamental from derivative ethical beliefs and principles is no simple matter. In particular, it is not clear how to find a criterion for describing a belief or principle as fundamental or derivative that doesn't presuppose a commitment to some fairly complex elements of an ethical conception—that is, to ethical notions which may themselves be the subject of considerable controversy and disagreement. Yet in coming to appreciate the methodological and conceptual difficulties inherent in attempts to establish fundamental ethical disagreement, the empirical researcher and the philosophical interpreter alike are reminded that there are important obstacles to surmount if one seeks to draw a supportable inference for meta-ethical relativism from the fact of cross-cultural disagreement.

1.3 Individual Uncertainty and the Roots of Ethical Pluralism

Reliance on the evidence of cross-cultural variability is not the only means—or even the most important means—by which philosophers have sought to understand the nature and sources of ethical diversity and disagreement. According to some philosophers, the decision-making processes of an individual agent experiencing ethical uncertainty can sometimes tell us as much (if not more) about the nature and sources of ethical diversity and disagreement than the comparative anthropologist's claims about cross-cultural conflict. On these accounts, when a sincere and reflective agent attempts to choose between equally compelling, but conflicting and even apparently irreconcilable, ethical ends, what that agent typically confronts is the fundamental plurality and diversity (and, on some views, sometimes even the ultimate incommensurability) of available and plausible ethical ends. Pluralists such as Isaiah Berlin and Charles Taylor believe that philosophers like Plato, along with those of his intellectual descendants who would defend the unity of ethical value, simply fail to understand that plurality and diversity are intrinsic features of ethical value. According to the ethical pluralist, ethically compelling ends and purposes cannot all be reduced to a single measure of ethical value; nor can they all be realized in a single life. This means that even the sincere and reflective agent (or, perhaps, especially the sincere and reflective agent) will eventually confront what Thomas Nagel has called the fragmentation of ethical value (Nagel 1979).

Those who understand ethical value as intrinsically plural and diverse thus have a way of explaining diversity in the beliefs and practices of various cultural and social groups in terms that go beyond any available on the standard anthropological account. On a pluralist conception of ethics, cross-cultural ethical diversity is simply an important—and essentially unavoidable—reflection of the fundamental plurality and diversity of ethical value itself. More controversially, some ethical pluralists go on to assert that neither individual human beings, nor cultures and societies, can escape fundamental ethical conflict—conflict, that is, between irreconcilable or incommensurable fundamental ethical principles and concepts. But some of the same difficulties inherent in the effort to defend the thesis of fundamental conflict across cultural groups, particularly the challenge of defining the contrast between derivative and fundamental ethical principles and beliefs, will attend any effort to show that no individual agent can avoid fundamental ethical conflict.

Following the lead of Isaiah Berlin, some pluralists contend that any individual agent who claims to experience no fundamental ethical conflict is in some way rationally deficient, or else deeply self-deceived. Yet there are many conceptions of human flourishing (both secular and religious) which purport to make fundamental ethical conflicts effectively impossible by identifying or articulating a single 'dominant end'—as John Rawls has described it—to which all other human ends must be subordinate, and with respect to which the subordinate ends can be unified. Such conceptions, particularly when combined with a willingness to allow other agents to reject them, have often been thought to embody defensible understandings of rational choice and rational agency. Moreover, some ardent defenders of the view that dominant-end conceptions of human flourishing are in some way deficient or irrational actually acknowledge that these conceptions do not intrinsically violate principles of rational choice. But they nonetheless insist that there remains something ultimately incomplete, or perhaps even irrational, about a life lived in accordance with such a conception (Rawls 1971, Hampshire 1983). In response to such assertions, the question of whether a compelling defense of ethical pluralism requires a commitment to the inescapability of fundamentally irresolvable ethical conflicts—across social and cultural groups, or in individual lives, or both—remains a subject of lively philosophical debate (Gowans 1987, Stocker 1990, Moody-Adams 1997).

2. *Implications of Disagreement for Understanding Ethical Argument and Inquiry*

Historically, philosophers have held quite differing views about what the facts of ethical diversity and disagreement might tell us about the nature of ethical argument and inquiry. The standard views can be divided up in terms of the position they take with regard to the objectivity of ethics—that is, with regard to the question whether there can be at least some right answers to ethical questions, where the rightness of the answer is independent of human beliefs and practices. But there is great variety within both the objectivist and the nonobjectivist positions, particularly with regard to important epistemological questions (questions of whether and how we can have moral knowledge) and serious metaphysical concerns (concerns about the existence or non-existence of objective value entities).

2.1 *Varieties of Ethical Objectivism and Serious Ethical Disagreement*

The most familiar variety of ethical objectivism is *absolutist ethical objectivism*, on which there is at most one right answer to any given ethical question, and according to which the ethical correctness of that answer does not depend upon human beliefs and practices. Plato's *Republic* contains one of the most fully developed and widely influential versions of this conception. The 'Allegory of the Cave,' in Book Five of the *Republic*, richly depicts the underlying epistemological and metaphysical assumptions. According to the allegory, the inhabitants of a cave who remained chained to a wall, seeing only the shadows of real things by the light of a humanly built fire, are deprived of any possibility of rationally understanding what is real, and their beliefs and practices reflect their ignorance. Only the person who is released from ignorance and illusion by being unchained, and allowed to leave the cave, can become capable of a rational appreciation of the real essences of things as illuminated by the genuine light of the sun. The metaphysical commitments associated with this view—in Plato's doctrine of the Forms—are developed in surrounding passages in the *Republic*, and in other Dialogues like the *Symposium* and the *Phaedrus*. On the resulting view, what the relativist takes to be fundamental ethical diversity and disagreement is simply a function of moral ignorance rooted in the tendency to our experience of imperfect copies and shadows of the real as though they might reveal the essence of the ethical.

But absolutist ethical objectivism need not involve this kind of metaphysical realism about value entities existing independent of human belief and practice, or even any kind of realism about independently existing value-entities or antecedently given moral facts. Nor need it involve the potentially problematic epistemological assumptions needed to explain how anyone might come to know the Form of the Good, and why so few seem genuinely capable of doing so. Immanuel Kant held a constructivist conception of ethical objectivity, on which humanly constructed practices (and their underlying beliefs and assumptions) are objective when they have been constructed in accordance with what Kant took to be the objectively valid (and already known) supreme principle of morality, the 'Categorical Imperative.' In its most basic formulation, the Categorical Imperative directs the agent to act only on those policies (reasons) that he or she could will to serve as universal laws of action. What the relativist identifies as 'fundamental' ethical disagreement is for Kant simply evidence that one or more parties to the disagreement has failed to subject the policy underlying a practice or a proposed course of action to the rational scrutiny required by the Categorical Imperative.

Some ethical pluralists believe that ethical objectivism need not be linked with the kind of absolutism found in the work of Plato or Kant. But whether ethical pluralism is indeed compatible with ethical objectivism remains a subject of rich, and ongoing, philosophical debate. How far can the pluralist go in rejecting the absolutist's 'one right answer' approach

and remain an ethical objectivist? Many think that the most plausible pluralist candidates for the label 'ethical objectivist' are forms of ethical pluralism which recognize the possibility of diverse answers to disagreements involving derivative principles, yet retain the 'one right answer' approach to analyse disputes involving fundamental principles. Of course, any such views must confront the problem of reliably distinguishing fundamental from derivative ethical principles. Moreover, while there is no evidence that this problem is not, in principle, capable of a compelling solution, some ethical pluralists avoid the problem altogether by defending a limited and moderate relativism. On these accounts, the relativist rightly posits the possibility—and the frequent occurrence—of at least some fundamentally irresolvable ethical disputes.

2.2 Varieties of Nonobjectivism and Serious Ethical Disagreement

Meta-ethical relativism is, perhaps, the most familiar form of ethical nonobjectivism. Its main claim, as noted above, is a negative thesis about the impossibility of rationally adjudicating (purportedly) fundamental ethical disagreements. But some meta-ethical relativists also attempt to defend a normative ethical relativism that makes a positive claim about the content of morality and about the nature and sources of ethical disagreement. In its bolder formulations, normative ethical relativism asserts the 'equivalence' of all ethical practices and beliefs. This version of the view has some important implications for a relativist approach to ethical practice—most often resulting in a demand to 'tolerate' all ethical practices as 'equally valid.' According to more modest versions of normative ethical relativism, we cannot confidently assert the superiority of one ethical stance over another with which it somehow conflicts, and we should therefore withhold judgment as a recognition of ethical uncertainty.

Metaethical relativism starts from the facts of ethical diversity and disagreement, but some forms of nonobjectivism posit very different explanations of those facts. One such view is ethical subjectivism, on which ethical claims are fundamentally statements about the individual speaker's subjective feelings (not about the practices of a particular social or cultural group). What the relativist identifies as a fundamental ethical disagreement is, for the ethical subjectivist, simply evidence of the deep-rooted feelings of the parties to the dispute. Yet both metaethical relativism and ethical subjectivism allow that ethical statements have some cognitive content. On the subjectivist views, ethical statements tell us something meaningful and informative about the feelings of the speaker—and indirectly about the feelings of any similarly constituted persons. On metaethical relativism, in contrast, ethical statements tell us what members of a particular social or cultural group believe to be good—and, ultimately, about the local social worlds in which ethical practices arise and have their (limited) application (Williams 1985).

It is important that some nonobjectivist views find ethical claims to be cognitively substantive, because there are varieties of nonobjectivism which deny that ethical statements have any cognitive content at all. The most influential and controversial such view is the theory of emotivism, first articulated in the early twentieth century by A. J. Ayer (1946). According to Ayer, fundamental ethical judgments (he called them 'pure judgments of value') are non-rational, non-cognitive expressions of emotion which cannot be true or false. Even the apparently most serious ethical disagreement, for Ayer, is not much different from a round of energetic 'boos' and 'yeas' for the opposing teams at a sporting event. Ayer's critics charged that such claims appear to deny that ethical disagreements ever occur. Ayer's efforts to mollify his critics were problematic: moral disagreements occur, he responded, but only as disagreements 'without formal contradiction.' This hypothesis can be confirmed, he urged, by the tendency for the parties to such disagreements to resort to 'mere abuse' when arguments fail.

3. The Infirmity of Ethics Compared with Science?

3.1 Ethical Disagreement as a Source of Skepticism about Ethical Methods

Yet despite its counter-intuitive claims about ethical disagreement, and its implausibly narrow understanding of what it is to have cognitive content, emotivism was a powerful and challenging embodiment of skepticism about the rationality of ethical argument and inquiry—a skepticism firmly rooted in the frequent intractability of ethical disagreements. There is a special irony in the fact that emotivism seems to deny the reality of the very phenomenon underwriting its skeptical challenge to the methods of ethics. But for many philosophers, even those who would explicitly reject emotivist understandings of ethical language, the emotivist's challenge to ethics retains a certain potency. The continued existence of intractable ethical disagreements, for these thinkers, is evidence (along with the explanatory and predictive success of science), that ethics, in the words of logician and philosopher of science W. V. O. Quine, is 'methodologically infirm' compared with science.

3.2 Alternatives to Skepticism

Yet the conception of science as the arbiter of rationality, capable of supplying standards which must be met by any domain of rational argument and

inquiry, has been challenged. Its critics object that it wrongly presumes that all domains of human inquiry might have the same aim. They maintain that ethics and science are fundamentally different kinds of enterprises—one claiming to explain and predict natural phenomena, the other seeking to help us to lead lives worth living—and that there is no reason to expect similarities between the methods of ethics and the methods of science. To be sure, some ethicists continue to search for fundamental similarities between the methods and aims of ethics and science. But their critics urge that such efforts can only make ethics look like a poor and distant relation of science, and that we distort the aims and purposes of ethics by trying to make it conform to structures of argument in science. Still further, these critics reject the notion that the persistence of disagreement in ethics—even intractable disagreement—is intrinsically a sign of the failure of ethical methods. Might it not be, they ask, that in some domains of human argument and inquiry disagreement is an important catalyst for serious reflection, and a crucial stimulus to avoiding smugness and self-righteousness?

4. *Implications of Ethical Disagreement for Practice*

4.1 *The Merits and Demerits of Tolerance*

The existence of ethical diversity and the persistence of ethical disagreement nonetheless pose important difficulties for ethical practice. How are we to respond to those whose ethical beliefs and practices differ, sometimes quite substantially, from our own? The ethical objectivist will argue that in some or even all ethical disputes, one or more parties to the dispute has made some kind of error in moral reasoning or perception. Ethical relativists, and some pluralists, who argue for tolerance in response to ethical disagreements urge that the objectivist response is too frequently associated with moral smugness and moral self-righteousness, and potentially dangerous and culturally imperialist ethnocentrism. But these associations are not intrinsic, and the demand for tolerance poses its own dangers when it functions (as it sometimes has) to sanction local practices which involve the violent coercion of innocent victims, or murderous intolerance of internal cultural dissent. The demand for tolerance also raises urgent questions about theoretical consistency. If it is intended as a non-relative demand, incumbent on any agent, then it is clearly incompatible with the relativist stance. If it is aimed only at the inhabitants of some societies—say Western liberal societies—then it violates relativist structures in demanding the extension of what may well be a locally compelling principle to a intercultural context. Still further, uncritical tolerance of ethical diversity and disagreement must not be confused with respect for cultural diversity. Many philosophers urge that we sometimes show the greatest respect for diverse ways of life by being ready to engage in open and noncoercive discussion with those who represent them.

4.2 *The Dangers and Incoherence of Ethical Isolationism*

Some relativists are so concerned about the dangers of ethnocentrism and the imperialist over-reaching of some cultures that they insist on an ethical isolationism. According to the ethical isolationist, cultural outsiders can never understand ethical practices and beliefs associated with a genuinely unfamiliar way of life, and thus have no rational basis for any kind of critical reflection on—let alone outright criticism of—those practices and beliefs. But, ethical isolationists typically defend their views by detailing their own special understanding of the practices and beliefs of the unfamiliar 'other,' richly conveying facts about those practices and beliefs in order to convince other cultural outsiders of the limits of their understanding. This tack shows how difficult it is to defend ethical isolationism except in terms which reveal the inconsistency and implausibility of the view.

4.3 *Pluralism and Multiculturalism*

Yet philosophers who reject ethnocentrism, relativism, and isolationism must still confront the persistence of ethical diversity and disagreement and the challenges they pose, especially in the culturally complex societies found in large, modern nation-states. An increasingly influential response, associated with some forms of ethical pluralism, is the doctrine of multiculturalism, which recommends that we act and judge on the presumption that the ethical beliefs and practices of every way of life are in principle valuable and worthy of respect. But compelling philosophical discussions of multiculturalism have construed this presumption as, at best, a 'starting hypothesis,' maintaining that a final verdict on the worth of any practice must always await the results of respectful, but sustained, critical reflection (Taylor 1992). In response, some philosophers have urged adoption of a critical multiculturalism (as a form of objectivist ethical pluralism) which leaves open the possibility that reflection on almost any practice might generate rationally compelling grounds on which to reject the practice as ethically indefensible (Moody-Adams 1997). The question of how to put this critical multiculturalism into practice—how to articulate and apply plausible principles for tolerating some stances, rejecting others, and intervening in practices deemed intolerable—will be a central topic of debate in the normative ethical and political philosophy of the twenty-first century.

Divorce and Children's Social Development

Parental divorce is a common experience in the lives of children. Each year in the USA, over one million children experience the breakup of their parents' marriage. Researchers are interested, therefore, in determining the effects of this event on child development. Although much of the knowledge about children's adjustment to parental divorce is limited to studies in which children are examined at a single time point after the divorce, a small number of researchers follow children over time, beginning with the divorce, and a few provide a rare look at children before the divorce occurs. The studies tap a variety of variables, including measures of personality, intelligence, mental health, and relationship quality with family and peers. This article summarizes literature across a variety of designs and indicators of children's development. The focus is predominately on work originating in the USA, an emphasis that reflects the fact that the national divorce rate is higher than that of other Western countries.

1. Rise of Divorce as an Area of Study

As compared to earlier decades, the divorce rate in the USA rose rapidly during the 1960s and 1970s. The annual divorce rate in 1940, for example, was nine divorces per 1,000 existing marriages. This figure almost tripled by the end of the 1970s, climbing to an annual rate of over 22 divorces per 1,000 marriages (see Cherlin 1992 for a discussion). Since then, the annual divorce rate has declined slightly, to around 20 divorces per 1,000 marriages, but remains far above the levels of the middle part of the twentieth century. The divorce rate in the USA is far higher than in other industrialized nations, more than 1.5 times the divorce rate in the UK, and more than double that of Germany, France, and Japan. As a consequence, it is estimated that as many as 60 percent of children in the USA will spend some of their childhood or adolescence in a single-parent family. The marked increase in divorce has led researchers to examine how variations in family arrangements affect the development of children.

The most common strategy used to investigate this topic has been to compare children who have experienced parental divorce with children who have not. Although the specific estimate varies across studies (see Amato and Keith 1991a for a meta-analysis), in general, about 20 percent of children experiencing parental divorce exhibit serious problems, compared to about 10 percent of children who have not experienced parental divorce. This finding can be interpreted in different ways to support opposing perspectives of the effects of divorce on

children's adjustment. Because this finding shows that risk of serious problems is doubled, it can be concluded that parental divorce has very negative consequences for children. Alternately, because the finding also shows that 80 percent of children who experience this transition show no serious difficulties, it can be concluded that parental divorce has limited negative consequences. These opposing interpretations, based on simple comparison studies, are evident throughout the history of divorce as an area of study (see Simons et al. 1996 for a discussion).

Over the last several decades, research strategies have evolved to provide a more nuanced picture of divorce and children's development. Improvements in the methods used in these studies, such as including statistical controls, broadening the taxonomy of outcomes assessed, obtaining assessments from multiple perspectives, incorporating observational measures, documenting changes in children's adjustment over time, and obtaining assessments of children and families prior to divorce, have allowed for a more detailed view of parental divorce and its aftermath. These studies have led to a growing awareness that children's responses to parental divorce are highly variable and dependent on the particular set of circumstances faced by families before and after the actual marital dissolution (see Hetherington et al. 1998 for a review). In this view, the experience of divorce brings with it a series of unique challenges and changes and entails a complex mixture of potentially positive and negative consequences. Researchers from this perspective, which is labeled a transactional or mediational model, view marital transitions as involving a cascade of predivorce and postdivorce changes in family relationships and economic/social circumstances. It is these changes, rather than divorce itself, that affect children's adjustment. This transactional model of divorce has become the dominant paradigm for contemporary research (Amato 1993, Emery 1988, Forgatch et al. 1995, Hetherington 1989, Hetherington et al. 1998, Simons et al. 1996).

2. *Adjustment of Children in Divorced Homes*

Compared to children who have never experienced their parents' divorce, those who have score lower on measures of well-being and higher on measures of a wide array of problems (see Hetherington et al. 1998 for a review). Children of divorce are more likely to have academic problems and difficulties in relationships with peers, parents, and siblings. They exhibit higher levels of externalizing problems, such as acting-out behaviors, noncompliance, aggression, hyperactivity, and delinquency. They also exhibit higher levels of internalizing problems, such as depression, anxiety, low self-esteem, and social withdrawal. As adolescents, they have higher rates of school dropout, substance abuse, sexual activity, and teenage pregnancy. As adults, they have lower occupational status and life satisfaction, and higher rates of economic hardship and mental health problems such as depression (see Amato and Keith 1991b for a meta-analysis of adult outcomes). In addition, their own marriages are more likely to be negative and coercive and to end in divorce. Although these adverse outcomes are more common in children from divorced homes than in children who have not experienced divorce, it is important to note that the majority of children experiencing this parental transition escape these problems.

Parental divorce may either initiate new difficulties or exacerbate existing ones. Studies that assess children prior to parental divorce demonstrate that problem behaviors are evident well before the marital dissolution (e.g., Block et al. 1988). In addition, many of the differences between children who have and have not experienced parental divorce are diminished once predivorce functioning has been controlled (Cherlin et al. 1991). Thus, it is possible that some of the difficulties exhibited by children of divorce are a result of factors that have existed prior to the divorce itself. Studies showing higher problem behavior among children of divorce therefore may be a consequence of simply having a greater proportion of more vulnerable individuals represented in the divorced population, a problem known as selection. In support, some studies have demonstrated that genetic factors play a significant role in the risk of divorce (Jockin et al. 1996). It is important to note, however, that several other studies show a significant increase in problems for children of divorce, even after controlling for predivorce factors (e.g., Chase-Lansdale et al. 1995).

Researchers have investigated whether the effects of parental divorce depend on the child's gender, age, or the length of time since divorce (see Hetherington et al. 1998 for a discussion). A clear picture from these studies has yet to emerge. With respect to gender, early studies showed that boys had more difficulty adjusting to divorce than girls. More recent studies cast doubt on these findings by showing that adolescents from divorced families demonstrate higher rates of conduct problems and depression, regardless of gender. In fact, emerging evidence indicates that females may exhibit greater long-term consequences when teen parenthood is involved. This early transition to parenthood is likely to have more adverse effects for females because of their more common role as custodial parents.

Relative to child age at the time of divorce, some researchers have concluded that preschool-age children are at greatest risk for long-term problems. They argue that limitations in cognitive development hinder younger children from understanding the complex nature of divorce, giving rise to fears of parental abandonment and problematic outcomes. Other researchers have countered that the results concerning age are inconsistent and inconclusive. In many studies, for example, the child's age is confounded with the

length of time since parental divorce: the greater difficulties found in younger children may reflect the fact that less time has passed since the divorce occurred.

It is also not clear how children's adjustment to divorce changes over time. Some studies have shown that children exhibit an increase in problem behavior in the immediate aftermath of divorce that dissipates over time, suggesting that at least some of the difficulties are transitory. Other studies have indicated that problem behavior may emerge at a later age such as adolescence, when children face new challenges (e.g., Hetherington 1989). Some long-term follow-up studies document that the effects of divorce on problem behavior persists into adulthood at least for a subset of children by affecting educational and occupational attainment (Amato and Keith 1991b, Chase-Lansdale et al. 1995).

In sum, although parental divorce is associated with an increased risk of problem behavior overall, children's responses to divorce are highly variable, and the particular trajectory of development is affected by the particular circumstances occurring before and after divorce. The environmental factors influencing children's adjustment to divorce are addressed in the next section.

3. *Risk and Protective Factors*

In the transactional model of divorce, changes in family relationships and environmental circumstances before and after divorce, rather than the divorce itself, are the critical determinants of children's postdivorce adjustment problems. These risk and protective factors influence the extent to which children will be adversely affected by parental divorce. Factors that are present prior to divorce include characteristics of the parents themselves (see Capaldi and Patterson 1991). Research indicates that parents who divorce are more likely to have a history of economic problems, alcoholism, depression, and antisocial behavior. Not surprisingly, they also are more likely to have poor parenting skills prior to the divorce. Postdivorce differences in children's adjustment may thus reflect predivorce exposure to inconsistent, inept childrearing practices and chaotic household routines. Moreover, couples who later divorce are more likely to display poorer conflict resolution skills and higher negativity. Through modeling and imitation, children may learn these ineffective strategies and employ them in other contexts. For example, in high conflict homes, children may be drawn into marital conflict as a way for spouses to gain relative advantage over each other, and these experiences may train children to manipulate their parents. Consistent with these notions, research has shown that children living in homes where the marriage is distressed but not yet formally dissolved fare worse than those who experience a relatively amicable divorce (see Hetherington 1999). In addition, divorce appears to improve the adjustment of children for whom postdivorce parental conflict is dramatically reduced over predivorce levels.

Some risk and protective factors involve changes occurring after divorce. For many families, parental divorce introduces a series of social and economic changes that may interfere with the functioning of both parents and children (see Forgatch et al. 1995, Hetherington et al. 1998, Simons et al. 1996 for more detailed discussion). Economic stress introduces deterioration in living conditions, as families move to neighborhoods and schools of lower quality. Custodial parents face the challenge of task overload in managing new household, childcare, and financial responsibilities. Custodial parents may lose friends who were part of the couple's network, resulting in isolation and reductions in social support. Adults dealing with such stressors show higher rates of physical and mental health problems that interfere with their ability to be competent parents. Consistent with this view, custodial and noncustodial parents are less effective and consistent in controlling and monitoring their children, and show higher levels of punitiveness and irritability with their children than nondivorced parents. Moreover, conflict between parents and children becomes more frequent and intense after divorce. Researchers have consistently demonstrated that child adjustment after divorce is explained in part by the effect of stressors experienced by custodial parents on their parenting practices and that high quality custodial parent–child relationships mitigate the negative effect of divorce-related stressors on adjustment problems.

In addition to deteriorations in the quality of the relationship between the custodial parent and child, most children experience a dramatic loss of contact with the noncustodial parent. Although noncustodial mothers are more likely to maintain contact with their children than are noncustodial fathers, simply maintaining contact with the noncustodial parent does not appear to enhance children's postdivorce adjustment. Involvement with a noncustodial parent is most beneficial when parents maintain an amicable postdivorce relationship. Moreover, the quality rather than the quantity of the involvement by the noncustodial parent appears to play a more critical role in children's postdivorce adjustment (Hetherington et al. 1998, Simons et al. 1996).

Following divorce, relationships with siblings and peers change as well. Sibling relationships become more negative and conflictual, and such changes in relationships have been related to increased aggression and other problem behaviors. Moreover, children of divorce are more likely to become involved with antisocial peers, and may experience a loss of positive peer support due to residential changes. These alterations in peer relationships may exacerbate potential

difficulties by increasing the child's exposure to delinquent activities or by removing a potential buffer from conflictual relationships within the family (Hetherington et al. 1998).

4. Future Directions

For a sizeable group of children, the initial divorce is the first in a series of parental transitions. About half of all children whose parents divorce will become part of a stepfamily, and 10 percent of children will experience two divorces of their custodial parent during childhood or adolescence. Many children will join new families through cohabitation rather than remarriage, and there is some evidence that cohabiting families experience even higher rates of dissolution than remarried families. A sequence of multiple family transitions places children at increased risk for problematic outcomes. Research is needed to understand how children respond to their custodial parents' dating, repartnering, and cohabitation, and to identify factors that promote or hinder children's adaptation.

Divorce and Gender

Divorce has a significant impact on the lives of both women and men. Men and women have different experiences at divorce, however, and divorce has different consequences for them. Typically, women experience economic decline after divorce and some divorced mothers fall into poverty. This article will examine recent trends in divorce in Europe and the USA, and will then consider the case of the USA in more depth.

While divorce causes women great hardship, it can also be liberating for them. Before divorce became legal, for example, married women who encountered abuse—physical or psychological abuse, or the abuse of alcohol—or who were otherwise trapped in bad relationships, had no way to get out of their marriages. Nineteenth and twentieth century women's movements fought for the right to divorce, which was legalized in the nineteenth century in the USA, and by various European countries throughout the twentieth century. The freedom to divorce is an important right for women, one still denied to wives in some countries (Goode 1993).

Even after the legalization of divorce, however, it took until the second half of the twentieth century for divorce to become socially acceptable in Western countries. States tried to discourage divorce until well into the twentieth century. To keep families together

and to 'protect' women and the family, divorce was restricted through fault-based systems that remained in effect until the 1960s (Goode 1993). Under these systems, divorce could take place only if one party was able to prove the other guilty of adultery, cruelty, or other serious offenses. In the event that a divorce did occur, the wife was to be financially protected by her ex-husband. Since the state put in place no mechanisms to enforce this system, however, it did not in fact protect women. In the United States, most women never received alimony from their ex-husbands nor did most women obtain much property from a marriage, as most couples had little property to divide (O'Connell 1988). Thus, a major contradiction existed between the law's assumption that the wife was dependent and should be protected in her domestic role, and the fact that most women received no such protection.

The last half of the twentieth century saw the stigma against divorce lifted and a rise in divorce rates in all North American and European countries (Goode 1993). The USA has one of the highest divorce rates—50 percent of all marriages now end in divorce (Stewart et al. 1997). Fundamental changes in divorce law in Europe and North America have also taken place. The most notable change has been the introduction of 'no-fault' divorce legislation. Most European countries have provisions for ending marriages without charges of fault, and in the USA by 1985 all states had passed 'no fault' laws, based on the principle of 'irretrievable breakdown' of the marriage, 'incompatibility,' or 'irreconcilable differences,' which permitted a divorce even if only one partner desired it (Kurz 1995). The no-fault system overturned the traditional view of women as dependents, stipulating that men are no longer responsible for the lifelong support of their former wives. In the USA, the new model looks at marriage as a partnership between husbands and wives, much like a business partnership. At divorce, women are expected to support themselves through paid work, supplemented by child support and an equitable division of assets from the marriage. Alimony, or lifelong financial support that in theory was available to a divorced wife, has been replaced by 'spousal support' awards of short duration, typically to the former wife, until she can begin supporting herself through paid work. Similarly women receive no special consideration in the division of property in the no-fault era. Property is to be divided equitably between divorcing spouses, much as one would divide property when dissolving a business.

No-fault divorce legislation with its gender-neutral assumptions has had benefits for women, particularly in overturning the stereotypic view of women as dependents of their husbands and substituting a view of men and women as equal. It has continued to leave women economically vulnerable, however. I will demonstrate below how divorce disadvantages women in the USA. While divorced women everywhere face economic difficulties, the USA provides an instructive case of what happens to women and children in a country that does not have adequate social supports for single mothers or a strong social welfare system that can mitigate the negative impact of divorce. The assumption behind current US policy, that divorced women would be able to support themselves adequately on their salaries and wages and on assets from their marriages, overlooks the realities of women's lives. In the following section, I will examine current divorce policies, how they impact on women's economic situation after divorce, and divorced women's ability to secure assets from the marriage and ongoing support.

1. *Economic Situation of Divorced Women*

In the USA, after divorce mothers' standard of living goes down by at least a third while the incomes of divorced fathers go up by 15 percent (Hoffman and Duncan 1988). Mothers' decreased standard of living affects not only themselves, but also their children, who typically live at the standard of living of their mothers. Why do divorced women have so much difficulty securing an adequate standard of living? First, many women cannot earn enough in the paid labor market to adequately support themselves and their children. Women make only 78 percent of what men do (Blau 1998) and many women are concentrated in low-paying jobs (England 1992).

Second, although women make an enormous life investment in their marriage, they are left on their own with little to show for it. Many divorced women receive no property of any value. The main asset of a couple is often the home, which in some cases is sold at the time of divorce so that each spouse can receive half its value. This usually leaves a woman and her children with smaller quarters and causes the children additional disruption. As well as having little property, only about one-sixth of divorced women have received spousal maintenance awards, most of which are of limited duration, are not large, and only half of which are paid in full (Weitzman 1985).

While divorced women have been unable to secure many assets from their marriages, in theory one resource remains available to the 85–90 percent of the divorced women who have physical custody of their children–child support. Most mothers are entitled to it, nearly all mothers need it, yet relatively few receive it: fewer than half of divorced women receive their full child support award (Roberts 1994). Child support can be critical for divorced mothers and their children, as well as other single mothers, to help them escape poverty. Researchers have established that regular child support payments would improve the standard of living of women and children and would lift a number of them out of poverty (Nichols-Caseboldt 1992).

Despite mothers' demonstrated need for child support, however, the government has not implemented an adequate child-support system. First, child support awards have been very low. As child support is currently calculated and awarded, it covers less than half the costs of raising a child and typically is no more than 10 to 20 percent of a father's income, never more than 30 percent (Weitzman 1985). Thus fathers contribute much less to the support of their children than do mothers. The problem is that child support awards are based on the costs of raising children in a two-income family; they do not take into account that divorced single mothers have many additional costs in establishing a new household. Further, career assets are not recognized as marital property. Thus the primary wage-earner, generally the husband, is permitted to keep most of the assets accumulated during his marriage and does not suffer financially at divorce, while the wife, who has invested in her family and in her husband's career, is deprived of a return on her marital investment.

As for child support enforcement procedures, fortunately the Federal government and states have recently legislated tougher policies. The most important and effective reform for child support enforcement enacted to date is income withholding, a procedure by which an obligator's (typically the father's) payment is withheld from his paycheck by his employer, who then sends the money to the state child support agency (Roberts 1994). This will surely help raise the rate of child support collections. Problems will remain for women in improving their receipt of child support, however. Even with income withholding, estimates are that between 23 percent and 35 percent of women will still not receive child support (Garfinkel 1992). One problem is that there is no child support enforcement system for women whose ex-husbands or former partners are self-employed. Collecting child support in interstate cases, which comprise 30 percent of all child support cases (Garfinkel 1992), is also a problem. There are new enforcement mechanisms for interstate cases; however the effectiveness of these new regulations depends on the ability of state child support agencies to take action on individual child support cases. Unfortunately, at this time state agencies are underfunded and labor under very large caseloads (Roberts 1994).

These problems with the child support system mean that the great majority of divorced mothers are in an economically dependent, vulnerable position. There are few social welfare programs or subsidies in the USA that enable them to live at an adequate standard of living outside of marriage. Some must resort to welfare, which provides a standard of living that is typically below the poverty level. Women who come from communities that have fewer resources and who experience discrimination, including many women of color, face even higher rates of poverty after divorce.

While there are problems with child support collection in many European countries as well, according to Glendon (1987) the legal system and public policies in the USA do less than those in any other Western country to help families cope with the consequences of divorce. By contrast, some European countries have social welfare systems that are typically much more supportive of single mothers and children. In the Scandanavian countries, the state actually pays child support to mothers and collects child support from fathers (Goode 1993). This policy is based on the belief that it is the state's responsibility to ensure that children are adequately provided for.

2. *Social Issues at Divorce*

While divorce brings economic disadvantage for women and children, it can also have positive consequences. US researchers have noted that many men and women are positive about having divorced and report a greater sense of well-being after ending their marriages. Some researchers believe that divorce brings particular contentment to women, who gain an increased sense of competency and control (Riessman 1990). In Kurz's (1995) study of divorced women, women's feelings about their divorce were related to the circumstances of their marriages. The majority of women reported feeling positive about the ending of their marriages, particularly the substantial number of women whose husbands had been violent, had used drugs and alcohol, had been controlling, or had rarely been at home. For these women divorce was a welcome release from a bad marriage, an outcome consistent with the goals of the nineteenth century divorce reformers. The exception to this pattern was those women who had been left by their husbands against their wishes, for whom adjustment to divorce was more difficult.

While a number of couples report their satisfaction with being divorced, however, a certain percentage of them report conflict after divorce. Arendell (1995), in her study of divorced fathers, found that some fathers report harassing their former wives over issues of payment of child support, custody, and visitation. Forty percent of the men in her sample described incidents in which they had threatened explicitly or resorted to acts of violence against their former wives since the end of their marriages. In Kurz's sample, 30 percent of women were fearful at some point during negotiations for child support, with similar percentages reporting fear during negotiations for custody and property. Those women who were fearful were most often those who had experienced violence during their marriages. Some of these women were afraid to demand child support. Some feminists have been concerned that new child support legislation mandating that mothers identify fathers and cooperate with child support enforcement could put some women with violent ex-husbands at risk (Kurz 1995).

These advocates argue that, for this reason, women who have experienced violence should not be forced to cooperate with child support enforcement agencies against their will.

The fear of harm or violence can have other negative consequences for women. In the case of negotiating for custody and child support, some fathers threaten to sue for custody even when they don't really want it, as a way to get mothers to reduce their demands for child support. In response, some mothers forfeit their right to child support in order to secure custody of their children. Recent changes in custody law make these kinds of suits possible. A presumption of joint custody has replaced the maternal presumption in the determination of child custody. Fathers' rights groups in particular have agitated for more rights to participation in their children's lives and many feminists have also hoped that fathers would become more involved with their children after divorce (Kurz 1995).

At the present time, most divorced parents have some type of joint custody agreement, most often joint legal custody mandating that both parents should be involved in major decisions about the child's life and in a small number of cases, joint physical custody, where the child goes back and forth between the mother's and father's residences. While joint custody can promote shared parenting that is good for the child, there has been some debate about whether joint physical custody is best for children (Maccoby and Mnookin 1992). For divorced mothers, however, joint custody can be disadvantageous. In many such custody agreements, children end up spending more time with their mother. Since fathers with joint custody agreements do not pay child support, however, mothers and their children then lose financially in this arrangement (Mason 1999). In addition, in the minority of cases when fathers actually do want custody, or at least sue for it, they have a greater likelihood of getting custody than the mothers (Mason 1999, p. 22).

Conflict is not only stressful for former spouses and financially disadvantageous for most women, but it can also have a negative impact on children. Scholars have disagreed on whether or not divorce harms children. Some argue that it does, while others claim that being a child of divorce is no more difficult than being a child of an intact marriage characterized by high levels of conflict (Johnston 1994). One thing scholars agree on, however, is that conflict between spouses during marriage and after divorce can be harmful for children (Stewart et al. 1997).

3. Conclusion

Gendered laws, procedures, and practices play a critical role in divorce and have a negative impact on the economic situation of divorced women and children. At the same time, the discourse on divorce and the assumptions underlying much divorce law are gender-neutral. Unfortunately, some researchers and policymakers have proposed divorce policies that ignore the gender-based aspects of divorce. They advocate policies to increase commitment to marriage and make it more difficult for people to get divorced—mandatory waiting periods before divorce, mandatory marriage counseling or marriage education, and the reintroduction of fault-based divorce (Popenoe 1996).

Women's rights advocates view such proposals with alarm. They favor strengthening child support enforcement and increasing child support awards. They also argue for supplementing private support with strong public measures such as are found in the Scandanavian countries, measures which provide guaranteed child support. Many also argue that the state should promote mothers' self-sufficiency through job training, higher incomes, subsidized day care and health care, and family allowances. Only such comprehensive measures, they argue, can reduce the high levels of poverty among divorced women and children.

Divorce, Sociology of

Among the striking features of family life during the latter part of the twentieth century has been the steep rise in divorce. This worldwide trend reflects the profound changes in relationships between men and women and in the laws that govern family stability. It carries new and still untold implications for the future of the family as a social unit. The obvious benefit of divorce is that it enables persons caught in wretched marriages to escape and to improve their lives either by remaining single or by embarking on a happier second marriage. The tragedy is that, in many countries, it leads to widespread impoverishment of mothers and children. At issue also is the long-term emotional and social impact on children's lives and on traditional family functions such as care of the aged.

The ripple effects of the high divorce rate overflow into many social domains. As reported throughout the industrialized countries, these include the diminishing propensity to marry, the rise in cohabitation, an increase in single-parent and remarried families, the greater presence of mothers of young children in the workplace, and the lowering of expectations for long-term commitment in young people who have yet to establish their own families (Cherlin 1992). Thus the accelerated rise in divorce is a major indicator of social and psychological changes and a powerful agent of these changes. It reflects not only the shifting life perspectives of men and women; it impacts powerfully on society in ways that were unexpected and probably unintended by those who led the political battles of the twentieth century to loosen the constraints of marriage.

1. Wide Variation in Divorce Laws and Practices Worldwide

It is impossible to compare divorce in different countries, except perhaps among the industrialized countries of Europe and North America. Nor is it prudent to try to delineate common antecedents or consequences of the breakdown in family life, because reports about divorce and postdivorce sequels are sparse or unavailable for much of the world. Legal constraints on divorce vary widely. In some countries divorce does not confer the freedom to remarry. Waiting periods to obtain a divorce can extend from a few months to many years. Even between contiguous countries within Europe there are widely varying restrictions in laws which reflect diverse cultural and religious attitudes (Goode 1993). But overall, there are similarities in the broad social patterns which show that the rise in the divorce rate began gradually, in different countries, during the late nineteenth and early twentieth centuries; it mounted rapidly throughout the 1970s, and seems to have reached a plateau by the 1990s. Whether this is a pause before another climb, or represents a real leveling off or downward swing, is not predictable at this time (Cherlin 1992).

The rise in divorce is most pronounced in the industrialized countries of North America and Europe, especially in the USA, Scandinavia, and the UK and remaining countries of the British Commonwealth. The fall of the last important bastion of resistance to divorce in Western Europe occurred in 1997, when Ireland adopted the Family Law Act. But divorce is increasingly evident as well in Central and South America, as it is in Eastern Europe (Everett 1997). In Japan and China, where traditionally divorce was not blocked by law—though it was discouraged by community disapproval and, in the case of China, by a burdensome bureaucracy—the divorce rate is rising (Mason et al. 1998). Family change has taken a much slower course in Muslim countries, where Islamic law has long made marital dissolution readily available to men, but has only fairly recently extended limited access to women. As the power of the traditional family and tribe was weakened by civil laws in sub-Saharan African societies, women were finally allowed to initiate divorce under very restricted circumstances (Aderanti 1997). The Moslem communities of South East Asia, on the other hand, have long institutionalized divorce and remarriage as an acceptable recourse for young women in arranged

marriages (Jones 1997). So that, except in fundamentalist Muslim countries, signs of greater freedom for men and women to free themselves from a bad marriage are apparent throughout the world.

2. Social Factors Underlying Divorce

The sheer number of divorces—especially in the USA and the Scandinavian countries, which lead the world in incidence of divorce—is an inaccurate measure of family life, because divorce statistics reflect only the dissolution of legal marriages, and millions of couples today reject marriage altogether in favor of cohabitation (Wallerstein 1998). Divorce in the West may be profoundly influenced by new and greater demands of relationships between men and women. Roussel (1989) and others have proposed that people today conceptualize marriage primarily as a vehicle for personal happiness and individual fulfillment, rather than as a family obligation and an economic and child-rearing contract. Obviously, marriages based on the participants' search for love and companionship are more fragile than those traditionally buttressed by law, church, family traditions, and social mores.

The rise in the world divorce rate is indeed a product of many complexly interacting social, economic, and psychological factors (Fu and Heaton 1995). Economic development, women's greater labor force participation, women's rising educational levels, and lower fertility rates as a result of improved contraception and the availability of abortion—all correlate positively with a country's divorce rate. Goode (1993) and other scholars have pointed to urbanization and industrialization as leading to the general weakening of the family unit as key provider of economic and social resources. As a result, individuals have greater freedom to define personal goals and to make career and marital choices separate from those laid down by traditions that demand conformity and continuity with the past.

Although it has been suggested that legal changes have spawned many divorces, the evidence is that diminishing legal barriers cause a short-term increase, but that over the long haul laws reflect rather than shape community trends. Women's employability has strongly influenced divorce by reducing women's economic dependence on men; in the USA and Europe, where women's emancipation is greatest, a majority of divorces are sought by women. But changes in the market participation of women are not necessarily accompanied by increased status or power, and certainly not by greater economic protection. Nor is there evidence that feminism as a political movement is a major influence in the worldwide rise in divorce.

The correlation between divorce and social class has varied. In earlier times divorce was the province of the affluent, but in recent decades it has been increasingly utilized by the lower social classes (Goode 1993). Divorce rose in the USA, Sweden, and other Western countries alongside the achievement of a higher social status for women. This was not true in the former USSR, where the divorce rate was high but there was no feminist movement of any consequence, and where women were consigned to more menial jobs (Everett 1997).

3. Psychological Effects of Divorce on Families

Although easier access to divorce has produced many benefits for adults locked into troubled marriages, it has carried a high cost in suffering for parents and long-term difficulties for millions of children raised in divorced or remarried families. The breakup of a marriage with children is rarely a mutual decision, and the parent who is left behind is often plunged into crisis. Approximately two-thirds of divorces in the USA and Europe involve minor children, often very young children, since typically divorce peaks during the first decade of marriage. There is mounting evidence that children in divorced families suffer with initial and long-term effects that place them at greater risk than their counterparts raised in intact families for problems throughout childhood and into adulthood.

The issue of whether children suffer as a result of divorce or whether they show the effects of the antecedent or continuing conflict in the family has long been disputed. There are now available a range of long-term studies (Amato and Booth 1997, Wallerstein 1998) which show that persons raised in divorced families have greater psychological problems in adult life, a higher divorce rate, a lower marriage rate, and more difficulty managing the interpersonal skills required for a stable marriage. Whether these sequelae can be changed by psychological or educational interventions with the parents or the children has not been demonstrated. Mediation programs which were expected to safeguard children by reducing the acrimony of the court adversarial process have not influenced psychological outcome among children (Wallerstein 1998).

4. Economic Consequences of Divorce

Women and children are economic casualties of divorce except in the Scandinavian countries, whose governments provide child support when the father fails to pay, and offer generous program child allowances and universal health care. They are somewhat protected in countries like Germany, where the father's wages can be garnished for child support. In most other countries, payments for child support are inadequate and poorly collected (Goode 1993). The court-ordered amount usually falls well below the

costs of raising a child. Moreover, women's employment is heavily gendered in most countries, and many women who were homemakers during the marriage have few marketable skills. In the former USSR, no alimony or regular child support is mandated and state assistance is meager. Many fathers are unable to pay child support and provide for their own needs. In the USA, in 1991, an estimated 40 percent of divorced women and their minor children lived below the poverty level (Teachman and Paasch 1994). Several governments are now putting more effort into collecting child support, but the plight of divorced mothers and children remains serious.

5. *The Continuing Dilemma*

The rise in divorce continues at the beginning of the third millennium to generate passionate controversy. In the USA, 'family values' has become a rallying cry among conservative groups who regard the high incidence of divorce as a symptom of moral decline and seek to reintroduce 'fault' into the 'no-fault' family laws that were adopted in the 1970s. Divorce has led to greater anger between fathers and mothers, as each group struggles for the custody of children and a larger share of economic resources. How to allocate family resources among children of first, second, and even third families is baffling. Concern has mounted about how to maintain the child's connection with both parents after divorce without disrupting the child's life.

Few dispute the importance of divorce as an avenue of escape from a brutal marriage. But many are concerned that divorce no longer reflects a necessary escape from exploitation, but rather promotes the unbridled freedom of the parents to give priority to their own desires and to overlook their children's needs (Glendon 1989). Much of the ongoing debate about the family has been motivated by clashing family ideologies and self-seeking groups. But much of it also derives from a genuine conviction that children need a stable family environment to ensure their proper emotional, educational, and moral development during their growing-up years.

Doctor–Patient Interaction: Psychosocial Aspects

1. *Introduction*

The quality of the interaction between doctor and patient in the consultation is central to effective healthcare delivery. Studies of doctor–patient interaction have focused on examining how doctors and patients communicate in a range of clinical settings. In addition to describing the nature of and variation in the communication process, many studies have also sought to examine how this interaction influences other healthcare outcomes, such as patient satisfaction and treatment adherence.

The development of audio and video-recording techniques has provided social and behavioral science researchers with a window into the private world of the medical consultation, allowing detailed investigations of the consultation process. From the early research it quickly became evident that there were considerable problems in the process and outcome of many consultations. Many patients reported that they had not been given sufficient information or had difficulty in understanding information which was presented in the consultation. Very often this was also

Figure 1
An input, process, and outcome model of the medical consultation (adapted from Frederikson 1993)

found to be associated with a subsequent reluctance or inability to follow the doctor's recommended treatment or advice. For example, in the landmark study of Korsch and Negrete (1972), which involved mothers taking their children to a paediatric outpatient clinic, about 20 percent of mothers were not informed clearly about the diagnosis and nearly 50 percent were uncertain afterwards as to the course of their child's illness. This and other studies have also shown that patients often report feeling that they have not been sufficiently involved in the decision-making which may have occurred in the consultation (Guadagnoli and Ward 1998).

Many studies which have analyzed the process and outcome of the medical consultation have revealed that there is considerable variation in the pattern of doctor–patient interaction and that this is influenced by factors which the doctor and patient bring to the encounter. As a result, current theoretical frameworks for understanding doctor–patient communication tend to focus on the relations between inputs (i.e., the attitudes, beliefs, expectations, etc. which patient and doctor bring to the consultation), process (the nature of the encounter), and outcome (the short and longer term effects on the patient). An example of one such framework is provided by Frederikson (1993) and is shown in Fig. 1, which provides an indication of the range of variables which have been studied. This article will, therefore, follow this structure and focus initially on these three broad areas. One of the practical benefits of this research has been the development of interventions to improve doctor–patient communication, and this work will be summarized in the final section.

2. *Input Factors in Doctor–Patient Communication*

The main input factors in doctor–patient communication reflect variations between and within both doctors and patients. Studies have shown that patients can differ along many dimensions (e.g., age, personality, coping style, expectations, etc.) which can influence the process and outcome of a medical consultation. Similarly, there is growing evidence that, despite having had a common medical training, doctors differ in their attitudes and role perceptions in ways which can have a significant influence on what happens in the consultation. This section will, therefore, review a selection of the evidence on the nature and effects of the two input factors.

2.1 *Patient Input Factors*

A number of studies have shown that patients not only cope with health threats in diverse ways but also show consistent differences in how they want to be involved in the healthcare process. These studies also show that patients differ in the amount of information which they would like to receive about their health problem.

For example, Miller et al. (1987) distinguish between two broad groups of patients whom they have labeled as 'monitors' and 'blunters,' with the former being more inclined to need and seek out information about their problem and treatment whereas the latter group prefer consultations in which relatively limited information is provided.

Patients come into the healthcare setting with different levels of biomedical knowledge, based on their past experience. There is also consistent evidence that patients have differing expectations for specific consultations and, for doctors, an awareness of these can be helpful in understanding not only why they are seeking help at that time but also in being able to respond effectively to their needs. Williams et al. (1995) have shown that the most common preconsultation expectation in primary care patients is for explanation and understanding of their problem, with much smaller numbers wanting tests, diagnoses, or support. These prior expectations can be important in determining outcomes since consultations in which patient expectations are met, have been shown to result in greater satisfaction and an increased willingness to follow advice or treatment.

These differences in patients' expectations are also related to their perceptions of the role of the doctor. A number of studies have shown that patients differ in their perceptions of the role of the doctor and the extent to which it is appropriate to discuss different types of problems, particularly those of a more psychosocial type (e.g., Bower et al. 1999). However, even when patients feel that it is appropriate to discuss psychosocial problems with their doctor, this does not necessarily happen since the doctor's own approach to the consultation may preclude this.

2.2 *Differences Between Doctors*

Doctors have been categorized in various ways according to their role perceptions and the extent to which they concentrate on the technical or more psychosocial aspects of patient care, as well as their beliefs about whether patients should be actively involved in the consultation and in decision-making about the management of the clinical problem (e.g., Grol et al. 1990). Inevitably these broad attitudinal differences are reflected in the way in which the consultation is conducted and in other aspects of professional behavior including decision-making, prescribing and management of clinical problems.

Although doctors undergo a common training and share a common body of knowledge and skills, wide variations in their consulting behavior have been noted. Part of this variation is a by-product of personality differences and can be seen in differences in interpersonal aspects of clinical practice but part is a reflection of differences in the approach to clinical problems. Some of these are between-individual differences whereas others reflect factors which can vary within the same individual, such as changing mood, time pressure, and various other contextual influences. In their overview of clinical decision-making, Schwartz and Griffin (1986) point out that there are often substantial disagreements between doctors when interpreting the same clinical information (e.g., x-rays). They also note that doctors may be inconsistent and disagree with their own previous judgments.

During clinical decision-making, the doctor is often faced with having to process a large amount of information about the patient and the possible diagnoses and treatment options. Since there are limits in what can be attended to and how much information can be held in working memory, doctors develop heuristics, or general strategies, for processing diagnostic and treatment information and these are subject to a range of influences. Kahnemann et al. (1982) have described a number of the heuristics which are used during clinical decision-making. Similarly, the doctor's attitudes and beliefs about the doctor's and the patient's role can influence the weighting given to information from patients (e.g., the relative attention given to physical and psychosocial information). In addition, the doctors' mood can affect information-processing in a number of ways by directly influencing the speed and accuracy of clinical problem-solving (Isen et al. 1991) or possibly by constraining access to mood congruent semantic information, as has been demonstrated in more general studies of the effect of mood on cognition.

3. *The Consultation Process*

There are a range of methods and frameworks for analyzing and describing the process of the consultation. One of the broadest distinctions made has been between consultations which are described as patient-centered and those which are doctor-centered, reflecting the extent to which the doctor or patient determines what is discussed (Grol et al. 1990). Doctor-centered consultations are ones in which closed-questions are used more often and the direction is determined by the doctor, typically with a primary focus on medical problems. In contrast, patient-centered encounters involve more open-ended questions with greater scope for patients to raise their own concerns and agendas.

A number of specific methods have been developed for carrying out detailed analyses of the social interaction between doctor and patient based on audio or videotapes or transcripts of the consultations (see Roter and Hall 1989). Early methods classified the verbal statements of the doctor and patient into those which were task or emotion-focused and then into more specific categories (e.g., asking questions, giving

interpretations, etc.). Attempts have also been made to define a number of more general ways of classifying doctor–patient interactions. For example, one can distinguish between verbal and nonverbal information and, within the verbal domain, six broad categories can be defined (information-giving; information-seeking; social conversation; positive talk; negative talk; partnership building). From a meta-analysis of these broad categories (Roter 1989) it has been found that for the doctor, information-giving occurs most frequently (approximately 35 percent of the doctor's communication) followed by information-seeking (approximately 22 percent), positive talk (15 percent), partnership building (10 percent), social conversation (6 percent), and negative talk (1 percent). In contrast the main type of patient communication consists of information giving (approximately 50 percent) with less than 10 percent involving information seeking.

A fairly recent and quite widely used method for analyzing the consultation process has been developed by Roter et al. (1997). This method classifies the doctor's communication patterns into five distinct groups: (a) 'narrowly biomedical' characterized by closed-ended medical questions and biomedical talk; (b) 'expanded biomedical' similar to the narrowly biomedical but with moderate levels of psychosocial discussion; (c) 'biopsychosocial' reflecting a balance of psychosocial and biomedical topics; (d) 'psychosocial' characterized by psychosocial exchange; (e) 'consumerist' characterized by patient questions and doctor information giving. They found that 'biomedical' approaches were used more often with more sick, older, and lower income patients by younger, male doctors.

4. *Outcomes of Doctor–Patient Communication*

Many studies of doctor–patient communication have attempted to evaluate the effects on a range of outcomes. Three broad groups of outcome have been studied, namely understanding and recall, satisfaction, and adherence, and each of these are now briefly discussed.

4.1 *Patient Understanding and Recall*

Changes in patients' knowledge, understanding, and recall of the relevant information provided in the consultation have been assessed in a number of studies. Ley and co-workers have shown that about half the information provided in the consultation is forgotten by patients a short time afterwards but there is considerable range in what is recalled (see Ley 1997). This variation partly reflects the type of setting and sample used and partly the method which is used to test for recall. There are a number of other factors involved including the content of the information, the patients' prior knowledge, and their level of anxiety. Generally information which is presented early in the consultation is recalled better (the primacy effect) as are statements which are perceived as being important or relevant. Moreover, recall is better for information which has been presented in an organised way based around specific themes (e.g., the nature of the problem, the details of the treatment, etc.).

4.2 *Patient Satisfaction*

Patient satisfaction is concerned with how patients evaluate the quality of their healthcare experience. It is increasingly being assessed in surveys of healthcare settings, as a marker of quality of care, along with other dimensions of quality such as access, relevance to need, effectiveness, and efficiency. Current research (e.g., Fitzpatrick 1997) views patient satisfaction as a multidimensional concept since patients differ in their views about specific aspects of their healthcare, such as the doctor's behavior towards them, the information provided, the technical skills of the doctor, and the access to and quality of the healthcare setting. Generally the most important factor is the behavior of the doctor since this can influence significantly ratings of all the other aspects of healthcare.

There are a number of difficulties in assessing patient satisfaction. Results from most satisfaction surveys reveal very skewed data, apparently indicating very high levels of satisfaction across patient samples, particularly amongst older patients. Part of this problem seems to lie in the reluctance of patients to criticise healthcare services and part of it is due to the structure of the questionnaires which have been used to assess patient satisfaction (Ware and Hays 1988). In addition, the use of more in-depth methods which require patients to describe their experiences of health from their own perspective, typically give rise to a more critical view.

A number of studies have attempted to examine the relation between indices of the consultation process and measures of patient and doctor satisfaction. For example, in a study based on their five distinct patterns of consulting style (see above), Roter et al. (1997) showed that the highest levels of doctor satisfaction were found in those using the consumerist approach and the lowest levels were found in those using the narrowly biomedical approach. In contrast, the highest levels of patient satisfaction were found with those who had seen doctors using the psychosocial communication pattern whereas the lowest satisfaction scores were recorded in those who had experienced either of the two biomedical patterns.

4.3 *Adherence to Advice or Treatment*

The most widely studied behavioral outcome from healthcare consultations is reflected in the extent to which the patient adheres to the advice or treatment offered by the doctor, and this topic is described in

much more detail in another article (*Patient Adherence to Health Care Regimens*). Many consultations result in the prescription of treatment or advice by the doctor and the appropriate adoption of self-care behaviors, including use of medicines, is a key aspect to the self-management of most chronic illnesses. The incidence of reported medication nonadherence varies from 4–92 percent across studies, converging at 30–50 percent in chronic illness (Meichenbaum and Turk 1987). Even patients who have experienced major health problems, such as heart attacks, may show low levels of uptake of rehabilitation programs as well as considerable variation in the adoption of recommended lifestyle changes (Petrie et al. 1996).

In the context of doctor–patient communication, one cause of nonadherence arises from the poor cognitive outcomes outlined above, particularly poor understanding and recall of information presented in the consultation. Many patients lack basic knowledge about their medication but the relationship between this and their adherence is complex. Although some studies have demonstrated a positive association between knowledge and adherence, there are more that had failed to demonstrate a link. Moreover, interventions which enhance knowledge do not necessarily improve adherence.

The quality of communication with the doctor can also influence patients' attitudes or beliefs about their illness or treatment which, in turn, have been shown to have significant effects on levels of adherence. Patients develop their own beliefs about the nature of their illness (Petrie and Weinman 1997) and these have been linked with a range of adherence-related behaviors other than the use of medicines. These include various self-management behaviors, such as dietary control and blood glucose testing in diabetes, attending rehabilitation, and the adoption of various lifestyle changes following myocardial infarction.

In addition to influencing patients' perceptions of their illness, communication with the doctor can affect patients' attitudes to their treatment. Work by Horne and Weinman (1999) has shown that patients develop very specific positive and negative beliefs about their prescribed treatment, both of which can have significant effects on treatment adherence. The positive beliefs are reflected in strong beliefs about the necessity of taking their medication in order to manage the illness whereas the negative beliefs reflect patients' concerns about treatment side-effects or long-term dependence.

5. *Interventions to Improve Doctor–Patient Communication*

The majority of communication training interventions have been aimed at improving the communication skills of medical students or practitioners at various stages of training but a few have been targeted at patients, to enable them to get maximum benefit from a consultation.

Communication skills training is now a core part of the curriculum for medical students. Typically, students are provided with an overview of the basic skills of 'active' listening, which include the importance of developing good rapport and the use of open-ended questions early in the consultation, appropriate eye-contact, and other verbal and nonverbal responses to help the patient talk, together with the ability to summarize and arrive at a shared understanding of the patient's problem (see Kendrick 1997). There is now consistent evidence that this type of training can result in enduring improvements in basic communication skills.

In addition to acquiring basic communication skills for work with all patients, medical students need to learn how to communicate about sensitive or difficult areas of clinical practice, including dealing with distressed patients or relatives and giving 'bad news.' Research in this area has shown that doctors tend to give detailed information rather than find out and respond to patients' concerns and informational needs. As Maguire (1997) notes, this avoidance of patients' worries can have negative effects in the short and longer term. An immediate consequence is that patients may remain preoccupied with their own concerns and fail to take in information or advice. They may also selectively attend to negative phrases or messages and be unresponsive or misconstrue more positive or neutral information.

Training in this area emphasises the value of patient-centered approaches, and exploring what patients know, think, and feel. Encouragement is given to take time to provide the patient with the information which they want, letting patients proceed at their own pace, and allowing information to be assimilated. The other key skills involve developing the ability not only to recognise distress but also to allow this to be expressed (Maguire 1997).

In recent years there have been a number of interesting interventions aimed at patients. Generally these have involved interventions for patients prior to a consultation in order to increase their level of participation, particularly to ensure that their own concerns are dealt with and that information provided by the doctor is clearly understood. A successful development of this approach can be seen in the work of Greenfield et al. (1985) who used a preconsultation intervention lasting 20 minutes for hospital outpatients who were helped to identify their main questions and encouraged to ask these in the consultation. Compared with control patients, these patients participated more actively in the consultation and this was also associated with better long-term health outcomes, including lowered blood pressure in hypertensives and better glycaemic control in diabetic patients.

6. Conclusions

Research on the nature, determinants, and effects of doctor–patient communication has revealed its complexity and its importance in effective healthcare delivery. Audio and videotaped recordings of the consultation have allowed the researcher to examine the nature of the interaction between doctor and patient. Although the tasks of coding and analysing this interaction have proved difficult, many studies have demonstrated that the interaction process can have major effects on a wide range of outcomes. These findings have been used for designing training in communication skills, and it will be a major task for researchers to evaluate the efficacy of these on the quality of healthcare delivery in the future.

Documentary and Ethnographic Film

The term documentary came into usage in the nineteenth century as an adjective referring to documentation, hence with connotations of evidence (Rosen 1993, p. 6). With reference to film, it was first employed by John Grierson (in his 1926 review of Robert Flaherty's film *Moana*) to indicate a body of work which documented reality, involving 'a creative treatment of actuality' (Grierson, cited in Barnouw 1974, p. 287). The twin roles of the documentary filmmaker, as a creator with an agenda and as a purveyor of 'actuality,' have been at the root of several debates concerning the truth claims of the documentary. In many accounts, documentary film was regarded as indexically representing a real world, mimetically reproducing pictures of reality with a view to providing knowledge about it, as is the case in any scientific endeavor.

On the one hand, developments in motion picture technology have perfected hardware enabling the unobtrusive documentation of reality; on the other, the very notions of 'documentary' and 'reality' have undergone radical reformulation. In theory and practice, the truth claims of documentary and its status as 'evidence' of a given historical world have increasingly been problematized. Over time, documentary film has come to embody diverse modes of negotiating the complex set of relationships between the author, the film text, and the world.

Ethnographic film comes under the rubric of anthropology, which traditionally involved scientific observation and recording of the lives and cultures of other races, usually 'primitive' indigenous communities in distant lands. Jean Rouch terms anthropology as 'the eldest daughter of colonialism' (cited in Winston 1993, p. 51), thus foregrounding the inherent relationship of power that underpins any encounter between the anthropologist and the other. The premise that ethnographic film is a value-free, indexical scientific record has been subjected to critical interrogation and revision, leading to dramatic changes in its theory and practice.

1. *Demarcating the Terrain of Documentary Film*

1.1 *Documentary vs. Other Nonfiction*

Documentary film has been regarded as a specific body of work under the broader rubric of 'nonfiction' film. The latter includes genres such as the first 'actuality' films of the Lumiere Brothers, the newsreel, the travelogue, and the educational film. These genres, while sharing in common with documentary the use of actuality footage, have been seen as distinct because of the differing context of their production and use (Barsam 1992). Though documentary and ethnographic films occupy distinct terrains within nonfiction film, the issues confronting both share a great degree of commonality.

1.2 *Documentary vs. Fiction*

The fiction film, to which the documentary and other nonfictional genres were opposed, involved an obvious process of construction to offer an illusion of reality. The documentary filmmaker, however, bore the onus of providing a window to the world. The twin positions eschewed by the documentary filmmaker were that of the 'manipulative' creator of fiction, on the one hand, and the didactic educator on the other. The control and omnipotence represented by both these positions, which 'told' audiences about an external reality, was rejected in favor of a position that purported to 'show' its viewers the world.

2. *Towards a Taxonomy*

The wide array of themes, styles, formats, and modes of address employed by documentary filmmakers make it difficult to construct an inclusive typology that accounts for this variety. Barnouw (1974), for instance, chooses to classify documentaries on the basis of the role of the maker (explorer, reporter, advocate, poet, observer, guerilla, and so on), while emphasizing that these roles are not mutually exclusive. However, certain roles have been privileged at certain historical moments, making it possible to construct a typology on this basis. Barsam (1992) follows a classification employing time and space (American/British/European and Asian, at various periods of time).

Nichols (1991) identifies four modes of representation. The expository mode, used by many of the early filmmakers, such as Grierson and Flaherty, as also in current television network news, tends to use 'voice-of-God' commentary or poetic narration to inform or enlighten the viewer about the world outside. The argument of the commentary is what propels the text, the visuals serving more as illustration or counterpoint. The expectation of the viewer is generally to obtain certain, authoritative knowledge about reality, to understand cause and effect, problems and solutions.

The observational mode (also referred to as Direct Cinema) was facilitated by the invention of lightweight equipment with synchronous sound recording capability. It rejects the relatively didactic stance of the expository mode, in order to bring to viewers, life as it unfolds. The filmmaker aspires to the role of a detached observer. The expectation of the viewer is to gain access in an unmediated external world.

The interactive mode (represented by the work of Jean Rouch, Emile de Antonio, Michael Rubbo, among others) also draws on the availability of mobile equipment, but rejects this detachment in favor of a more interventionist role. The filmmaker's relationship with the subjects of the film comes to the fore and is not invisible, as in the observational mode. The focus is on local knowledge; the filmmaker is not confined to creating continuities in time and space, but could employ unusual juxtaposition, archival material, and other devices in constructing the narrative. The viewer's expectations are situated in the realm of the interpretative, since the mode makes no claim to absolute truth and neutral knowledge.

In the reflexive mode, the act of representing the world itself becomes central to the film's narrative. The premises from which the narrative is constructed and the process of construction are available to the viewer. While it bears some resemblance to the interactive mode, the reflexive mode, in addition to problematizing the relationship between the filmmaker and the subjects, also problematizes the relationship between the narrative/filmmaker and the viewer. The camera is not an evidence gathering

apparatus. The conventions of realism, when used, are interrupted and put to question. Broadly speaking, the reflexive mode draws on the poststructuralist critique of the indexical and instrumental view of language and the speaking subject (see *Semiotics*).

3. *A Brief History of Documentary and Ethnographic Film*

The theoretical positions and the narrative strategies within the discourse of the documentary film have undergone fundamental changes, making it impossible to establish continuity across them. In spite of this apparent diversity, they could perhaps be classified in terms of the notions of authorship and viewership that they are, implicitly or explicitly, putting forth or negating. A useful device in establishing intelligibility across the vast corpus of documentary and ethnographic film practice is, therefore, to look at the various authorial stances that inform it. This, by no means exhaustive, historical account explores the work of major figures and movements, which contributed to the development of new conventions, styles, and norms within documentary film.

3.1 *The Author as Reconstructing the Authentic Other—Robert Flaherty*

Flaherty's *Nanook of the North* (1922), which celebrates the heroic struggle for survival of its Inuit protagonist, could perhaps be regarded as the first ethnographic film. Flaherty manipulated reality in order to reveal what he regarded as the 'true spirit' of the culture; at times, this recreation involved danger and discomfort to the subjects of his films. In hindsight, his work has been critiqued for its mythologizing of the 'noble savage' and its elision of the 'real' social and political circumstances of his subjects' lives. Flaherty's work poses questions about the nature of 'truth,' the relation of the documentarist to the 'reality' s/he creatively appropriates, and the politics of representing the other.

3.2 *The Author as Social Educator—Grierson*

Grierson's extensive writings on the place, function, and codes of the documentary regard it as performing the function of educating and involving citizens in democratic civil society. In 1930, Grierson established the EMB (Empire Marketing Board) Film Unit, later to become the GPO (General Post Office) Film Unit. This was a nucleus for the work of documentary filmmakers such as Basil Wright (*The Song of Ceylon*, 1934, *Night Mail*, 1936, co-directed with Watt), Harry Watt (*North Sea*, 1938), Alberto Cavalcanti (*Pett and Pott*, 1934, *Coalface*, 1935) and Humphrey Jennings (*A Diary for Timothy*, 1944). The themes handled included the lives of working people, social problems related to health, housing and unemployment, and wartime propaganda.

3.3 *The Author as Reflexive Roving Eye—Dziga Vertov*

Denis Arkadievitch Kaufman called himself Dziga Vertov, meaning 'spinning top.' His writings and films were produced in the context of the post-Revolution ferment in the Soviet Union. His work, influenced by Futurism, represents a seminal contribution to film theory and practice, repudiating all pre-existing forms of cinema. Vertov regarded the cinematic way of seeing, the 'Kino-Eye' as establishing a radically different relationship with reality, making the 'invisible visible,' turning 'lies into truth,' propagating 'the communist decoding of reality.' His work on the Kino Pravda series, among others, and his film *The Man with the Movie Camera* (1929) created much debate and controversy for its formal illusionism, its subjectivism, its radical play with elements of picture and sound so that a sense of dislocation from reality is achieved. Its reinvention of cinematic language in a mode which reflexively foregrounds the act of construction and directly interpellates the viewer with revolutionary fervor stands as unique and perhaps far ahead of its time.

3.4 *The Author as Propagandist—Leni Riefenstahl*

Leni Riefenstahl is known for her documentaries that mythologized the politics of German National Socialism. While her work is noteworthy for its aesthetic virtuosity, it raises questions of the politics of aesthetics. *The Triumph of Will* (1935) documents the 1934 National Socialist rally in Nuremberg, a spectacular celebration of the myth of fascism. Sontag (1982) discusses how the actuality of a film like *The Triumph of Will* was constructed through carefully choreographed rituals of domination and enslavement, that contrast the hypnotic presence of the omnipotent leader with the faceless regimentation of large masses of ordinary people.

3.5 *The Author as a Fly on the Wall—Direct Cinema*

Direct Cinema represents a significant departure in the American documentary of the 1960s. The term Direct Cinema is sometimes used interchangeably with cinema verité (from which, however, it is distinct). It positions the author as an unobtrusive observer, thereby attempting to reclaim the scientific project of documentary film. The camera as well as the filmmaker occupy neutral positions, endeavoring, 'to convey [to the viewer] the feeling of being there' (Leacock, cited in Winston 1993, p. 43). The invention of lightweight

equipment with synchronized sound was first utilized by Drew Associates to produce *Primary* (1960) in the election campaigns of John F. Kennedy and Hubert Humphrey. Drew collaborated with Richard Leacock, Pennebaker, and Albert Maysles in the making of this film. The filmmakers had themselves perfected the technology and the now legendary shot of the camera following Kennedy through the crowds on to the podium, shot by Maysles, demonstrated the versatility of the new technology.

The then prevailing dominant empirical traditions of the scientific method, which took sides with the 'body,' in an age old debate on its antithetical position to the 'mind,' was at heart of the positioning that the proponents of Direct Cinema aspired to. The dichotomies of mind/body, subject/object held center stage, not only in the debates on documentary cinema, but also in the discourses of the social sciences and linguistics.

The truth claims of the proponents of the American Direct Cinema did not pass uncontested. In response to its critics, the movement of Direct Cinema had to allow for subjectivity, while retaining its claim to authenticity. Frederick Wiseman, who terms his work 'totally subjective,' represents a new denouement in the Direct Cinema debates. While the work of Leacock and Pennebaker focused on portraiture and recording of events, Wiseman's work investigates various institutions such as hospitals, high schools, and prisons, revealing patterns of behavior, which raise disturbing questions about institutional morality and social values. His first film *The Titicut Follies* (1969) was an indictment of an institution for the criminally insane and saw him embroiled in legal controversy. Wiseman does a tightrope walk between the subjectivity of the film-maker and the imperative to provide the viewer with fair evidence so that she/he can make up his/her own mind on the reality that is represented.

3.6 The Author as a 'Fly in the Soup'—Cinema Verité

Henry Breitrose (cited in Winston 1993, p. 53) uses the interesting analogy of a 'fly in the soup' to describe cinema verité (a term borrowed from Dziga Vertov). In contradistinction to Direct Cinema, cinema verité resolves the question of objectivity by situating the film-maker as an *agent provocateur*. The work of Jean Rouch and Edgar Morin typifies this stance. Rouch's *Moi, un Noir* (1959) represents a turning point in ethnographic film; in this film, the role of the camera shifts from a recording device to a precipitator of action. The film presents the inhabitants of Treichville, playing out scenes of their choice for the camera. After viewing themselves on screen, they reflect on the recorded events, reinterpreting them. This complex and novel process of representation explored a new relationship between the film-maker, his subjects, and the narrative. Rouch's project was rooted in an attempt to redefine the relationships of power in ethnographic film-making which had hitherto been a colonial gaze at the other. *Chronique d'une Été* (1961), in a reversal of ethnographic roles, turns the camera on 'the strange tribe that lives in Paris' (Morin cited in Winston 1993, p. 51). With all its reflexivity and radical revision of the project of ethnographic film, Rouch and Morin are unable to escape the hegemony of science and the promise of the image as evidence, if not of an objective world, then of the documentarist making a documentary (Winston 1993).

3.7 The Postcolonial 'Other' as Author

Indigenous documentary film production in the postcolonial context was sometimes state-sponsored (as in Cuba and India) and often projected the dominant agenda of modernity. Over time, the rise of independent documentary production gave voice to marginal groups and looked critically at larger political questions. The work of Fernando Solanas and Octavio Gettino in Argentina (*Hour of the Furnaces*, 1968), Patricio Guzman (*The Battle of Chile*, 1974–9), Santiago Alvares in Cuba (*Now*, 1965), Nana Mahomo in South Africa (*Last Grave at Dimbaza*, 1975), and Anand Patwardhan (*Father, Son and Holy War*, 1998) in India are but a few examples of a vibrant tradition of political engagement. The technology of video and the possibility of broadcast by international television networks have created a market for stories from the South. Many 'independent' documentary film-makers in the South are dependent on these markets for support. The market demand is for images that present the other as exotic, oppressed, or disaster-ridden. Raul Ruiz's *Of Great Events and Ordinary People* (1979) ironically comments on this endless dividing practice that sustains international documentary production and consumption.

The 'linguistic turn' within postcolonial ethnography, which regards the ethnographer as an author constructing narratives, has led to a rethinking of the relationship between the ethnographer and his/her informants. Since this perspective attempts to render apparent the process by which the narrative is produced, the informants in a sense become co-authors. Given the unequal power flows between the ethnographer and his/her informants, various modes of integrating the voices of the other in ethnographic texts have been explored. Some of these have involved the informants taking control of the medium to construct representations of themselves. The Navajo project, initiated in 1966 by Sol Worth and John Adair, was an experiment in teaching the Navajos, in Pine Springs, Arizona, to use the technology of film-making. The attempt was to understand the modes of representation that were at work in the narratives produced by the Navajos (Worth and Adair 1970). The extent to which such projects can redefine power flows is debatable, for the other continues to be the

destination of a scientific experiment, by the ethnographer.

Eric Michaels (1994) explores the space of alternative production and distribution by the Warlpiris. The project, initiated in 1985, involved local production and illegal transmission by the Warlpiri Media Association, at Yuendemu, in Central Australia. Michaels identifies significant differences between aboriginal and European creative practices. These pertain to 'ideological sources and access to inspiration, cultural constraints on invention and imagination, epistemological bases for representation and actuality, indistinctness of boundaries between authorship and oeuvre and restrictions on who makes or views expressive acts' (Michaels 1994, p. 105).

3.8 The Reflexive Author

The reflexive mode, already discussed earlier, gained prominence in the 1970s and 1980s. On the one hand, it was a response to the current debates on language and signification, subjectivity and ideology, involving formal strategies that question the 'materiality of the cinematic signifier' (Wollen, cited in Nichols 1991, p. 65). On the other hand, it arose in the context of movements (feminist, civil liberties, gay and lesbian, revolutionary struggles in the Third World and so on) that questioned the 'materiality of social practice' (Wollen, cited in Nichols 1991, p. 65). The films of Chris Marker (*Sans Soleil*, 1982), Errol Morris (*The Thin Blue Line*, 1987), Michael Moore (*Roger and Me*, 1989), and Jill Godmilow (*Far from Poland*, 1984) are few examples of emerging trends. Nichols (1991, p. 65) points out that reflexivity is not merely a matter of formal narrative strategies, but an engagement with the marginal and alternative ways of seeing and acting in the world. Examples of such politically reflexive films are Georges Franju's *Blood of the Beasts* (1949), Emile de Antonio's *In the Year of the Pig* (1969), Wiseman's *High School* (1968), and Joris Ivens' *The Spanish Earth* (1937).

The early independent women's films (*Union Maids*, 1976, *Joyce at 34*, 1972, and *Janie's Janie*, 1971) were situated within the realist tradition, and made as tools for consciousness raising and mobilization (Kaplan 1982–3). Semiological film theory tends to dismiss the radical potential of these films, a view which is contested by Kaplan, who argues that 'the same realist signifying practices can indeed be used to different ends' (Kaplan, cited in Nichols 1991, p. 68) and that a consideration of the strategies of reception is also important (see *British Cultural Studies*). Feminist films such as Mitchell Block's *No Lies* (1973) and Michelle Citron's *Daughter-Rite* (1978) problematize cinema verité techniques by drawing the viewer into an illusion of reality, only to reveal at the end that the narrative was scripted and the protagonists are actors.

Postfeminist work attempts to rewrite feminist themes to break away from the white/middle-class/heterosexual character of the women's movement in the West. Trinh T. Minh-Ha's *Surname Viet Given Name Nam* (1989), for instance, contests the systems of representation at work in a patriarchal ethnography, rejecting an essentializing of the heroic, suffering Vietnamese woman.

4. Current Issues

Debates regarding documentary and ethnographic film have revolved around various sets of relationships: between the author and the narrative (the question of realism), between the author and the subjects filmed (the question of the ethics and politics of representation), and between the narrative and audiences (the question of effects and audience reception). An issue that has received relatively less attention is the question of how mass media institutional dynamics, the economics of documentary production, and the structures of distribution have influenced the politics and aesthetics of documentary production (see *Media Imperialism*; *Television: Industry*). For instance, the fact that television constitutes a major market for documentaries today sets the agenda for documentary film production and its reception.

With new technologies such as digital image manipulation and inexpensive portable video camcorders that are redefining the realm of the real, the project of recording reality has never been more problematic. A variety of other genres, ranging from reality programming on television to fiction films, have begun to appropriate the idiom of the 'real,' blurring the divide between fictional and nonfictional narratives. When the technology for appropriating actuality in the Direct Cinema dream has become a reality, it is this very actuality that has become elusive, thus making imperative for the documentary and ethnographic film 'to negotiate an escape from the embrace of science' (Winston 1993, p. 57).

Domestic Life and Material Culture

1. *Definitions and Nomenclature*

Domestic life and material culture are terms used in both the social sciences and the humanities. The first is widely known; the second less so. The first serves as a covering term for a range of societal activities; the second represents a distinctive type of cultural evidence.

Domestic life includes those familial/societal interactions that take place within the context of a residential environment—be it a single family home, an apartment complex, a tribal lodge, or any other form of human dwelling. Hence the study of domestic life involves understanding child-rearing practices, kinship patterns, life-cycle history, *foodways*, gender divisions of labor, and use of household goods. It is a field (or subfield) for historians of the family and childhood, folklife researchers, economic historians, cultural anthropologists, as well as those who study architectural interiors and decorative arts.

Material culture study boasts an equally expansive research agenda and diversity of scholarly clientele. But, despite the fact that humans were making things before they were writing about them; that is, creating artifacts before alphabets, it is a relatively new term in scholarly discourse. Only in 1875 did British anthropologist A. Lane-Fox Pitt-Rivers, in an essay, *On the Evolution of Culture*, first urge researchers in the emerging social sciences to consider material culture as 'the outward signs and symbols of particular ideas in the mind.'

Anxious to be able to make more precise distinctions in their examination of human behavior as well as to widen the evidential base for their social research, some anthropologists and a few folklorists heeded Pitt-Rivers' injunction. They developed a tripartite division of cultural data. The first component was ideological (evidence found usually in the form of oral or written data). The second division was sociological (evidence documented by fieldwork observation of human behavior, such as parent–child or sibling relations). A third resource was material (evidence found in the work of human hands such as furniture, cooking utensils, and houses).

In both past and present scholarship, 'material culture' is often considered a synonym for terms such as 'artifacts,' 'objects,' or 'things.' Such interchangeability is frequently evident in both professional and popular writing. However, instead of treating these four terms as co-equals, it is more useful to regard them as nouns of increasing specificity of meaning, with 'things' seen as the most general rubric and 'material culture' as the most specific label.

For example, only in its tertiary meaning does the word 'things' connote a sense of inanimate entities distinguishable from living organisms. The word 'objects,' like the term 'things,' is another highly abstract collective noun, whereas 'artifacts' (artefacts in Britain), coming from the Latin *arte*, meaning skill, and *factum*, meaning something done, at least includes an indirect reference to a human being (an artificer) in its meaning. Objects lack this sense of implied human agency and, unlike artifacts, are commonly (and imprecisely) used to describe everything in both the natural and the man-made environment.

By contrast, the general definition of material culture specifically includes the factor of human artifice and also aptly circumscribes the scope of physical data within its research domain. What is useful, therefore, about the term 'material culture' is that it suggests, at least among its current students, a strong inter-relation between physical objects and human behavior. Despite its cumbersomeness, the phrase continually presses the researcher to consider the complex interactions that take place between creators and their culture. In other words, the assumption is that there is always a culture behind the material.

In recent scholarship, the terms 'material' and 'culture' have been extended in academic usage. The concept and content of their meaning now includes the objects of high culture (for instance, Charles Wilson Peale's painting of *The Peale Family*, 1773 or William Rinehart's sculpture of *Latona and Her Children*, 1874) as well as artifacts of popular and vernacular culture (for instance, a Los Angeles bungalow or a Louisiana shot-gun house). The term 'material' has also been

expanded. For example, James Deetz (*In Small Things Forgotten: The Archaeology of Early American Life*, 1977) sees cuts of meat as material culture, since there are many ways to dress an animal and the scientific breeding of livestock is human manipulation of a species. Kinesics (for instance, the body motions involved in performing Aaron Copland's *Appalachian Spring* ballet or a southern Indiana clog dance) and proxemics (for instance, the spatial uses and interactions of people at a Midwest home quilting bee, a Great Plains threshing crew noon dinner, or a courting couple in a Victorian parlor) are other culture expressions that assume, if but for a limited time, physical form, and could be included within the legitimate boundaries of material culture.

What might be an adequate (but not elaborate) working definition of material culture? Here is a brief one that informs this article: material culture is that segment of humankind's physical environment that has been purposely made or modified, consciously or unconsciously, by people according to culturally dictated plans. Material culture entails those artifacts that humankind creates to cope with the physical world, to regulate its social relations, to perform its work, to delight its fancy, and to create symbols of meaning. Material culture research can be best described at present as an expanding movement or coalition of individuals (Deetz calls it 'an emerging research community') working in museums, historical societies, and cultural agencies, as well as in academic departments in colleges and universities, who are intrigued by the idea of studying the (possibly unique) explanatory potential of material evidence as cultural meaning.

What, if anything, do the diverse practitioners of material culture research have in common? In addition to an obvious evidential concern with physical objects as cultural data, the movement works under at least three assumptions. Most studies of material culture usually involve fieldwork research during which artifacts are collected, identified, compared, and categorized either *in situ* or in museums, in private and public collections, and in historical agencies. A historical perspective also characterizes most material culture studies. As several of their names indicate—the history of technology, art history, historical geography—they seek to measure and understand change over time. Finally, in their analyses, most researchers use the culture concept in varying ways. While some see culture only with a capital C, the majority view it as an anthropological construct.

2. *Interconnections and Common Topics*

In what ways have analyses of domestic life intersected with material cultural studies? How has the recent scholarship of the latter contributed to the former? Conversely, how have contemporary trends in domestic life research set certain agendas in material culture inquiry? Finally, what paradigms or interpretive models have been most influential in the interaction of these two approaches to cultural study?

In order to answer, albeit briefly, these questions, three specific areas of common interest—residential spaces, household artifacts, women's roles—to both investigators are summarized here. The format of the three is deliberately bibliographical in order to provide a sampling of recent work. Examples cited are primarily Anglo-American, while the concluding entry bibliography emphasizes broader interpretations.

2.1 *Residential Spaces*

When John Demos devoted part one ('The Physical Setting') of his *Little Commonwealth: Family Life in Plymouth Colony* (1970) to the domestic shelter and artifacts of the seventeenth-century Pilgrim community, he was recognizing a fact crucial to much material culture research: as the elementary unit of humankind is the individual, the elementary artifact on the human landscape is the dwelling. Housing represents social and economic identity; it is a microcosm of domestic culture. Demos explored the domestic implications of architectural evidence (for example, its correlation to economic status, privacy, social-segregation, repression of familial anger and aggression, and child-rearing practices) in his pioneering application of social and behavioral science concepts to the houses of seventeenth-century Massachusetts.

Although Demos' analysis of the material culture of a single seventeenth-century New England colony was brief, inferential, and only a case study, it does represent one type of material culture that has employed housing as significant evidence. Others include Gwendolyn Wright's *Building The Dream: A Social History of Housing in America* (1981) and Richard Bushman's, *The Refinement of America: Persons, Houses, Cities* (1992). Such research eschews the usual approach of the traditional architectural historian in that it avoids mere facadism (interpreting a house primarily through its front elevation and aesthetic style) as well as elitism (researching only structures designed by professional architects).

Housing sites, as well as the housing, has always been an important material culture subfield. Other scholars have investigated the history of urban middle- and working-class neighborhoods through their extant housing stock. Tenement districts, slums, and even alley residences have received attention. Zoning and property controls, residential class segregation, and subsidized public housing have also been topics.

Folklorists studying the construction techniques involved in erecting and furnishing housing often explore changes in a community's economic and social organization of work through building practices. In two pioneering books—*Pattern in the Material Folk Culture of the Eastern United States* (1968) and *Folk Housing in Middle Virginia: A Structural Analysis of*

Historic Artifacts (1975)—Henry Glassie has researched such historical processes in order to understand the persons who employed them and the products that resulted from them. In *Folk Housing*, Glassie approached material culture by means of the paradigm of twentieth-century structuralism, particularly as articulated by Noam Chomsky and Claude Lévi-Strauss.

Glassie, following Chomsky, argued that 'culture is pattern in mind, the ability to make things like sentences or houses.' Rejecting the concept that objects are the simple products of passive minds, Glassie attempted to develop a systematic model that would account for and help analyze the design abilities of an idealized maker of artifacts. As a case study, he investigated the builders of 156 houses constructed between the middle of the eighteenth century and World War I in a 70-square-mile (182-square-kilometer) area of central Virginia. His research objective, using almost exclusively material culture data left behind by anonymous builders, was to discover the unwritten boundaries or 'artifactural grammar' of the creative process as it was exercised in a particular region's domestic architecture.

American material culture structuralism has drawn criticism from various camps. Some historians claim that despite its gestures toward tracing a change in minds, the approach tends only to work in areas of relative cultural stasis. Fellow folklorists have complained that Glassie's subjective system of binary mental opposites (intellect–emotion, internal–external, complex–simple, and 12 others) merely substitutes one kind of interpretive arbitrariness for another in plotting human behavior patterns. Still others remark that the results from such structural analysis are not adequately comparative.

2.2 Household Artifacts

In keeping with the folk proverb that claims that a house is not a home, historians have researched the material life of Americans as revealed in patterns of home furnishings, foodways, clothing, and organization of domestic spaces as ways of gaining insight into the social past of middle-class and working-class culture. For instance, Lizabeth Cohen's interpretation of the material culture of American working-class homes between 1885 and 1915 ('Embellishing a Life of Labor: An Interpretation of the Material Culture of American Working-Class Homes' in Thomas J. Schlereth, ed., *Material Culture Studies in America*, 1982, 1992) is an example of how the study of the domestic material culture environment can contribute to the historical understanding of the familial and residential experience of Americans.

Some material culture researchers in the decorative arts have sought to expand the standard cultural history surveys of American domestic life by studying a whole range of common household items—parlor furniture, mourning pictures, eating utensils, cleaning devices, family photograph albums, kitchen appliances—that are seen as indices of a society's values as important as its elite artifacts or its literary remains. The material culture of nineteenth-century hallways (hat and clothing stands, mirrors, hall chairs, and card receivers), parlors (especially its ubiquitous home parlor organ), and dining rooms (table settings, massive sideboards, and eating accoutrements) have been imaginatively analyzed by Kenneth Ames (*Death In the Dining Room and Other Tales of Victorian Culture*, 1992), while Edward O. Laumann and James S. House ('Living Room Styles and Social Attributes: The Patterning of Material Artifacts in a Modern Urban Community,' *Sociology and Social Research* **54**: 1970) have studied the patterning of material artifacts in the living rooms of twentieth-century working-class families. Still others have attempted to write American social history using wallpaper, silver, ceramics, chairs, and other commonplace domestic artifacts as important evidence in their research. Several of these studies have also employed quantification techniques in their comparative analyses of past material culture. Such data are found in the form of probate inventories, craftsmen's ledgers, auction lists, wills, deeds, and sales records. Historians of Colonial America were the first to turn to inventories to study social and economic behavior and they have subsequently contributed a substantial corpus of material culture research based on inventories.

Photography, an artifact created in the nineteenth century, has also been of immense use to historians interested in American domestic life. Historical photography, when examined closely and in sufficient quantity to ensure a representative evidential sample, provides valuable inferences as to how occupants organized and used space as well as how they interacted with one another. Using photography, much can be learned about increasing compartmentalization of residential spaces such as kitchens, bedrooms, hall passages, pantries, inglenooks, nurseries, servants' quarters, as well as in parlors, living rooms, porches (front and back), plus lawns, patios, and garages.

Strangely, few material culture scholars have paid much research attention to eating, assuredly one of humankind's most common necessities. What research has been done focuses primarily on rural and preindustrial communities. It has also focused largely on artifacts of twentieth-century food preparation, service, and disposal.

In calling for the integration of domestic foodways (and all other relevant material, statistical, and documentary data) into a cultural, historical, and anthropological approach to material culture, James Deetz has argued for a research paradigm that seeks 'the detection and explication of apparently unrelated changes in *all* [Deetz's emphasis] aspects of a people's culture, material and otherwise.' Although not directly

influenced by the devotees of a *mentalité* approach to the past, he shares this school's interest in the study of popular beliefs, attitudes, customs, sentiments, and modes of behavior as well as its commitment to 'thick description.' Deetz, a historical archaeologist long associated with the historical reconstruction of Plimoth Plantation (Massachusetts) developed his theory and method in *In Small Things Forgotten and has now continued it in Flowerdew Hundred: The Archaeology of a Virginia Plantation* (1993).

Of particular interest is the challenge Deetz's paradigm presents in *In Small Things Forgotten* to the traditional interpretive claim of political and diplomatic history that the American independence movement was the major cultural watershed of American colonial history. The domestic material data (house forms, furniture types, ceramics, funerary arts, musical instruments, refuse dumps) that Deetz assembled and integrated suggest that the Revolution actually had little impact on American cultural history; in fact, the general American cultural pattern of involvement with English material culture, both before and after the war, remained remarkably constant.

In some ways, Deetz's *In Small Things Forgotten* can be viewed as an American counterpart to Fernand Braudel's *Capitalism and Material Life* (1973). For example, although much briefer and lacking Braudel's extensive documentation, the Deetz interpretation, like Braudel's, stays close to home for its data. The changing domestic technologies of house building, heating, lighting, plumbing, food preparation, and garbage removal are resources in both histories. Extant artifacts are often the only data by which such past behavior can be reconstructed. For example, utility fixtures have been carefully studied in order to speculate on how innovations in such domestic technology drastically altered the traditional evening orientation (a shared communal space around a single hearth) of the pre-nineteenth-century family, thereby prompting major changes in parent–child and sibling relationships. Others have documented behavior changes in domestic history with the advent of indoor plumbing (especially the appearance of the bathroom) and the installation of central heating.

2.3 Women's Roles

Understandably, the material culture of domestic life has figured in the work of historians of women. A special interest among some such scholars in the decorative arts and in the history of technology has focused on kitchen tools and appliances and their roles in defining, confining, or undermining a 'woman's place.' While various researchers have contributed to this scholarly enterprise, the work of Ruth Schwatz Cowan, Dolores Hayden, and Susan Strasser aptly represent their general concerns.

Cowan's research has moved from the study of a single artifact genre (*A Case of Technology and Social Change: The Washing Machine and the Working Wife* 1974) to kitchen appliances in general ('The "Industrial Revolution" in the Home,' *Technology and Culture*, 1973) to women's interaction with technological material culture throughout American history (*More Work for Mother: The Ironies of Household Technology From Open Hearth to Microwave*, 1983). In an essay titled 'Virginia Dare to Virginia Slims: Women and Technology in American Life,' *Technology and Culture* (1979), Cowan points out that none of the standard histories or bibliographies of America technology contain adequate reference to such culturally significant artifacts as the baby bottle. Here is a simple implement that, along with its attendant delivery system, revolutionized a basic biological process, transformed a fundamental human experience for vast numbers of infants and mothers, and served as one of the more controversial exports of Western technology to underdeveloped countries.

According to Cowan, there is a host of questions that scholars might reasonably ask about the baby bottle. For how long has it been part of Western culture? When a mother's milk could not be provided, which classes of people used the bottle and which the wet nurse, and for what reasons. Which was a more crucial determinant for widespread use of the bottle, changes in milk technology or changes in bottle technology? Who marketed the bottles, at what prices, to whom? How did mothers or different social classes and ethnic groups react to them? Can the phenomenon of 'not enough milk,' which was widely reported by pediatricians and obstetricians in the 1920s and 1930s be connected with the advent of the 'safe' baby bottle? Which was cause and which effect?

Hayden's interests have been more spatial and environmental than technological. Her *Seven American Utopias: The Architecture of Communitarian Socialism, 1790–1975* (1976) details the social and cultural history of several countercultural societies through their extant structures and sites, as well as through their furniture and household technology. Hayden's *The Grand Domestic Revolution: A History of Feminist Designs for American Homes, Neighborhoods, and Cities* (1981), provides the social historian with a useful review of the interaction of domestic feminism, cooperative housekeeping, the community kitchen movement, and projects for social reform.

Susan Strasser's *Never Done: A History of American Housework* (1982) has set the agenda for future research into basic topics such as food preparation, housekeeping and housecleaning, and domestic consumerism. On the last topic, Strausser has followed up on her own work and written books on the material culture of advertising, particularly its orientation toward women consumers and on the history of trash.

How might the nexus of domestic life and material culture appear in the near future? One prediction is that the three subfields outlined above will continue to thrive. In each research area there are scholars

experimenting with new methodologies as well as widening the boundaries of traditional evidential data.

For example, a few individuals in organizations such as the Vernacular Architecture Society (Great Britain) and the Vernacular Architecture Forum (United States) now study prefabricated and manufactured housing, condominiums, and assisted-care residences for the elderly. Some decorative arts historians are venturing beyond museum period-room settings as well as the old prescript maintained by dealers, collectors, and the US Customs office that 'one hundred years doth an antique make,' and are examining post-World War II kitchen remodelings, family rooms, the changing functions of the garage, plus patios and decks. Within the interdisciplinary gender studies movement, investigators have turned their attention to the social and material culture of Tupperware parties, to the current popularity of replica/reproduction nineteenth-century household goods, and the artifacts (computers, fax machines, telemarketing devices) of an increasing number of home offices serving as career centers for a variety of occupations.

Two, relatively recent, scholarly perspectives should influence future work on domestic life research and material culture studies. First, the re-emergence of anthropology, a parent-field for material culture, will strength both areas, particularly in paradigm building and in social science rigor. Material culture sessions at the International Congresses of Ethnological and Anthropological Sciences suggest this trend. It has also been argued that consumerism studies may become the most noticeable cynosure of contemporary material culture research. Perhaps. The twentieth-century data appears omnipresent and continually proliferating. While some basic research has been done over the past several decades, the full impact of door-to-door sales, general/specialty merchandising, department, chain, and franchise stores, shopping centers, mail-order cataloging (perhaps reaching more homes now than in the nineteenth century), suburban and megamalls on domestic life awaits at least a generation of researchers.

Whatever the future configurations of those who explore the intersections between domestic life and material culture, they will most probably share common cause in the vernacular, the populist, the typical; and in the desire to make human experience, as the novelist William Makepeace Thackeray once hoped 'more familiar than heroic.'

Domestic Violence: Sociological Perspectives

The issue of 'domestic violence' is an important area of public, political, and academic concern that goes to the heart of the institution of the family and marriage and of gender relations between men and women. It encompasses public and private life as well as social,

political, and economic institutions. At the social level, it involves ideological beliefs and institutional policies and practices. At the individual level, it involves personal attitudes and prejudices as well as individual behavior and conventions of daily life.

The area is characterized by a history of recent, rapid, social change in institutional policy and practice and is steeped in controversy. There have been political, ideological, and academic controversies about the term itself, the definition of the phenomenon, the nature of the problem, research methods used in its study, findings about the nature and occurrence of the problem, and about the focus and effectiveness of social and legal interventions. Since its rediscovery in Britain and the USA in the early 1970s, virtually every aspect of this issue has been the subject of development and the object of debate not only within the academic community but also across a wide spectrum of society as the media, community activists, academic researchers, and policy makers have taken different positions and entered into sustained and sometimes heated debates. The lively nature of this very important social issue warrants further examination of each of the issues touched upon within this characterization which, by virtue of its it brevity, can only introduce each topic and provide a broad view of it.

1. *Definition*

The terms wife beating, battered wives, wife abuse, woman abuse, spouse abuse, partner violence, family violence, and domestic violence have all been used to describe this phenomenon and have themselves been the topic of debate and controversy. Two main issues have been at stake: (a) the terms reflect different conceptions of intimate relationships between men and women, with some terms reflecting the idea of formal marriage while others encompass long-term intimate relationship without the formal sanction of marriage; and (b) the terms reflect different conceptions of the phenomenon, as male violence, mutual violence, or female violence. Both of these general issues were the subject of considerable debate when the problem was rediscovered, described, and named. While the term 'wife abuse' contained a clear imagery of men's violence against a woman partner, it also contained notions of formal marriage as a necessary condition of concern and attention. By contrast, the term 'domestic violence' included the notion of state and nonstate sanctioned relationships but lost the conception of gender asymmetry in the perpetration of the violence. For reasons of popular usage rather than resolution of these debates, the term 'domestic violence' became the term in common usage throughout most of the world.

2. *History*

Very ancient customs, beliefs, and laws dating back to the early Roman empire and many of the first conventions of marriage, allowed a husband to kill his wife for infidelity and serious challenges to male authority, these 'rights' were slowly eroded over time through the development of Canon law and the gradual alteration of legal systems in Europe and Britain to punishments allowing chastisement that did not kill or maim. In 1765, Sir William Blackstone's *Commentaries on the Laws of England* noted that conventional cultural beliefs and common legal practices endorsed a man's right to use 'moderate' chastisement against his wife. Blackstone's Commentaries codified this patriarchal right and thus confirmed a husband's authority over his wife for a considerable period of time. Such ideals and legal views crossed the Atlantic with some of the pioneers who brought familiar social attitudes and legal systems to the newly forming nations of North America. While there were some departures from this position it, nonetheless, constituted the normative position in many European and North American cultures across a fairly long period of time. Indeed, contemporary evidence from a wide range of societies, reveals strong cultural beliefs expressing such ideals, often endorsed by legal practices which illustrate direct support for 'wife-beating' or at best weak reactions to its victims and perpetrators.

In European and North American societies, the history of challenges to and changes in social and institutional responses to the problem, is punctuated by three historical periods in which domestic violence was discovered anew and obtained widespread recognition as a social problem. Recognition eventually resulted in changes in the laws regulating the institution of marriage and the family as well as developments in the responses of agencies of the state, particularly law and law enforcement, but also in economic, political, and social institutions.

In the 1870s, 1910s, and 1970s, the problem of 'wife beating' was discovered by women in Britain and North America who were engaged in more general campaigns for changes in women's marital, economic, political, and/or social status. Over this time period, wider campaigns about changes within the family and marriage (such as, the ability of women to own their own property, or to obtain a divorce for excessive cruelty—1870s), about changes in the political status of women (the right to vote—early 1900s), about changes in the economic status of women (equal pay and equal opportunities within the job market—1970s) and changes in social relations between men and women in general each spawned an interest in the specific issue of physical violence against women within the home, usually by intimate, male partners/husbands within the context of marriage. At each of these junctures, radical community groups (usually

though not always feminist) were formed, there were public protests, public recognition was increased, the agencies of the state were challenged and responded with public hearings, legislation, and various new policies and practices. After the first two periods of recognition and public response, the issue was soon forgotten and was marked by a return to an older, established status quo in which men maintained social, political, and economic authority over women throughout society and particularly within the institution of family and marriage where this right could be exercised legally and morally through the use of violence against women/wives for various real or perceived violations of male authority.

The third period of challenge began in the 1970s, again in Britain and the USA and, rather than being forgotten after a brief period of interest, has instead continued to expand and develop throughout much of the world. Public awareness of the issue and community and state responses to it are now global, resulting in violence against women being defined by the United Nations as an issue of human rights and social justice. At present, many, although certainly not all, societies have experienced challenges to the complacency and social and institutional tolerance that once prevailed and in many countries new laws and institutional practices have been initiated.

3. *The Nature of the Problem, Research Methods, and Findings*

Controversies about the nature of the problem itself have been intense and are intertwined in other controversies about research methods and resulting findings. The debates regarding these issues were apparent at the onset of the rediscovery process and have altered little since, although the amount and type of research grew at a tremendous rate in the last quarter of the twentieth century. Debates about the phenomenon itself center on whether the violence is asymmetrical in nature (men as the most usual perpetrators, with women the usual victims) or symmetrical (women and men as equally violent toward one another). Debates about research methods have focused on whether one method should supersede all others in producing the 'best' or indeed the only findings of value in answering the question of 'who is violent to whom.' One camp has claimed variously that only surveys based on national probability samples produce valid and reliable findings. Research using this approach has focused on questions of the prevalence of this form of violence in the population and on the relative levels of violence of men and women. Others defend the use of a wide variety of research strategies which include historical studies showing continuities and changes in patriarchal beliefs and institutional practices over time and ethnographic studies with an intensive focus upon cultural practices as well as the more traditional sociological approaches of victim surveys, criminal statistics, intensive interview studies, studies of strategic sites, and evaluations of new interventions. Proponents of the broad- based sociological and contextual approaches claim that such studies address more pressing and relevant questions about the problem such as 'what is the exact nature of the violence,' 'how are victims and offenders processed by agencies of the state,' and 'what works at stopping violence.' Such investigations also attempt to examine in detail the contextual dynamics of violent episodes and violent relationships as well as the meaning and consequences of being a victim and/or perpetrator.

Survey research, particularly in the US, has relied primarily on a single measurement tool that only attempts to assess violent acts with little or no concern for the intentions, meanings, and consequences associated with these acts. The resulting findings of these assessments appear to demonstrate symmetry in the perpetration of domestic violence, with women equally or more violent than their male partners. A corollary of the claims of symmetry in domestic violence is that theoretical accounts will be gender neutral, based on the conclusion that gender is not related to differential rates of violence within intimate relationships. Other surveys and more intensive research methods, not based on these purely act-based measurements, whether used in the US or elsewhere, show asymmetry in domestic violence, with men the most likely perpetrators and women the most likely victims. Predictably, these contradictory findings have resulted in considerable controversy with claims and counterclaims regarding the validity and reliability of this single type of measurement and scepticism regarding the veracity of findings produced by this type of research.

Over time, controversy about the simple question of 'symmetry–asymmetry'—who perpetrates the majority of violent acts (men or women)—has become more complex with the addition of further research questions regarding who is most likely to be responding in self-defense, to be harmed, to live in fear, and to experience other consequences of violence as well as additional research efforts to differentiate violent acts from acts of verbal aggression or mere conflicts between partners.

Despite the controversies in the area of domestic violence, there is a growing body of evidence-based literature that identifies strong and consistent patterns across cultures and historical periods. Most researchers and policy makers now agree that the problem of domestic violence is primarily one of men's violence against women in state as well as nonstate sanctioned relationships. Evidence suggests that serious, malevolent violence is perpetrated largely by men and often results in serious injuries. Survey research in several

countries indicates that at least a quarter of all women who have lived in marital and marital-like relationships with men report at least one incident of violence and a considerable proportion of these women report repeated violence. It is now clear that men's violence also includes acts of sexual aggression and rape; research indicates that a fair proportion of women experience forced sexual relations and rape by intimate male partners, and women who experience physical assaults are also likely to experience sexual violence. Homicide statistics further suggest that women are most at risk of lethal violence from male partners; research in Britain and North America reveals that every year 40 to 50 percent of all women who are killed, are killed by intimate partners and ex-partners. By contrast, very few men are killed by their women partners. Men's violence directed at women in the domestic setting also is linked intrinsically to other techniques and strategies of intimidation and control, such as threatening violence and restricting and/or closely monitoring women's activities.

Intensive and extensive research has identified the risk factors associated with lethal and nonlethal violence against women in the home. Although this violence occurs at all levels of society, higher rates are apparent among the economically and educationally disadvantaged. Young women and those living in non-state sanctioned relationships are more at risk than older and married women. Situational risks include high levels of conflict, jealousy, sexual proprietariness among male partners, and alcohol abuse. Risk of serious nonlethal and lethal violence is also associated with separation and women's attempts to leave violent relationships. In the 1970s investigations of policy and institutional practices revealed considerable failure on the part of legal and social agencies to provide support and protection for victims and children and a considerable reluctance to deal with male perpetrators. More recent research has charted the changes in policy and practices and revealed that some developments have resulted in decreased risks of violence and important benefits to women and children.

4. *Theoretical Accounts*

Theoretical explanations of domestic violence predictably have included a plethora of competing, at times contradictory, accounts, ranging from the sociocultural to the individualistic. Sociological, usually feminist, explanatory frameworks stress the historical and contemporary existence of male violence across almost all societies and locate its perpetration within patriarchal ideals and practices, emphasizing male power and control. In these accounts, violence is seen as functional, a resource used in men's attempts to enforce and maintain their domination and control, with conflicts associated with male jealousy, household labor, and economic resources constituting the contexts of violent events. Other sociologically-based gender-neutral accounts emphasize power but note that this social attribute is not skewed toward either gender—men and women possess significant amounts of power—and the symmetrical violence which occurs is an expression of such power. Variants of 'gender-neutral' explanations of domestic violence emphasize the importance of individual psychology and/or social traits that are deemed to have similar effects on the violence of men and women alike, these include, stress, frustration, socialization into (sub)cultures of violence, poor anger control, and impoverished social skills. Evolutionary psychology has challenged the foundations of these sociocultural explanations.

While evolutionary approaches also stress the functional nature of men's violence and locate it within patriarchal structures, explanations of this violence emphasize a universally evolved male psyche involving male sexual proprietariness toward women. This evolved psyche leads men to attempt to control women through various means including violence. Other, individualistic accounts have emphasized the pathological personalities of violent men.

An important strand in explanatory approaches is attempts to understand the predicament and actions of women who live with violent men. Sociological accounts have emphasized how male violence includes a range of intimidating and controlling acts as well as concerted actions to isolate women from family and friends. Continuous forms of intimidation and isolation make it very difficult for women to seek help, although it is now clear that most women suffering domestic violence engage in active efforts to deal with the violence. The vast majority seek help from family and friends and some also seek assistance from agencies of the state. Despite these efforts, women find it difficult to leave and sociocultural explanations stress men's threats of further violence, women's lack of economic and social support, a moral order emphasizing women's obligations to maintain family unity, and, until very recently, the inadequate responses of agencies of the state. Other commentators, particularly in North America, have proposed the importance of personality disorders in women as the primary reason that they are unable to leave violent relationships. According to these theoretical accounts women who do not leave violent relationships suffer from masochism, relationship addiction, 'battered woman' syndrome, and learned helplessness.

By the 1990s and into the 2000s, the enhanced and refined nature of the research questions, along with an increasing concern to evaluate the relative effectiveness of new innovations further expanded the theoretical questions in this area and, consequently, the relevant research strategies. Future research in the area will continue to concentrate on efforts to explain domestic violence and the predicament of the women who experience it as well as more focused questions about the impact of social and legal interventions on the

safety of victims and the violence of men. While much of the earliest research was shaped within sociology, criminology, women's studies, and law, the global expansion of interest in this social problem has been mirrored by an equal expansion of disciplines contributing to its study. In the future research, disciplines such as psychology, healthcare, and medicine will contribute to advances in knowledge about this significant social problem.

Dramaturgical Analysis: Sociological

Dramaturgical analysis of social interaction is based on the assumption that social acts are staged, consciously or unconsciously, and thus embody all the elements found in enactments in the theater. Plays on the theater stage highlight all the elements of ordinary social life to present to an audience a new perspective on some aspect of social interaction. Thus, concepts used in theater production can be turned back again for the analysis of the social behavior that they are designed to reflect.

1. The Main Concepts

The main concepts that can be used in dramaturgical analysis center on the stage or action area (Hare and Blumberg 1988). The action area can be divided into two parts; backstage and stage. The backstage area is where the actors prepare for their roles and where special effects are produced to influence the audience. The stage is where the action takes place in full view of the audience. Even if only two people are involved in the interaction, they take turns providing an audience for each other. When one is speaking the other is listening. As an audience, an actor provides consensual reality, cueing, social reinforcement, and continual observation (Sarbin in Allen and Scheibe 1982).

For any action area there may be offstage areas in which persons who have organized the activity (producers), as well as those who have rehearsed the cast (directors) and are providing cues for action remain hidden from the audience. In addition, there may be a person or group who provided the original idea or script for the performance (playwright). This does not complete the list as there may also be persons who cater for the audience.

The meaning of the event binds all the participants together. The overall meaning has been termed the definition of the situation, the frame, and the illusion. In the progress of the development of social interaction over time, agreement on an actable idea consistent with the overall meaning is the first phase. A second phase involves staging by locating or constructing an action area and providing resources such as props, costumes, and other necessary equipment. In the third phase, which may overlap with the second, actors are recruited, if they are not already involved in the development of the actable idea, and the actors are trained for their roles. The fourth phase is the period of enactment when the play is performed. In the final phase, after the performance, new meanings for selves, others, and the situation may be assessed by the actors and audience.

The actable ideas that form the basis for social dramas may be either very general or very specific in their implications. On one end of the continuum is an

actable idea in the form of an image, an emotionally loaded set of words, physical object, or event, for example, ghetto or bacchanalia. An image has a program of action packed into it, much like a symbol in a dream may be a merger of waking events. An image often guides interaction in a small informal or therapy group. The actable idea may be a more complex theme (including a direction of movement, an emotional tone, and a minimal set of roles to be enacted) or a plot (with a detailed scenario, defined roles, and an indication of the phases a group must go through to reach its goal). At the specific end of the continuum, the idea may be as fully developed as a script for a play, with parts for each member of the cast and stage directions to guide the performance. A script is most evident in organizations, especially where the actors must use equipment.

Building on the perspective of (Burke 1968), Duncan (1968) emphasizes the importance of symbols, especially as they reflect authority relationships. For MacCannell and MacCannell (1982), the study of signs and symbols had become so important by the late 1900s that they suggested a semiotic interpretation of modern culture as an approach to the time of the sign. Brissett and Edgley (1990) add to the list variables that follow from the work of Goffman (1959) with a primary focus on the way in which individuals present themselves to others. These variables include: role distance, the case when an individual is playing with a role with full consciousness and thereby has the choice of either modifying the role or ceasing to play it altogether; ecstasy, stepping outside the world of everyday life; and remedial work, when a person attempts to change the meaning of an act from one that is seen as offensive to one that is acceptable.

2. *Academic Fields that Contribute to Dramaturgical Analysis*

Dramaturgical analysis has been used in several ways. One way is used more by sociologists of the symbolic interaction tradition with a focus on role playing (cf. Goffman 1959). The second way, introduced by the philosopher–linguist Burke (1968), is based on the analysis of the act. Another approach, used primarily by anthropologists, is to analyze the function of social dramas that are enacted by members of a society to bring about conflict resolution (Turner 1974), to signify a rite of passage, or to memorialize some important event in the history of the society.

Since role and script are central concepts for drama, the fields of psychology, political science, philosophy, linguistics, psychotherapy and the methods of narrative and qualitative analysis, also include descriptions of similar relationships that can be incorporated in the dramaturgical perspective.

3. *Earlier Definitions of the Dramaturgical Perspective*

Evreinoff, in *The Theatre in Life* (1927), records that, at least since the sixteenth century, the similarity between life and the theater has been noted by Shakespeare and others. However, the dramaturgical perspective was not widely used until it was popularized by Goffman in the 1960s. The 1930–35 edition of the *Encyclopedia of the Social Sciences*, edited by Seligman and Johnson, does not include an entry on the dramaturgical perspective, although there is an entry for drama, covering activity in theaters. Burke's entry on dramatism in the 1968 *International Encyclopedia of the Social Sciences*, edited by Sills, presents Burke's pentad of the five terms: act, scene, agent, agency, and purpose. Sets of concepts are linked in ratios, such as the scene–act ratio, where the scene (the situation) has implicit in it the attitudes and behaviors that will become explicit through action. Burke places his own work clearly in the symbolic interaction tradition with references to Mead (1938).

For Brissett and Edgley (1990), in a second edition of their source book on *Life as Theater*, dramaturgy is the study of how human beings accomplish meaning in their lives through interaction with others. Just as meaning is created through enaction it can be recreated through re-enaction. Moreno observed that 'every second time is a liberation from the first' (Hare and Hare 1996) and developed psychodrama as a method of group therapy based on re-enactment.

In the 1992 *Encyclopedia of Sociology* edited by Borgatta and Borgatta in the entry on Dramaturgy, Warner records that the unique insight of dramaturgy is that daily social interaction consists of performances, that individuals stage and in which they present themselves to others. As with Brissett and Edgley (1990) the emphasis is on the work of Goffman and the symbolic interaction tradition of Mead and the Chicago School.

4. *Methodological Issues*

Brissett and Edgley (1990) provide a list of some of the critiques that have been made of dramaturgy. For some critics, dramaturgy is a pedestrian, nonsystematic form of inquiry that does not possess the properties of formal theory. Brissett and Edgley agree, but indicate that is it linked propositionally to other forms of social thought, such as symbolic interactionism, ethnomethodology, existential sociology, interpersonal psychology, and other humanistic models in the social sciences.

A second criticism is that dramaturgy does not produce universal statements about human behavior. It is said to be an artifact of studying the situational behavior in Western culture. In response, Brissett and Edgley first note that understanding how people

interact in Western society is no small achievement, but go on to point to the fact that the expressive behavior of individuals is well-documented in the anthropological literature.

Dramaturgy, or at least Goffman's version of it, has also been criticized for its methodology. It is said to have no specific, systematic method of testing propositions about the world. Brissett and Edgley claim that there is nothing special about doing dramaturgy. Being sensitive to the expressive dimension of behavior demands no special methodology or observational skills. However, there should be an unnerving and single-minded commitment to the observation of people's doings.

Another criticism is that dramaturgy slights the impact of larger social units, such as institutions, on human behavior. In response, Brissett and Edgley assert that there can be no doubt that people's interaction contexts are circumscribed by structural arrangements. However, rather than dwelling on the limitations, dramaturgy focuses on what people do within the contexts that are available to them. The concept of role is used as a way of accounting for people's connections to one another as well as to the structures and organizations with which they are identified.

Finally, the most prevalent critique has to do with the theatrical metaphor. Critics say that the theater is make-believe and everyday life is real. Brissett and Edgely respond that life is neither theater nor is it different from theater. It is theater like.

5. *Future Directions for Theory and Research*

A first act to begin the analysis of social interaction would be to use the dramaturgical perspective to describe the stage, the various actors who are on or off the stage, the audience, and the overall meaning of the event (definition of the situation). As one turns the spotlight on the various actors in turn, their functions (formal and informal) and the process through which they express themselves in their roles can be described in terms of other perspectives, drawn from the social sciences and humanities, until all aspects of social behavior have been included.

Dreaming, Neural Basis of

From the animistic dawn of consciousness to the modern psychoanalytic era, dreams have been central to the mythologies of human cultures. Because of their peculiar formal differences from waking consciousness, dreams have typically been thought to represent cryptic messages emanating from sources outside of the dreamer (such as the godhead and other disembodied spirits) or from within the self (such as unacceptable desires arising from the depths of one's own unconscious mind). Dreams have thus been considered to be proverbial, privileged, and prophetic signals so deeply encoded as to require interpretation by a specialist. The interpretation of dreams has fallen to shamans, to priests, and since 1900, to psychoanalysts. But despite vigorous self-promoting appeals, not even the latter group could make any legitimate claim to a genuine science of dreaming. It is only within the second half of the twentieth century that sleep research has provided an objective, experimental foundation for the study of dreaming. By establishing a solid tie with neurobiology, it has also created the opportunity to understand this fascinating mental state in terms of brain physiology.

In such a young field, the data and the conceptualizations of them are still naturally fragmentary, preliminary, and rapidly evolving. And it should be recognized that while animistic and external agency models can no longer be countenanced, a new psychology of dreaming that emphasizes undisguised personal meaning might find a scientifically legitimate place. In fact, it would appear that one of the important functions of dreaming could well be the reconfiguration of emotionally salient biographical information. If this were true then the interpretation

of dreams might be quite simple: the dream is its own interpreter; its meanings are transparent; and its formal peculiarities are the straightforward expression of the unique information-processing mode of the brain in sleep.

1. *Definition of Dreaming*

Dreaming is a distinctive mental state that occurs periodically in normal human sleep. Typical dream reports include such psychological features as hallucinations, delusions, cognitive abnormalities, emotional intensifications, and amnesia. These five remarkable features of dreaming have invited its comparison to abnormal states of mind that occur during waking in certain clinical conditions, especially delirium and the organic mental syndromes. The exploration of the neurobiological basis of dreaming therefore constitutes not only an aspect of mind-body interaction but also provides a model for understanding the brain basis of mental illness.

An obvious obstacle to the scientific study of dreaming is that the unconfirmable nature of all subjective experience is compounded by difficult access to the mind in sleep. The recent development of sleep laboratory recording techniques has given the study of dreaming an instrumental and systematic character, and the emerging data encourage psychophysiological integration. The constellation of psychological features of dreaming, their concomitance with objectively identifiable physiological states, and the occurrence of the same physiological states in all mammals allows the investigation of the neurobiology of dreaming in animal preparations.

1.1 *Psychological Features of Dreaming*

Dreams are characterized by vivid and fully formed hallucinatory imagery with the visual sensory domain predominant; auditory, tactile, and movement sensations are also prominent in most dream reports. Compared with the common representation of these sensorimotor domains, taste and smell are underrepresented. Reports of pain are exceedingly rare despite the involvement of dreamers in frightening and even physically mutilating scenarios. Table 1 summarizes the formal features of REM (rapid eye movement) sleep dreaming.

Dreaming is properly considered delusional because subjects have virtually no insight regarding the true nature of the state in which they have their unusual sensorimotor experiences. Thus the tendency is great to consider dream events as if they were completely real during the dream even though they are promptly recognized as fabrications when recalled in subsequent waking states. This lack of insight is all the more surprising since uncritical belief in the reality of dream events must overcome high degrees of improbability and even physical impossibility.

The lack of insight that makes dreams delusional is part of a broader set of cognitive disturbances. Dreams are characterized by discontinuities (with unexplained changes of subject, action, and setting); by incongruities (with social inappropriateness and cognitive illogicality); by improbabilities and impossibilities (with defiance of physical law); and by uncertainties (with explicit vagueness). Dream characters and dream objects may be banal or they may be altogether fantastic and impossible collages of existing reality; they may behave normally or indulge in the most absurd, improbable, or impossible actions in settings either familiar or bearing only the faintest resemblance's to those of real life. To explain these unique and remarkable dream features, illogical thought processes such as non sequiturs, *post hoc* explanations, and mythical, metaphorical, and symbolic elaborations are the norm.

Memory undergoes a paradoxical intensification and suppression during dreaming; remote recall is intensified within the dream as characters, scenes, events, and concerns from previous experience are knitted into the fanciful and evanescent fabric of the plot. Dreams can thus be said to be hypermnesic within the state itself. This increased access to memory

Table 1
The formal features of REM sleep dreaming

Hallucinations—especially visual and motoric, but occasionally in any and all sensory modalities
Bizarreness—Incongruity (imagery is strange, unusual or impossible; Discontinuity (imagery and plot can change, appear or disappear rapidly); Uncertainty (persons, places and events often bizarrely uncertain by waking standards)
Delusion—we are consistently duped into believing that we are awake (unless we cultivate lucidity)
Self-reflection absent or greatly reduced—relative to waking
Lack of orientational stability lack—persons, times, and places are fused, plastic, incongruous and discontinuous
Narrative story lines—explain and integrate all the dream elements in a confabulatory manner
Emotions increased—intensified and predominated by fear-anxiety
Instinctual programs—(especially fight-flight) often incorporated
Volitional control—greatly attenuated
Memory deficits—across dream–wake, wake–dream and dream–dream transitions

within the state of dreaming contrasts markedly with the virtual impossibility of recovering the dream product after the state has terminated. On awakening, even from a dream in progress, subjects have difficulty holding the vivid experiences in short-term memory long enough to give a report or transcribe the dream scenario in detail. Thus there is amnesia for the hypermnesic dream. It can be conservatively stated that at least 95 percent of all dream mentation is entirely unremembered.

Emotion fluctuates widely in association with the abnormal and vivid mental content of dreaming; anxiety, elation, and anger are the three affects that undergo most marked intensification during dreaming. Obsessional concerns are common with dreamers focusing their worry on nudity, being lost, missing trains, and a host of other incomplete arrangements. Depressive affects are markedly under-represented with shame and guilt playing a relatively small part in dream emotion. Contrary to the predictions of psychoanalytic dream theory, sexual dreams are disappointingly rare.

Mental experience with some or all of these dream features can occur in any physiological sleep stage but it is most common at sleep onset, in REM sleep, and in late night light NREM sleep. Early in the night, deep NREM sleep is usually accompanied by little or no recallable mentation or by perseverative thinking about the individual's ongoing events and concerns.

2. *The Association of Dreaming with REM Sleep*

In 1953, Eugene Aserinsky and Nathaniel Kleitman noted that the sleep of children began and was periodically interrupted by activation of the electroencephalogram and by bursts of saccadic eye movement, the so-called rapid eye movements, or REMs. William Dement confirmed the hypothesis that these periods of brain activation during sleep were correlated with dreaming. The capacity to recall dreams appeared to be related to the nature of the awakening process: subjects who learned to obtain a fully aroused state without moving increased their recall capacity. Home-based recording methods, such as the Nightcap (see Ajilore et al. 1995) have recently confirmed these laboratory observations. Because they are simpler, less disruptive, and cheaper, they can greatly extend this data and put objective dream research within reach of any scientifically inclined psychologist, anthropologist, or social scientist.

Within each REM period, dream intensity tends to parallel the intensity of phasic physiological events, especially the eye movements; arousal during REM sleep with flurries of eye movement activity yielded reports fulfilling the definition of dreaming given here in 90–95 percent of the cases (some aspects of this physiology are shown in Fig. 1). When scored

Figure 1
Recording of physiologic activity in one human NREM-REM cycle

for vividness, emotionality, and imagined physical activity, these measures were correlated positively with the quantitative intensity of the eye movement in the REM sleep just prior to awakening.

Estimations of dream duration correlate positively with the time spent in REM sleep prior to arousal. When subjects were aroused after only 5 minutes of REM sleep, they gave shorter reports; after 15 minutes had elapsed, reports were considerably longer and more detailed. Thus it would appear that despite expansion and contraction of temporal duration estimates within individual dream scenarios, the overall correlation between time estimation of dream duration and real time elapsed in REM sleep is quite good. This finding helps to dispel the skeptical notion that dreams occur in the instant before awakening or as part of the awakening process. To test the resistance of memory to dreams, awakenings were performed in the non-REM sleep phase at intervals following the termination of REM. The incidence of reported dreams dropped to non-REM levels within 5 minutes, indicating the extremely fragile state of memory within sleep and highlighting the strong state dependency of recall upon arousal from REM sleep.

3. *A Psychophysiological Theory of Dreaming*

The simplest and most direct approach to the correlation of dream mentation with the physiological state of the brain is to assume a formal isomorphism between the subjective and objective data. By isomorphism is meant a similarity of form in the psychological and physiological domains. For example, the subjective experience of visually formed imagery during dreaming implicates activation of perceptual elements in the visual system in a manner formally similar to that of the waking state. Other details of psychophysiological correlation are assumed to obey the same general law; for example, the vivid

Figure 2
The Activation-Synthesis Model. (**A**) Systems model. As a result of disinhibition caused by cessation of aminergic neuronal firing, brain stem reticular systems autoactivate. Their outputs have effects including depolarization of afferent terminals causing phasic presynaptic inhibition and blockade of external stimuli, especially during the bursts of REM; postsynaptic hyperpolarization causing tonic inhibition of motoneurons which effectively counteract concomitant motor commands so that somatic movement is blocked. Only the oculomotor commands are read out as eye movements because the motoneurons are not inhibited. The forebrain, activated by the reticular formation and also aminergically disinhibited, receives efferent copy or corollary discharge information about somatic motor and oculomotor commands from which it may synthesize such internally generated perceptions as visual imagery and the sensation of movement, both of which typify dream mentation. The forebrain may, in turn, generate its own motor commands which help to perpetuate the process via positive feedback to the reticular formation. (**B**) Synaptic model. Some of the directly and indirectly disinhibited neuronal systems are schematized together with their supposed contributions to REM sleep phenomena. At the level of the brain stem, five neuronal types are illustrated: midbrain reticular neurons (MRF) projecting to thalamus convey tonic and phasic activating signals rostrally; burst cells in the peribrachial region (PGO) convey phasic activation and specific eye movement information to the geniculate body and cortex (dashed line indicates uncertainty of direct projection); pontine reticular formation (PRF) neurons transmit phasic activation signals to oculomotor neurons (VI) and spinal cord which generate eye movements, twitches of extremities, and presynaptic inhibition; bulbar reticular formation (BRF) neurons send tonic hyperpolarizing signals to motor neurons in the spinal cord. As a consequence of these descending influences, sensory input and motor output are blocked at the level of the spinal cord. At the level of the forebrain, visual association and motor cortex neurons all receive time and phasic activation signals for nonspecific and specific thalamic relays

hallucinated sensation of moving is assumed to be related to patterned activation of motor command systems and those central brain structures subserving the perception of position, and changes in position, of the body in space.

To be fully adequate, a psychophysiological hypothesis has to account for the following processes, which are illustrated in Fig. 2 and described in more detail in the entry on *Sleep States and Somatomotor Activity*.

3.1 Activation

The brain has to be turned on and kept internally activated to support dream mentation throughout the REM sleep episode. A possible mechanism for this activation process is disinhibition of sensorimotor circuits (related to cessation of activity in aminergic inhibitory neurons) and internal excitation (owing to the reciprocal increase in cholinergic activation) Aminergic neurons decrease their output by 50 percent in non-REM sleep and virtually cease firing during REM while cholinergic neurons resume their high waking levels of discharge and fire in clusters as the eyes move back and forth.

3.2 Input Blockade

Input from the outside world to the internally activated brain has to be prevented in order for sleep and the illusions of dreaming to be maintained. This is accomplished in at least two ways. One is presynaptic

inhibition of the afferent terminals of the group-Ia afferent nerves, which impedes access of external stimuli to the central nervous system. Presynaptic inhibition has also been recorded at secondary relay nuclei throughout the brain stem and thalamus guaranteeing even more complete insulation of the activated brain from the outside world. The second mechanism for excluding sensory input is the occlusion by internally generated messages that occupy the higher levels of brain sensory and perceptual circuits. Rodolfo Llinas and Denis Paré theorize that the deafferentation of REM sleep is a major determinant of the difference between dreaming and waking consciousness.

3.3 Output Blockade

The internally activated and aminergically deafferented brain must also quell motor outputs to prevent the disruption of sleep by reafferent stimulation and to halt the enactment of dreamed motor commands. This is accomplished by postynaptic inhibition of final common path motor neurons in the spinal cord. The dreamer who fancies him- or herself walking, running, swimming, or flying is, in fact, paralyzed from the neck down.

3.4 Internal Signal Generation

It remains to provide the activated but sensorially disconnected brain with internal signals, which it can then process as if they came from the outside world. This appears to occur in part by a mechanism intrinsic to brain activation: the reciprocal interaction of aminergic and cholinergic neurons in the brain stem. In most mammals including humans, the so-called PGO waves (P, pons; G, (lateral) geniculate; and O, occipital cortex), present themselves as candidates for an internally generated information signal arising at the level of the pontine brain stem. In association with oculomotor activity, strong pulses of excitation are conducted by reticular pathways to the thalamus and radiated by independent pathways to the visual and association cortices.

It is now known that the PGO waves are generated by cellular activity, which faithfully replicates the directional aspects of generated eye movements at the level of the brain stem. Thus not only is internal information generated but the information has a high degree of spatial specificity. According to the activation-synthesis hypothesis of dreaming, the now autoactivated and autostimulated brain processes these signals and interprets them in terms of information stored in memory. Recent evidence indicates that the PGO system is facilitated by cholinergic and restrained by aminergic neuromodulation.

Three important observations concern the origin and fate of motor command signals arising in the brain during REM sleep.

The first observation, suggesting that the motor commands would generate behavior if not inhibited, is the revelation by Michel Jouvet and by Adrian Morrison of elaborate motor behaviors during REM sleep in cats that have lost their capacity to inhibit muscle tone; these behaviors include running, pouncing, attack and defense postures, and intense fear reactions accompanied by hissing and piloerection.

The second observation, suggesting a brain stem origin of the motor patterns generated in REM, is that the locus for the elicitation of locomotion by electrical and chemical stimuli is immediately adjacent to the cellular controllers of REM in the anterodorsal pontine brain stem.

The third observation, offering dramatic proof that brainstem motor commands are actually the building blocks of dream plots, is the emergence of dream content specific movements in human subjects who have lost their ability to inhibit motor activity in sleep owing to degenerative disease of the brainstem.

4. The Neuropsychology of Cognitive Deficits in Dreaming

Although, the basis of the cognitive disturbances occurring in dreaming is not yet well understood, it is possible that the deficits are related to the cessation of activity in aminergic neurons. The REM sleep arrest of aminergic neuronal activity affects the entire brain including the cerebral cortex by depriving it of the tonic modulatory influence of both norepinephrine and serotonin. This tonic aminergic modulatory influence may be essential to waking attentional processes, including the capacity to organize information in a logical and coherent manner and to achieve full self-awareness. In the absence of external cues and deprived of internal modulatory influences by aminergic systems, the activated forebrain thus could interpret its internally generated signals as if they were external stimuli.

By a similar mechanism it may be speculated that the synthesized dream product is unremembered. That is, the activated forebrain circuits which mediate the dream experience are simply not instructed to keep a record of the transaction. The mnemonic instruction is also postulated to be carried out by signals from the aminergic interneurons to their vast postsynaptic domain in waking (when they are active) but not in dreaming (where they are inactive). Current models of learning and memory at the cellular level evoke the intervention of an aminergic interneuron. The attribution of dream amnesia to the loss of aminergic modulation is consistent with these hypotheses.

Table 2
Four features of dream psychology—motor hallucinosis, emotion, bizarreness, and memory deficits—can now be mapped on to the physiological findings

Region	PET studies of activation in REM	Lesions studies of effects on dreaming
Pontine tegmentum	↑	—
Limbic structures	↑	↓
Visual cortex	—	—
Parietal operculum	↑	↓
Dorsolateral prefrontal cortex	↓	—
Mediobasal frontal cortex	—	↓

KEY: ↑ Increase; ↓ Decrease; —No Change.

The complementary results of recent positron emission tomography (PET) imaging and brain lesion studies of dreaming have greatly enriched the experimental study of dreaming in humans. These results are summarized in Table 2.

Two forebrain regions appear to be critical for the maintenance of dreaming. One is the parieto-temporal-occipital-cortex, a region known to be important to visuomotor imagery. The other is a subcortical zone connecting the limbic emotion centers with the frontal cortex. PET studies indicate that both of these regions are selectively activated in REM sleep, and when either is damaged by a brain lesion, subjects report a marked dimunition in the subjective experience of dreaming. The PET studies also indicate that while emotion centers in the amygdala and related limbic cortical regions are turned on, the dorsolateral prefrontal cortex is selectively deactivated in REM. This reciprocal pattern maps on to the intensification of emotion and to the deficiencies in cognition that typify dreaming.

5. *Summary*

The activation-synthesis model of dreaming and the reciprocal interaction theory of sleep cycle control on which it is based are both incomplete and controversial models. They represent linked working hypotheses about the fundamental physiology of sleep and the way in which that physiology may help us to understand unique features of the dream process. The attribution of automaticity to the control system and the feature of randomness in the information generator model should not be taken to exclude the meaningful nature of the synthetic process carried out by the activated dreaming brain. The brain–mind of each dreamer is obliged to make as much sense as it possible of its internally generated signals under the adverse working conditions of REM sleep. Thus, the dream product of each individual may reveal unique stylistic psychological features and emotional concerns that are worthy of scrutiny by individuals interested in reviewing life strategies. But the new theory challenges the psychoanalytic idea that the many meaningless aspects of dream mentation are the result of an active effort to disguise the meaning of unconscious wishes, which are in turn postulated to be the driving force of dreaming. Instead, it ascribes these defective cognitive properties of dreaming to unusual operating features of the internally activated, autostimulated brain during REM sleep.

Dress and Fashion

1. *Introduction*

Before reading and writing there was dress. Styles of dress and patterns of appearance were visual images designed to inform self and other of social responsibility and social rank. These visual images formed a language culled from a body of images accumulating in the group's public memory, a language that became codified as fashion. Past research has concentrated on how fashion, a period's desired appearance, was designed to support the social superiority of those who had acquired wealth in the form of money. By the end of the twentieth century social science was focusing on how fashion was emerging as a means of social criticism that commented on cultural taboos and integrated ethnic ideology into Western dress.

2. Basic Images and Fashion

A group's basic images represent what Emile Durkheim (1893/1947) called the group's 'collective consciousness,' i.e., the group's ideas, beliefs, and values. Lasting images enter into the group's collective memory. When these images are codified, the result becomes a language for social communication. Fashions involving such images as a reshaped head, a lip plug, scissored teeth, or trousers for men and skirts for women convey such a language.

2.1 Collective Memory

Every society has a body of images and meaning that it considers essential. Many images are transmitted from one generation to the next, forming the public memory (Halbwachs 1980). These images become a part of core culture, like time and space, and affect a child's orientation to social realities. Images relevant in a particular period give shape to societal discourse.

A group searching for a visual image to embody its ideas might create a new synthesis from among the elements represented in its public memory—elements that are found in carvings in places of worship, in manuscripts, and in museums and other public places. Mussolini, for example, wanted to create 'a new organic whole' composed of people of all levels of society. He commissioned artistic representations that combined images from classical art of the past with those from traditional folk art. In this genre, men assumed the postures of victory portrayed in ancient Roman times and were seen as victors in agricultural setting. Through this appeal to pride in a shared past, Mussolini gained support for his political program (Malvano 1988).

2.2 Language

Clothes worn by a stranger inform the public of the person's sex, occupation, nationality, and social standing, making it possible for the observer to adjust his or her behavior accordingly, noted Flugel (1930). Writing about Western European societies, Flugel observed that the basic clothing images underlying social interaction are those of *power*, *authority*, *gender distinction*, and *seductiveness*.

Power is identified by images indicating access to human power and superhuman force. The archetypical elements of the image of power are a sword and a crown. Power is also conveyed when a person's appearance is augmented by elements that extend the body's reach, a guard carrying arms, for example. Such elements increase the person's physical ability to control the environment.

Authority is conveyed by body-concealing attire, a vertical continuity of fabric, and a generalized unity from head to toe. The styles traditionally worn by judges, priests, and nuns increase the size and volume of the person. The resulting commanding presence makes it easier for office holders to perform their roles. Conversely, clothing that is too big, too tight-fitting, or too small can dwarf the body and imbue the wearer with a sense of insignificance (Flugel 1930, p. 36).

Gender distinction, as affirmed by the church fathers, was determined by sexual characteristics at birth (*Corinthians* 1, Chap. 11). Men were expected to wear clothes that support activity and work. Women customarily wore clothing alluding to their reproductive role.

Seductiveness, the church fathers claimed, was achieved by such elements as color, ornament, and dress that clung to the body or exposed it. They proscribed such attire. As a result, these elements of image became established as a sexually alluring look (Prusack 1974).

According to this type of linguistic model, clothing 'speech' can be defined as an individual's manipulation of the language of clothing to produce specific utterances characterized by personal intonation and style. People interpret fashion, just as they decode other forms of speech, to ascertain the meaning behind the utterance. To understand the meaning of a cultural expression, research from a variety of fields has suggested that knowing something about the author's purpose, intention, and social situation is essential to valid interpretation (cf. literary critic E. D. Hirsch Jr. (1967), art historian Michael Baxandall (1985), and sociologist Wendy Griswold (1989)).

An example of such a cultural expression is the *Codex Manesse*, a manuscript in the Heidelberg Library illuminated between 1298 and 1304, that teaches morals and manners. One of the scenes involves a classroom. Sitting on a platform and higher than anyone in the room is the teacher, *Magister Henricus*. Imposing in size, and voluminously dressed, he lectures from a manuscript. In his left hand he holds a birch branch. The birch is an emblem of Grammatica, one of the Seven Liberal Arts. It is a symbol of learning, but it also extends the teacher's reach and can inflict punishment. Across the room on a lower level sits the assistant teacher. He is smaller in size and wears a dark tunic not long enough to cover his ankles. His birch branch is smaller. Two students facing him are trembling, as if they had already been hit by the birch rod. The illustration demonstrates that one must listen attentively to the teacher, or the consequence will be punishment and humiliation.

3. Semiotics of Dress

Clothes that indicate expected behavior are called clothing signs. Elements of dress and styles of appearance that reflect the achievement of cultural values are clothing symbols. Clothing tie-signs are clothes

that signify membership in a group and are different from those proffered by mainstream culture. Clothing tie-symbols, on the other hand, represent a preference for a political agenda, a public persona, or a particular social group. It may also reflect an individual's fears, hopes, or dreams. Clothing tie-signs and clothing tie-symbols are forms of publicspeak, the individual's response to existing social arrangements.

3.1 Signs and Tie-signs

Patterns of dress and styles of appearance designated by mainstream culture as identifiers of group membership are clothing signs. Such signs are styles of dress and patterns of appearance required for social participation. They are mandated by a formal code, are instrumental to achieving a goal, and have one meaning. A typical case of sign analysis is dress indicating power, authority, gender, and seductiveness; Flugel's previously identified as clothing signs. Clothing signs are mandated by a formal code, and are instrumental to achieving a goal.

3.2 Symbols and Tie-symbols

Veblen (1899, pp. 118–30) coined the term 'status symbol' to identify images that reflect the achievement of cultural values. Unlike clothing signs, which identify positions within social institutions and are governed by rules of conduct, the wearing of clothing symbols entails personal choice (Goffman 1951).

Every society establishes its own set of values or goals that members of the society should attempt to achieve. The values lead to the norms that guide behavior. In the Amazon, the desire of the indigenous *Yanomamo* for equality leads to norms that forbid the amassing of surpluses and show strong attachment to tradition. For adornment they use sticks, feathers, and paint, which are readily available in their environment.

Social change in Western history encouraged new cultural values. Each of the values was accompanied by the appropriate visual image. Until the fourteenth century *spirituality* was the core value of Christian Europe. Unlike the Romans, who had conceived of the body as a neutral thing placed between nature and society, Christian leaders saw the body as a clearly visible locus of spiritual order. Early Christian writers insisted that what separates Christians from non-Christians is spirituality. Sexual desire and the longing for sensual garments therefore had to be curtailed. Approved clothes were garments that were monochromatic and body concealing.

Wealth as a cultural value emerged in the twelfth and thirteenth centuries. Acquisition of wealth was symbolized by sumptuous fabrics, gold, and costly jewelry. The term 'elegant' referred to the ideal of *harmony*. It entailed creating a costume in which fabrics, colors, and ornaments were coordinated to create a complementary whole.

Fashion is a category of dress that indicates the openness of the society to social change. Fashion in Western society emerged in the fourteenth and fifteenth centuries with the growth of international trade and the resultant spread of affluence to the mercantile class. Fashionableness became the most desired feature of a person's appearance (Bell 1976). It reflected awareness of the novel.

Beauty as a cultural ideal emerged in nineteenth-century England in response to industrialization and urbanization, as strangers were brought together to live and work close to one another. The resulting tension led to a new search for beauty which the ancient Greeks defined as symmetry, harmony, and perfection of the physical form. These qualities were considered to have a calming effect. Beauty as a cultural value was manifested as a preference for better looking servants and employees, for example, and in beautification of gardens and parks (Marwick 1988).

Youth as a cultural value emerged at the end of the nineteenth century as manufacturers chose a younger, more energetic labor force, and desired a population of consumers. The young, having fewer financial burdens, were freer to buy the products of industry. *Health* as a cultural value was informed by increased awareness that illness could be prevented through cleanliness, vaccination, and consumption of healthful food. At the end of the nineteenth century, charts listing appropriate weights for given heights were hung on the bathroom doors of hotels in London.

Since the United States is ethnically and racially diverse—a nation of immigrants and thus strangers—the values of beauty, youth, and health are particularly poignant. They form the fashionable ideal, and provide criteria for social acceptance and self-evaluation. By the end of the twentieth century the desirability of the fashionable ideal was being promoted in the media, drugstore shelves, and establishments offering cosmetics, vitamins, exercise, diet plans, and plastic surgery.

A different category of clothing symbols entails styles of dress and elements of appearance that cover up what Goffman (1963, p. 45) termed '*stigma symbols*,' i.e., an appearance that deviates from cultural values and results in feelings of vulnerability, inadequacy, and fear. Such styles are long and wide to conceal deformities such as crooked spindly legs or a hunchback.

Tie-symbols are clothing that reflect alternative values and suggest a desired association. People often wear tie-symbols to inform themselves and others of their support of groups, political ideas, or social agendas. Examples are T-shirts with messages such as 'Save the Earth' and Spike Lee's black baseball cap with the mark 'X' reflecting his admiration for Malcolm X. Because clothing tie-symbols express

grass-roots sentiments, the wearing of tie-symbols may be the first step in the development of a social movement.

In the 1990s there were about 70 million young adults, teenagers, and school-age children in the United States. The styles they preferred were identified as 'trendy' and included hippie, 'cutting edge,' 'freaky,' and hip-hop. The most popular of these styles was hip-hop. Originating among urban black ghetto youth, the hip-hop style related to a type of music and lyrics; baseball cap turned backwards, pants several sizes too big and other baggy, oversized clothing emblazoned with logos; and to a swaggering manner, all violating the norm of self-restraint. The style was intended to counteract the longstanding perception that blacks and other minorities in America should be invisible. As one rap lyric went, you 'don't see us/but we see you.'

Hip-hop music is used in backing rap, a form of rhythmic speaking in rhyme that is repeated again and again. Rap songs deliver a message that is streetwise and reality-oriented. As a listener noted, 'You listen and you say, yeah that's right' (Farley 1999, p. 56).

The lyrics encourage listening and evaluating how one feels or what one thinks. The music is composed of a collage of excerpts or samples of familiar songs. The rap of the early 1990s was called Gangsta rap because it emphasized crime as a means of acquiring wealth. Gangsta rap, however, also emphasized the drawbacks of such behavior: paranoia, betrayal, revenge, and bloodshed (Reynolds 1999). The required dress was the baggy style that could hide knives, guns, and other implements of attack and self-protection. It was initially worn or advertised by rap musicians, and their youthful audience regarded the attire as empowering (Staples 1996).

By 1999 the rap in hip-hop songs had changed to the 'player style,' celebrating the economic success of the performer, and reveling in the consumption of luxury goods (Reynolds). Hip-hop music and style had become popular in black city ghettos, in affluent white cities like New Canaan, Connecticut, as well as in the dirt-poor Indian reservations of Arizona (Farley 1999, p. 13), and went on to acquire international recognition.

4. *Fashion*

On the European continent up to the twentieth century, the wearing of fashionable attire by the middle and lower classes was regarded as an attempt to violate social order by concealing one's social origins. In nineteenth century England, Thomas Carlyle criticized the wearing of fashionable attire by those not entitled to it, as signifying the pursuit of frivolity rather than the pursuit of spirituality.

Fashion in eighteenth century America was seen by American social critics as representing European decadence, violating Protestant norms of simplicity and hard work. Social crusaders in the nineteenth century, Veblen in particular, argued that the function of fashion is to demonstrate access to wealth. Made of sumptuous fabrics, to order, in a style that made it impossible to engage in productive labor, fashionable attire represented 'conspicuous consumption' and encouraged social inequality and waste.

The American mass production of fashion was found wanting by European social critics. Techniques of mass production 'shatter' the renewal of the human spirit, argued W. Benjamin (1973). Breward (1995) argued that fashion tends to obscure nationality, social status, and gender identity. Coleridge (1988) protested that fashion makes 'bad clothes' look good and in doing so, the fashion industry and fashion magazines assault the notion of beauty.

4.1 *American Fashion*

Fashion in the United States is governed by advances in technology, making possible mass production of clothing at prices affordable to middle class and working class consumers. The main source of style was Parisian fashion. Paris designers used to set the standards, and American manufacturers adapted couture originals for the mass market. This mode of production led to the full-skirted 'New Look' after World War II, the 'sack' in the 1950s, and the space age sleek look of the 1960s notes Agins (1999, p. 9).

Youth revolution of the 1960s led to a decline of Parisian influence as a source of American fashion ideas. In the 1970s name brands became important (Agins 1999, p. 179). Also American designers introduced new themes in to American women's fashion such as *masculine tailoring* and '*sweats*,' fashions based on dance and exercise clothing. Through advertising, editorials, and fashion shows designers communicated directly with the consumer, and designer labels became household names. Styles most emotionally relevant to consumers were copied, and designated the fashion.

Department stores organized their sales floors into brand name boutiques, geared largely to career women of the baby boom generation who needed clothes to wear to work. As brands began to dominate, store buyers were less inclined to try new and unfamiliar labels. Dozens of specialty chains appeared with their own private labels. In the early 1980s the industry, through market research, also geared itself to respond to a new demand. The profitable way of doing business, they insisted, was to find out what the consumer wanted, and make and market it. 'The consumer-is-king' approach became the practice in the United States.

In the fall of 1987, American designers tried, with little success, to take back the authority for the production of fashion. Growth in women's fashions came to a halt (Agins 1999, p. 182). European fashions also failed to find a profitable market in the United States. Styles introduced by couture designers like the

'waif' look, the unkempt grunge look, and the 'fishtail' dress with asymmetrical hemlines were commercial flops.

In the early 1990s, marketing analysts coined the term 'commoditization of fashion.' It described a new era in the move to low-cost factories and offshore production. The trend, which began many years ago with production of cheap lines of clothing, expanded on a vast scale in the 1990s. This time the aim was to manufacture clothes in 'classic' (nontrendy) 'simple chic' and minimalist styles that were good-looking and moderately priced. The large-scale production of attractive, reasonably priced clothes emerged as megabrands.

Traditionally, apparel manufacturers had produced several lines and retailers could reorder styles that were successful. In the trend toward greater economy, megabrand manufacturers produced an initial output that included several styles to be retailed at moderate prices. These, however, could not be reordered. To insure that their output would sell, design houses hired stylists to help create new lines that would respond to emerging consumer preferences. The stylists scouted the streets and clubs to identify new trends. Their influence on new styles emphasized comfort and fun, and some stylists developed into designers. In 1999 about 100 designers—more than ever before—participated in the fashion show '7th-On-Sixth,' organized by the Council of Fashion Designers of America.

4.2 European Fashion

In Europe, the quality of fabric and the integrity of design are paramount. The fashion elite decides on the desirable styles and these styles are found in most stores. The demand for clothing is met by machine-made clothes on a smaller scale than in the United States, and by custom tailoring and dressmaking.

A powerful trade group, Chambre Syndicale de la Couture Parisienne, sets the standards for couture fashion. It holds the right to designate who can be called a couturier, the highest 'occupational' category in the production of fashion for the elite. In the year 2000 only 14 design houses held the title of couturier, which accords social rewards. Although each design house has its own unique style, each is able to draw the audience in, envelop it, and infuse the air with a sense of awe. The trade group is thus the guardian of the expectation that fashion will be an aesthetic experience.

In the 1980s, male and female and European and non-European designers demanded a voice in the production of fashion. Joining together to present their own designs, they formed an international fashion circuit and presented their ideas at fashion shows in Paris, Milan, London, and New York. By the early 1990s there were over 1,500 major showings on the fashion calendar in Paris. The styles they created departed from the traditional criteria of beauty and expressed their own personal experience within a particular cultural milieu. The fashion shows became media events where designers and their sponsors seemed to outdo each other with 'seminude costumes, strange hair and makeup, and gimmicky staging' (Agins 1999, p. 37). TV cameras joined in capturing runway footage for news programs.

Their seemingly 'wild and crazy' fashions conveyed several themes. The *grunge* and the '*heroine chic*' styles reflected the *malaise* that characterized the period. The *seminude costumes and strange hair* told of the need to *restructure gender and sexual arrangements*; the *gimmicky staging* reflected *the split between work and play* that governs everyday life. The fashions presented on the international circuit addressed the problems experienced in contemporary society.

The history of the Western world had been marked by centralized control over clothing and appearance. In the twentieth century these strictures loosened significantly. As a result, fashion evolved to give people of all social classes more opportunities for expression of personal preference in clothing and fashion than ever before.

Drinking, Anthropology of

Since at least the 1940s, alcohol has been the focus of a growing interdisciplinary cadre of researchers. Some have proposed 'alcohology' as an academic discipline of its own (Heath 1987, p. 100). Anthropological data and viewpoints have played a part from the start. Their influence has perhaps been greater than expected, considering the limited number of professional anthropologists involved. The first appeal for anthropological studies of drug dependence came from Edward Glover (1932), a leading British psychoanalyst who needed data for psychoanalytic theory. Ruth Bunzel (1940) offered an early response.

The scrutiny of social and cultural aspects of alcohol consumption can be seen as anthropological in the sense that it benefits from comparison between societies. The most ambitious endeavor is still that of Donald Horton; in his own words, 'an experiment in scientific method' (Horton 1943, p. 202). He examined anthropological statements on drinking from 77 'primitive' societies and concluded that the primary function of alcohol is to reduce human anxiety and fear, a view that has been questioned by later scientists. Horton's aim was to study the 'functions' of alcohol as a starting point for a psychocultural theory. The available data were, however, of varied character and quality. The lack of systematic descriptions of ordinary drinking prevented useful conclusions.

It has been an anthropological aim to focus on relatively small and homogeneous groups and there to indicate the social and cultural structures encompassing and supporting the patterns of drinking. Ethnographic analyses show rich variation in the use of alcohol in the multitude of cultural contexts. Neither the use of alcohol nor its effects and consequences are universal, or in any way anchored in inherent properties of alcohol, or in 'human nature,' or in 'male nature'—for a long time women were not made particularly visible in the literature on drinking, although times are now changing (see, for example, Gefou-Madianou 1992).

A complex, diverse and often paradoxical pattern of belief and behavior has come to surround a simple chemical product. Alcohol is simultaneously considered a stimulant and a sedative, both food and poison. It has a close connection to religious practice, though drinking is often characterized as 'diabolic.' A great many phenomena, from the most positive to the most negative, have been attributed to the use of alcohol, although most people are well acquainted with its allegedly negative effects on human behavior.

1. *Fusing the Symbol*

It is not strange that alcohol holds a special position in human life. Its influence on motor activity and its gradual effect on human consciousness are sufficiently dramatic as a 'sign' that alcohol is something out of the ordinary. Reports from other cultures often repeat that the purpose of drinking is to achieve drunkenness, sometimes to the extent of unconsciousness.

Bunzel (1940, p. 384) notes that the Chamula 'drink for pleasure—direct somatic pleasure of warmth, relaxation and deep untroubled sleep,' a sequence comparable to what Radó (1957) calls 'alimentary orgasm' She declares that alcohol has replaced all other forms of aesthetic expression: 'People are too engrossed in drinking to develop the arts of life. Commitment to one form of gratification has blotted out every other possibility' (Bunzel 1940, p. 385). Bunzel's use of 'commitment' brings up the human ability to fuse, under certain circumstances, with a symbol, a phenomenon that could cause everything else to seem of little importance.

The unique position of alcohol—despite a simple and natural origin—easily identifies it as symbol. As symbol, alcohol has the quality of allowing or even calling upon *fusion* with its human imbibers. The description of a symbol is certainly poor and empty if severed from the human experience for which the symbol is crucial.

The basis of the argument is the possible relationship of commitment between man and symbol. Intoxication through alcohol may be seen as a relation of symbolic commitment. This also implies that the inebriated *use* this possibility for some purpose, for instance to get an outlet for thoughts and feelings otherwise not permitted, or perhaps just hard to express. Commitment to a symbol does not imply cultural consensus. All those committed, even if enjoying social consensus, need not agree on the meaning of drinking. Drunkenness, like religious experience, is abstract in relation to its content.

2. *Alcohol as Ornament*

In a relatively early interpretation, Harold Fallding (1964) places drinking in a wide civilizational context. Civilization, he suggests, may be understood as 'the dignifying of human existence through adornment.'

Human beings—at any cultural level—always use a 'surplus to devise need-gratifications not strictly related to survival' (Fallding 1964, p. 714). Alcohol is such a surplus, such an ornament. Men might be enslaved by excessive devotedness to their ornaments, a main predicament and principle of fetishism. Men, growing dependent on things they have unnecessarily produced themselves, are degraded by their own invented rubbish.

Fallding deprives alcohol of its demonical and divine disguise and exposes it as a dead thing, unnecessary for human existence. In the same breath alcohol is rehabilitated to only *one legitimate function* in society: as symbol for a necessary community. Community is indispensable for the trust which humankind cannot do without for its common survival, its common production.

Fostering of community keeps the 'fount of trust open in the midst of the garden of civilization' (Fallding 1964, p. 714). Trust must be maintained despite society's acceleration in numbers and specialization. Production will develop only if reciprocal trust is there. To the extent that drinking symbolizes an *existing* community it represents 'the most precious support men can experience' (Fallding 1964, p. 717).

The occurrence of intoxication may offer a specific experience of community. To share a drunken moment could produce a feeling of trust and a touch of being a participant in something potentially dangerous. The individual feeling unsafe, or with a position to defend, may disallow himself from becoming intoxicated, even if drinking.

The 'ornamental, community-symbolic drinking' suggests an already existing community. If this drinking appears to be rare in modern society, it might indicate a decline of community. Community and trust must in that case be restored first, since 'nothing could be less sufficient for the genesis of community than to supply the materials by which it could be symbolized, if present' (Fallding 1964, p. 719).

3. *Drinking as a Problem*

Mutual drinking can contribute to the maintenance of social structure. Harriet Kupferer observes that studies asserting that 'drinking together enhances social solidarity and increases sociability' (Kupferer 1979, p. 198) obviously take their starting point in Durkheim and Radcliffe-Brown. Mary Douglas (1987), however, warns that the literature might overemphasize the idea of community as an answer to alcohol problems. Authority, ritual, and solidarity—on a foundation of community and trust—certainly seem to bring the drinking under control. But sometimes the community is aggressively competitive. The drinker following norms in such company risks his health.

It is however necessary, not least in the anthropological context, to distinguish between addiction and the 'nonpathological heavy indulgence in drinking' (Jellinek 1941, p. 777) of which the Bolivian Camba is a good example (Heath 1962). Horton reminds us that 'primitive peoples' are unaware of alcohol 'problems' (Horton 1943, p. 200). They just know that some of their beverages produce certain characteristic sensations and behaviors. Bales (1946) also emphasizes the need to avoid the confusion between the extent to which alcohol is *used* in a given culture and the extent to which alcohol causes problems in that culture.

Comparing Jewish and Irish Americans, Bales presents an illustration to the fact that differences in cultural context influence the incidence of alcohol problems. He suggests that despite the fact that practically all Jews drink some kind of alcoholic drink every week, the number of alcoholic Jews is small (Bales 1946, p. 480). Snyder observes that Orthodox Judaism, as a normative and cultural system, seems to have restrictive influences on its members. 'But this effect may depend in the long run upon the continuing participation of Jews in the ceremonial and ritual activities of the traditional religious community' (Bales 1946, p. 112).

Alcohol abuse among Jews in New York is thought not to depend on their assimilation into American norms of consumption, but rather on their distance from traditional Orthodoxy and from ceremonial participation renewing solidarity and moral authority. Catholicism and Protestantism offer no similar ritual control of personal behavior. The priests advocate soberness or moderation but are as a rule isolated from popular drinking. Church ceremonies do not incorporate drinking other than the Communion.

Kunitz et al. discuss notable differences between Navaho and Hopi in the incidence of cirrhosis (Kunitz et al. 1971). Drinking is customary among both groups, but patterns differ. The authors suggest that drinking in Navaho society is a 'normal pursuit of young men and tends to be outgrown' (Kunitz et al. 1971, p. 715). The individual who drinks is not expelled from the community except in rare cases. Higher prevalence of cirrhosis near the border towns might be a consequence of a freer access to alcohol, and some might develop cirrhosis before they outgrow their drinking. 'Many of those currently abstaining had been very heavy drinkers previously and some no doubt would have been diagnosed as alcoholics. Nevertheless, they stopped drinking with relative ease and without the problems commonly reported by Anglo alcoholics' (Kunitz et al. 1971, p. 716).

The fact that the Navaho drinkers are not sent away from the community, and are not isolated, seems to allow them a kind of shelter. The Navaho possibly retain a traditional pattern for drinking immoderately when there is alcohol. They appear not to see self-control as a social value in the same way as the Hopi do. The Hopi situation is thus different. The Hopi way has emphasized harmony and peace and avoided

'acting out.' The traditional method of social control has included gossip, witchcraft allegations, and final expulsion from the community. As a result the drinker may become isolated and released from restraint.

Differing fatality rates as a result of cirrhosis could depend on the Navaho pattern of heavy drinking at an early age, which is abandoned so early in life that cirrhosis, if it occurs, is reversible. The Hopi pattern, on the other hand, might lead the individual ejected from the community to become isolated, and to continue drinking until illness becomes fatal.

4. *Alcohol and Health*

Some of the value of anthropological study on alcohol lies in the way it contrasts with the segmentation that is otherwise characteristic of alcohol research: there are inquiries into alcohol and violence, alcohol and traffic, alcohol and health, and so forth. Anthropology instead cherishes the idea of studying alcohol in its full social and cultural setting, and anthropologists therefore have a perspective on drinking activities grounded in fieldwork. They do not necessarily treat alcohol as a problem, and seem to find that medicine and sociology may be inclined to some exaggeration in this regard. 'Even in the United States where there is so much concern about alcohol abuse, the most pessimistic estimate is that alcohol-related troubles afflict fewer than 10 percent of those who drink' (Douglas 1987, p. 3).

The anthropological approach challenges the assertion that drinking leads to anomie. It is rather anomie that leads to alcoholism, and the anthropologists are of course ready, adds Douglas, to confront the theoretical problems of the anomie concept. Nor do they find any clear relation between drinking and disposition to aggressiveness and lawbreaking, and they question the idea of drunken misbehavior as an example of alcohol's capacity to slacken cultural restrictions.

An anthropologist focusing on alcohol abuse probably will conclude that the most efficient way to control misuse is through socialization. But there is no way to stipulate 'a cultural level of tolerance for alcohol' against which questions implied in a cultural approach could be asked: 'Do cultural constraints dictating a restricted framework for drinking enable more individuals to absorb more alcohol with less apparent physical effect? Does cultural training which enables individuals to hold their drink more easily protect their livers from damage? Most likely not. Does the individual breaking out of a set of cultural constraints drink more deeply and more dangerously than one whose heavy drinking is culturally expected and approved? What difference does the surrounding culture's attitude to drunkenness make to the prospects of an addict's cure?' (Douglas 1987, p. 5).

Gender differences in alcohol use may imply a greater freedom for men, and contribute to men's collective construction of 'real masculine identities' (Gefou-Madianou 1992, p. 11); a prerogative possibly counterbalanced by women's avoidance of an obvious health risk and conspicuous capacity for 'getting drunk' on conviviality (Gefou-Madianou 1992, p. 15). A pessimistic prediction, not without empirical evidence, is that females will catch up with males primarily in what Fallding characterizes as drinking in 'protest of distrust against the community' (Fallding 1964, p. 721).

Anthropology has no immediate solution to alcoholic health hazard. It is possible but not proven (or even properly studied) that heavy alcohol consumption is less hazardous to health if symbolizing community than if in protest against exclusion. Most people drink alcohol without suffering in any observable way. That reservation is important. The causal connection supposedly established between drinking and illness is not easily confirmed or refuted in the anthropological field, although anthropology, back from field, may profitably 'meet' other branches of learning (Demers et al. 1996).

A fundamental contribution from the anthropological quarter could be the statement that studies from the biomedical or the cultural sphere, as well as true interdisciplinary attempts (Lucia 1963) and consensual policy efforts (Edwards 1994)—though welcome for furthering a deeper understanding of alcohol use—may not provide a solution to the drinking problem. The solution will not come about by way of any research program, but rather, if at all, as the result of a major cultural achievement.

Drug Addiction

1. Drug Addiction

Drug abuse and addiction are among the largest and most challenging problems facing society today. Scientific advances over the past twenty-five years have greatly contributed to our understanding of drug abuse and addiction. We now know that drug abuse is a preventable behavior and that drug addiction is, fundamentally, a treatable chronic, relapsing disease of the brain. We also now have tremendously detailed knowledge of what drugs actually do to an individual's brain and behavior. For example, it is known that drugs work by attaching themselves to a particular class of proteins called receptors. Many different proteins can serve as receptors for drugs. Scientists have identified and cloned the receptors in the brain for every major drug of abuse. They have identified the cellular sites where drugs like cocaine, marijuana, nicotine, and opiates bind to the brain. For example, in the case of cocaine and methamphetamine, they have recognized the dopamine re-uptake transporter as a major site of action. Researchers have not only discovered specific brain circuits involved in drug experiences, like euphoria, but the processes of addiction and drug withdrawal as well. Research also shows that addiction occurs as a result of the prolonged effects of abusable drugs on the brain—and that addiction results in a brain that is changed both structurally and functionally.

2. Why People Take Drugs

To fully understand the phenomenon of addiction, we need to have a thorough understanding of why people take drugs in the first place. Although we know some of the initial reasons why people take drugs—to modify their mood, perception, emotional state, or to self-medicate in an effort to cope with their problems—no one single underlying factor determines which individuals are more or less likely to abuse drugs and which will later become addicted to drugs. An individual's vulnerability to becoming addicted to drugs is dependent on a number of complex factors, including a variety of genetic, biological, emotional, cognitive, and social risk factors.

Researchers have identified many of the risk factors that increase the probability that someone will develop drug problems. These factors can be found at the individual, the family, peer group, and at the broader community level. Researchers have also identified many of the protective or resiliency factors that protect individuals from developing drug-related problems. An individual's vulnerability to becoming a drug user and later an addict is likely to be due to environmental and genetic factors interacting in some, as yet, unknown way. We also know that regardless of the reason for initial drug use, continued use can lead to neuroadaptation in brain reinforcement circuits.

Clear evidence exists demonstrating that almost all drugs of abuse have effects on brain circuitry involved in the control of motivated and learned behaviors. Although each class of drug may have its own specific mode of action, in tracing the pathways through which a variety of drugs exert their effects; certain commonalities for all drugs of abuse have emerged. This evidence originated from studies in animals (Weiss 1996, Wise and Bozarth 1981) and is being confirmed in humans with recent developments in brain imaging techniques. Anatomically, the brain circuitry principally involved in most of the actions of the major addictive drugs is the reward center or the mesolimbic pathway. This pathway consists of cells (mesolimbic neurons) that originate in the ventral tegmental area (located in the middle of the brain) that terminate and signal other cells in distant brain areas.

These cells (like all neurons) do not actually touch each other but are separated by specialized gaps called synapses. Neurons communicate with each other via chemical messengers referred to as neurotransmitters, which cross the synapses. In the case of mesolimbic neurons, the neurotransmitter used in the communication process is dopamine. It is at the synapse that

drugs of abuse disrupt the normal communication process among neurons. Scientists have found that all drugs of abuse cause an increase in dopamine levels in the brain's reward pathway. Activation of this reward system appears to be a common element in the reinforcement of drug-taking behaviors. Increased dopamine levels are associated with the feelings of euphoria and reward that are often associated with drug use. Researchers are also finding that the dopamine system may help play a role in determining what makes some individuals more susceptible to addiction than others (Volkow et al. 1999). Through the use of neuroimaging, researchers at Brookhaven National Laboratory have found that individuals who have higher densities of dopamine receptors before any drug exposure, report having a pleasant response to a mild stimulant; whereas individuals with lower dopamine 2 receptor levels report having unpleasant responses to the same mild stimulant. These findings are in concurrence with studies in laboratory animals indicating that dopamine receptors mediate reinforcing responses to drugs of abuse. Not only does this finding suggest that an individual's resting brain chemistry may predispose how he or she responds to different drugs of abuse, but it potentially helps to predict who will develop drug problems. The finding also serves as a critical piece of information to help facilitate the development of more effective prevention and treatment approaches.

3. *The Transition from Drug Abuse to the Disease of Addiction*

The fact that addiction is tied to changes in both brain structure and function is what makes it fundamentally a brain disease. For many of the individuals who do not have an initially negative reaction to their first drug-administration, continued repetition of 'voluntary' drug taking begins to change—often undetectably—into compulsive drug taking, ultimately to the point where the behavior is driven by an overwhelming craving for the drug. The compulsion to get and use drugs becomes the most powerful motivator in a person's life. It is at this stage that addiction becomes a chronic disease with relapse and remission. We often make the analogy that a methaphorical switch in the brain is thrown that changes an individual user/abuser into a drug addict. The individual changes from a totally voluntary drug user into a compulsive, often uncontrollable drug user.

Although research has significantly advanced our understanding of the behavioral, biological, and molecular factors which underlie initial drug use and the actual state of addiction, we are lacking a thorough understanding of the mechanisms that are involved to explain what literally occurs when an individual transitions from a voluntary drug user to an addict. We know that the full course of a typical drug use disorder evolves through a whole series of transitions over a period of years that begins with the initial onset of drug use, the maintenance or continuation and eventual escalation of use, movement from one drug class to another, escalation within that drug class, and multiple drug use (in many cases). Typically once treatment is provided, the individual discontinues drug use, but often relapses even after long periods of abstinence (Glantz and Hartel 1999). Although this is a frequent pattern for this chronic relapsing disease, we do not know if the changes in the brain are in fact gradual or precipitous in nature. The 'switch' seems to flip at different points for different individuals. That is, for some it may happen slowly or not at all, whereas for others it may happen rapidly. Researchers do know that once the switch is turned on and the individual becomes addicted, it is extremely difficult for most people to stop using drugs without treatment. Understanding this transition is a major area of investigation for researchers.

4. *Long-lasting Changes in the Brain*

Studies in both humans and animals have demonstrated that chronic drug use changes the brain in fundamental ways that persist long after the individual has stopped taking drugs. This addicted brain is different from the nonaddicted brain, as manifested by changes in brain metabolic activity, receptor availability, gene expression, and responsiveness to environmental cues. These induced changes are responsible for the uncontrollable, compulsive drug-seeking and use—that are the essence of addiction. How long these brain changes last is just now being determined. Some of these long-lasting effects may also affect an individual's emotional responses and his or her learning and memory capacity. One of the most recent examples can be seen with the drug methylenedioxymethamphetamine (MDMA) or 'Ecstasy.' MDMA is being used increasingly by teens and young adults who attend organized all night social gatherings or 'raves.' Chronic use of MDMA has recently been found to produce long-term damage to serotonin-containing neurons in the human brain. The neurotoxic effects of this drug have long been known in animals, but now we are seeing its damaging effects in humans as well. Given the important role that the neurotransmitter serotonin plays in regulating emotion, memory, sleep, pain, and higher order cognitive processes, it is easy to see how MDMA use can impair ones memory; and probably generate other behavioral consequences as well (McCann et al. 1998). MDMA can decrease an individual's ability to remove this important neurotransmitter from the synapse, thereby amplifying its effects within the brain. This effect lasts at least three weeks after the individual has stopped using Ecstasy.

Given serotonin's critical role in many behaviors, one can speculate that this change in the serotonin system might be responsible for some of Ecstasy's long-lasting behavioral effects.

5. *Reversing or Compensating for Brain Changes Through Treatment*

Given that the brain fundamentally changes when an individual becomes addicted to drugs, preventing the initial use of drugs is of course the best treatment for preventing a lifetime of drug problems (National Institute on Drug Abuse 1997). If, however, the compulsion to use drugs takes over an individual's life, treatments are available that can help an individual to stop using drugs and maintain a drug-free lifestyle. Many of today's behavioral and pharmacological treatments for addiction can reverse or compensate for the brain changes that occur during prolonged drug use. Given that these changes in brain function do not occur in isolation, and are in fact interacting with environmental factors such as stress and situational triggers as well (O'Brien 1997) addiction is never simple to treat. It is often these external factors that cause an individual to relapse to drug use, even after successful treatment. Researches are working to determine what treatments work best for individuals who are likely to be affected by these environmental factors. Given that the ultimate goal of treatment is to return the individual back to a functioning member of society, it is critical that individuals can cope with these factors without relapsing to drug use.

Just as addiction affects all aspects of a person's life, his or her treatment program must address the 'whole person.' It must address not only the individual's drug use, but also provide him or her with the tools necessary for maintaining a drug-free lifestyle, while also helping with the achievement of productive functioning in the family, at work, and in society. Because addiction is so complex, and can impact so many aspects of the patient's life, effective treatment programs typically must incorporate many components, each directed at a particular aspect of the illness and its consequences.

Fortunately, as with other illnesses, drug abuse professionals have at their disposal an array of useful tools to treat addicted individuals, though admittedly not enough. Treatments vary depending on the characteristics of the patient and the type of drug to which they are addicted. Treatment can include behavioral therapy, medications, or their combination. The best programs provide a combination of therapies and other services to meet the needs of the individual patient, which are shaped by such issues as age, race, culture, sexual orientation, gender, pregnancy, parenting, housing, and employment, as well as physical and sexual abuse (National Institute on Drug Abuse 1999).

Maintenance treatments such as methadone and LAAM (levo-alpha-acetyl-methadol) exist for treating heroin addiction; psychoactive medications such as antidepressants can be particularly useful when patients suffer from a co-occurring mental disorder; and notable behavioral interventions, such as cognitive behavioral therapies and contingency management, can be used effectively to treat both adults and adolescents. Another effective medication for treating some opiate patients, especially those with co-occurring alcohol dependence problems is Naltrexone. For persons addicted to nicotine, nicotine replacement products (such as patch, gum, or nasal spray) or an oral medication (such as bupropion) can be an effective component of treatment.

It bears repeating that the commonly held misperception that two of the most effective medications for treating heroin addiction—methadone and LAAM—are simply substitutes for heroin is wrong. Instead of destabilizing the individual, as heroin does, methadone and LAAM stabilize the patient and facilitate a return to productive functioning (Ball and Ross 1991). It is also important to note that detoxification itself is not a form of drug treatment. At best, detoxification is a first step in beginning treatment, but by itself does little to affect long-term drug use.

Research studies have repeatedly demonstrated that addiction is eminently treatable and is comparable with the results found with other chronic disorders such as diabetes or asthma (O'Brien and McLellan 1996). Drug addiction treatment reduces drug use by up to 60 percent and has been shown to be effective in reducing the spread of HIV, diminishing the health and social costs that result from addiction, and decreasing criminal behavior (Hubbard et al. 1997).

6. *Conclusion*

Although the onset of addiction begins with the voluntary act of taking drugs, the continued repetition of voluntary drug taking begins to change into involuntary drug taking, ultimately to the point that a compulsive craving for the drug drives behavior. This compulsion results from a combination of factors, including in a large part, the dramatic changes in brain function produced by prolonged drug use. This phenomena explains why addiction is considered a brain disease—one with embedded behavioral and social aspects (O'Brien 1997, Leshner 1997). Once addicted it is almost impossible for most people to stop the spiraling of addiction on their own without treatment. Fortunately there are quite a number of effective treatments available to manage addiction.

Drug Addiction: Sociological Aspects

The main aim of this article is to understand how sociology has considered the recent social phenomenon of drug addiction. This article will not deal with all the areas concerned with drug problems, notably crime and criminal justice (see Weisheit 1990) or drug control policies (see e.g., Musto 1987) that have become legitimate topics for social scientists. It will relate the history of the principal sociological theories concerning drug addiction. In turn, it will discuss the respective concerns and impact of these theories, as well as their contributions and failures in understanding this type of deviant behavior.

1. *Medical Definitions*

First, it is necessary to define the terminology. Generally speaking, a drug (heroin, crack, ecstasy, cannabis, cocaine, alcohol, or psychoactive medicines) is either a natural or a synthetic substance that can alter the mind and influence mood behavior and perception. But common points of view and modern Western law generally consider drugs to be only those psychotropic substances that are illegal and that can lead to addiction. The concept of addiction remains very controversial and troublesome (Akers 1991), but physicians usually define drug addiction as a personal inclination to use drugs that can provoke dependence. From this medical point of view, drug addicts experience at least one of two kinds of dependence: (a) a physical dependence characterized by withdrawal symptoms that follow abstinence from drug use; (b) a psychological dependence that manifests itself by a strong desire to continue using drugs. But this medical definition does not offer any information and knowledge about what sociology is actually concerned with: the social dimension of the drug user's experience.

2. *The Recent Development of Drug Uses*

People have always used drugs for medical, religious, and artistic purposes (opium was used in Babylon), and those uses have long been culturally regulated and socially integrated in all kinds of traditional rituals (Escohotado 1998, Knipe 1995). But in the middle of the nineteenth century, some drugs formerly used as medicines came to be regarded as dangerous (Bachmann and Coppel 1989, Yvorel 1992): Abuse of certain substances gradually became regarded as pathological. The medical concept and the term 'drug addiction' appeared at the end of the nineteenth century (the term 'alcoholism' was invented by Magnus Huss around 1850), but in those times drug addiction was restricted to only a few soldiers

and officers in the colonies, artists, and some physicians who had experimented with these substances on themselves. Both the use of drugs and of the term 'drug addiction' became more widespread in the 1920s (Bachmann and Coppel 1989), and the stereotypes according to which 'drugs are a demon, leading to social and moral misery,' 'drug addicts' behavior is completely irrational,' 'drug addiction is an epidemic disease,' etc., started to spread in Western countries.

Sociological research began to consider drug addiction as a legitimate object when drug use became very widespread in Western countries at the beginning of the 1950s. Indeed, in the 1950s in the USA and from the early 1960s in Europe, drug use and abuse developed considerably and behaviors appeared not to be as socially and culturally patterned as they were previously considered: chronic and massive individual use started to spread in slum neighborhoods. For that reason, drug addiction was soon viewed as a kind of deviance, and not surprisingly, sociological theories concerning drug addiction, drug experiences, and drug addicts emerged from the sociology of deviance, at least at the beginning: The theoretical issues were then quite similar to those existing in this older sociological field. Apart from the diversity of the results of these studies, they almost all contributed, willingly or not, to the denial of commonly held beliefs and the contradiction of medical conceptions (see e.g., the causal theory developed by Dole and Nyswander 1967 about opiate addiction as metabolic disease) and psychological reasoning (see e.g., the psychoanalytic points of view of the French specialists Bergeret and Fain 1981 which considers drug addiction as basically determined by traumas which have occurred during childhood). All the more so since these points of view quickly dominated the discourse on drug care policies. Indeed, research in social sciences about drug addiction was a lot less developed than biomedical and epidemiological studies (Berridge 1988, Ogien 1992).

3. *Ethnography and Sociology of Drug Use and Addiction*

The theoretical perspective of most of the sociological research of the 1950s and 1960s was heavily grounded in symbolic interaction, labeling, and role theory. An exception is the theory of Cloward and Ohlin (1960), inspired by the work of Finestone (1957), in which drug addiction is considered to be an extreme case of 'retreatism adaptation' (known as the 'double failure' hypothesis), emphasized by the functionalist theory of anomie by Merton (1949) and which attempts to discover a social causality for drug use. After having criticized the perspective of theories (Cloward and Ohlin, Merton) that are primarily concerned with social structure, and having distanced themselves from social psychological research (Jessor and Jessor 1977, Kandel 1980) which tries to discover the etiology of drug addiction in individual dispositions and in the immediate social context of the individual, most of these works focused on the mechanisms of social control (Becker 1963), but above all, on social aspects of drug use and drug addiction experiences as well as on the lifestyles of drug users and addicts (Ogien 1992).

Though now much criticized (McAuliffe and Gordon 1974, Stephens 1991), the first and most famous of these studies are certainly those of Lindesmith (1938, 1947, 1968), instigated by Herbert Blumer of the Chicago School of sociology: After having intensively interviewed about 60 heroin addicts, he concluded that if drug addicts keep on taking opiates, it is not in search of euphoria but to counter the pain suffered by withdrawal. From this perspective, he pointed out, as Becker (1953, 1963, 1967) did later on, the fact that to become addicted, one has to recognize the effects of the drug and to associate these effects with it. Becoming a drug addict is a learning process in group interaction, by which, in contradiction to the ideas of many, the pharmacological properties of the drug are not sufficient in themselves. Thus, Lindesmith suggested, to be an opiate addict, one has (a) to recognize withdrawal symptoms as resulting from abstinence and (b) to take drugs again conscientiously in order to neutralize those symptoms. This theory explains the well-known fact according to which a large number of people who have been prescribed opiates for medical reasons do not become addicted: They would associate the withdrawal symptoms with tiredness or another pathological cause.

Yet another set of studies, a little later, greatly contributed to the understanding of the social conditions of the lives of many drugs users and addicts and helped change common misperceptions about drug addiction. The well-known survey of Preble and Casey (1969) thus depicted drug addicts 'taking care of business' as 'compulsive hardworking business executives,' harassed with many intensive activities (find the dealer, get good dope, avoid the police, etc.) in which the moment of euphoria following absorption is very brief. Another study by Feldman (1968, 1973) conducted in the Lower East Side of New York argued that using heroin can be a means of obtaining the highest status in the street hierarchy (to be a 'stand-up cat' and to avoid being considered a 'chicken,' 'punk,' 'square,' or 'faggot'), and thus ruled out the thesis, described by Cloward and Ohlin, of drug addiction as a retreat strategy (see also Lindesmith and Gagnon 1964). Both studies seem to prove that many drug addicts can manage organized activities and the pursuit of an eventful life (see Adler 1985, Cusson 1998, Johnson et al. 1985, Williams 1989 on user–sellers and drug dealers' activities), and that for these reasons drug addiction cannot be regarded as a way of escaping reality. These studies also suggest that drug addicts are not so different from other social actors, in

that they have to maintain lasting social relationships and develop all kinds of skills and competences (hustling, avoiding getting caught by police, finding a trustworthy dealer, learning how to administer drugs, etc.) to survive in the street and to cope with their passion. For Stephens (1991), street addicts from the inner cities of US large urban areas, in fact, adopt a singular lifestyle which certainly contains many disadvantages but which may give dignity and a sense of belonging to them, while also being full of excitement. Concerning this last point, many studies (see e.g., Johnson et al. 1990) point out that some drug addicts (especially those who are also engaged in drug-dealing and can thus afford a lifestyle that they would not have if working in the legal economy, see Adler 1985), are as much addicted to the lifestyle linked to drug consumption as to the drugs themselves.

Moreover, analysis of the data not only sheds light on the social conditions of drug addicts' lives, but also proves that there are many users who do not necessarily become addicted and go downhill. After having demonstrated that some drug addicts could terminate their addiction and easily achieve abstinence by changing context (such as soldiers in Vietnam who abused heroin but quit it once they returned to the USA), Zinberg (1974), in a very important book, and also Castel and Coppel (1991), have offered evidence that many chronic drug users can continue to have a normal social life while using very addictive drugs such as heroin. Consumption can not only be self-controlled but also regulated in all kind of rituals, and addicts usually learn what is socially acceptable in terms of quantity, frequency, and behavior while consuming drugs (see also the study by Zimmerman and Wieder 1977, which describes how marijuana use in groups is a socially regulated practice); in fact, many regular drug users appear to be able to control their consumption and to remain mild habitual users, and can interrupt their habit for months or years. Finally, drug addiction, these studies suggest, would characterize the situation only of those who have lost control of their habit: becoming a 'greasy dope fiend' is not the destiny of every user. Other well-known studies (Biernacki 1986, Hanson et al. 1985) have come to similar conclusions: There are many regular users unknown to the police, judicial, or hospital authorities (the 'hidden populations') and among whom many belong to the middle class (Granfield and Cloud 1996). These individuals are capable of not becoming addicted and can manage the fact that they are participating both in the world of normality and the world of delinquency or criminality. But these studies also reveal that drug addicts do not necessarily become delinquent (Biernacki 1986), and that the causality between drug addiction and delinquency is not so obvious. Many studies (for a synthesis see Jobart and Fillieule 1999) wish thus to prove that delinquency, for a lot of people, precedes drug use and that drug use has only intensified an old practice of delinquency. But they also explain why the commonly held belief according to which drug use causes delinquency and crime is so widespread: One of the reasons could be the fact that police officers usually arrest drug addicts who are not successful at delinquent activities because they were not socialized in such a culture and social context. As a result, most of the police statistics accredit the idea that drug addiction is a cause of delinquency (Jobart and Fillieule 1999).

More recently, a great deal of work has tried to consider the reasons why individuals first try drugs, become and remain addicted but above all, achieve abstinence. This last entry point (cessation stage) is an interesting one because biological, social pathologies, or psychological theories have difficulty in explaining why many addicts stop using drugs. This type of sociological research takes from interactionism the concept of career, adopts a more rationalist view on the behavior of the addict, is more focused on decision making and choice of the actors. It has certainly produced results that contradict conventional wisdom but also medical, social psychological, and psychological perspectives like psychoanalysis, for instance, which considers drug addicts as basically determined by unconscious psychic forces (Bergeron 1999) and has never taken seriously addicts' reasons for their behavior. Taking into account the fact pointed out by many epidemiological surveys according to which most heroin addicts are free of heroin when they are 35 years old, Castel (1994, 1998), Ogien (1994), inspired by the research of Stimson and Oppenheimer (1985), and also Bennett (1986) and Stephens (1991) have tried to discover the reasons for quitting drugs (e.g., the expense; marriage, social, and medical risks; end of euphoria; experience of violence; imprisonment, etc.). Here they demonstrate that drug addicts have to build or rebuild social networks that can help them on the road to a drug-free life and that many of them can achieve abstinence by themselves (Waldorf and Biernacki 1981), without any professional or medical help. In this perspective, drug addiction is not, as Biernacki (1986) showed, untreatable: It is not a fatal sickness, and the phrase 'Once an addict, always an addict' is no longer relevant.

4. *Conclusion*

Finally, all these studies have tried to destroy both the psychological predisposition theory (psychologically damaged individual) and the social structural weakness of 'poor suburbs' theory and have succeeded in drawing a more complex and diversified image of reality concerning drug addicts and drug experiences. They, of course, do not deny the fact that drug addiction remains for many people a terrible experience, but at the same time they offer evidence that drug addicts are not all doomed to go downhill, that the pharmaceutical properties are not sufficient to

make somebody become an addict, that drug addiction is a learning process in association with others, in which one has to learn how to use drugs and to appreciate their effects, that some can control their consumption even while using very addictive drugs, that drug addiction can be a lifestyle that is chosen by people adopting the role appropriate to this way of life, etc. There is no longer any reason for the exclusive domination of the 'sickness model' (Stephens 1991) in the way societies respond to the drug addiction phenomenon. In this perspective, sociology and political science have studied state reaction to such a social problem and helped discover which models and values determine the public policies of each Western country. Most of the researchers have thus tried to discover specificities of national drug-care policies (see e.g., Bergeron 1999, Cattacin et al. 1996, *Déviance et Société* 1999, Tham 1995), and the conclusion has been the same: Drug control and drug care policies of Western countries are now interdependent and it will be more and more difficult to maintain autonomous views and solutions on this issue (Albrecht and Van Kalmthout 1989). In addition, many sociologists, like Ehrenberg (1998), argue that the now old-fashioned barriers between alcohol, illicit drugs, and psychotropic medicines must be abolished: public health authorities should pay more attention to the way people use a wide range of psychotropic products, legal or illegal, in our modern societies. It is thus clear that policies in Western countries toward addiction problems have to take these research results into account.

Drug Use and Abuse: Cultural Concerns

In popular and scientific publications, addiction is often referred to as a chronic, relapsing disorder. In support of this claim, individuals who obtain treatment for alcoholism, drug addiction, and smoking more often than not relapse (Thombs 1994). However, if the population of addicts is expanded to include those who do not seek treatment a different picture emerges. Most addicts recover. More generally, when the study of addiction includes epidemiological, ethnographic, and experimental research, as well as clinic studies, the image of the addict as a victim of drug cravings becomes difficult to support. In its stead emerges a more complicated picture in which cravings are but one of several competing influences on drug consumption, and addicts actively choose whether or not to continue using drugs. For instance, the state of being addicted, although debilitating, does not preclude the salutary influences of nondrug activities and goals, such as employment, new relationships, and the desire to be a positive influence on others. A woman who was a regular cocaine user for 16 years describes quitting in terms of economics and parenting (Waldorf et al. 1991, p. 202): 'Oh, for a time my nose opened up when I went out partying and drinking, but I learned how to handle it…Once I stopped selling, I didn't have the money to buy it anymore. I would have literally had to say, "Sorry girls [her daughters], you don't eat this week" to buy some.' This article will flesh out these introductory remarks, focusing on three issues: the criteria for distinguishing drug use from drug abuse, the correlates of addiction, including pharmacological, social, and individual factors, and the correlates of recovery.

1. *Terminology: Substance Dependence, Abuse, and Use*

On the basis of a series of collaborative research projects (e.g., Spitzer et al. 1979), clinicians have crafted a set of diagnostic criteria that reliably distinguish three levels of drug use: 'substance dependence,' 'abuse,' and social or recreational use. An important consequence of this advance in terminology is that the results from different studies can be meaningfully compared, thereby setting the stage for a cumulative science of drug use and addiction.

According to the diagnostic manual of the American Psychiatric Association (1994), the 'essential feature' of *drug dependence* 'is a cluster of cognitive, behavioral, and physiological symptoms indicating that the individual continues use of the substance despite significant substance-related problems.' The physiological symptoms include tolerance and withdrawal. The cognitive-behavioral symptoms include taking the substance in larger amounts than was intended, a persistent desire to curtail drug use, increases in time spent in drug-related activity, and drug-related failures in fulfilling obligations at work and at home. In other words, the technical term 'substance dependence' replaces the more commonly used term 'addiction.'

Substance abuse is similar to dependence in that the central feature is continued use despite adverse consequences. However, other aspects of dependence, such as tolerance, withdrawal, and a persistent desire to control drug use, are absent.

Social or recreational drug use is a level of consumption that produces little or no harm. This is often a matter of learning from negative experiences. For example, the APA manual (1994) points out that when social drinkers experience alcohol-related problems, they learn to moderate their future drinking.

The World Health Organization has published a similar set of diagnostic criteria (1992). For instance, in both accounts the key concept is the relationship between drug use and drug-related aversive consequences.

1.1 Earlier Definitions of Substance Dependence

Earlier definitions of substance dependence put more emphasis on tolerance and withdrawal than do the current APA and WHO criteria. This reflects trends in drug use. Until the late 1970s, heroin dependence was the prototypical addiction, and it is characterized by a well defined set of withdrawal symptoms, including spasms ('kicking the habit'), chills, goose bumps ('going cold-turkey'), muscle aches, diarrhea, and agitation. However, in the late 1970s and early 1980s, cocaine use greatly increased. Cocaine leads to many of the same cognitive-behavioral signs of addiction as heroin, but without any obvious withdrawal syndrome. For example, withdrawal from cocaine may elicit dysphoric feelings but it does not produce somatic, flu-like symptoms, as does withdrawal from heroin. Accordingly, the diagnostic significance of withdrawal symptoms has decreased.

1.2 'Addiction' and 'Substance Dependence'

In everyday speech, heavy drug use is usually referred to as 'addiction' not 'substance dependence.' The different terms identify the same patterns of behavior, however 'addiction' has an additional meaning. It implies that drug consumption is involuntary or against one's will. For example, the Oxford English Dictionary defines *drug addiction* as 'a compulsion and need to continue taking a drug as a result of taking it in the past,' and it defines *compulsion* as '[acting according to an] irresistible impulse…' However, the idea that drug dependence entails irresistible urges is not a matter of fact, but a hypothesis that experts do not agree on. For example, experimental, clinical, and autobiographical reports show that addicts learn to resist drug cravings (e.g., Cohen et al. 1971, Waldorf 1983), especially when offered incentives for abstinence. Thus, the prudent course is to use the term 'substance dependence.' Its meaning is restricted to a pattern of behavior that different observers reliably identify, and it does not imply a mechanism as to why drug use persists. (Although 'addiction' is an ambiguous word, it often fits better into sentences. Accordingly, when the word 'addiction' or 'addict' is used in this article, the referent is a pattern of behavior or a drug user who exhibits that pattern of behavior.)

2. Correlates of Drug Abuse

The transition from drug use to abuse depends on the interplay of three factors: characteristics of the drug, the setting, and the individual.

2.1 Pharmacological Impact

The importance of the drug is illustrated by two comparisons. First, although there are scores of highly reinforcing substances and activities, only a few support addiction, and these few are all drugs (with the possible exception of gambling). Second, changes in drug structure or route of administration can markedly influence the likelihood of addiction. For example, opiates were used for thousands of years with little or no mention of the dangers of addiction. However, in China during the eighteenth century, opium dependence became a national problem and the subject of governmental legislation. The key precipitating event was a change in the manner of consumption. The Chinese began smoking opium instead of taking it orally. Smoking increases the rate at which the psychoactive components of opium (e.g., morphine) enter the circulatory system, and this, in turn, greatly increases brain levels of these substances. There are similar stories for alcohol (the development of distillation), tobacco (the development of cigarettes), and stimulants (the development of the syringe and smokable forms). In each case, increasing the rate and magnitude of the pharmacological effect increased addiction rates.

However, pharmacology was not the only factor in the rise of opiate addiction in China. During the eighteenth century, smoking and opium use were familiar practices in many parts of the world, but only in China did the two combine to produce a significant social problem. Historical studies (e.g., Spence 1975) suggest that members of the bureaucratic classes were especially vulnerable to opiate addiction, and this may have been due to their wealth and available free time.

2.2 A Pharmacological Common Denominator for Dependence?

Much of the research on the pharmacological basis of addiction has been guided by the hypothesis that dopamine, a neurotransmitter that plays a key role in

reward and motor activity, is an essential component of the biology of addiction (e.g., Wise and Bozarth 1987). In support of this hypothesis, laboratory studies with animals show that self-administration of addictive drugs increases the availability of dopamine in areas of the brain that play an important role in motivated behavior, and, conversely, drugs that block dopamine receptors decrease or eliminate drug self-administration in animals. However, other laboratory findings indicate that it is too simplistic to equate addiction with dopamine. For instance, many non-addictive consummatory activities are associated with increases in brain dopamine levels, and in a series of recent experiments, mice self-administered cocaine even though they were missing the protein that mediates cocaine's ability to increase dopamine levels (Caine 1998). Thus, increases in brain dopamine levels are not a sufficient condition for drug dependence or a necessary consequence of drug self-administration.

Although there may not be a common receptor-level event for different addictions, there are common drug-related behavioral effects (Heyman 2001). These include rapid onset of action, few if any inhibiting mechanisms for self-administration (e.g., drugs do not satiate), intoxication (except for cigarettes), and the capacity to undermine the ability to engage in competing, nondrug related activities. For example, intoxication and withdrawal symptoms interfere with most work responsibilities and social conventions.

2.3 Setting

Interviews and questionnaires provide much of the information on the influence of setting on drug use. As these research methods depend on self-report, the results may not be valid. However, the literature presents a coherent account of drug use, with different studies producing quantitatively similar outcomes (e.g., compare Anthony and Helzer 1991 with Warner et al. 1995).

One of the strongest cases for the influence of setting on drug consumption is the story of opiate dependence among American soldiers in Vietnam (Robins et al. 1975). In contrast to conditions at home, the men entered a situation in which opiates, including heroin, were widely available, cheap, and largely free of sanctions.

Among the young enlistees, opiate use increased from less than 5 percent to 43 percent. Among those who used just once, about 60 percent became addicted. Among those who used more than four times, about 90 percent became addicted. However, upon return to the United States, dependence rates declined to near their pre-Vietnam levels (from about 20 percent to 1 percent). Even most of those who were regularly injecting heroin while in Vietnam were not dependent on heroin during the three-year period that they participated in the study.

The researchers were able to provide some information about the specific factors that influenced opiate dependence and recovery. Their results suggest that the increase in dependence was largely due to the increased availability of opiates, and that, conversely, the decline in dependence was largely due to the reassertion of negative drug-related consequences. For example, the veterans reported that they knew where to buy heroin—and 50 percent did at least once—but that they quit because of the 'sordid' atmosphere that surrounded its purchase and use, the higher prices, the criticism from relatives and friends, and the possibility of being arrested.

2.4 Individual Differences

Individual differences play an important role in the etiology of substance dependence. For instance, in studies that compare same sex siblings or neighbors, the adolescent with a history of delinquency is significantly more likely to experiment with addictive drugs, especially heroin, and given experimentation, delinquency predicts dependence. However, it is not yet clear which individual traits are most important in relation to drug use and dependence. The following examples were selected as they are intuitively plausible and well established.

2.4.1 Psychiatric comorbidity. In the early 1980s the US National Institutes of Health sponsored a nationwide survey of psychiatric disorders and their correlates in a representative national sample (the Epidemiological Catchment Area study, Robins and Regier 1991). There were approximately 20,000 subjects, and they were evaluated according to the APA criteria for mental disorders. For those with a history of substance dependence or abuse, the expected likelihood of a nondrug related psychiatric disorder was 22 percent (Regier et al., 1990). The observed frequency was more than twice as great, 53 percent. Moreover, the likelihood of additional psychiatric disorders varied with type of drug abuse. For example, it was 65 percent and 76 percent for opiate and cocaine dependence, respectively. These results are consistent with (but do not prove) the ideas that substance dependence is sometimes a form of self-medication (for the underlying psychiatric disorder), and that addicts with psychiatric disorders are less likely to engage in activities that would displace drug use, such as holding a good job.

2.4.2 Individual differences in pharmacological response. There is also evidence of etiologically significant individual differences in the pharmacological response to addictive drugs. For instance, in a long-

itudinal study, the intoxicating effects of alcohol at age 20 predicted the development of alcoholism at age 30 (Schuckit 1994). Surprisingly, the men who reported the lowest intoxication scores were most likely to become alcoholic. The author reasoned that feeling less intoxicated invites heavier drinking.

2.4.3 Is there a genetic basis for some types substance dependence? The discussion of individual differences can be taken one step further. In general, individual differences reflect both genetic and experiential factors. Thus, there may be a genetic predisposition for substance dependence. This has been studied in regard to the etiology of alcoholism.

The basic finding is that male children of alcoholic fathers are about four times more likely to become alcoholics than male children of nonalcoholic fathers. Twin and adoption studies show that a significant component of this difference is heritable. For instance, in one frequently cited report (Pickens et al. 1991), the correlation for alcoholism was about 60 percent higher in identical twin boys than in fraternal twin boys (concordance rates of 0.59 and 0.36). The research also shows that the degree of heritability varies according to gender and pattern and level of drinking.

But heritability only specifies the extent to which genes influence the likelihood of the trait of interest. For both clinical and scientific purposes, it would be useful to know the processes that the genes influence. Broadly speaking, the possibilities are direct reactions to alcohol, such as tolerance, or behaviors that indirectly influence drinking, such as impulsivity and delinquency. These are not mutually exclusive outcomes, and the available data support both pathways (Cloninger 1987, Schuckit 1994). Also note that gene-influenced behavioral processes do not ineluctably lead to alcoholism. Rather, they establish a bias for alcoholism, just as Vietnam established a bias for opiate addiction.

2.5 On the Prerequisite Conditions for Substance Dependence

In representative populations, unassisted recovery from heroin addiction is common (e.g., Waldorf 1983). As heroin is the most addictive drug, this suggests that pharmacological processes establish a necessary but not a sufficient condition for addiction. The Vietnam experience demonstrates the importance and the limits of environmental influences. With easy access to heroin, there was about a 20-fold increase in addiction, yet 40 percent of those who experimented with this drug did not go on to become regular users. This suggests that there is no setting in which all drug users will become drug abusers. Similarly, the twin data show that individual characteristics matter, but not enough so that pharmacology or setting can be ignored. Strictly speaking, then, a substance is not addicting. Rather some substances are more likely than others to become the focus of an addiction given the presence of other contributing factors. Similar statements can be made about dependence promoting settings and individual characteristics.

3. Recovery: Is Substance Dependence a Chronic Relapsing Disorder?

Clinic outcome studies show that individuals in treatment for substance abuse often relapse back to drug use. However, most of the men who were regular users of heroin in Vietnam stopped using upon return home. Which population is representative of most addicts? There are two large, epidemiological studies of psychiatric disorders that collected information on drug use (Anthony and Helzer 1991, Warner et al. 1995). Both found that most of those who at some point in their life met the criteria for substance dependence no longer did so. And according to the larger of the two studies (Robins and Regier 1991), substance abuse had the shortest duration and highest recovery rate of any other psychiatric disorder.

The common factor in the studies with higher recovery rates is that subjects were selected independently of their treatment history. In contrast, in studies that find high relapse rates, the subjects are drawn from clinic rosters. The clinic data include two biases. First, most addicts do not seek treatment (e.g., Anthony and Helzer 1991). Second, the frequency of psychiatric comorbidity is much greater for the clinic population. For example, in the ECA study, 64 percent of the addicts who were in treatment had an additional nondrug related psychiatric diagnosis, whereas the comorbidity rate for addicts not in treatment was 29 percent (Regier et al. 1990). Thus, higher relapse rates for clinic populations are correlated with higher comorbidity rates.

4. Factors that Influence Recovery

4.1 Values, Employment, and Cultural Milieu

Autobiographical accounts of recovery often include a pivotal event that triggers evaluative judgments about drug use, such as the desire to change in order to please parents and children. In support of these accounts, which may be biased, an ethnography of a population of recovered heroin addicts found that the most frequently cited reason for change was an event that led to feelings of regret about addiction or the junkie lifestyle (Waldorf 1983).

In a series of longitudinal studies on heroin addicts and alcoholics, the strongest correlate of recovery was the ability to hold a job (Vaillant 1992). The author hypothesized that a job weakens drug use by removing

the addict from drug taking cues and by reinforcing patterns of behavior that are incompatible with drug use, such as keeping to a daily schedule.

Since 1964 more than 50 million people have quit smoking in the United States (e.g., Schelling 1992). This decline is correlated with the 1964 publication of the Surgeon General's report on the health risks of cigarette smoking and the subsequent changes in the culture of cigarette smoking. For instance, movies no longer represent the cigarette as a sign of sophistication, and many if not most public places are now smoke free.

4.2 Pharmacological Treatments

Methadone and nicotine replacement therapies increase abstinence rates for addicts in treatment. This does not contradict the research on the situational correlates of recovery. Rather, by attenuating the distracting effects of withdrawal symptoms, the pharmacotherapies increase the likelihood that conventional alternatives to drug use will take hold.

4.3 Correlates of Recovery and the APA Criteria for Substance Dependence

An important theme in the study of recovery is that factors that are important in bringing drug use to a halt play much less of a role, if any, in disorders that are widely acknowledged as entailing compulsions, such as obsessive compulsive disorder or Tourette's syndrome. For example, incentives and social disapproval can persuade addicts to stop using drugs (Higgins et al. 1994, Robins et al. 1975) but, in general, do not markedly decrease symptoms such as repetitive hand washing or motor tics. This comparison suggests that the APA criteria for substance dependence although useful are overstated. Addicts may be less sensitive to the negative consequences of drug use than nonaddicts, but, as shown in laboratory and natural experiments (e.g., Vietnam), they are not immune to them. Put another way, the nature of recovery from addiction implies that it is not a compulsive disorder.

5. Brain, Substance Dependence, and Recovery

In recent brain imaging studies, drug users and control subjects differed in terms of dopamine receptor density and dopamine related neural functioning (e.g., Volkow and Fowler 2000). Interestingly, the differences were in areas of the brain that are believed to play a role in decision making. This work is new, and it is not known if the imaging results reflect drug use, the correlates of drug use (e.g., a pre-existing state), or both. Similarly, it is not known if the neural correlates of drug use influence decision-making capacities or preference for the drug (leaving rationality intact). A further complexity is that the relationships between drug consumption, brain function, and behavior can also be initiated by changes at the 'surface.' Just as drugs may alter the brain in ways that promote future drug consumption, the environmental events and changes in behavior that lead to recovery must modify the brain in ways that decrease the likelihood of future drug consumption. For example, when cognitive-behavioral treatments for obsessive-compulsive disorder are effective they lead to changes in brain structures that are correlated with the patients' symptoms (Schwartz 1998). A number of research groups are beginning to study the complex interrelationships between drug use, decision-making, and brain functioning. Thus, the next generation of addiction studies promises a wealth of new information on the biology and psychology of decision-making as well as on the biology and psychology of substance use and abuse.

Drug Use and Abuse: Psychosocial Aspects

The use of psychoactive drugs has existed among various human cultures through the millennia. The abuse of many such drugs has been an important though socially defined, adverse consequence of their use.

1. *Psychoactive Drugs*

The term 'drugs' as commonly used today is a shorthand for 'psychoactive drugs'—compounds or substances which alter the neurological functioning and/or structure of the organism in such a way as to directly influence perception, mood, consciousness, and/or energy levels. There are many compounds that have such effects, ranging from those occurring naturally in plants (e.g., cocaine, caffeine, nicotine, cannabis, opium, psilocybin) and natural process (fermentation of fruit and other plant products containing carbohydrates, yielding alcohol) to compounds that are synthesized (e.g., amphetamines, LSD, 'ecstasy,' and PCP).

2. *Distinguishing Characteristics of Drug-using Behaviors*

There is one central characteristic that distinguishes psychoactive drug use from most other classes of behavior. Drugs influence the neurological system directly and provide pleasure or other forms of reinforcement (Koob and Nestler 1997). This reinforcement occurs without any of the intervening 'adaptive behaviors' which normally would be associated with such reinforcement because, in evolutionary terms, those behaviors that were adaptive evolved as having reinforcing effects due to their importance in the survival of the species. In essence, drug use involves a shortcut to the pleasure centers of the brain—a bypassing of adaptive behavior. Two other characteristics, which derive from this central one, also characterize this domain of behavior. First, because of this shortcut, drug-using behavior can come to interfere with, or displace, many behaviors that are adaptive such as eating, forming appropriate bonds to family and community, working, or performing well academically. Put another way, it can come to assume a higher position in the hierarchy of needs. It can also disrupt fundamental psychological processes essential to performing a wide range of other behaviors or tasks by altering or impeding perception, memory, decision making, motivation, and energy levels. Second, the direct reinforcing properties of psychoactive drugs on the neurotransmitters in the brain can alter the structure and function of the neurological system itself, such that a need is created for the drug in order for the individual to attain what had previously been a normal level of neurological functioning. In other words, the user can become dependent on or addicted to the drug; thus, the underlying motivation for using a drug can shift quite dramatically from what might have motivated use at earlier stages of involvement.

3. *Illicit vs. Licit Drug Use*

There are many psychosocial determinants of the use of psychoactive substances, two of the most important of which are the legal and normative status of particular substance-using behaviors in the society. The primary focus in this article will be on psychoactive substances, the use of which is considered illicit in most societies. Tobacco and alcohol are generally

licit to use and legal to possess; but because they are dealt with at some length in other entries, they will receive only very general treatment here. It should be noted, however, that even the use of alcohol and tobacco by people under certain ages is considered illegal and illicit. Three general social classifications of psychoactive drugs will be distinguished, and the importance of their classification considered: psychotherapeutic drugs, legal drugs, and illegal drugs.

3.1 Psychotherapeutic Drugs

Certain drugs can be either licit or illicit to use, depending on the conditions under which use occurs; and they can be legal or illegal to possess, depending on how they have been obtained. A number of psychoactive drugs—the so-called psychotherapeutic drugs—have medical applications, so their use is considered as legitimate for the medically supervised therapeutic treatment of particular conditions. These drugs include tranquilizers (most of which are benzodiazepines, used to alleviate anxiety), sedatives (most of which are barbiturates, used to induce sleep), amphetamines (used to treat hyperactivity disorders), and various opium derivatives and their synthetic analogues (used to control pain, coughing, and diarrhea). All of these drugs have regulated access, through the requirements of a doctor's prescription and pharmacy dispensation. However, the sale, possession, or use of these substances outside of prescribed medical regimen is considered illicit and illegal, in part because all of these drugs have the potential to produce dependence in the user; and dependence is presumed to be more likely to develop under conditions of unsupervised use.

3.2 The Legal Drugs

Certain psychoactive substances have emerged as legitimate to use in most societies outside of any medical regimen and without any therapeutic purpose, usually because at the time of their emergence, they are presumed to be safe. These include alcohol, nicotine, and caffeine. All of these substances have been in fairly widespread use for some centuries in different cultures. Although there have been some concerns in the past about the health and societal consequences of alcohol and tobacco, such concerns increased considerably over the course of the twentieth century, leading to increased stigmatization of their use and legal controls on their sale and distribution.

3.3 The Illegal Drugs

In the twentieth century most other psychoactive substances have been deemed illegal and illicit to use, possess, or sell in most societies. This illegal status is based largely on their presumed negative impact on the functioning of the individual, family, and/or larger society. Various international treaties have had the effect of making the legal status of various of these drugs (plus most of the psychotherapeutic drugs) fairly homogenous throughout the world, sometimes changing traditional and accepted drug using behaviors in certain societies into illegal and illicit ones (United Nations 1971, 1972). The potential beneficial uses of these drugs, if any, generally are considered to be outweighed by potential negative consequences. Among them are marijuana and hashish, various hallucinogenic drugs, including LSD and PCP, cocaine powder and crack cocaine, methamphetamine, opium and heroin.

The term 'presumed' is used throughout this discussion to describe both the negative effects and the benefits of these drugs, because the presumptions sometimes turn out to be quite erroneous. This was true of the presumed safety of tobacco products and of cocaine, to take but two examples. Also, there remains considerable controversy, and incomplete scientific knowledge, about the consequences of various of the psychoactive substances in use today, particularly the newer ones.

The boundaries of social legitimacy and illegality of the use of various psychoactive substances are themselves subject to change, as knowledge accumulates about the effects of the drugs and also about the effects of the control mechanisms intended to control their use. In fact, there has been a vigorous policy debate over whether reclassifying a previously illegal drug, like marijuana, as a psychotherapeutic drug might also affect the extent to which that drug is used in society outside of its newly legitimated medical regimen. Some argue that such a reclassification would destigmatize the drug and make its use seem less dangerous—both important psychosocial determinants of use, as will be discussed further below.

4. Religious and Cultural Constraints

The fact that many drugs are taken for reasons other than instrumental ones—that is, their use does not have accepted therapeutic purposes and does not facilitate task performance—but rather for pleasure (or other directly reinforcing properties of the drugs) itself stigmatizes their use for many people. Against the Protestant work ethic, such behavior can be seen as slothful, self-indulgent, hedonistic, and therefore inherently immoral. In the Mormon religion alcohol use is explicitly prohibited, and in the Islamic religion the use of alcohol and most other psychoactive substances is banned.

On occasion the use of illegal drugs may take on symbolic meanings that change their acceptability within the society, or at least within certain sectors of

society. A dramatic instance of this occurred in the United States during the Vietnam War era, when the use of marijuana and LSD, in particular, came to be associated with being a part of the counterculture and the antiwar movements of the time (Zinburg and Robertson 1972). Within the context of a major generational division over values, use of these drugs became legitimate, and even positively valued, within a large sector of the youth generation. Use of these drugs at once symbolized defiance of adult norms and a statement of solidarity with those social movements. During that period of generational rift, the normative constraints among youth on the use of these drugs eroded considerably, and thus came to diverge from the prevailing norms in adult society. It was just a few years after this historical period that illicit drug use among adolescents and young adults reached its pinnacle in the country. In the years since, these symbolic meanings have virtually disappeared as the movements themselves have become part of history; and youth norms against use strengthened considerably. Not coincidentally, illicit drug use among young people declined quite substantially between the late 1970s and the early 1990s.

In sum, religious and other cultural considerations, as well as more practical concerns about the costs and benefits of use, and the costs and benefits of various control mechanisms, weigh heavily in determining the legality and social acceptability of using various psychoactive compounds. Legal status and social acceptability, in turn, are among the most powerful psychosocial determinants of use, as is evidenced by the fact that the psychoactive substances that are considered legal and socially acceptable—including alcohol, nicotine, and caffeine—have by far the greatest prevalence of use.

Use of these drugs is widespread not only because their use is legally and normatively accepted, however, but also because their legal status allows those who sell them to engage in massive advertising and promotional campaigns aimed at encouraging and facilitating consumption of the drug. One of the major reasons given by those who oppose the legalization of marijuana or other illegal drugs is that legalizing these drugs would unleash just such powerful marketing forces, which could further dramatically increase use (Inciardi and McBride 1991).

5. *Research Traditions*

Many subareas of research on psychoactive drugs have evolved, particularly in the past forty to fifty years. These include etiology, epidemiology, neurology, psychopharmacology, molecular biology, prevention, and treatment. The psychiatric tradition in epidemiology and treatment has emphasized accurately diagnosing and effectively assigning treatment regimens to individual cases. The other social sciences have looked more at drug use in the normal population, with an emphasis on causes, correlates, and consequences. There have emerged a few large, ongoing epidemiological survey studies of national populations that have as their primary focus the tracking and studying of drug use in the normal population. Two are in the United States: the National Household Survey of Drug Abuse (SAMHSA 2000) and the Monitoring the Future study (Johnston et al. 2000) that began in 1971 and 1975, respectively. More recently a coordinated series of national school surveys, modeled largely after Monitoring the Future, has been launched in more than two dozen countries in Europe under the auspices of the Council of Europe and the government of Sweden (Hibell et al. 2000).

The fact that addiction has long been conceptualized as a disease within certain scientific circles has led to terminology that is medical in nature in defining the subfields of research (e.g., epidemiology, etiology, prevention, treatment). In fact, Alan Leshner, the current director of the National Institute on Drug Abuse, has asserted that drug addiction is a disease of the brain, evidenced by lasting structural and functional changes in the brain induced by drug use, but that drug use short of addiction is a preventable behavior (Leshner 1999).

The importance of the disease concept, for which there is increasing neurological evidence, is that it implies that drug dependence should be responded to as more than just a moral failing. It implies that dependent users have important changes in their neurotransmitter systems that reduce to a considerable degree the extent to which they have reasonable control over their drug-using behavior.

6. *Use vs. Abuse*

One important distinction in psychosocial aspects of drugs has been between use and abuse, though it is a distinction less discussed in the literature today than it was early in the epidemic of illicit drug use. In theory, the distinction lies in whether the drug-using behavior has reached the stage at which it is adversely affecting the normal functioning and well-being of the individual and, therefore, has become 'abuse.' Is the individual's drug use disrupting normal emotional, cognitive, social, or work functioning, including school performance for those in school, or is it endangering physical health? Is it interfering with the user's functioning in key social roles such as spouse, parent, child, friend, student, worker, and citizen? As may be obvious, such a distinction is easier to conceptualize than to operationalize. Beliefs about the adverse effects of drugs influence not only the larger society's view of, and constraints on drug use, but the likelihood that a given individual will engage in using

drugs—a point to which we will return below. Because many of the dangers of a particular drug are not well documented in the early years after it comes onto the scene—witness cocaine use in the late 1970s—'correctly judging whether there are serious health or addiction hazards, say, and therefore whether use constitutes 'abuse,' is not at all straightforward.

Some research on the reasons adolescents give for using various drugs may help to elucidate the theoretical distinction between use and abuse (Johnston and O'Malley 1986). Young people who have used a drug only once or twice usually give as their primary reason curiosity, 'to see what it was like.' Those who have used only a reasonably limited number of occasions, but have gone beyond experimentation, most often mention reasons such as 'to feel good or get high' or 'to have a good time with my friends'—what might be called social and recreational reasons for use. However, those who have used a drug with some frequency start to mention what might be called psychological-coping motives for their use—'to get through the day,' 'to get away from my problems,' 'because of anger or frustration,' 'to relax or relieve tension.' That is not to say, necessarily, that using drugs created these psychological coping needs, although drug use may well contribute to them. More likely it means that youngsters who are having trouble coping, or are dysphoric for whatever reason, receive more relief and, therefore, reinforcement from using the drug. These most likely are the individuals at greatest risk of progressing to abuse or even dependence. Needless to say, the drugs usually offer a false promise of helping them cope with the vicissitudes of life.

7. *Stages of Involvement*

The research literature on substance use has distinguished a number of stages of involvement with a drug (Clayton 1992). In general, the stages of use of a drug can be described as abstention, initiation, continuation, progression, dependence, and relapse. In addition, cessation of use can occur after initiation, progression, dependence, or relapse. Psychiatric researchers have been most concerned with defining, understanding, and intervening in the later stages of this continuum.

Explaining progression in the earlier stages of the continuum of involvement, and trying to intervene in that progression, has fallen largely to the social sciences. Though many social scientists who work in this field are informally called epidemiologists or etiologists, in fact they have tended to come mostly from psychology (including social, clinical, counseling, and community psychology), sociology, social work, anthropology, and, more recently, public health and economics. Two very general fields have evolved here—first, the study of the natural phenomena and second, the development of interventions (e.g., education, prevention, persuasive communication). Because prevention is the subject of another article (see *Substance Abuse in Adolescents, Prevention of*), it is mentioned here only to note that the scientists and program developers in prevention tend to have quite similar disciplinary backgrounds and theoretical underpinnings as those who work on the etiology and epidemiology of substance use. Social learning theory has been widely adopted in all of these subareas, for instance.

The notion of a continuum of involvement applies not only to individual drugs, but also across drugs. The use of certain substances tends to precede the use of other ones with a high degree of regularity (Kandel 1975, Kandel et al. 1992). Marijuana use, for example, is usually preceded by the initiation of cigarette smoking, and the two behaviors remain highly correlated at later ages. Alcohol use also tends to precede the use of marijuana; and marijuana use, in turn, usually precedes use of most of the so-called 'hard' drugs like stimulants, opiates, and hallucinogens. The regularity of this pattern of progressive involvement has led to work aimed at predicting specific details of these transitions.

8. *Attitudes and Beliefs about Drugs*

8.1 *Social Connotations of Use*

One of the many influences on substance use is the symbolic meaning the individual sees it as having within society at large or within various social circles. It is obvious that cigarettes and alcohol have acquired certain associations in peoples' minds as a result of intentional manipulation through advertising. Less obvious perhaps is the fact that even unadvertised substances acquire social connotations, and that these may change considerably over time. The high degree of association of marijuana and LSD came to have with the counterculture already has been mentioned. When cocaine use first started to grow in the late seventies, it was very expensive and thus was used disproportionately by the rich and sometimes famous. As a result it acquired a certain caché that made its use more desirable to many, whereas a number of other drugs, like heroin, were more associated with marginal groups and the less affluent. It seems likely that adolescents come to see inhalants as 'kids' drug' as they get older, and that their use declines as a result.

8.2 *Perceived Risk*

Whether drugs are seen as dangerous to the user or to others can likewise affect how they are seen more generally. The dramatically lowered social acceptability of tobacco over the past two decades illustrates the point. As smoking came to be seen as carrying high

risk of morbidity and mortality, it became a less popular behavior, primarily with adults. And as the evidence grew of the adverse effects on others from their passive exposure to tobacco smoke, smoking in many public places, once an assured right, became a frequently denied privilege. Social norms, as well as regulations and laws, shifted quite dramatically. A not dissimilar thing happened with alcohol, when the many adverse effects of drinking came to be more widely recognized and, in particular, when the consequences of drunk driving were emphasized in the eighties. In that decade drinking and driving declined substantially among adolescents in the United States, and even occasions of heavy drinking declined considerably (O'Malley and Johnston 1999).

A number of the illicit drugs have also had considerable transformations in their social acceptability, as their adverse consequences were documented and made widely known. In the late 1970s, as cocaine use became more widespread, there was little convincing evidence of adverse effects, as 'experts' proclaimed that cocaine was neither lethal nor addictive. The evidence eventually cumulated to prove them wrong, but it took some years because there turned out to be a long lag-time on average between the initiation of use and the development of dependency and other serious problems. Researchers at the University of Michigan have demonstrated the importance of perceived risk as a determinant of trends not only in cocaine use, but also in the use of marijuana and other drugs (Bachman et al. 1998, Johnston et al. 2000). Among other things they have shown that a turnaround in the aggregate-level perceived risk associated with a drug by adolescents often presages a turnaround in actual use a year later.

8.3 Disapproval of Drug Use

As illustrated in the cigarette example above, perceived risk can influence the social acceptability of using a drug, though it is only one such determinant of social acceptance. At both the aggregate and the individual level, personal disapproval of using a drug also has been shown by the Michigan researchers to be an important determinant of use. It is not uncommon for disapproval to show a turnaround a year later than perceived risk, consistent with the notion that risk can influence disapproval.

9. Individual Susceptibility

In addition to attitudes and beliefs about drugs, there are a great many other known individual risk factors for psychoactive drug use (e.g., Clayton et al. 1995, Glantz and Pickens 1992). Some of the strongest among youths and young adults have to do with their degree of attachment to, or integration with, key institutions in society. At the broadest level, deviance from societal norms in general, as reflected by delinquent behavior, is a strong correlate of virtually all forms of illicit drug use (including under-age drinking and smoking). It should not be surprising that one class of illicit behaviors (drug use) correlates strongly with a range of other illicit behaviors. It simply means that people who are willing to violate legal and normative constraints in one domain of behavior are willing to do so in others, as well. One result of this fact is that the correlates and determinants of the various 'problem behaviors' among youth tend to be the same. Among them are attachments to various other institutions, but in particular the family, school, and church (Brook et al. 1990).

Young people who have a low degree of attachment or 'bonding' to school—meaning that they are not performing well, do not like school, and may frequently be absent or truant—are at particular risk of involvement with illicit drug use. The same may be said of those who are frequently out of the parental home in the evening and/or who are having difficulties with their family, and of young people who are not very religious (regardless of religion or denomination) as reflected in low levels of religious attendance and rated importance of religion in their lives (Petraitis et al. 1995).

10. Future Directions

It has become increasingly clear that both licit and illicit substance use must be viewed in terms of age, period, and cohort effects, since all three different types of change have been observed and documented (Johnson and Gerstein 2000, Johnston et al. 2000). The factors explaining each of these three types of change are likely to be different, as is the timing of their action. The continual emergence of new illicit drugs onto the scene will yield new drug-taking phenomena to be understood and influenced. Undoubtedly more will be learned about the neurological action and effects of the many drugs, which may well change the importance of certain psychosocial factors, such as perceived risk, in determining their use.

The field is extremely multifaceted as has been illustrated here. The number of drugs is large and growing, and they have a wide range of psychological and physical effects. There are many levels of social and psychological determinants of this group of behaviors, ranging from legal, moral, normative, and religious, to neurological, psychological, sociological, political, and economic. (Because drugs are commodities, market considerations also influence use.) Further, drug use is the object of many social interventions, from various forms of education and persuasion to treatment. Thus, despite the considerable resources currently going into research on the determinants of drug use, it is clear that there will remain a great deal to be learned about this unique domain of behavior for some time to come.

Drugs and Behavior, Psychiatry of

At the beginning of the twentieth century, Western culture had few drugs that were useful to treat central nervous system (CNS) disorders, including mental illness. Ethyl alcohol, used alone or as a component of numerous patent medicines, had use, perhaps as a sedative. Other sedatives, such as chloral hydrate, were available as sleep-inducing agents. More potent sedatives such as nitrous oxide and diethyl ether were used as general anesthetics. Morphine had been isolated from crude opium and was used as an analgesic. Cocaine was used as a local anesthetic. Virtually all of these drugs had abuse potential. By the 1920s, drug abuse had become a significant problem, and this problem continues into the twenty-first century.

This situation continued until the 1950s, at which time a revolution in psychopharmacology began, a revolution that continues into the twenty-first century. Thus, the field of psychopharmacology is really only about 50 years old! In the 1950s and 1960s, significant advances (Julien 2000) included:

(a) Development of the *barbiturates* as sedative-hypnotic drugs. Recognition of their toxicity and abuse potential led to identification and development of the *benzodiazepines* as safer agents for the treatment of anxiety states and insomnia.

(b) Development of the *phenothiazines* for the treatment of schizophrenia. Recognition of the therapeutic limitations and toxicities of these drugs led to development of the *atypical antipsychotics* in the 1980s and 1990s.

(c) Development of several classes of *antidepressant drugs* effective in the treatment of major depression and dysthymia. These included the monoamine oxidase inhibitors and the tricyclic antidepressants. This was followed in the 1980s and 1990s by development of less toxic antidepressants such as the serotonin-specific reuptake inhibitors and 'dual action' antidepressants. As the twenty-first century begins, additional classes of safer and even less toxic antidepressants are being introduced. These include a specific norepinephrine reuptake inhibitor, COMT-inhibitors, a selective, reversible MAO-inhibitor, a

Figure 1
Transporter proteins involved in the active uptake of dopamine (DA). Two transporters are shown. The first is a 'vesicular DA transporter' located in the cytoplasm of the presynaptic neuron, bound to DA-containing storage vesicles. This transporter carries DA from the cytoplasm into storage. The second type of DA transporter is found on the synaptic membrane of the presynaptic neuron and functions to transport DA from the synaptic cleft into the presynaptic nerve terminal, 'recycling' the transmitter and ending the process of synaptic transmission. It is this second transporter that is blocked by cocaine, prolonging the action of DA in the synaptic cleft. Amphetamines function to induce the release of increased amounts of DA from the storage vesicles into the synaptic cleft. The end result is the same: increased amounts of DA at the postsynaptic receptor (DA-R)

neurokinin-1 receptor antagonist, and 'natural' products such as St. John's wort and DHEA (an adrenal androgen).

(d) Identification of the therapeutic efficacy of *lithium* in the treatment of bipolar illness. In the 1990s, safer and less toxic alternatives were developed. These included at least 6 different *antiepileptic drugs*, atypical antipsychotic drugs, and 'natural' products such as omega-3 fatty acids.

(e) Identification of the usefulness of certain of the antidepressant drugs and atypical antipsychotics in the treatment of specific anxiety disorders (e.g., post-

traumatic stress disorder (PTSD), phobias, panic disorder, and obsessive-compulsive disorder), and behavioral disorders with associated symptoms of agitation, aggression, and violence.

(f) Development of *psychostimulant agents* effective in the treatment of childhood, adolescent, and adult attention-deficit/hyperactivity disorder (ADHD), Alzheimer's disease, narcolepsy, and other disorders of attention, thought, and memory.

(g) Development of drugs useful in the treatment of Parkinson's disease. Here we include dopamine replacement agents, dopamine receptor agonists, and a variety of other drugs that have improved the lives of individuals suffering from this disorder.

(h) Development of new anesthetic agents, allowing for the provision of safe anesthesia in patients in any state of health, debility, or surgical requirement. Such agents include ketamine, etomidate, non-toxic inhalation agents, and ultrashort-acting narcotics and muscle relaxants.

Thus, major psychiatric illnesses and other brain disorders have become, for the first time in human history, amenable to pharmacologic treatment; and the search for more effective, more tolerable, and safer drugs continues. As of 2001 at least 102 new medications are in development for treating mental illness. This includes 23 drugs for dementias, 19 for substance abuse disorders, 18 for depression, 15 for schizophrenia, 16 for anxiety disorders, 5 for eating disorders, 4 for ADHD, and 2 for treating PTSD.

It is important to note, however, that psychopharmacology involves much more than the development and testing of new therapeutic agents. Psychopharmacology has also provided powerful tools to study and characterize neurochemical pathways in the brain, and how these pathways may be involved in the pathophysiology and treatment of psychiatric illness (Duman 1999). This work has focused largely on neurotransmitter systems, including the synthesis, release, and metabolism of neurotransmitters and also of the receptor subtypes that control both presynaptic release and postsynaptic actions of neurotransmitters. All of this is to enable science to better understand brain physiology as well as to expand our knowledge of therapeutic targets.

In recent years, the fields of molecular pharmacology and pharmacogenetics have contributed mightily to neuroscience. Many of the enzyme and receptor targets for psychotherapeutic drugs have been identified, sequenced, cloned, three-dimensional structures proposed, and shown to be part of larger families of receptors with multiple homologous members (Julien 2000, Tallman 1999). Both therapeutic actions and side effects of drugs can often be explained by the interactions with multiple different types of receptors. For example, some antidepressants bind to and block the presynaptic transporters for serotonin and norepinephrine as well as postsynaptic receptors for histamine and acetylcholine. Other classes of antidepressants are quite specific for blocking either a single presynaptic transporter or a specific postsynaptic receptor (Figure 1; from Amara and Sonders 1998). This allows one to tailor a specific drug for a specific patient.

With the identification and cloning of different receptor subtypes, whole new generations of drugs specific for each subtype will allow for new advances in the treatment of mental disorders. For example, there are over 15 subtypes of serotonin receptors all of which are potential therapeutic targets. Tallman (1999) states that 'taken together, over 1,000 G-Protein Couples Receptors, over 100 ligand-gated and other ion channel subunits, over 20 reuptake proteins, almost 50 cytokine, 25 nuclear receptor, and several thousand other molecular targets have been cloned, expressed in mammalian, yeast, or insect cells, and are currently available to the pharmaceutical drug discoverer as potential therapeutic targets for agonist or antagonist discovery.'

Classically, a drug is often characterized by a fairly rapid-onset action in a specific model (i.e., it blocks a specific receptor). However, the therapeutic action may take days or weeks of therapy to become evident. This difference in time course has led to the hypothesis that the therapeutic action of many drugs is dependent on adaptations to the acute drug action (Duman 1999). For example, antidepressants acutely block a reuptake transporter, but the clinical relief of depression may take 6 weeks to become evident. Identification of the relevant adaptations, which can be thought of as a form of drug-induced neural plasticity, could occur at several cellular levels, including receptor and second-messenger coupling, modification of intracellular signaling pathways, alterations in nuclear transcription of receptor protein production, or 'remodeling' of intracellular architecture by regeneration, reconfiguration, or modification of intracellular 'neurotropic factors' (Duman 1999, Russo-Neustadt et al. 1999, Brown et al. 1999). Figure 2 (Duman et al. 1997) illustrates a model of such an interaction between acute drug effects and chronic 'plastic' neuroadaptations. The complexity of these adaptations is at least comparable to that of the complex neuronal circuitry in the brain and in the etiology of psychiatric illness. In addition, drug action interacts with genetic and environmental influences to modulate these neuroadaptive influences. For example, a 'Brain-Derived Neurotropic Factor' (BDRF) is poorly expressed in clinical depression and in stressful situations characterized by elevated levels of glucocorticoids (Duman 1999). The combination of exercise and an antidepressant (either a tricyclic-type or a monoamine oxidase inhibitor) exerts a positive and additive effect on BDRF messenger RNA expression in rat hippocampus over a period of 20 days (Russo-Neustadt et al. 1999). This is consistent with enhanced BDRF mRNA expression after antidepressant treatment and increased expression of the tran-

Figure 2
A model for the molecular mechanism of action of long-term antidepressant treatments. Antidepressants induce short-term increases in 5-HT and NE. Longer-term use decreases the function and expression of their receptors, but the cAMP sinal transduction pathway is increased, including increased levels of *adenyl cyclase* and cAMP-dependent protein kinase (PKA), as well as translocation of PKA to the cell nucleus. Antidepressants increase expression and function of the transcription factor cAMP response element-binding protein (CREB), suggesting that CREB is a common postreceptor target for antidepressants. Brain-derived neurotrophic factor is also increased by antidepressant treatment; upregulation of CREB and BDNF could influence the function of hippocampal neurons or neurons innervating this brain region, increasing neuronal survival, function, and remodeling of synaptic or cellular architecture

scription factor cAMP response element binding protein (CREB) in rat hippocampus (Duman 1999, Nibuya et al. 1996, Tao et al. 1998). One implication of this is that it explains the additive effects of medication and behavioral therapies in the treatment of depression. It may also encourage the development of better behavioral treatments aimed at reducing depression and anxiety, and enhanced psychological capacity for dealing with chronic stress (Duman 1999).

Here, we have been discussing the interface between the molecular actions of drugs and their clinical utility in the treatment of disorders of the nervous system. This interface lies within the purview of neuropsychopharmacology; a unique, integrated area of science and medicine that is ideally positioned to ask fundamental questions about drugs, their actions on minute subunits of the nervous system, and how these drugs may be used for therapeutic benefit in human beings (Walker 1999). While molecular biology holds out the promise of giving a complete understanding to all aspects of biology, pharmacology is charged with understanding the actions of a drug at all levels of biology, from its effects on the genetic code or biomolecule to large populations of human persons. Indeed, it is equally important for the pharmacologist to determine the interaction of a drug with its 'receptor,' with the transduction mechanisms that result and lead to cellular action, to integration at the

Figure 3
Two-dimensional representation of the anandamide receptor, which is a protein consisting of a chain of more than 450 amino acids (the first letter of each individual amino acid is shown). Like the opioid receptors, the anandamide receptor is a G-protein linked, seven-membrane spanning structure with three extracellular loops

organ or system level, and to the effects on the whole person. Thus, pharmacology offers a complete picture in which a drug is 'mapped' all the way from its initial action at a bio-macromolecule through to effects on a human population with all of the social, economic, and geographic constraints of the latter (Walker 1999). In essence, pharmacologists will translate fundamental genetics and structural biology into drugs with therapeutic value (Burks 1999). To illustrate this characterization of a psychoactive drug, we consider *tetrahydrocannabinol*, the active ingredient in marijuana.

In 1964, delta-9-tetracydrocannabinol (THC) was isolated from marijuana and identified as its pharmacologically active ingredient. About 10 years later, it was hypothesized that THC and other cannabinoids act via a distinct set of receptors. In 1986, THC was found to inhibit the activity of the intracellular enzyme *adenylate cyclase*, and such inhibition required the presence of a newly identified G-protein complex. In 1990, that receptor was isolated, purified, the amino acid sequence determined, and the receptor cloned. The receptor was found to be a specific G-protein-coupled receptor that inhibits adenylate cyclase, binds cannabinoids, inhibits calcium ion flux and facilitates potassium channels (Childers and Breivogel 1998, Felder and Glass 1998). This 'cannabinoid receptor' is a chain of 473 amino acids with seven hydrophobic domains that extend through the cell membrane (Fig. 3). When THC binds, it activates G-proteins that act upon various effectors including the second-messenger enzyme adenylate cyclase and both potassium and calcium ion channels (Fig. 4; from Childers and Breivogel 1998).

The identification of a naturally occurring 'ligand' that might function as a 'natural THC' remained to be demonstrated. In 1992 the arachidonic acid derivative *anandamide* was identified. This substance not only bound to the cannabinoid receptor, but produced cannabinoid-like behavioral, hypothermic, and analgesic effects that parallel those caused by THC. Indeed, anandamide exhibits the essential criteria required for its classification as the *endogenous ligand* at cannabinoid receptors.

In 1999, it was demonstrated that anandamide functions as a 'partial agonist' at hippocampal glutamate-releasing neurons to 'reduce, but not totally block, excitatory transmission' (Shen and Thayer 1999). This may explain not only an antiepileptic action of THC, but THC's 'neuroprotective antioxidant' action as well (Hampson et al. 1998).

A cannabinoid *antagonist* has been synthesized; and mice lacking the cannabinoid receptor were bred and a lack of response to cannabinoid drugs demonstrated (Ledent et al. 1999). These same anandamide antagonists have been used to study dependence on THC; and, in 1999, a 'marijuana abstinence syndrome' was described (Haney et al. 1999a, 1999b).

Anandamide is synthesized within neurons by a condensation reaction between arachidonic acid and ethanolamine, under the regulation of calcium ions and cyclic adenosine monophosphate enzyme. It is broken down by a process of hydrolysis after carrier-mediated neuronal and astrocyte reuptake by an

Figure 4
Several proposed signal transduction mechanisms of cannabinoid receptors. After THC (or anandamide) binds (top), the receptor activates G proteins, which in turn act upon various effectors including: adenylate cyclase (AC), calcium (Ca^{2+}), and 'mitogen-activated protein kinase' (MAPC). Inhibition of adenylate cyclase and subsequent decreases in cAMP decreases activation of cAMP-dependent protein kinase (PKA), which leads to decreased potassium (K^+) channel fluxes. Stimulatory effects are shown by open arrows and inhibitory effects by filled arrows. The 'open' or 'closed' states of the channels and 'Xs' over some arrows reflect the final effects of cannabinoid agonists

amidase for rapid hydrolysis (Piomelli et al. 1999). Anandamide, THC, and other anandamide-receptor agonists inhibit the presynaptic release of the excitatory neurotransmitter glutamate in the hippocampus (Shen et al. 1996). Thus, the hippocampus, cerebral cortex, cerebellum, and basal ganglia are major loci of action of THC because these structures are involved in cognition, learning, memory, mood, and other higher intellectual functions, as well as motor functions, all of which are affected by THC.

In the early 1990s, the unique pattern of localization of cannabinoid receptors in the brain was delineated (Herkenham 1992), with large numbers of receptors found in the basal ganglia, cerebellum, and cerebral cortex. The latter receptors for THC mediate the psychoactive effects of the drug. Cannabinoid receptors are also dense in the hippocampus; accounting for THC-induced disruption of memory, memory storage, and coding of sensory input. Brain stem structures do not bind cannabinoids; they do not depress respiration; and they are relatively nonlethal. Perhaps we can now rename the cannabinoid receptor as the anandamide receptor, recognizing the endogenous neurotransmitter for the receptor just as we define other transmitter-activated receptors.

How does this knowledge of THC pharmacology translate into clinical useful information? One of the major effects of marijuana in humans is disruption of memory, presumably due to the reduction in hippocampal activity. Such memory impairments can be attenuated by cannabinoid antagonists, implying that THC- and anandamide-induced memory disruption is mediated by cannabinoid receptors and not by any indirect sedative mechanism (Mallet and Beninger 1998). THC impairs cognitive functions, perception, reaction time, learning, and memory. These impairments have obvious implications for psychomotor functioning, for example in the operation of a motor vehicle (Kurtzthaler et al. 1999).

THC and anandamide are both analgesic (at both spinal and brain stem levels). Cannabinoids produced analgesia, potentiating the analgesic action of morphine, increasing morphine's potency; this action is blocked by cannabinoid antagonists, indicating again that THC is again acting through a cannabinoid receptor mechanism (Smith et al. 1998). In primates, THC decreases aggression, decreases the ability to perform complex behavioral tasks, seems to induce hallucinations, and appears to cause temporal distortions. THC causes monkeys to increase the frequency

of their social interactions. Finally, THC can disrupt appetite regulation, inducing overeating in rats exposed to anandamide; providing evidence for the involvement of a central cannabinoid system in the normal control of eating.

Currently, there is one approved and several possible therapeutic uses for THC and its various derivatives. *Dronabinol* (Marinol), which is synthetic THC formulated in sesame oil, has been available for many years for use as an appetite stimulant in patients with AIDS and for use in the treatment of nausea and vomiting associated with chemotherapy in cancer patients. Other potential uses of dronabinol are to reduce the muscle spasms and pain in multiple sclerosis and reduce the intraocular pressure in glaucoma. Antidepressant and analgesic effects are also claimed, with analgesic actions best described in animal studies (discussed above).

The recent passage of initiatives legalizing the use of marijuana for medicinal uses has reopened this issue of therapeutics. Does marijuana have true therapeutic efficacy, equal to or greater than those of existing agents? The answer is muddied both by smoking as a route of administration and by the use of a crude product containing THC, which is only a weak agonist at cannabinoid receptors. Both of these facts limit the therapeutic use of smoked plant material as a therapeutic choice. The advent of highly potent synthetic analogues (pure anandamide agonists) and specific antagonists may make possible the development of compounds that lack the undesirable side effects of marijuana plant material (Adams and Martin 1996).

A 1999 report (Institute of Medicine 1999) concluded that cannabinoids have potential applicability for some human symptoms. However, the cannabinoids should be delivered by a mechanism other than inhaling smoke; the future may be non-smoked, inhaled molecules, whether they be natural THC from marijuana or totally synthetic compound. This entire area of research, drug development, and social discussion involves the input and opinion from both research and clinical pharmacologists.

Drugs, Decriminalization of: Cultural Concerns

1. Introduction

The issue of drug legalization or decriminalization is whether and to what extent the state should use criminal sanctions to regulate drug-related activities such as production, sale, purchase, possession, and use. Analysis of the issue must therefore focus on consideration of the legitimate uses of the criminal law, with special attention to the moral and political rights of citizens to use drugs and to the costs and benefits of criminal prohibition. After considering the definitions of drugs and legalization and the basic limits on the use of the criminal law, this article will discuss the contributions of rights and cost-benefit analyses to the decriminalization debate.

2. Defining Drugs and Decriminalization

Despite common belief to the contrary, there is no uncontroversial definition of 'drug' or 'legalization,' but clarity about both is necessary to understand the legalization debate and to guide public policy.

2.1 Drugs

Virtually all definitions are vague or overinclusive, permitting categorization as a drug of almost any substance that may be consumed. Some definitions are circularly dependent on legal regulations: if a law regulating 'drugs' includes a particular substance within its ambit, it is a drug; if it is not so included, it isn't. Vague, overinclusive, and circular definitions cannot sensibly guide public policy, especially when the state's awesome power to blame and punish for illegitimate use is dependent on the definition.

Definitional problems concerning drugs and legitimacy cannot be entirely avoided by using allegedly scientific or value-neutral medical/therapeutic or nutritional concepts. Concepts like disease and therapy are themselves value-laden and inevitably problematic and controversial. Many substances that have unquestionably legitimate medical or nutritional uses can also be used for nonmedical or non-nutritional purposes that may be of questionable legitimacy. Finally, definitions that define a substance as a drug in terms of its intended use rather than in terms of its inherent properties obscure important questions of legitimate use.

Despite the conceptual problems attending the definition of a drug, a loose but common sense definition is possible for discussing decriminalization, which centrally concerns substances that are consumed recreationally, that is, primarily to produce pleasure, whether or not those substances have other legitimate uses. For the purpose of understanding the current debate, then, recreational drugs can be defined as consumable substances that (a) can affect mood, cognition, and behavior in pleasurable ways; (b) can be used primarily for recreation, including relaxation, excitement, and pleasurable states generally; and (c) can be used so as to endanger the user and others. Although admittedly loose, this definition covers both legal recreational substances such as ethanol (alcohol), nicotine, and caffeine, and substances that are illegal either *per se* or if they are not properly prescribed by physicians such as marijuana, cocaine, opiates, heroin, barbiturates, amphetamines, phencyclidine (PCP), and the like.

2.2 Legalization and Criminalization of Drugs

Legalization (decriminalization) and criminalization are as difficult to define as drug because each includes widely varying legal responses to drug-related activities. The core of decriminalization proposals, however, is the limitation or abolition of present criminal prohibitions of actions related to recreational drug use by competent adults. Some prefer the term legalization to refer to the limitation of criminal prohibitions and penalties. Other, primarily rights-based theorists, believe that state criminal prohibition of recreational drug activities is not *prima facie* justified, so they prefer the apparently more politically neutral term decriminalization. For ease of exposition, the latter term will be used.

The specific details of particular decriminalization proposals depend on the proponent's position on rights and on the costs and benefits of the proposal compared to the current regime of criminal prohibition. Proponents recognize that some criminal law regulation and substantial civil law regulation will probably be necessary to respond to recreational drugs, but all agree that substantially less use of criminal law is desirable and that it should not be the primary mode of regulation.

The core of criminalization proposals is that the criminal law should be the primary means of regulating recreational drugs, but the proper scope of criminalization is disputed and virtually all defenders of criminal prohibitions believe that noncriminal means such as education and treatment should also be used. Virtually no proponent of criminalization argues for expanding the scope of criminalization, say, by prohibiting the recreational use of currently legal substances such as alcoholic beverages or by substantially increasing the criminal penalties for drug offenses. The current debate is about limitation, not expansion, and whether criminal law should be the primary mode of regulation.

3. *The Limits of the Criminal Law: The Harm Principle*

The state's police power to apprehend, prosecute, convict, and punish citizens is one of the most awesome and probably the most afflictive power it exercises. Infliction of such pain requires substantial justification in liberal democracies that seek to protect individual rights and liberty. Afflictive and expensive criminal regulation should be avoided in favor of less intrusive means unless the harm is great, punishment would be deserved for causing it, and criminal prohibition seems necessary to reduce the level of harm and will not unduly impose on other important interests. Criminal law theorists term these limitations on the state's power to criminalize the 'harm principle.' For example, intentionally inflicting emotional cruelty on others is morally despicable, but such behavior is not criminalized because the harm is insufficient to justify criminal punishment. Socialization by families, religious organizations, and schools is reasonably effective to limit such conduct, and regulating such behavior by criminal law might intrude on protected liberties, such as the right to free speech.

There is little debate about the state's justification for prohibiting and punishing traditional crimes against the person, such as homicide and forcible rape, and against property, such as theft and arson that cause grievous harm. Although individual liberties are precious, no citizen has a right to kill, rape, steal, or burn the property of others for private advantage and the criminal sanction seems necessary to curb such behavior. Societies can disagree about the scope of appropriate criminalization. For example, there may be reasonable dispute on how much creation of homicidal risk should be necessary to warrant criminal penalties in addition to civil damages or how severely arson should be punished, but the state's power to criminalize great harm to others is uncontroversial.

The harm principle suggests caution before criminalization, however, when the harm is primarily inflicted on oneself, when the harm is primarily moral and not physical, psychological or economic, or when using criminal law to prevent the harm appears to intrude on important rights or appears unnecessary effectively to reduce the harmful behavior. In liberal societies, the right of the state to criminally prohibit actions that harm primarily the actor (so-called legal paternalism) is more controversial than the right to prohibit harm to others because respect for individual liberty and autonomy generally entails that citizens have greater liberty to harm themselves than to harm others. Such liberty is most arguably extensive and the state's right to regulate criminally is most questionable when the threatened harm to self is apparently solely moral and no other harm to self or to others can be discerned. Most liberal theorists reject the state's power to use criminal law solely for the purpose of enhancing the moral perfection of its citizens—so-called legal moralism. Such goals are not the business of the state and should be achieved by other, less intrusive means.

In political and moral regimes that grant the state more authority to regulate individual liberty, both legal paternalism and moralism might be less controversial. For example, theocracies may coherently use the criminal law more extensively than liberal states to achieve paternalistic and moralistic goals. Even within liberal regimes, the permissible scope of paternalism and moralism may vary, although both require more substantial justification than criminalizing harm to others. Consideration of the state's justifiable use of criminal law to regulate recreational drug use, however, must attend to the appropriate limits of state power within a particular political regime. The remainder of this article assumes that the regime considering decriminalization is liberal.

4. *Recreational Drug Use and Rights*

People often assume that there is no right, no liberty interest to use drugs recreationally and, consequently, that the state has appropriate authority to use criminal law to prevent such use. Such an assumption is seldom supported with cogent argument, however, and it is not easy to give compelling moral and political reasons for rejecting such a right.

Sensible discussion must begin with the recognition that people take drugs recreationally because they desire the pleasurable effects produced by consuming substances that alter mood and cognition. It seems clear, however, that the state has no justifiable interest in criminal prohibition simply because the primary or even sole goal of behavior is pleasure or because the behavior involves consumption of a substance that can alter mood or cognition. Many people might consider it wrong to engage in activities solely for pleasure, especially if alteration of mood and cognition were involved and there were some danger of de-

pendence on the activity, but a liberal society does not interfere with a citizen's right to make autonomous choices to engage in such activities. Citizens surely have a *prima facie* right to seek pleasure for its own sake and it is very difficult to imagine a secular, liberal argument suggesting that such a goal is immoral or harmful *per se*, even if some danger might sometimes be involved.

For example, suppose that a citizen engages in meditation solely for recreational purposes. No persuasive liberal moral or political theory would justify criminal prohibition of meditation, even if some citizens became dependent on meditating. Recreational drug use involves the consumption of a substance, but it is hard to imagine why the source of the recreation alone should make a difference. Currently, illegal drugs produce pleasure by altering mood and cognition, but so do many legal activities, including meditation, and legal drugs such as caffeine, alcohol, and nicotine. The state's right to criminalize alterations of mood and cognition *per se* is questionable because such alterations are not *per se* immoral or harmful.

Citizens appear to have a *prima facie* right to engage in recreational alteration of mood and cognition by drug consumption and the state surely has the burden of justifying criminal prohibition of such recreation by powerful arguments. No right is absolute, however, and the possible right to pursue recreational drug use must yield to a powerful state interest in preventing such use, especially the undoubted state interest in curtailing the threat that drugs will cause substantial harm. Nonetheless, the harm limitation counsels caution before using the criminal law.

Some proponents of decriminalization refer to illegal drug use as a 'crime without a victim' because the person potentially most harmed—the user—in effect consents to the threat. But virtually no action affects only the agent, and recreational drug use sometimes threatens families and communities with economic, psychological, and physical harms. Many of these harms may be paradoxically produced or enhanced by criminal prohibition itself, but many surely are not. Moreover, harms one consents to suffer are nonetheless harms. The question is whether the harms to others or to self that drugs produce are sufficient to trump the individual's *prima facie* right to use drugs and thus to warrant criminalization of drug use.

The next section on cost-benefit analysis considers the harms drugs produce, but it must be remembered that liberal societies often permit dangerous behavior in order to protect the right of citizens to pursue their own visions of how life should be lead. Such dangerous behavior is regulated noncriminally, if at all. For example, knowingly following unhealthy dietary habits can severely harm and even kill, and the harm or death can threaten economic, psychological, and physical harms to others. The enormous costs of unhealthy diets are well known, but it is unthinkable in a liberal society to use the criminal law to regulate individual eating habits. To promote the health of the populace, the state can properly regulate the manufacture and sale of food and can impose a duty on manufacturers to warn consumers of potential health risks associated with particular foods. It can even use the criminal law to police egregious failures to comply with such regulations, but it is unthinkable that it would criminally prohibit unsafe eating habits. For another example, consider the immense costs to many users and to society at large that flow from the consumption of alcohol and nicotine. Again, the state can appropriately regulate many aspects of such substance consumption to reduce the consequent harms, including the use of criminal law for egregiously harmful forms of misuse, such as drunk driving. For many reasons, however, importantly including the right to make one's own choices unencumbered by undue state interference, criminal prohibition of the consumption of alcohol and nicotine by the state is considered unwarranted.

If drugs produce great harms *per se* and no one has a right to use drugs recreationally or if that right is insubstantial at best, then the only question for analysis is whether criminal regulation is justified by the benefits it achieves. But if there is a weighty liberty interest in making choices about how to live one's life, including potentially unwise and dangerous choices about drugs, then the creation of harm is insufficient *per se* to warrant criminalization. Some dangerous behaviors must be permitted to protect liberty and regulated only by civil remedies, including damages when the harm occurs. Any adequate analysis of decriminalization must therefore include consideration of the strength of the liberty interest and it appears that in liberal societies the right is substantial. Empirical analysis of the consequences of various behaviors under various regulatory regimes is necessary to inform decisions about the appropriate scope of criminalization and decriminalization of drugs, but the question of rights cannot be avoided.

5. *Cost-benefit Analysis*

The outcome of a cost-benefit analysis of decriminalization of drugs will inevitably be indeterminate because much of the data are unavailable, unreliable, or fluctuate and because the costs and benefits of a new regime must be speculative. Also, debate too often focuses on worst case scenarios that depend on salient but unrepresentative data. Insufficient information and biased misinformation often suggest the wisdom of maintaining the status quo rather than risk making matters worse by changing public policy. Policies such as the criminal prohibition of drugs that arguably fail and that impose great costs, including the infringement of citizens' rights, should be and are debated and cost-

benefit analysis plays a crucial role in these debates. Unfortunately, historical and cross-cultural comparisons are of extremely limited value because social variables, which vary radically intertemporally within a society and across different societies, immensely affect the consequences of drug use and regulation.

5.1 Harms of Drugs and the Benefits of Criminalization

Most currently illegal drugs would create some potential risks to the user and others, even if they were pure, inexpensive, and legal. For example, misuse of drugs can cause addiction and other extremely serious and well-known health, psychological, and economic effects. People can arguably become addicted to substances other than drugs and to activities such as gambling. Moreover, the concept of addiction is itself problematic. Nonetheless, assume that, for various cultural and biological reasons, most currently illegal drugs have greater addictive or other harmful potential than most other substances and activities.

Much decriminalization debate mistakes the probability and extent of the risks drugs pose. For example, most people who use most drugs recreationally do not become addicted and the moderate recreational use of drugs is not *per se* dangerous if the drug is pure and properly consumed. Nonetheless, the ease of access to drugs following decriminalization would surely increase the prevalence of use, abuse, and addiction and their further harmful consequences. The harms might be especially great in poorer and minority communities, where the prevalence of drug use is no higher than in other communities, but where the effects have been more devastating. Indeed, some responsible observers believe that decriminalization might effectively destroy poorer and minority communities already ravaged by drug abuse and addiction.

The relation between drugs and other criminal activity and health harms is fraught because it is difficult to disentangle the effects of criminalization itself from the independent effects of drug use. Some drugs, especially if used heavily, can substantially impair judgment, facilitate impulsivity, and have other effects that increase the risk of criminal offending and other dangerous behavior such as careless driving or sharing needles for intravenous injection. Increased drug use, especially heavy use, will raise the rates of such undesirable behavior.

Criminalization of drugs surely inhibits use generally by making production, sale, possession, and use more expensive and dangerous and by sending the clearest possible message that drug use is wrong. For example, there may have been both rights-based and consequential reasons to repeal Prohibition in the United States, but the data suggest that consumption and consumption-related diseases such as cirrhosis of the liver both decreased when most alcohol production and sale were illegal. Criminalization also helps prevent drug use by minors. Although minors regrettably have access to and consume drugs in a regime of criminalization, ease of access generally would also increase use and abuse among minors.

The use of criminal law to regulate drug use and related harms is obviously not fully successful by any standard and it is immensely expensive, but the proponents of continued criminalization argue that the current regime provides greater benefits than costs and that the unknown benefits, if any, of decriminalization would pale in comparison to the costs of inevitably increased use and abuse.

5.2 The Costs of Criminalization

Criminal law enforcement, including imprisonment, is an especially intrusive and expensive form of regulation of any behavior. The cost-benefit critique of criminalization argues that such costs are not outweighed by the benefits because criminal law is powerless to make more than a small dent in the use of drugs and because criminalization itself creates many avoidable harms.

The attempt to eradicate drug use by criminal prohibition cannot fully succeed because large numbers of people want recreational drugs for the pleasure or relief they provide and it is widely recognized that the dangers of drugs are often exaggerated. The criminal law's so-called 'war on drugs' in the United States is fighting a fluctuating but always immense number of citizens, most of whom are not addicts or abusers and whose use does not pose grave danger to society or themselves. It is hard to enforce laws that such large numbers of people wish to violate and that have no immediate and direct complaining victim. Furthermore, public hypocrisy about drugs inevitably undermines law enforcement. Western society is not nearly as monolithically antidrug as many claim, as public policy towards alcohol and nicotine indicates.

Given the powerful factors that motivate the desire for drugs, the criminal sanction appears ineffective. The criminal justice system cannot prosecute and imprison more than a tiny fraction of the enormous numbers of people involved in the illegal drug trade unless the justice system massively diverts resources from other, undisputed criminal law needs and abandons civil liberties protections. The criminal courts of the United States are already clogged with drug cases and the ever-expanding prison population includes an enormous proportion of drug offenders. Even spending vastly more money seemingly will provide only limited benefit. Despite billions spent on drug enforcement each year, undoubted law enforcement successes and the huge numbers of people in prison for drug-related offenses, drugs are still freely available and ever-purer and ever-cheaper. Fluctuations in drug usage appear far more related to major social, cultural,

and economic forces than to criminal law enforcement. The limited decrease in use criminal law enforcement produces does not seem to justify the gargantuan costs.

Criminalization also threatens its own effectiveness and creates other problems. For example, criminal prohibitions raise the price on a good or service—the so-called 'crime tariff'—and insure that there will be an endless supply of producers and dealers who seek to realize the monstrous profits to be made through any means necessary, including violence, and that many users will be impoverished and driven to a life of further crime simply to support themselves and to obtain drugs. The immense profits facilitate the growth and power of domestic and international organized crime and can be used to corrupt law enforcement, the criminal justice system in general, and both domestic and foreign politicians. Moreover, the consensual nature of drug offenses insures that law enforcement will unwittingly—and sometimes wittingly—use illegal means to enforce drug laws, thus further corrupting law enforcement and the administration of justice and causing disrespect for both. Criminalization decreases the probability that inevitable drug consumption will occur under conditions safest to health. Finally, primary emphasis on criminal law virtually insures that fewer resources will be devoted to investigating and implementing less intrusive and potentially more effective means to reduce the harms drugs cause.

5.3 *The Benefits of Decriminalization*

Specific decriminalization proposals would produce different benefits, but the potential general benefits of decriminalization are the opposites of the costs of criminalization and can be stated easily in the abstract. They include an increase in personal liberty, probable cost savings, decrease in the crime, violence, and corruption that criminalization produces, increased respect for law enforcement, and increased attention to possibly more effective means such as education, treatment, and civil regulation to reduce use and the harms drugs cause. Criminal law would be used only to prohibit particularly dangerous drug-related activities such as drugged-driving or selling to minors. Such traditional use of the criminal law would receive broad public support.

6. *Conclusion*

Proponents of criminalization sometimes grudgingly concede the problems with the criminal law enforcement approach, but virtually always criticize decriminalization proposals for their abstract or theoretical nature. They fear that decriminalization will produce an administrative, medical, economic, and social tragedy far worse than the current situation, and they ask for highly specific details and guarantees that this will not happen. Proponents of decriminalization recognize that they cannot provide such guarantees, but properly request in return that proponents of criminalization provide the details of how their approach will finally succeed after nearly a century of ever greater expenditures but apparent failure. Neither position appears able to convince the other on theoretical or empirical grounds, but only in recent years has decriminalization been openly debated. Nonetheless, at least in the United States, it appears that the political support to experiment with decriminalization is still weak.

Drugs: Illicit Use and Prevention

For the present article, drugs are defined psychoactive chemical agents, i.e., substances that alter cognitive processes. Within this definition two classes of illicit substances emerge. Some legal psychoactive sub-

stances reside in *consumer products* that are widely used, normative approved, and not usually perceived as drugs at all. Examples of these are nicotine in tobacco products, ethanol in alcoholic beverages, and caffeine in coffee or tea. Norms binding consumption of these goods vary in sanctions, but keep the list of permissible users and contexts broad. The next class of legitimate drugs is *medicines*. They can be legally acquired and consumed but only if matching symptoms have been verified by a physician. Drugs belonging to either of the two categories are also abused, i.e., consumed in a problematic or harmful manner. A third group of psychoactive drugs has been declared illicit because of the problematic effects or consequences caused by any of its constituents.

Illicit drugs that are widely used include central nervous system stimulants (such as crack cocaine, cocaine, and amphetamines), central nervous system inhibitors (opiates, heroin and sedative-hypnotics such as benzodiazepines or barbiturates), or hallucinogens (hemp products such as marijuana or hashish, LSD, and phenocyclidine) (AOD 1995). Some goods employed as illicit drugs have legal uses also; examples are home and office products containing solvents or propellants, the fumes of which can be inhaled. Finally, so-called designer drugs are derivatives of illicit substances that technically are not illegal, but produce comparable effects. Experimentation with illicit drugs may lead through various mechanisms involving social, psychological, and pharmacological connections to *dependency* and *abuse* (Des Jarlais and Hubbard 1997).

This article describes ways to combat illicit drug abuse at a national level, including equivalent products, a task that has been characterized as a failure in twentieth century health promotion (Fielding 1999). After the introduction to the situation in the United States and Europe—broadening the perspective is impossible as even authorities have only a vague conception of illicit drug use in many sites (United Nations International Drug Control Programme 1997)—attention turned towards evidence concerning the significance of prevention efforts in communities, schools, and families. Obviously, more is already known than have been put into practice—it is important to disseminate the knowledge—but nevertheless more research is needed on the results of general social policy measures, community and family interventions, and interventions directed to those already marginalized.

1. *Breadth and Risk Factors of Illicit Drug Use/Abuse*

Quantitative information on use exists from industrialized countries including the United Sates (Johnson et al. 1996, NIDA 1997) and most European countries (EMCDDA 1998). Having had at least one occasion of use seems to be a quite variable phenomenon in terms of type of drug, period, region, and ethnic group in the United States. Substantial geographical variability is observed in Europe also, from which a much more limited time series is available.

It is noteworthy that though the countries with statistical information available are usually classified as illicit drug consumers as opposed to producers, this labeling does not describe the situation accurately: drugs are also consumed where they are produced. Development of a global illicit drug use information system is timely.

Statistics on illicit drug use are based on self-reporting. While there are good reasons to have doubts about the accuracy of this information (Hser 1997), many experts (including Preston et al. 1997) have provided evidence about its usefulness. Only surveys are feasible and their results permit reliable comparisons of time points and cultures even though level-of-use estimates based on them are diluted.

United Nations' experts (United Nations International Drug Control Programme 1997) contend that global illicit drug consumption is higher than ever. Surveys indicate accordingly that both experimentation with drugs and their regular use have increased substantially in industrialized countries since World War II. At present illicit drugs involve both genders in the age range from early teens to young adulthood almost equally. In the United States, tenth graders (15–16 years of age; this is the age of the average first user) reported in 1996 the following lifetime use of illicit drugs: marijuana 42 percent, inhalants 18 percent, hallucinogens 11 percent, cocaine 7 percent, crack cocaine 4 percent, heroin 2 percent, stimulants 17 percent, and steroids 2 percent. As a comparison, the daily use of marijuana was admitted by about one in every 10 lifetime users of teen age, and 30 days' consumption of the above-mentioned drugs varied between one third and one sixth of their respective lifetime consumption among US teenagers.

In 1997, at least experimenting with hemp products was admitted by 33 percent of 15–16-year-olds in the UK, 18 percent in Denmark, but only 3 percent in Greece. The corresponding figures for solvents were 20 percent, 12 percent, and 7 percent, and for amphetamines 18 percent, 2 percent, and 4 percent, which represent high, medium, and low ranges of their respective consumption in the 14 European Union countries (EMCDDA 1998). While some calming information exists about the former socialist countries situated in Europe (EMCDDA 1998), this area must be included among those that need a better monitoring system for reliable conclusions (eesv MSDP 1998).

There are numerous risk factors for drug use (Newcomb 1994) involving cultural and structural, interpersonal, psychosocial, or biogenetic factors. Cultural and societal risks include drug use promoting social norms, economic hardships, and drug availability. Among the interpersonal influences are family

use, favorable familial attitudes, family or peer conflict and economic difficulties, and connections to peers using drugs. Psychosocial determinants involve earlier persistent problem behavior, rebelliousness, poor school achievement, early experimentation, and positive drug attitudes. Among the biogenetic causes, genetic susceptibility and psycho-physiological vulnerability to drug effects must be mentioned.

2. *Ways to Control Illicit Drugs*

Illicit drugs are consumer goods subject to economic laws of supply and demand. Increases in world travel, opening of national borders, deregulation of trade and finance, and political instability and conflicts have led into increased supply of these drugs. To reduce the supply, countries have started to network in many ways, including cooperation in such international organizations as the United Nations and World Health Organization. The traditional goal of control politics has been the elimination of illicit drugs from the market. When in fact drug use has increased in spite of efforts to achieve the opposite, some European countries have added harm reduction as a goal for educating youth in general (Uhl and Springer 1998).

International cooperation of law-making and law-enforcing organizations is one of the instruments to control illicit substance use (Van der Stel 1998). Another vital method involves social policy directed to the prevention of marginalization of citizens. Societies form a web of complex social systems in which the role of governmental control varies. Irrespective of their position in that dimension, a few countries have already established health political programs for illicit drug prevention. They, like all health promotion programs (Green 1999), must be implemented in the basic social units, communities.

2.1 *Community Programs to Influence Supply and Demand*

Aguirre-Molina and Gorman (1996) described community programs in drug prevention in the United States, although few of them exist in large numbers (see *Health Interventions: Community-based*). These are comprehensive, empowering, and developmental community-based interventions that target multiple social systems and employ manifold strategies. They aim at all factors in the environment that contribute to the risk or protective factors. Programs already tested and three decades of experience with cardiovascular community programs encourage the continued cooperation of prevention workers and researchers.

Community-based programs usually cannot affect the production and manufacture of drugs (although this may be possible), but they can influence drug availability and access. Second, community organization involves both law enforcement and the local media, and can involve broad-based community change interventions. Furthermore, high-risk groups of people or high-risk neighborhoods need to be focused upon. Third, community-based intervention programs may aim at individuals at different phases of their life cycle.

2.2 *School Programs to Control Demand*

Drug education can be directed to different audiences: in the most general form, it is directed to populations via the mass media in community programs. The next lower level is that of groups—most notably school classes. Finally, education may be executed on a face-to-face basis to individuals. As youth is the subpopulation most at risk and can be addressed in school programs, these have be the main focus of efforts and most of the research (see *Health Promotion in Schools*).

School programs have been largely developed and implemented in the United States (Tobler 1997, Kreft and Brown 1998), but they have also been applied in Europe (White and Pitts 1998, Uhl and Springer 1998). Programs properly tested involve contents such as knowledge (drug effects, social influences, actual use of drugs), emotions (self-esteem, self-awareness, values), refusal skills (drug refusal, public commitment, cognitive behavioral skills, nondrug support systems), more generic or life skills (communication, assertiveness, decision making, coping, social, goal-setting skills), safety skills (own-peer security when drugs are used), extracurricular activities (job, sports, culture, leisure time, community work), or what can be termed prosocial activities (peer counseling, home work, rewards, parent and/or community involvement). Participation of the peer group in the program implementation varies on the dimension of noninteractive vs. interactive. In the list above, the divide is between programs clarifying emotions and teaching refusal skills: programs dealing with knowledge and emotions are noninteractive, the rest are interactive.

Kreft and Brown (1998) present sharp critique directed towards the poorly conducted bulk of illicit drug education studies. Dusenbury and Falco (1997) also note that extra care must be taken when making a purchase among programs available. The review by Tobler (1997), however, enumerates studies defying that criticism and uses sound meta-analytic techniques to yield conclusions, but not, however, verifying whether multilevel modeling important for school studies where students of same class unit have a common environment has been adopted or not. White and Pitts (1998) came to essentially the same results also.

Only interactive school programs of drug education can be deemed effective. Among the interactive programs, the highest effects were observed for general

life-skills programs, followed by programs having either prosocial nonschool activities or social influence as content. Second, the effects when they exist are usually modest in size. As effect size estimates are bound to be subjective, it is helpful to contend that if an effect size of interactive programs were to be observed in a study concerning effects of medicines, a recommendation for use would be made. Third, the effect includes postponing experimentation—often the interactive programs' effects are to be seen for 3 years. Fourth, when programs were implemented in larger groups, the effectiveness attenuated, except among multicultural audiences. This may indicate either poorer administration of larger programs and/or increasing methodological problems posed by larger intervention to internal validity. Fifth, sizeable effects in postponing drug experimentation have been observed in small studies using interactive delivery. Sixth, the effects seem to be equivocal for different drugs.

Educational programs have been targeted at audiences from 8 to 25 years old in a variety of settings including schools and colleges, community settings, the family, medical/therapeutic settings, and mass media (White and Pitts 1998). Tobler and White and Pitts made it clear that most of the available programs are meant for school and for primary and secondary prevention. There is a serious lack of programs to be implemented in other contexts or directed at groups at special risk (White and Pitts 1998).

2.3 Family-based Interventions to Increase Prosocial Bonding and Help with Problems

The community and schools have to be named as important contexts of the above interventions. The possible sites of impact include recreational and religious settings, work, and, importantly, the family, in which the primary socialization takes place. Because of centrality of the family in illicit drug use prevention, this contexts attracts primary interest.

Biglan and Metzler (1998) noted that drug use among young people is associated with engagement in diverse problem behaviors and certain parental practices (lack of effective monitoring, discipline, and positive involvement with children). Three types of family interventions can be discerned: universal to the general population of families, selective to families with high-risk youth, and indicated interventions to dysfunctional families with many risks (Kumpfer 1998). Of these, the most significant from the public health perspective are universal interventions (Catalano et al. 1998).

At the beginning of the twenty-first century, some promising interventions involving the social developmental model, using prosocial bonding family, school, and peers as a protection against the development of conduct problems, school misbehavior, and drug use, are in the evaluation phase. It is hypothesized that strong prosocial bonding to others reduces the risk of substance abuse. It can be expected that the success of this undertaking is dependent on the extent to which prosocial involvement within the family is available to the child, skills necessary in participating in the family interactions, and rewards/punishments provided by parent for conforming/nonconforming with the family expectations and beliefs. As in the case of community research, more studies need to be reported before definite conclusions of their real worth can be arrived at.

3. Conclusion: Towards More Effective Cooperation

Illicit drug abuse prevention continues to be an important task of health promotion, both nationally and internationally. Although all undertakings in prevention may not be easily evaluated (a good example of which is international control measures), scientific rigor should always be aimed at when making the choice. Only school-based programs have been reliably evaluated so far, leading to a recommendation of adopting interactive programs relying on life or refusal skills. Both community and family interventions seem to be important to consider, although they need to be applied and then evaluated further before firm conclusions can be made. At the highest level, national policy goals need to be adapted to changing circumstances in many countries, a global information system should established, and international cooperation at all levels strengthened for the success of prevention and developing its objectives.

Drugs: International Aspects

Although the term 'drug' has a wider range of meanings, we are concerned here with substances which are psychoactive, that is, which alter the mental state of humans when ingested. Such drugs have been both prized and feared throughout human history. They have long been a substantial item in international trade, and indeed concerning the European colonial systems of 1500–1960 they have been described as the glue of empires. In the twentieth century, they also become the subject of ambitious international control structures. In connection with such control structures, brief consideration is given, too, to performance-enhancing drugs, a category overlapping with psychoactive drugs.

1. *Psychoactive Drugs and How They are Used*

There are a wide variety of psychoactive substances, naturally occurring and synthesized, including tobacco, alcoholic beverages, coffee, tea, chocolate, and some spices, as well as substances legally available only through medical channels such as benzodiazepides, cannabinols (including marijuana), opiates (including heroin), and cocaine. Such substances often have other use values, along with their psychoactive properties (Mäkelä 1983). Users may like the taste, or the image of themselves that the use conveys. Use may be a medium of sociability, or part of a religious ritual. Some substances have other useful properties; alcohol, for example, is a source of calories, and is the solvent in many tinctures and medicines.

Psychoactive drugs differ in their metabolic pathways and mechanisms of action in the human body, in the strength of their effects, and in the states of mind and feelings they induce. In particular, it is easy to become intoxicated with some substances— alcohol is

a prominent example—while it is much less likely with others. But the effects of drug use are also powerfully dependent on the pattern of use, and on set and setting—this is, the expectations of the user and of others present, and the context of use (Zinberg 1984). While the psychoactive effect of tobacco may not even register in the consciousness of a habituated cigarette smoker, in other circumstances the effect of tobacco use may be so strong that the user is rendered unconscious, as early Spanish observers reported concerning native South Americans.

Three social patternings of psychoactive drug use can be distinguished as prototypical: medicinal use, customary regular use, and intermittent use. In many traditional societies, particular drugs or formulations have been confined to medicinal use—that is, to use under the supervision of a healer to alleviate mental or physical illness or distress. For several centuries after the technique for distilling alcoholic spirits had diffused from China through the Arab world to Europe, for instance, spirits-based drinks were regarded primarily as medicines. This way of framing drug use has been routinized in the modern state through a prescription system, with physicians writing the prescriptions and pharmacists filling them. Drugs included in the prescription system are usually forbidden for nonmedicinal use.

Where a drug becomes a regular accompaniment of everyday life, its psychoactivity is often muted and even unnoticed, as is often the case for a habitual cigarette smoker. Likewise, in southern European wine cultures, wine is differentiated from intoxicating 'alcohol'; wine drinkers are expected to maintain the same comportment after drinking as before. We may call this a pattern of 'banalized use': a potentially powerful psychoactive agent is domesticated into a mundane article of daily life, available relatively freely on the consumer market.

Intermittent use—for instance, on sacred occasions, at festivals, or only on weekends—minimizes the build-up of tolerance to the drug. It is in the context of such patterns that the greatest attention is likely to be paid to the drug's psychoactive properties. The drug may be understood by both the user and others as having temporarily taken over control of the user's behavior, and thus to explain otherwise unexpected behavior (Room and Collins 1983). Given the power attributed to the substance, access to it may be limited: in traditional societies by sumptuary rules keyed to social differentiations, in industrial societies by other forms of market restriction.

In industrial societies, a fourth pattern of use is commonly recognized for certain drugs: addicted or dependent use, marked by regular use, often of large doses. Since the pattern of use of the drug in question is not defined in the society as banalized, addiction is defined as an individual failing rather than as a social pattern. While attention is paid to physical factors sustaining regular use, such as use to relieve withdrawal symptoms, most formulations of addiction focus on psychological aspects, including an apparent commitment to drug use to the exclusion of other activities and despite default of major social roles. An addiction concept thus also focuses on loss of normal self-control, but the emphasis is not so much on the immediate effects of the drug as on a repeated or continuing pattern of an apparent inability to control or refrain from use, despite adverse consequences.

Among the attractions of psychoactive substances is that, at least up to a certain point, they potentially enhance one or another kind of performance by the user: For instance, coffee or a cigarette may modestly improve mental performance, a limited amount of alcohol may improve dancing or other expressive activity, amphetamines may improve wakefulness on a long watch. There are also nonpsychoactive substances (steroids, beta-blockers, etc.) which can potentially improve one or another kind of performance. In particular, in the context of competitive sports, international attention has been focused on a wide variety of substances which can improve some aspect of athletic performance.

2. *Problems from Drug Use, and Systems of Control*

From ancient times, it has been recognized that problems can result from drug use. Formerly, the main concerns were with social and political problems seen as associated with drug use. In medieval England, the government's main concern in controlling alcohol sales was with enforcing discipline in the labor force. Violence, disturbances of the peace, and harm to dependent family members would also be commonly recognized, particularly in relation to alcohol consumption. Often it was rebellious or countercultural elements of a society which introduced or became associated with new drugs. Reacting to this, political establishments in Europe tried at first to control coffee houses, and in Turkey and elsewhere imposed severe punishments on tobacco use (Austin 1978).

New social concerns about problems from drug use entered the scene in the modern era. Concerns about the physical health of the drinker were a factor in responses to the English 'gin epidemic' of the eighteenth century. In the early nineteenth century, the idea of addiction became established, at first for alcohol and in the USA (Levine 1978). By the late nineteenth century the idea had spread to other societies, and was applied also to other psychoactive drugs. As safety became identified as a social problem in the late nineteenth century, attention was also directed to the potential effects of drinking in degrading performance of mechanical tasks. In recent decades, as the automobile became a central part of daily life, this concern became much stronger, and was extended too to other drugs.

Social concerns about problems from drug use have resulted in a variety of kinds of efforts to control availability (MacCoun et al. 1996, Room 2000). One option has been a flat prohibition on use, or at least on recreational use. Combined with this, sometimes, has been a system for use of the substance as a medication. The prescription system in modern states is essentially a state-sanctioned form of rationing of availability, with doctors and pharmacists delegated to serve as the gatekeepers on access. A third option has been a system of state control or licensing of sales, such as the systems of alcohol control through state monopolies and licenses in North American states and provinces. Such a structure can be combined with other discouragements for use, such as excise taxes and restricted opening hours. A fourth option, applicable for instance nearly everywhere for tea and coffee, is that the psychoactive substance is treated as an ordinary commodity, with no special controls. For intoxicating substances, choice of the third or fourth option is often accompanied by 'harm reduction' measures (in the terminology of the illicit drug field), since the options involve official acceptance of the fact of recreational drug use.

Where a psychoactive substance is seen as causing great problems, prohibition of use has been a fairly common societal response. Such a prohibition on alcohol had long been imposed on all faithful Muslims by the Koran. Legal prohibition of alcohol, initially on a local basis or for special population categories such as indigenous peoples, became a feature of some Christian societies in the late nineteenth and early twentieth centuries. Prohibition of alcohol sales extended to the national level around the time of World War I in the USA, Canada (briefly), Iceland, Norway, Finland, and Russia. The USA, in particular, had some success in gaining international cooperation with its prohibition through bilateral treaties (Tyrrell 1994). A flourishing worldwide temperance movement succeeded in pushing the European powers with colonies in Africa into adopting treaties prohibiting aspects of the distilled spirits trade in Africa (Bruun et al. 1975). These fell into disuse by the 1940s.

The alternative to prohibition in the early twentieth century was 'state control', and comprehensive systems of alcohol control were eventually adopted, not only in the societies which had tried prohibition, but also in many other nations. These systems have been gradually weakened, particularly since 1950 (Mäkela et al. 1981). On the other hand, in a broad range of societies there has been a steady strengthening of controls over drinking in specific circumstances, in particular over drinking and driving (Gusfield 1981).

In the early twentieth century, the idea of a prohibitory regime was extended from alcohol to other psychoactive substances. In the realm of 'narcotics', which came to refer to opiates, cocaine, and marijuana, the first international treaty was signed in 1906, and extended globally as part of the treaties concluding World War I (McAllister 1992). The agreement on narcotics can be seen as part of an emergent tradition of such regimes for social problems defined as international in scope (Nadelmann 1990). A series of subsequent international agreements were codified in the 1961 Single Convention on Narcotic Drugs (amended 1972). While the system had always included provision for a legal market in narcotic medications under a prescription system, in a 1971 convention its scope was broadened to extend international control to other synthesized medications such as amphetamines, barbiturates, and benzodiazepines. A 1988 convention extended control also to 'precursor chemicals' used in manufacturing controlled drugs. By 1996, more than 240 substances were in principle under the system's control (Room and Paglia 1999).

In the mid-1990s, the international narcotics control system included the United Nations Drug Control Program (UNDCP), with about 200 staff, headquartered in Vienna. The political organ of the system is the Commission on Narcotic Drugs, with an elected membership of 53 nations. The International Narcotics Control Board (INCB) serves as the control board for the legal (pharmaceutical) markets in controlled drugs. Alongside this international effort is a substantial global antidrug effort by the USA, including over 400 Drug Enforcement Agency staff stationed in 50 countries in 1993, and an annual certification process to the US Congress on the extent of cooperation by each other country with antidrug actions.

Although effective action has been taken to diminish use of prescribed drugs like barbiturates, the system has by most accounts been relatively ineffective in suppressing illicit international traffic in drugs. The system's own summation, in the *World Drug Report* (UNDCP 1997), is that the 'outcome is undoubtedly less than satisfactory' in terms of the decreased availability of drugs.

At the end of the 1990s, two other international systems for the control of psychoactive drugs were in formation. In late 1999, in the wake of a World Conference on Doping in Sport, a World Anti-Doping Agency started operation in Lausanne, as a joint venture between governments and the International Olympic Committee (WADA 2000). Prior to this, in 1989 the Council of Europe had put forward an Anti-Doping Convention which by 2000 had been signed by 40 European countries and other countries such as Australia and Canada (COE 2000).

In October 2000, the World Health Organization began negotiations on a global Framework Convention on Tobacco Control. Among topics discussed for inclusion in the Convention were the harmonization of taxes, cooperation against smuggling, elimination of duty-free sales, and control of advertising and sponsorship (Joossens 2000). Unlike the international narcotics control system and the nascent

antidoping system, the tobacco control effort is thus not prohibitory of use, at least by adults.

In the meantime, in 2000 there is no prospect of any international agreement on alcohol control. For tobacco and alcohol, as well as other psychoactive substances not under international control, international treaties have operated in the opposite direction. The World Trade Organization and related treaties, and regional free trade agreements, have been used to weaken national and local alcohol controls (Holder et al. 1998, Jernigan et al. 2000).

3. *Traditions of Social Science Analysis*

Dominant patterns of use of a drug in a society, and shifting conceptions about its use, greatly affect the size and shape of the social science literature concerning that drug. In particular, the very different sociocultural positions of 'illicit drugs', benzodiazepines, alcohol, tobacco, and coffee in most developed societies means that the literatures about these different psychoactive substances are often quite separate.

Novel substances have proved a potent catalyst in many societies in crystallizing free-floating fears about the younger generation and the future. Culturally accepted psychoactive substances, on the other hand, become deeply entrenched in the culture, although often with the potential to again become contested. Social concerns about drugs have thus often ensured substantial funding for social scientists to work in the area. For instance, a substantial part of Polish sociology was financed to work on alcohol problems in the difficult days of martial law there in the 1980s. But while much social science work has been funded and expected to proceed within the parameters of official frames, the work of sociologists and other social scientists has also played a key role in broadening the base of scholarship and understanding.

In the first place, alcohol and drug issues have proved fertile grounds for constructivist analyses by sociologists. Historical and comparative work has identified a number of alternative governing images or models of alcohol and drug problems, and shown that these governing images change over time (Bruun 1971, Gusfield 1967). Constructivist perspectives have often been combined with a positivist concern about measuring and comparing social and health problems associated with drug use, and about distinguishing problems attributable to the drug use from problems that are secondary to societal reactions (e.g., Fischer et al. 1997). Some analyses point to a function for illicit drugs of providing 'suitable enemies' for the modern state, in comparison with the 'unsuitable enemies' of tobacco, alcohol, and pharmaceuticals (Christie and Bruun 1996).

In the second place, there is a long sociological tradition of critical analysis of the concepts of alcoholism or addiction as a disease (Room 1983), concepts which were the dominant discourse in the last half of the twentieth century. The alcohol and drug arenas have thus figured prominently in sociological analyses of the 'medicalization of deviance'— and its demedicalization (Conrad and Schneider 1992). Applying perspectives from Foucault and Rothman, Levine (1978) showed that the addiction concept has a history, first coming to the fore in the early nineteenth-century USA, as an explanation of the mystery of continued drinking by the drunkard, even after pledging to abstinence. Analyses in this tradition point to the centrality to addiction concepts of the focus on self-control (Valverde 1998). The economist's concept of 'rational addiction' has also contributed to the ferment in the late 1990s in thinking about addiction concepts (Elster and Skog 1999).

There are as yet few social science analyses of the burgeoning international systems for control of psychoactive substances. Bruun et al (1975) studied the development of the international drug control system until the early 1970s, but arms-length analysis of the expansion of this system's scope after then has been sparse (Room and Paglia 1999), and analyses of the development of new international instruments and agencies around doping in sports (Houlihan 1999) and around tobacco (Taylor 1996) as yet come primarily from those involved in building the systems. The issues of why the three systems are developing separately, of the nature and practicability of their goals, and of their place in the developing international system, are still important topics for future work.

Du Bois, William Edward Burghardt (1868–1963)

William Edward Burghardt Du Bois was born in Great Barrington, Massachusetts on February 23, 1868. Ninety-five years later, having renounced his citizenship of the USA, he died an exile in Accra, the capital of the newly decolonized republic of Ghana on April 29, 1963. An unorthodox and multidimensional career had unfolded between these two events. An unwavering devotion to the cause of human progress underpinned Du Bois' cosmopolitan life that was also characterized by bold shifts in ideological outlook. He moved through pragmatism, elitism, socialism, nationalism, and several versions of Pan Africanism in an idiosyncratic, but always thoughtful sequence that terminated amidst the gloom of the Cold War when the old savant, aged 93 and deprived by his government of the means to travel freely, applied to join the Communist Party of the USA and then fled the land of his birth.

Du Bois had been identified as an outstanding student at an early age. After completing high school in Massachusetts, he continued his studies initially at Fisk University in Nashville. When he entered the college in 1885, it was a haven lodged in a bitterly segregated world still resonating with the destructive energies released by civil war. Life there, confined within what he called the veil of color, was a very different proposition from anything that Du Bois had experienced in the New England environment that had nurtured him. It was there that he discovered and wholeheartedly embraced the black cultures of the American South that he encountered inside the historic college, and discovered in more intense and ambiguous forms while working as a schoolteacher in rural Tennessee during the summer vacations. He concluded his studies at Fisk in 1888, choosing the German Reich's Chancellor Otto Von Bismarck as the topical subject of his oration at the college graduation ceremony.

In fulfillment of a childhood dream, and in recognition of the opportunities it would bring, Du Bois moved on to continue his education at Harvard later the same year. Among other classes, he studied

philosophy with William James, who would become a friend, and read Kant with George Santayana. He took economics under Frank Taussig and history with Albert Bushnell Hart who helped to pilot his career through numerous institutional obstacles. After graduating *cum laude* in Philosophy in 1890, he applied to pursue postgraduate study in Political Science and gained an MA degree in 1891. It was at this point that Du Bois began to seek ways to continue his education in Europe. Financial support was difficult to find but in 1892 he was eventually rewarded with a year-long grant to study in Germany. Later that year, he entered Friedrich-Wilhelm III University in Berlin where his teachers included Gustav Von Schmoller, Adolf Wagner, and Heinrich Von Treitschke. It was also there that he first encountered Max Weber and Georg Simmel.

Du Bois attended several meetings of the Social Democratic Party (SPD) while living in Berlin. He had been working towards a German doctorate in economics but, to his disappointment, was denied the degree on the grounds that he had been registered at the university for an insufficient length of time. After extensive travel in Europe he returned to the corrupting provincialism of 'nigger-hating America' to complete his thesis in Harvard's History department in 1895. Shortly afterwards, he became the first black person to receive the Ph.D. degree from that University, but as a result of this success was hugely overqualified for the limited professional opportunities available to him in a world that could not concede the intellectual capacity of 'the Negro' and consequently viewed him as something of a curiosity.

He eventually found a position at Wilberforce College in Ohio where he taught Classics, Greek, and English. His growing interest in Sociology was manifest in some unsuccessful attempts to have the new discipline added to the curriculum. He married Nina Gomer, who had been a Wilberforce student, in 1896 and, later that year, his first book *The Suppression of the African Slave Trade to the United States of America 1638–1870* (1896) was published to very favorable reviews. This welcome development boosted Du Bois' career prospects and enabled him to move to the University of Pennsylvania, where he was employed to produce a groundbreaking sociological study of Philadelphia's black population. Work on that project would continue after he accepted a Professorship of Economics and History at Atlanta University the following year.

This new post provided an institutional platform from which Du Bois organized an ambitious program of sociological investigations into various aspects of black life in the USA. It resulted in a flow of major publications between 1898 and 1914. His substantial empirical study of Philadelphia was published under the title *The Philadelphia Negro* in 1899; it was given a distinctive character by well-developed interests in economics and comparative history. It is rightly remembered as a landmark publication: the first academic monograph to consider the life of an American black community in depth. The Du Bois household was struck by calamity when Burghardt, their two year-old son, died of diphtheria in May 1899. This tragedy seems to have led to estrangement between Du Bois and his wife. However, it combined with his growing academic and political ambitions to endow an elegiac and sometimes melancholy tone in his next book: *The Souls of Black Folk* published in 1903. This was a remarkable, multivoiced collection of his essays, autobiographical reflections, and fiction. It made him a leader of black Americans.

Du Bois' commitment to resolutely open-ended, liberal, and humanist education which would nourish the needs and responsibilities of a black elite destined for leadership at both local and global levels, brought him into conflict with the more modest and practically-oriented educational proposals that were being advocated by Booker T. Washington and were on show at his Tuskeegee Institute. This national debate, which exposed the molten core of black America's political and economic marginality, resulted in Du Bois leaving Atlanta University to pursue a new para-academic career as a writer, editor, and activist based in the North. In 1910 the newly formed National Association for the Advancement of Colored People (NAACP) hired him as Director of Publications and Research. He was the founding editor of, and a prolific contributor to, the organization's influential and dynamic monthly magazine *The Crisis*, a post he would hold until 1934. His first novel, *The Silver Fleece* was published in 1911, the same year that he attended the Universal Races Congress organized in London by the English Ethical Culture movement.

The death of Booker T. Washington and the advent of the 1914–18 war transformed the political conditions in which Du Bois argued for the equality of black Americans and indicted the catastrophic impact of racism on the American polity stratified by color. Though he never completed a proposed volume on the experience of African-Americans during the war, the immediate aftermath of the conflict provided the impetus for the first of several Pan African congresses, which was held in Paris in 1919. After the war, Du Bois' voice was raised against America's failure to recognize its black citizens and in opposition to the gross violence that greeted the returning soldiers. He was severely critical of the more populist and militaristic forms of Black Nationalism associated with Marcus Garvey's United Negro Improvement Association (UNIA) which was growing in importance as the influence of the NAACP diminished.

Du Bois' cosmopolitan outlook and the breadth of his published work made him a pivotal figure among the younger writers, artists, and thinkers who led the artistic and literary movement known as the Harlem Renaissance. He contributed a memorable essay to *The New Negro* anthology, edited by the philosopher

Alain Locke, that defined this important cultural departure but conflict soon followed with some of the younger writers, who were regarded by Du Bois as insufficiently attentive to their world-historic political responsibilities. *Dark Princess*, a vibrant political novel that concerns a grand planetary alliance of peoples of color against imperialism and colonialism and which was identified by Du Bois as his own favorite among his many books, was published in 1928.

The thirties saw Du Bois renewing his interest in Marxism and developing an original and complex critique of Marx's political theory. This striking synthesis was elaborated in a monumental historical study: *Black Reconstruction In America* (1935). The first of his several autobiographical volumes appeared in 1940. Du Bois rejoined the NAACP as their director of special research in 1944. He was sacked four years later after yet another bout of political disagreements, this time resulting from his intermittent affiliation to communist causes that the utterly respectable and sometimes conservative organization was unable to tolerate. Anti-colonialist and anti-capitalist commitments led Du Bois into further battles with the US government. In 1951 he was arrested and charged with the crime of operating as an unregistered agent of a foreign power. The charges were eventually dismissed but this unhappy experience galvanized him in support for the Soviet bloc. This phase of his life was explored in yet another book *In Battle for Peace: The Story of My eighty-third Birthday* (1952).

1. *Du Bois' Scientific Contribution*

Du Bois was the first sociologist of the American South. He articulated the complexities of African-American life in comparative and historical terms that owed much to his multidisciplinary training. He placed sociological reason at the disposal of black Americans' freedom struggles and sowed the seeds that would bear fruit in the mid-twentieth century legal judgements that cited later sociological studies in support of desegregation. His own timely empirical contributions, particularly *The Philadelphia Negro* (1899) were also important because they replaced top-heavy theoretical speculation with an honest blend of theory with practical innovations in research technique. Guided as much by Schmoller as by the spirit of Charles Booth, Du Bois was also the first American social scientist to make empirical research the pivot of an investigation. His investment in the power of properly scientific sociology as a stimulus for governmental intervention and the pursuit of democracy unmarked by racial categories was considerable; however his faith in progress was neither simplistic nor naïve. Sociology was obviously indispensable but it was also insufficient. Its hard-won truths had to be communicated in several tongues, and made accessible to the widest possible audience. But more than this, Du Bois' achievements suggested that sociology was always at its most eloquent when supplemented and enhanced by the power of poetry.

2. *The Contemporary Influence*

In addition to his accomplishments as a distinguished social scientist Du Bois is still remembered as an essayist, editor, novelist, historian, and political leader. The breadth of his intellectual interests and the skill with which he turned them into a host of compelling written material in several distinct disciplines and styles made him the dominant African-American thinker of the twentieth century. Close to the aftermath of slavery and against the expectations of those who had judged 'Negroes' to be incapable of higher learning, his extraordinary work boldly redefined America's racial hierarchy as intrinsic to the incomplete workings of American democracy. In making that unpalatable argument in potent language which was both scholarly and poetic, Du Bois created a black intelligentsia which understood itself and its historical and sociological predicament in terms he had specified. His exceptional scholarly insights were articulated in a prolific output that continued throughout his long life. All of this work was characterized by a double achievement to match the double consciousness from which it grew—a sense of black intellectuals caught, or as he put it 'imprisoned,' within the folds of European civilization developing interests of their own distinct from those of the black poor.

He transformed understanding of African-American history and society while supplying the intellectual cornerstones for new varieties of critical and oppositional consciousness that could move beyond the task of defending America's black communities as they emerged from the twilight of slavery. In articulating an especially rigorous, energetic, and durable brand of dissident intellectual work, Du Bois not only provided solid foundations for the scholarly study of racism, he enabled his many successors to challenge white supremacy in the world of ideas, and provided important conceptual and historical resources for anticolonial movements worldwide.

P. Gilroy

Dual Task Performance

1. Introduction

Studies on dual task performance belong to the core research areas on divided attention and also have strong applied relevance. In the epoch of automation, it is important to know which tasks can be performed together more or less easily and how they contribute to work load. Intuitively people can do only a limited number of 'things' at once, but much may depend on the level of skill. During the 1970s this wisdom was expressed in terms of the influential conceptual metaphor of the human as a limited capacity processor which was inspired by the early digital computers. Present theoretical formulations emphasize 'cross-talk' and 'specification of action' as the main sources of performance limits in dual task performance. This article presents a concise review of the various theoretical positions. A more complete account can be found in Sanders (1998).

2. Limited Capacity Theory

The limited capacity was thought to be distributed over the tasks, permitting time sharing as long as the joint task demands did not exceed the limits, with the exception of a little capacity which was required for coordination of the tasks or for monitoring the environment. Effects of skill on capacity demands were described originally in terms of more efficient programming of the individual tasks. More recently, the notion of automatic vs. controlled processing has gained currency. In contrast to a controlled process, an automatic process—the ultimate result of practice—was not supposed to demand any capacity, and could therefore be always time shared. Sometimes, capacity was assumed to be constant (Moray 1967, Navon and Gopher 1979), whereas it was thought to vary as a function of arousal on other occasions (Kahneman 1973). A variable capacity has the problem that performance measures of capacity limits are basically unreliable. This was the reason why Kahneman proposed physiological measures with pupil size as favorite. Among others, pupil size was found to increase as a function of cognitive processing demands, e.g., the number of items to be rehearsed in a memory span task. However, such effects are easily overruled by the reaction of the pupil to light. More generally, there is the problem that cognitive information processing and autonomous physiological responses have no common conceptual framework.

Figure 1
A performance–resource function describes the relation between performance and the number of allocated resources. In an easy task (a) data limits are reached much sooner than in the more difficult tasks (b, c) (from Sanders A F 1998 *Elements of Human Performance*. Erlbaum, Mahwah, NJ)

The most elaborate capacity theory stemmed from economics rather than from the digital computer (Navon and Gopher 1979). A performance–resource function (PRF, Fig. 1) depicts the relation between performance and invested capacity or resources. Performance improves as more resources are invested—the resource-limited part of the function—until reaching a maximum, which signals the start of the data-limited part of the function. As is clear from Fig. 1, a data limit means that performance does not improve further when more resources are allocated. Task difficulty is defined as marginal efficiency of the resources.

Unlike in economics, a behavioral PRF cannot be obtained directly but it can be estimated from a performance operating characteristic (POC) which describes the relation between performances of two

Figure 2
A performance operating characteristic describes the exchange relation between two tasks when performed singly or in combination. (a), (b), and (c) are examples of linear trade-off; (d) illustrates the case of perfect dual task performance; (e) shows initial time sharing followed by a linear trade-off; (f) shows a case in which trade-off is not gradual but occurs in a few rough steps (from Sanders A F 1998 *Elements of Human Performance*. Erlbaum, Mahwah, NJ)

tasks in a dual task setting. Examples of POCs are given in Fig. 2.

Figures 2(a)–(c) have linear exchange relations, suggesting that, when performed alone, either task consumes all resources so that performance suffers when the second task acquires some resources as well. The slope of the POC expresses the relative difficulty of the two tasks. Thus, in Fig. 2(c), task A is more difficult than task B, since a small loss on task A has the effect of a relatively large gain on task B. Figure 2(a) shows a case in which maximum performance on task A, when carried out alone, is somewhat better than dual task performance with an exclusive emphasis on task A. This difference is labeled concurrence costs, which is the opposite of concurrence benefits (Fig. 2(b)) in which case maximum performance on task A profits from the presence of task B. Doing two tasks together without any performance loss on either one (Fig. 2(d)) suggests pronounced data limits in both tasks. The available resources cannot be used by either task, thus enabling maximum joint performance. In Fig. 2(e) maximum performance on task A can still be combined with some activity on task B, followed by a linear exchange relation between both tasks. Presumably task A has some data limits but much less strongly than in Fig. 2(d). Finally, Fig. 2(f) raises the question of continuous vs. a discrete trade-off between the tasks. People may be only capable of dividing resources by way of a few discrete steps.

The main difference between economics- and computer-based capacity models is that the economics view assumes that people always aim at investing all resources. A proper study on dual tasks, therefore, should only be concerned with the resource-limited parts of the PRF. The difference between a difficult and an easy task is that people do more on the easy task but all resources are fully invested in either case. In contrast, computer models have usually defined difficulty in terms of resource demands, a difficult task leaving less spare capacity than a simple task. The two hypotheses have different predictions when capacity shrinks somehow. The economics theory suggests that the easy task will suffer most, since the quantitative effect of removing resources is larger on the easy task. In contrast, the computer model suggests that the difficult task has largest capacity demands and will therefore suffer most. The evidence appears to favor the economics model; as long as both tasks are resource-limited, limiting resources appeared to have more effect on the easy task.

The above capacity concepts are aspecific and assume task invariance. Aspecificity means that any task or activity consume the same resources. Task invariance means that the quantity of performance may vary with resource allocation but the nature of the task remains the same. All models implicitly assume a central executive which is responsible for the allocation policy. The distinction between resource and data limits adds the important suggestion that tasks may be timeshared because each one only needs part of the available capacity to reach its maximum performance. This will usually refer to capacity demands over time. Indeed, one popular measure of workload—timeline analysis—involves a time record of activities; an operator is supposed to be overloaded when task demands overlap in time, which implies the assumption that only a single activity is possible at any moment. It should be noted, though, that this issue—serial vs. parallel processing of demands from various tasks—is not raised in capacity models. The point is that they never specify whether 'capacity demands' refer to a single moment or to an extended period of time.

It is not surprising that models of dual task performance started with the above simple capacity notions They had the advantage of providing a simple approach to the applied problem of mental workload—the more demands, the higher is the load—and of task difficulty. In addition, they give a straightforward definition of selective attention in terms of capacity limits and allocation policy, and they suggested basic rules why two tasks can be sometimes timeshared whereas they are mutually exclusive on other occasions. An aspecific limited capacity was also an appealing metaphor during the 1960s and 1970s and had at least one interesting prediction. Thus the level of dual task performance should not depend on the specific characteristics of the various activities involved. In other words, if a task A suffers more from task C than from task D, task B should also suffer more from task C than from task D (Navon and

Gopher 1979). Perhaps the most compelling failure of this prediction stems from a classical study by Brooks (1968). He found that a task requiring spatial working memory (task A) was performed better in combination with a verbal processing task (task B) than with a spatial processing task (task D), whereas a task demanding verbal working memory (task B) was performed better in combination with spatial processing (task D) than with verbal processing (task B). Other evidence showed that search in verbal short-term memory was more easily combined with manual tracking than with recalling abstract words. However, searching spatial short-term memory was performed better in combination with recalling abstract words than with tracking. Various other examples are discussed by Wickens (1992). They all relate to effects on dual task performance of structural alteration, i.e., changing the structure of a task while keeping its difficulty constant, and to difficulty insensitivity, i.e., conditions in which increasing the difficulty of one task hardly affects the performance level of another. Both effects are at odds with a single aspecific limited capacity.

3. *Multiple Resources*

This was the reason for considering multiple and mutually independent resources (e.g., Sanders 1998), in which a task is characterized by its profile of demands for various resources. Wickens (1992) proposed three resource dimensions, one relating to input modality (visual vs. auditory), one to the relative emphasis in central processing (perceptual/cognitive vs. response) and one to central processing codes (verbal vs. spatial). This last dimension relates to the finding that a spatial task is usually easier to combine with a verbal task than with another spatial task. Similarly, there is evidence that, when two tasks have the same input modality, their joint maximum performance is less than when input modalities differ. Finally, a predominantly motor task, e.g., tapping a regular interval, can be combined more easily with a predominantly cognitive task, e.g., classifying letters, than with another motor task such as tracking. Tapping is insensitive to demands on classification (Donk and Sanders 1989).

Multiple resources have some important theoretical implications. Thus, there will usually be ample spare capacity. Whenever a task is limited to certain resource pools, the demands on those pools may exceed capacity whereas capacity from the remaining pools is not used. This undermines the notion of task difficulty. Indeed, one task may only need and overload one particular resource pool, whereas another task may require all resource pools without imposing a heavy load on any. Which one is harder? Viewed from the perspective of total resource consumption, the last task may be the most demanding. However, the first cannot be completed successfully, which may be decisive in the discussion of workload. This point also bears on assessing workload. In the single-capacity models this was simply a matter of resource consumption. In the case of multiple resources, resource allocation is multidimensional, which prohibits a single-dimensional workload concept. As an example, the proposal of assessing workload by measuring performance on a second task derived from the assumption that a main task leaves aspecific spare capacity which is allocated to the second task. However, from the perspective of multiple resources, the cognitive architecture of the main and second tasks controls the second task performance. The multiple resource view has the obvious merit of recognizing the role of the cognitive architecture of tasks. Finally, Wickens' three dimensions capture some important cognitive differences which are particularly relevant from an applied point of view. For example, when, as in car driving, a task is spatially loading, additional information, e.g., route information, should be processed verbally. In fact, studies showing almost perfect time sharing in complex tasks, such as piano playing and repeating a verbal message (Allport et al. 1972), used tasks that differed in all three of Wickens' dimensions. Thus, piano playing may proceed from visual input to analogue representation to manual output, whereas the verbal message was auditorily presented, verbally encoded, and ended with a vocal output. In addition, the participants in such studies were always highly skilled, which means a large marginal efficiency of resource consumption.

Despite these merits, the heuristic value of resource models has come under heavy attack (Neumann 1987). One reason was that, in line with the enormous processing capacity of the brain, the new generation of computers overruled the notion of limited capacity as a viable metaphor. Second, 'interference among tasks is usually much more specific than predicted on the basis of a limited amount of resources and, on the other hand, there is unspecific interference that seems not to depend on any specific resource' (Neumann 1987, p. 365). For instance, timesharing a spelling task and a mental arithmetic task is better than timesharing two arithmetic or two spelling tasks. However, they would all be subsumed under Wickens' verbal central processing resource. It is obvious that not much is gained by postulating a new resource for each new case in which timesharing is found. In regard to aspecific interference, Gladstones et al. (1989) had participants perform two machine-paced serial reaction tasks, singly and in combination, and found no indication for better shared performance when the stimuli for one task were visual and of the other task auditory in comparison with visual stimuli in both tasks. Performance did not profit either from a difference in effectors, that is, when one task had a vocal and the other a manual response, in comparison with two manual responses. Third, merely distinguishing

among resources runs the risk of conceptualizing information processing in terms of a set of distinct faculties without detailed process descriptions and without an integrative account. An attempt to account for the last point was the assumption of an additional general-purpose resource responsible for attention control in scheduling and timing. The notion of attention control was fostered by evidence that practice not only has the effect of diminishing resource demands but also that attention control profits from practice. Thus, practicing two single tasks until full proficiency does not mean that they can be easily time shared without additional practice in dual task performance (Detweiler and Lundy 1995). The relevance of scheduling and timing is evident from findings that two tracking tasks—which presumably share the same resources—are much easier to do together when their temporal dynamics are the same than when they deviate (Fracker and Wickens 1989).

4. *Interference*

The above objections led to accounts in terms of interference—outcome conflict and cross-talk—among simultaneous tasks, depending on the extent the various task demands compete in an abstract space. There may be cooperation, conceived of as a single more complex action plan for both tasks, or confusion, referring to problems in establishing correct input–output connections (Wickens 1992) As an example, in a dual task consisting of manual tracking and discrete choice reactions, tracking proficiency appears to impair briefly before a choice reaction, suggesting outcome conflict in motor programming. Neumann (1987) suggested two reasons for limits in performance, both concerned with the control of action, namely effector recruitment and parameter specification. The issue is not that the capacity is limited but that one has to choose among competing actions. Effector recruitment refers to the selection of effectors which should become active at a given moment. The main meaning of effector recruitment is to abort competing responses, in which way it may lead to a bottleneck in response selection. Parameter specification refers to getting the proper values, e.g., direction, force, size of a movement, but also selecting appropriate stimuli for completing an intended action. Practice has the effect that default values develop which means that the action can be completed without time-consuming specifications. Effector recruitment and parameter specification at the time of an action prohibit other actions from occurring at the same time. The consequence is that time sharing two actions is hard when they are independent. In contrast, complex skills usually consist of integrated sequences, summarized in chunks and groups of actions which are initiated by a single command. This may account for the finding that time sharing has been found mainly in well-trained complex tasks and not in uncorrelated reactions to successive stimuli, as for instance in the study of Gladstones et al (1989). Time sharing is better as tasks (a) allow processing and acting in larger units, (b) permit preview and advance scheduling of demands, and (c) do not involve similar or competing patterns of stimuli and actions.

Thus, formulating performance limits by way of interference puts full weight on processing architecture and timing of action. Its popularity is at least partly due to the advent of performance models in terms of connectionist networks (Detweiler and Schneider 1991) and to the present interest in the neurophysiology of behavior. A potential problem for the interference models may be a lack of predictive power. Thus far the research has been insufficiently specific about constraints and too occupied with the description of the existing results beyond the concept of limited capacity. Although the connectionist models are quantitative, their detailed predictions are still open to *post hoc* parameter setting.

With regard to future research, patterns of interference should be described as a function of the stage of processing at which such patterns are supposed to arise. This should lead to a more detailed catalog of actions which are liable to output conflict and, hence, to be avoided in task design. There are interesting recent developments into this direction, among which Pashler's research on the extent of parallel versus serial processing in responses to successive stimuli (e.g., Pashler 1994) and the EPIC simulation (Meyer and Kieras 1997) of human performance. In addition, much may be expected from the analysis of brain images while performing a dual task. The new approaches should enable a more detailed account of dual performance and of attention control of multiple tasks than was possible on the basis of capacity notions.

Dubos, René Jules (1901–82)

René Jules Dubos, the French-American microbiologist, medical researcher, environmentalist, and Pulitzer-prize-winning author, was born in Saint-Brice-sous-Fôret, France on February 20, 1901. He was the eldest son of Georgesand Adeline DeBloëdt Dubos, proprietors of a series of small butcher shops. Two years after his birth, the Dubos family moved to neighboring Hénonville, a small agricultural village in the Île de France region fifty miles north of Paris. René Dubos spent the next dozen years of his life there exploring the French countryside, reading avidly, and excelling as a student at *l'ecole communale d'Hénonville*, the local one-room primary school. Encouraged by his mother to pursue a scholarly career, he dreamed of attending France's distinguished schools of higher learning. The family moved to Paris in 1914. Dubos won a fellowship in 1915 to attend the *Collège Chaptal*, part of the French secondary school system. His father's untimely death at the conclusion of World War I, his family's concomitant financial difficulties, and his own periodic bouts with poor health resulting from an early battle with rheumatic fever, however, prevented René Dubos from studying to become a historian, his first choice among academic careers. Instead, he gained admission in 1919 to the *Institut National Agronomique* (INA), France's National School of Agronomy.

Although many graduates of the INA pursued careers in scientific agricultural research, Dubos disliked laboratory work. Instead, he accepted a fellowship from the French government of Indochina to study at the *Institut National d'Agronomie Coloniale*, where he prepared for a position as a colonial administrator. However, the colonial government revoked its offer of employment at the conclusion of the training program when Dubos failed a physical examination. Having few alternatives, Dubos accepted an editorial position at *l'Institut International d'Agriculture* in Rome, where he abstracted technical articles for publication in the *Journal of International Agricultural Intelligence*. While in Rome, Dubos experienced a change of heart regarding his career plans. Inspired by an argument made in an article by the Russian agricultural bacteriologist, Sergei Winogradsky, Dubos reconsidered his decision to steer clear of laboratory research. In this article, Winogradsky encouraged his colleagues to reject pure culture techniques in favor of studies that more accurately monitored soil microbes in their natural environments. This more ecological approach to microbial investigation appealed to Dubos because it emphasized themes familiar to him from the training he had received as an agricultural engineer in Paris. Dubos gained the opportunity to study soil microbes himself when, at the 1924 International Congress of Soil Science, Jacob Lipman of the New Jersey Agricultural Experiment Station invited the young Frenchman to study soil microbiology at his institution. Dubos accepted the offer, sailed to the USA, and spent the next three years in a doctoral program under the direction of Selman Waksman at Rutgers University and the New Jersey Agricultural Experiment Station.

Soon after completing his Ph.D. in soil microbiology, Dubos received an unusual and compelling offer to join the research team of Oswald Avery, an immunochemist at the Rockefeller Institute for Medical Research. Few agricultural researchers received an opportunity to apply their skills to medical research in the 1920s, particularly at the nation's most prestigious medical research institution, but Dubos's doctoral research on cellulose decomposition filled a specific need in the Avery laboratory. For years, Avery's laboratory group had tried unsuccessfully to strip the polysaccharide coating from the type III pneumococcus responsible for lobar pneumonia. Avery theorized that the coating protected the bacillus from the human body's natural defenses. Dubos suggested that he could find a soil microbe with the ability to produce an enzyme capable of dissolving the polysaccharide coating. Avery gave the young agricultural scientist a chance.

Thus, in 1927, René Dubos began a nearly fifty-year association with the Rockefeller Institute for Medical Research (later Rockefeller University). Only a two-

year stint as George Fabyan Professor of Comparative Pathology and Tropical Medicine at Harvard Medical School, 1942 to 1944, interrupted his career-long affiliation with the Rockefeller Institute. As a medical researcher, Dubos made numerous contributions to bacteriology and medical science. In the Avery laboratory group, he extracted an enzyme from a soil microbe that proved effective against the polysaccharide coating of the lobar pneumonia bacillus. Although the advent of sulfa drugs precluded the use of the Dubos enzyme in the clinical treatment of pneumonia, the process he used to extract the enzyme proved beneficial in the late 1930s, when he returned to the soil to find a microbe with broader bactericidal properties. In 1939 he earned international recognition by developing gramicidin, the first clinically useful antibiotic. His success suggested the clinical potential of soil microorganisms to researchers around the world. News of Dubos's advances spurred Oxford University's Howard Florey and Ernst Chain to resurrect Alexander Fleming's long-dormant research on penicillin. Dubos's work also inspired the effective development of streptomycin by his graduate school advisor, Selman Waksman. Collectively, these advances marked the beginning of the antibiotic era. Dubos's leading role in antibiotics research earned him the status of full member at the Rockefeller Institute, and, in 1941, election to the National Academy of Sciences.

Although his advances in antibiotics research represented his most celebrated contributions to medical science, they were by no means his only accomplishments. In the late 1940s Dubos gained recognition as an outstanding tuberculosis researcher. With the assistance of Bernard Davis, he developed an effective culture medium for tuberculosis bacilli. This new Tween-albumin medium permitted researchers to study the difference between virulent and nonvirulent bacilli and was credited with catalyzing a 'renaissance in tuberculosis research.' A strong advocate for vaccination against tuberculosis, Dubos also established guidelines for the standardization of BCG vaccines worldwide. Finally, in the 1950s Dubos collaborated with physicians in the Rockefeller Hospital on a study which revealed that prolonged bed rest did not expedite the recovery of tuberculosis patients receiving antibiotic therapy. This discovery had profound implications for sanatoriums, the traditional sites for tuberculosis treatment.

Despite his pathbreaking contributions to the modern pharmacopoeia, Dubos is more often remembered for his provocative ideas on human health. No one contributed more to the hubris of medical science at mid-century than Dubos with his breakthroughs in antibiotics research, but shortly after unveiling gramicidin, he publicized his concerns about the adequacy of antibiotic therapy for handling infectious disease. As early as 1942 he warned that the unmitigated enthusiasm for antibiotic wonder drugs should be tempered by a concern that overprescription of the drugs could lead to the development of more virulent, resistant bacterial strains. He argued that scientists gained an incomplete understanding of infectious disease when they focused solely on infectious agents. His studies of tuberculosis and the loss of his first wife to the disease taught him that, particularly in the case of latent infection, the host's ability to resist a disease is at least as important as the presence of an infectious agent. Pathologic processes, in his opinion, depended upon the total environment of the host, and deserved the serious attention of scientists. This challenge to the specific etiology of disease contributed significantly to the formulation of current conceptions which now include social factors, mental and physical disturbances, and environmental conditions in the understanding and management of disease.

Dubos's reconceptualization of disease, environment, and human health reached a broad audience of medical researchers, social scientists, politicians, and laypeople. He developed his ideas through over twenty books, countless articles in scholarly and popular journals, and an ever-increasing number of public addresses between the 1940s and the late 1970s. His most influential writings on human health include *The White Plague: Tuberculosis, Man, and Society* (1952), *Mirage of Health: Utopias, Progress, and Biological Change* (1987), and his Pulitzer-prize-winning text, *So Human an Animal: How We are Shaped by Surroundings and Events* (1998). In *The White Plague*, a book Dubos co-wrote with his second wife, Jean Porter Dubos, they mined historical accounts of tuberculosis outbreaks to demonstrate that the incidence of tuberculosis increased during times of social strife and decreased during less tumultuous eras. By linking it to poverty, they argued that tuberculosis was as much a social as well as a microbiological disease. In *Mirage of Health*, Dubos again challenged his readers to recognize disease as the indirect outcome of a constellation of circumstances rather than the direct result of a virulent microorganism.

Microbial disease, when it occurred, was due to an imbalance in the host's equilibrium caused by any of a number of factors in the external or internal environment—be it weather conditions, availability of food, working habits, emotional status, or emotional stress. Therefore, he argued, by ameliorating social and environmental conditions, social reformers had been more effective than scientists in reducing mankind's susceptibility to disease. Disease, according to Dubos, could not be eradicated simply by medical treatment. Social conditions must also be managed. His message enjoyed broad appeal among social scientists, many of whom, like Dubos, refocused their scholarly inquiries toward research that revealed how changes in an organism's social environment affected its health. Scientists also utilized Dubos's biopsychosocial perspective on health to construct a theoretical justification for the study of psychosomatic medicine.

By the 1970s, Dubos had become one of the USA's most visible scientists. His message appealed to a large number of Americans interested in the increasingly apparent connection between the environment and human health. Although organizations invited Dubos to speak on the environmental aspects of health and disease as early as the 1950s, his influence among environmentalists grew substantially after the publication of his Pulitzer-prize-winning book, *So Human an Animal*, in 1998. The book appeared when the USA was in the midst of the largest grassroots environmental movement in its history. Humans, like soil microbes, argued Dubos, adapt to their changing environments. Therefore, the quality of the environment in which a human develops holds great significance in the determination of human health and well-being. Although some environmentalists took issue with Dubos' notion that humans could improve on nature, many embraced him as an elder statesman of their movement. They adopted several of his maxims, including 'Think globally, but act locally' and 'Trend is not destiny,' as rallying cries for their cause. Dubos remained active in environmental activities years after his 1971 retirement from Rockefeller University. He co-wrote *Only One Earth* with economist and political scientist, Barbara Ward. This document provided scientific and social guidelines for the First UN Conference on the Human Environment in Stockholm in 1972. In 1977, Dubos lent his name to the New York-based René Dubos Center for Human Environments, an organization charged with the planning of international forums to promote beneficial human interventions into nature.

Dubos traveled an uncommon path from his early days as a French agricultural engineer to his respected position within the Rockefeller University and twentieth-century biomedical research. Although recognized and applauded as part of the scientific establishment by the 1940s, Dubos never hesitated to challenge the methodologies of his colleagues. Because he believed that all living organisms must be understood in the context of their respective environments, he advocated less reductionistic laboratory research, studies that traversed interdisciplinary boundaries, and an ecological understanding of disease. He followed his inner logic outside the confines of scientific safety, where he found diverse and interested audiences willing to engage his provocative message. René Dubos died on his 81st birthday in New York City.

Due Process in Law

The concept of due process emerges from the central paradox in the creation of state authority. Following Thomas Hobbes, the governmental state may be seen as an evolutionary response to the failings of the state of nature. In the war of all against all, no man has an incentive to industry, writes Hobbes in the *Leviathan*, because each lacks security in investment, planning, and the ability to exchange. Each faces the threat of bodily violence, invasion of the home and seizure of property. The response, per Hobbes, is the creation of the state, a body that can impose order, lift mankind from the pitiable war of all against all, and secure collective benefits. The paradox emerges in that the creation of the state also produces a magnified form of the threat that was ever-present in the state of nature. The state represents the largest entity capable of inflicting bodily violence, invading the home, and seizing property. Indeed, all states reserve to themselves the right to do just that to their citizens, and most include the right even to punish by death. What then differentiates the modern state that claims political legitimacy from the state of nature? The answer must be an abiding respect for procedural fairness in the imposition of punishment and the regulation of the conduct of the citizens' lives.

This conception of procedural fairness is at the heart of the concept of the rule of law, and of its more technically exigent offshoot, the guarantee of due process. The typical formulation of due process, as that concept has developed in Anglo-American jurisprudence, is derived from the Magna Carta, issued by King John in 1215 in the face of rebellious barons seeking restraint upon the exercise of royal prerogatives:

> No free man shall be seized or imprisoned, or stripped of his rights or possessings, or outlawed or exiled, or deprived of his standing in any other way, nor will we proceed with force against him, or send others to do so, except by the lawful judgment of his equals or by the law of the land.

The crux of the original formulation was to limit the power of the royal sovereign by granting legal protection to the life, liberty, and property of English freemen. The significance of the Magna Carta's guarantees emerges from the form of the limitation on sovereign authority. The document does not attempt to deny the sovereign the capacity to imprison, outlaw or banish the rights-holding citizenry, or to have restraints imposed on the enjoyment of property or other rights held by citizens. Rather it imposes a condition of procedural regularity in the exercise of the sovereign's power, including central, orderly trial processes and formal proclamation of the applicable legal standards. This notion of procedural regularity is captured in the actual phrase, 'due process of law,' which first appeared when the Magna Carta was issued in an English version in 1354 by King Edward III. Its modern vitality draws from the efforts of Sir Edward Coke in the seventeenth century to revive the Magna Carta as a check on the power of the Stuart monarchs.

Not surprisingly given these origins, due process emerged from medieval Britain primarily as a restraint on the executive power of the sovereign, specifically of the Crown. The concept of due process was transformed when the American colonists adapted the Magna Carta as a limiting principle not only on the use of executive power, but also on the scope of the laws that could be passed. For colonists lacking the rights of participation in the creation of laws, the insult of arbitrary state power occurred whether power was exercised legislatively or by the sovereign. As recast by the colonists, due process became a limitation that extended beyond the power of the crown, to encompass as well local assemblies and, by the time of the revolution, Parliament. Thus, even as England adopted a system of increasing parliamentary sovereignty, the concept of due process as a constraint on the exercise of governmental power retained its vitality in the colonies. As a result, the newly independent Americans established a more limited government, reflected by the Bill of Rights (including a due process clause), as an explicit limitation on the use of state power, including the legislative branch. As articulated by James Madison, 'The legislature, no less than the executive, is under limitations of power,' and hence the rights of the people were to be secured 'against legislative as well as executive ambition' (Madison 1896). The source of the limitation was a constitutional command that stood apart and above the normal operations of state authority.

The American focus on legislative power also highlights the importance of due process as a restraint not just on the penal powers of the state, but on its civil regulatory powers as well. Due process emerges from this historical origin with two central features. First, it protects substantive rights independently secured by positive law by requiring procedural regularity in the exercise of all governmental power. Second, the requirement of procedural regularity may not be altered by the normal operations of political power. As reflected in the American constitutional experience, the guarantees of due process are not directly accountable to the political dictates of either the executive branch of government (the closest in form to the sovereign), or the legislative will of the majority. As a constitutional guarantee, the requirements of due process may not be altered though the customary political processes of legislation. It is these two features of procedural regularity and independence from direct political accountability that define due process as it has emerged most clearly in American constitutional law, which long ago held due process to be a protection of 'those fundamental principles of liberty and justice which lie at the base of all our civil and political institutions' (*Hurtado* vs. *California*, 110 US 516, 535 (1884)). Because the development is most clear in American constitutional law, that will serve as the template for further elaboration.

There are five basic elements of due process that may be adduced from American case development, particularly after the post-Civil War amendments to the Constitution extended the command to the conduct of the States toward their citizens. The two given the greatest significance are that, 'Parties whose rights are to be affected are entitled to be heard; and in order that they may enjoy that right they must first be notified' (*Baldwin* vs. *Hale*, 68 US (1 Wall.) 233 (1863)). The opportunity to be heard and its 'instrumental corollary, a promise of prior notice' (Tribe 1988), according to the Supreme Court, 'seem to be universally prescribed in all systems of law established by civilized countries' (*Twining* vs. *New Jersey*, 211 US 78, 110–11, 1908). The additional elements of due process are further corollaries necessary to make the right to a hearing meaningful: the right to an impartial arbiter, the right to be represented by counsel, and the right to timely resolution of claims.

The articulation of these elements of due process leaves unanswered a central question dating from the time of the Magna Carta: are these due process rights intended as affirmative entitlements of the citizenry, as indispensable restraints on the state, or as instrumental checks against arbitrary, capricious, or simply misguided state conduct? Put another way, the constitutional enshrinement of a principle of due process can be seen as creating a distinct set of rights among the citizenry, or as a constraint on governmental processes. Measured against this template, it is possible to characterize the development of twentieth-century due process law as passing through three central phases.

1. Substantive Due Process

The most forceful introduction of due process into the American constitutional canon came in the closing years of the nineteenth century with the emergence of the substantive due process doctrine. Federal courts gave independent substantive meaning to the Fourteenth Amendment's prohibition on states' restricting the enjoyment of life, liberty, or property without due process of law. Under this view, state incursions upon the affirmative rights of citizens to be secure in their life, liberty, and property were presumptively invalid and subject to exacting judicial scrutiny. The key to this period was an expansive set of presumed individual claims against state regulation. The domain of legitimate state activity was restricted to insuring the public health, protecting against inherently hazardous activities, and protecting those who could not fend for themselves at law. This last group included (at the time) children, the mentally incompetent, and women. The most controversial feature of substantive due process came with the expansive definition of 'liberty' to include a broad range of market freedoms that in turn prompted federal courts to strike down state regulatory measures by the dozens. Most famous no doubt was the Court's 1905 ruling in *Lochner* vs. *New York* (198 US 45, 1905), a case that struck down a maximum hours regulation for the employment of bakers on the substantive due process grounds of 'liberty of contract.' The hallmark of this period was the use of a high threshold of procedural presumptions against the legitimacy of state regulatory initiatives. The period of substantive due process lasted until its repudiation by the Supreme Court in the New Deal period of the 1930s. Nonetheless, the reaction to the perceived hostility of the Court to progressive social legislation earned the '*Lochner* period' notoriety as a constitutional epithet and removed substantive due process from the constitutional lexicon, until its tentative re-emergence at the end of the twentieth century in difficult cases such as the constitutional review of assisted suicide (*Washington* vs. *Glucksberg*, 521 US 702, 1997).

2. Procedural Due Process

The second great phase of due process activism came with the Warren Court of the 1960s. Unlike the *Lochner* period's focus on the expansion of substantive claims that triggered due process, the hallmark of the second phase was a focus on 'procedural due process,' which was understood as an expansion of the process-based requirements for the state to act adverse to the interests of affected citizens. In a series of decisions involving legislatively-conferred benefits, ranging from driver's licenses to welfare benefits, the Court interposed an elaborate series of processes required before such benefits could be withdrawn. The right to a hearing was repeatedly invoked in this period as an affirmative right of participation in governmental processes that inhered in the rights of citizens. The Court did not seek to expand the ambit of positive rights—entitlements were created by the normal processes of government—but instead used the Due Process Clause to enforce heightened procedural hurdles before government could deny a benefit. Instead of the liberty to contract of the early twentieth century, the aggrieved due process claimant of the post-War period would claim a 'right to be heard' prior to adverse governmental action. Critics charged that the elevated procedural steps created a presumption against adverse governmental action almost as certain as that of the substantive due process period. But more problematic, as evidenced in the ensuing case law, was how to reconcile near-categorical requirements of an inherent participatory right to process with a range of governmental conduct that required swift response to emergency situations. The case law struggled to find a mediating principle that would allow emergency responses, as with police searches, the impounding of goods in flight, the embargo on goods threatening public health or safety, and a range of comparable conduct whose successful implementation could not await notice and an adversarial hearing.

3. Due Process Functionalism

The tension in the heightened proceduralism of the Warren Court prompted a scaling back of inherent rights in favor of an instrumental approach to due process. Where both the substantive due process and procedural due process period had read the due process command to vest the citizenry with affirmative rights against the state, the functional period beginning in the mid-1970s saw in due process a check against improper or incorrect governmental decisions affecting life, liberty, or property. Thus, in the watershed case of *Matthews* vs. *Eldridge* (424 US 319, 1976), the Supreme Court analyzed a challenge to the termination of social security disability benefits not in terms of whether due process protections attached, but rather in terms of how much process was due. By contrast to cases of the *Goldberg* vs. *Kelly* period that assumed that process would have to be the full panoply of evidentiary protections, *Matthews* vs. *Eldridge* held that the amount of process required prior to adverse governmental conduct would be determined by a balance of interests heavily weighted toward considerations of cost and likelihood of error:

> [D]ue process generally requires consideration of three distinct factors: first, the private interest that will be affected by the official action; second, the risk of an erroneous deprivation of such interest through the procedures used; and the probable value, if any, of additional or substituted

> procedural safeguards; and finally, the government's interest, including the function involved and the fiscal and administrative burdens that the additional or substitute procedural requirement would entail. (424 US at 334–35)

In the decades since *Matthews* vs. *Eldridge*, this form of due process functionalism has come to command this area of American constitutional law. All the critical elements of due process—from the right to an evidentiary hearing to the right to counsel—are now subject to the balancing of magnitude of loss versus likelihood of error, versus governmental interest in swift action. Some of the applications appear inevitable, as with the ability of police to immobilize illegally parked cars, even in the absence of notice and a prior hearing. Some are more problematic, as with the denial of the right to have counsel provided to an indigent prisoner facing civil proceeding for termination of parental rights. But, nearly 800 years after the Magna Carta, this functional view of due process has firmly taken hold in the most developed of due process legal regimes.

4. *Due Process in Other National Legal Systems*

Broadly speaking, a large number of the fundamental rights accorded to individuals under the American conception of due process are also found in other nations' laws, with one critical caveat. The conception of due process, particularly in civil law systems, primarily addresses rights of criminal procedure—e.g., the French Declaration of the Rights of Man, which explicitly grants the right to be free from arbitrary arrest and detention. Various international agreements—such as the Convention for the Protection of Human Rights and Fundamental Freedoms—contain similar language. Many national constitutions similarly guarantee the rights to notice, choice of counsel, a speedy trial, and appeal.

Even in the sphere of criminal procedure, there are significant differences between the American notion of due process and that found in other countries. Perhaps the most striking example is the absence in many foreign legal regimes of the right to be presumed innocent that is considered so fundamental in the United States. Also absent in many countries is a notion that both sides in a criminal trial have equal opportunity to advocate their positions.

More revealing is a comparison of the American and German conceptions of due process. On one level, the two countries' approaches are similar. Both put a pre-eminent value on human liberty. Thus, Article 1(1) of the German constitution states that 'the dignity of man shall be inviolable.' This notion of human dignity is akin to the American concept of substantive due process. Both are tools that have been utilized by the respective courts to 'discover' hitherto unenumerated rights. In this sense, both countries have a conception of due process that is, to a certain extent, open-ended. As a consequence, both must grapple with an abstract and amorphous concept—often with controversial results.

But perhaps the most fundamental difference lies in their highest courts' approaches to constitutional interpretation. While the German Constitutional Court has interpreted its constitutional mandate to develop a systematic approach to constitutional jurisprudence, the United States Supreme Court, by emphasizing procedural regularity, has exhibited a tendency to act in a piecemeal fashion. The result is that, in some ways, the German view of due process appears even more comprehensive than that of the United States. Most importantly, Germany guarantees the protection of 'personality rights' and 'physical integrity,' which are akin to the American procedural due process. But, unlike the United States Supreme Court, which has often worked to construe due process narrowly, the German Constitutional Court has consistently taken a broad view of due process, viewing as properly furthering the fundamental principle of human dignity—a far more sweeping command than recognized in the initial procedural focus of Anglo-American law.

Durkheim, Emile (1858–1917)

Émile Durkheim's writings, though they cover a vast range of topics, reveal a single, focused, organizing vision of sociology's subject matter and objectives. These went beyond the purely scientific and were also moral and political. He sought, through education, to contribute to the stability and legitimacy of the French Third Republic and, more widely, to find cures for modern society's ills. His writings include several

classics that remain central to the discipline of sociology, through teaching and through successive reinterpretations in which advances continue to occur by confrontation with Durkheim's ideas. These ideas, developed in close collaboration with a school of remarkably talented younger colleagues grouped around the journal, *L'Année sociologique* which flourished before World War I, had a considerable impact within France and later far beyond, within sociology and across several other disciplines.

1. Biography

Born on April 15, 1858 in Épinal in the Alsace-Lorraine region into a close-knit rabbinic family, he abandoned Judaism at an early age. He thereafter treated religion agnostically as a social phenomenon demanding sociological explanation (from the mid-1890s it was increasingly central to his thought) yet maintained that in studying it one is blind without a certain religious sentiment. After his studies at the *École Normale Superieure* in Paris, he taught philosophy in secondary schools. On a government grant he visited Germany, for whose scientific education there was widespread admiration in defeated France. His encounter with German social scientists strengthened his so-called 'social realism.' In 1887 he was appointed to teach social science and pedagogy at the University of Bordeaux, as part of a national drive for a new system of republican, secular education. In 1896 he was appointed the first Professor of Social Science in France and in 1897 founded *L'Année sociologique*. While at Bordeaux he published three major works, *The Division of Labor in Society* (Durkheim 1893), *The Rules of Sociological Method* (Durkheim 1895), and *Suicide* (Durkheim 1897) and his Latin doctoral thesis on Montesquieu. He also lectured and published across a wide range of topics including education, the family, the incest taboo, crime and social health, the evolution of punishment, the state, professional ethics and civic morals, religion, Rousseau, the history of sociology, and the history of socialism—the last in response to his students' political concerns. Averse to the sharpening of class conflict and believing revolutions to be as impossible as miracles, he stressed the need for institutional reforms that would encourage cross-class solidarity around common principles of social justice. He favored an interventionist State offset by a plurality of local, civic, and especially occupational associations, believing that out of this conflict of social forces individual liberties are born (Durkheim 1950). He remained close to the liberal socialism of Jean Jaurès, but in the late 1890s the Dreyfus Affair induced him to break his principle that the social scientist should, as such, keep apart from everyday politics. An active Dreyfusard, he denounced those who defended the army and the Church as sacred national institutions and proclaimed that modern society could only be integrated around the religion of individualism, protecting the sacredness of the individual and individual rights, the 'sole link' still binding citizens to one another.

In 1902 he moved to Paris to teach education and sociology. He continued to lecture and write across a wide range, publishing a study of *Primitive Classification* with Marcel Mauss (Durkheim and Mauss 1903) and his masterpiece *The Elementary Forms of the Religious Life* (Durkheim 1912). He debated with philosophers, historians, and psychologists and exercised a magisterial influence on the institutional development of sociology and on educational thinking and practice in France. On all these fronts his doctrines generated controversy and opposition, often fierce, to which he responded vigorously. Much of his energy went into the editing of *L'Année*, of which 12 volumes had appeared by 1913. These contained monographs and reviews of works in many disciplines and languages, systematically classified and mined for their theoretical and empirical usefulness to a progressing research program. An extraordinary collaborative achievement, they constitute the Durkheimians' ongoing debate with the sociologically relevant literature of their time, distinctive, among other things, in its comprehensive attention to the ethnographic record of the world's remoter peoples. All of this ended with the onset of the World War on whose battlefields several, including the most brilliant and promising of them, including Durkheim's son André, met their deaths. For a second time Durkheim broke his principle of political noninvolvement, contributing to the war effort and writing patriotic pamphlets, but, unable to overcome his grief at his son's death, he died in Paris on November 15, 1917.

2. Major Contributions

The focus of Durkheim's sociological vision was his so-called 'social realism': the view that social phenomena, or as he called them *faits sociaux*, are *sui generis*, with their own characteristics: they are general among, external to, independent of, and constraining upon particular individuals and typically are recognizable by their obligatory force. They constitute a distinct level of reality and are not reducible to the meeting of individual intentions. Hence, his attacks on social contract theorizing and on other forms of methodological individualism that attempted just such a reduction, as practiced for instance by utilitarians, economists, psychologists, and the English sociologist Herbert Spencer. At different stages he focused on *faits sociauz* of different kinds: on 'morphological' phenomena such as population volume and 'dynamic density' and spatial distribution, on types of law (see Cotterrell 1999), on institutions and, increasingly, on what he came to call *représentations collectives* (Durkheim 1924). By this he meant collective ideas and sentiments which could, moreover, be evanescent, like crowd enthusiasms or fashions, or more 'crystal-

lized' or institutionalized, like legal codes or most stable of all, the fundamental categories of thought. *Faits sociaux* were what we would now call emergent phenomena whose properties, resulting from the structured interactions of their constituents, could not be accounted for exhaustively in terms of individuals' presocial properties.

Durkheim advanced this view polemically, as a doctrine, above all in *The Rules*. It has been suggested that this is best understood in its context as the forging of a vocabulary suited to securing French citizens' allegiance to their Republic (Jones 1999). What is certain is that Durkheim's social realist rhetoric generated unproductive controversies and, worse, led to misunderstandings that have, even until today, deflected attention from his explanatory practice, to which his methodological pronouncements are an inadequate guide. Thus he claimed that only social causes can explain social effects and that every time a social fact is explained directly by a psychological fact one could be sure the explanation is false. In various places he uses language that personifies collectivities, making 'society' appear as a subject of experience, with a *conscience commune*, or as an agent with a unified will, requiring conformity, pursuing ends, and imposing ways of acting on its members.

But against such passages one can cite others that stress that society only exists in and through individuals, that neither can exist without the other, and that *représentations collectives* are the product of individuals' activity and, indeed, of an immense cooperation extending across space and time. In fact, Durkheim's actual explanations are by no means confined to the macrolevel: he sometimes seeks to explain the micro by the macro, as in *Suicide*, and the generation of macrophenomena at the microlevel, as in the generation and regeneration of religious faith through collective effervescences and rituals in *The Elementary Forms*. In short, Durkheim's explanatory practice was interactionist, not holistic. Unfortunately, his polemical antimethodological individualism and hostility to psychological explanation precluded him from reflecting on the microunderpinnings of his macro explanations and, in general, on micro–macro connections, so that these aspects of his explanations remain under-theorized. Yet this very inattention may have generated insights. By not seeing certain things, perhaps he focused more intensely on what he did see.

Faits sociaux, he wrote in *The Rules*, should be treated 'as things' ('*comme des choses*'), independent of and external to observers as well as actors, and enabling one to decide between competing theories. This expresses his commitment to scientific method as he saw it, as against philosophical theorizing uncontrolled by empirical evidence (to philosophize, he once told a doctoral candidate, is to think what one wants) and as against the Positivism of Comte, committed to the identification of a small set of transhistorical laws, rather than the systematic study of specific causal mechanisms (he rejected the label 'positivist,' preferring that of 'rationalist'). Social scientific method required the abandonment of pretheoretical preconceptions, the systematic testing of theories by evidence, quantitative where appropriate (as amply illustrated in *Suicide*), the careful selection of indicators, the rejection of teleological and functional explanations (though not the identification of social functions), the use of comparison (sociology's substitute for experiment), and the construction of social typologies. He conceived of types of society within a broadly evolutionary framework, proceeding from the least to the most advanced societies (and citing recent and contemporary tribal societies and those of Antiquity as instances of the former). He further thought that one could distinguish between 'normal' and 'pathological' developments within each type, at each stage of its development. This enabled him, he thought, to diagnose certain aspects of modern industrial societies, notably the prevalence of *anomie*, as pathological. The problem here was that his notion of normality was ambiguous between a statistical definition and one that embodied an implicit theory of social and psychological health or equilibrium relative to a given society's 'conditions of existence.' (How could a pathological phenomenon be both prevalent and abnormal?) Such diagnosis and the elaboration of feasible institutional remedies were, he thought, the chief ways in which the sociologist could contribute to social progress.

The Division of Labor contains (a) the positing of two ideal types of society, which Durkheim took to characterize less and more advanced societies respectively (but which can evidently co-exist), (b) an analysis of the mechanisms claimed to explain the transition from the former to the latter; and (c) a diagnosis of the latter's pathological forms. Mechanical solidarity, held to typify preindustrial societies, based on resemblances, exhibits identical and juxtaposed elements, segmentally structured and with weak social bonds, low population volume and moral density, undifferentiated social organization, repressive or penal law, and collective beliefs and sentiments (which at that stage he called the *conscience collective*) that strongly tie the individual to the society as a whole, while organic solidarity, typical of industrialized societies (in their 'normal' state of functioning), based on the division of labor, the fusion of markets, and the growth of cities, exhibits interdependence and strong social bonds, high volume and density, an increasing differentiation of social functions, restitutive or cooperative law, the gradual withering away of the *conscience collective*, and the emancipation of the individual, allowing space for individual initiative and reflection. The transition from mechanical to organic solidarity, which constituted the 'progress of the division of labor and of civilization,' occurs, Durkheim maintained, 'mechanically' as a consequence of growth in the social mass and its social or dynamic

density, through expanding markets, a 'struggle for existence,' a resultant development of new occupations and of corresponding consumer demand. Durkheim intuitively assumed an equilibrium outcome of increasing division of labor but did not specify the parameters that would generate that outcome. The division of labor exhibits perverse effects and thus abnormal forms where the conditions for the social equilibrium of organic solidarity are not satisfied. *Anomie*—the lack of appropriate rules—is evident in industrial and commercial crises, veering between prosperity and depression, resulting from ignorance and uncertainty of producers concerning demand, in the antagonism between capital and labor, and also in increasingly fragmented scientific specialization, and results in general from a too rapid industrialization in which the appropriate rules have not had time to stabilize relations between social functions and roles. The 'forced division of labor' exists where inequality is seen as illegitimate, as when unequal chances of mobility violate the meritocratic principle. And a third abnormal form, which Besnard calls 'bureaucratic' (Besnard 1987), is found where excessive specialization is combined with weak productivity and poor mutual adaptation of functions.

Durkheim considerably deepened his notion of *anomie* and his diagnosis of capitalism's ills in *Suicide*. *Anomie*is one of the two major modern social causes of suicide: a condition of rulelessness in which individuals lose their moorings: their expectations exceed the possibilities of satisfying them, potentially insatiable desires are no longer regulated within a stable and legitimate normative framework of economic rewards or status ranking or conjugal sexual relations. The other major modern social condition causing suicide is egoism: a breakdown of integration, a lack of attachment of individuals to common values, to socially approved relationships, activities, and purposes, isolating and privatizing their lives. (Excessive regulation, or fatalism, and excessive integration, or altruism, are less prevalent, Durkheim thought, in modern societies.) Suicide is the extreme response of the small, randomly distributed but statistically stable minority of suicide-prone individuals whose social situations expose them to the social causes in question. He expounded this theory by accounting for differential suicide rates (e.g., higher among Protestants than Catholics, lower among married men, higher during economic crises, lower during wars) by characterizing suicide's social causes as 'suicidogenic currents,' thereby suggesting a macro–macro explanation that evaded the microlevel, in line with his anti-individualist methodological stance. In reality his theory of suicide is a macro–micro theory of the social conditions for individual psychological equilibrium, or health (*anomie*being the 'malady of infinite aspiration'), which that stance deflected him from elaborating. *Suicide* has been widely seen as remarkable for its sophisticated use of statistics (albeit questionable in abstracting from suicide's social meanings to which, likewise, Durkheim paid no attention), including the use of multivariate analysis to exclude alternative explanations. But above all, the work exhibits its author's typical boldness in extending sociological explanation to what might seem least amenable to it: the most private and individual of acts.

The same boldness is evident in *The Elementary Forms*,whose introduction and conclusion advance a theory of the fundamental categories of thought, while the rest of the work advances a theory of the origins, meaning and functions of religious beliefs and practices, of magic, and of the relation of both to science. All this he developed with reference to ethnographic evidence of totemism (assumed to be the most primitive form of religion and its evolutionary origin, or at least its earliest known form) as found in 'simpler,' tribal societies in Australia and America. He made the questionable assumption that the essential elements of religious thought and life should be found, at least in germ, in the most primitive religions, regarding the study of a 'very simple' religion as particularly instructive, since the relations between its constituent elements are 'more apparent' there.

Observing that such categories as space, time, number, causality, the person, etc. impose themselves on us inescapably as the framework of our understanding, Durkheim rejected as nonexplanatory Kant's account of them as given *a priori*, arguing that they express the most general relations existing between things which are revealed to us through social action and mutual communication: their necessity has a social basis. Moreover, they are fundamental to commonsense and to science (natural and social) and across cultures. Religion he defined by its universal dichotomizing of the world into the sacred and the profane, uniting believers around the sacred to which they accord a special, awed respect. Starting from the assumption that religious beliefs cannot be illusory (for otherwise they would not persist), he asked to what reality they correspond, answering that, once decoded, they express our understanding of our society and our obscure and intimate relations with it. They require decoding since, until social science, these cannot be apprehended directly: religion is, in this respect, a sort of mythological proto-sociology. (Thus, the idea of the soul is the way religion represents the duality of human nature, part corporeal, part social.)

This exclusively society-oriented interpretation of religious symbolism has been much criticized (it was Durkheim, not the savage, Evans-Pritchard suggested, who made society into a God). A further contentious issue is whether or not accepting it challenges religious belief (Durkheim claimed it did not). In the domain of knowledge science replaces religion but religion continues to symbolize and dramatize social relations, strengthening and re-animating social bonds and believers themselves through the collective enactment of rituals. This aspect of religion survives and would,

he speculated, remain basic to the political cohesion of modern, secular societies as civil religion. Religious beliefs themselves originate in such collective effervescences and are renewed by their re-enactment.

Cognitively, religions are, he held, cosmologies, offering a 'first explanation of the world,' seeking realities behind appearances, teaching people to unite what the senses separate, and thus prefiguring science. Religion and science are alike in that they both seek to render the (natural and social) world intelligible, but only the latter disposes of methods that subject its observations to systematic control. Likewise, magic, which occurs within profane or everyday life, draws on prevailing religious beliefs and seeks to predict and manipulate the world, but without benefit of scientific tests, statistics or experiments, adducing (as scientists also do) auxiliary hypotheses to account for its failures. So for Durkheim, humanity is unitary in its thinking, not, as Lucien Lévy-Bruhlbelieved, divided between prelogical primitives and logical, science-based moderns.

3. *Influence, Impact, and Current Significance*

His collaborators applied and developed Durkheim's ideas in many directions, from economics to Chinese thought (in the work of Marcel Granet) to primitive and ancient law (see Besnard 1983). They also had a considerable contemporary impact on neighboring disciplines in France, for instance, on historians, initially through Henri Berr and his *Revue de synthèse historique* and later through Lucien Febvre, Marc Bloch, and the *Annales* school, on human geography, beginning with Paul Vidal de la Blache, on jurists, notably Léon Duguit, and on the study of comparative mythology in the work of Georges Dumézil. The surviving Durkheimians continued into the 1930s but their research program gradually lost its dynamism and, as Raymond Aron observed, it came to seem increasingly irrelevant to the times. Among those who have made a significant impact on subsequent work, one can single out Robert Hertz's studies of death and of right and left (Hertz 1907, 1909), Maurice Halbwachs's work on collective memory (Halbwachs 1925) and, above all, Marcel Mauss, Durkheim's nephew, pupil, and collaborator, author of several major works on Durkheimian themes, including magic and sacrifice (co-authored with Henri Hubert), seasonal variations among the Eskimos (with Henri Beuchat), the techniques of the body and the category of the person (Mauss 1950), who succeeded in breaking down Durkheim's conceptual dichotomies and methodological rigidities vis-à-vis other disciplines, in the interest of studying the *fait social total*, as in his classic and influential study of *The Gift* (Mauss 1925). In several ways, Mauss rendered Durkheimian sociology more subtle, complex, and forward-looking. Through Mauss, it influenced French structuralism via his impact on Claude Lévi-Strauss (see his introduction to Mauss 1950) and also on Louis Dumont, author of the major work on the Indian caste system, *Homo Hierarchicus*and of parallel studies of Western individualism. Its influence is also evident in the *Revue de MAUSS* (*Mouvement anti-utilitariste dans les sciences sociales*) which since 1993 has published anti-utilitarian articles on various aspects of social life. Among French sociologists, George Friedmann, Pierre Bourdieu, and Raymond Boudon (see Boudon 1999) have incorporated Durkheimian ideas, albeit far from uncritically, the latter insisting upon a convincing interactionist reading of Durkheim. This has, in turn, been developed by Mohamed Cherkaoui (Cherkaoui 1998) who has, moreover, resurrected for close attention Durkheim's sociology of education, in particular his remarkable study of the evolution of French educational thought and institutions, and their interaction, since the early Church (Durkheim 1938), which explores various themes less than evident in his better known works: class power and conflict and the struggle for cultural domination, the role of intellectuals and the sociology of educational knowledge focusing on dominant epistemologies and disciplinary hierarchies. Another important work is the definitive study of the concept of anomie and its career within sociology (Besnard 1987). Besnard also inaugurated the valuable *Études durkheimiennes* in Paris in 1977 as a forum for scholarship on Durkheim and the Durkheimians. It moved to Urbana, Illinois under the editorship of Robert Alun Jones in 1989 and to Oxford in 1995, published by the British Centre for Durkheimian Studies along with a continuing series of important Occasional Papers.

The Durkheim school's impact on British social anthropology has been immense, initially through Radcliffe-Brown but chiefly through his successor E. E. Evans-Pritchard, whom it helped liberate from his predecessor's structural-functionalism. Despite serious reservations, he identified himself with the work of the Durkheimians, praising it as an indispensable theoretical capital, embodying rigorous methods of scholarship (see his introduction to Hertz 1907). In the early 1950s he launched an extensive series of English translations of works by Durkheim and his collaborators, and himself drew on Durkheimian ideas, especially in his work on the Nuer. The impact of Durkheimian ideas is also evident in the work of other Oxford anthropologists, particularly that of Rodney Needham and Nick Allen on symbolic classification, but also in the various writings of Mary Douglas on pollution and symbolic boundaries, and in the work of Robin Horton on African religions.

Durkheim's reception into American sociology began early, influencing, among others, Elton Mayo and W. Lloyd Warner, but it was Talcott Parsons's extended treatment of his work in his *Structure of Social Action* that marked his canonization as a 'grand

theorist,' treated there as a pre-Parsonian proto-structural functionalist, with a distinctive solution to the 'problem of order' through the internalization and institutionalization of consensual, society-wide values.

Substantively, the impact of his ideas was pervasive, influencing innumerable accounts of industrialization, urbanization, social control, social disorganization, and collective behavior. These were, directly or indirectly, extrapolated from Durkheim's picture of advancing social differentiation leading through rapid social change to the breakdown of social ties. According to such accounts, rapid industrialization generates disharmony between life experiences and the normative framework which regulates them, leading to virtually unlimited possibilities for group conflict and thus to a variety of social movements: peaceful agitation, political violence, millennarianism, nationalism, revolution, underground subversion, etc., that in turn attract those suffering most severely under the displacements created by structural change. Examples of this approach are found in the work of Samuel Huntington, Chalmers Johnson, Ted Gurr, and Neil Smelser. Such accounts were criticized by Tilly (1981) for relying on three basic 'Durkheimian' arguments that are held to have been refuted by the historical evidence: (a) that conflict varies directly with the prevalence of differentiation within organization and the scale of groups; (b) that social disorder correlates with accelerated urbanization or industrial growth; and (c) that the various forms of 'disorder,' such as crime, suicide, conflict, and protest, vary together, in the same settings and circumstances. In short, Tilly rejects the 'Durkheimian line' on conflict, protest, and collective action, which he explains instead in terms of group solidarities, common interests, and mobilization. But, first, the 'line' is extrapolated from, not argued by, Durkheim, who never sought to explain so much by so little; it is his American successors, not Durkheim, who posited the strains resulting from rapid industrialization as the catch-all source of so many 'disorders,' which he never treated as equivalent and associated. Second, his ideas about the processes creating and re-animating collective solidarity are surely not irrelevant to the explanation of collective action. And third, his focus on the consequences of rapid economic and social change outstripping the norms that could regulate it has an inescapable relevance for the diagnosis of the distinctive ills of the most advanced forms of contemporary capitalism, in particular the corrosive effects of technical change on social relations and individual lives.

The concept of *anomie* has had an impact in other fields. Robert Merton imported it in his influential paper on *Social Structure and Anomie* (Merton 1949) but in the process mis- or re-interpreted Durkheim's notion as a maladaptation of means to ends, rather than a sociopsychological condition of deregulation (so that the problem, on Durkheim's account, should be seen as lying in the success ethic itself, not in the socially structured inability of some to realize its promises). But this idea, together with the other causes of suicide, and indeed the structure, content and mode of its attempted explanation, have exercised a continuing and productive stimulus within the sociology of deviance and criminology, as often through attempts to develop or revise Durkheim's contribution as through more or less radical refutations of his whole approach.

It is, however, his later 'religious sociology' that has had most impact within sociology during the1990s, applying its concepts, insights, and hypotheses to historical and modern societies. Durkheim and the Durkheimians never did this, and indeed a surprised Mauss could write in the late 1930s, contemplating Nazism and Fascism, of the tragic 'verification' of their theory in the spectacle of large modern societies 'hypnotized like Australians are by their dances' (Ranulf 1939, cited in Lukes 1972). From the 1960s through the 1980s, practitioners of historical sociology were largely focused on the rise and development of capitalism and were class-oriented and state-centered in approach: Marx, Weber, and Tocqueville were the presiding ancestors. Since then a growing interest in cultural analysis has been evident, with an associated interest in Durkheimian ideas. Initially, this development had a Parsonian, consensual emphasis. Edward Shils argued that secular, differentiated societies have sacred 'centers' that explain the allocation of status (Shils 1975), Clifford Geertz interpreted cultural systems in a way that linked sacredness, ritual and the mobilization of solidarity (Geertz 1973), and Robert Bellah published and stimulated studies of civil religion under modern conditions (Bellah and Hammond 1980). More recently, there has been a growing interest in symbolism and ritual and their relation to the institutionalization of power and social control but without the assumption of social consensus. In Jeffrey Alexander's words, a 'late Durkheimian framework' is applied to 'analyze phenomena which are disruptive, contingent, and related to social change,' while Randall Collins, exponent of conflict sociology, has sought to combine Durkheim with Erving Goffman, in exploring how 'focused and emotionally arousing interaction produces group solidarity' (Alexander 1988). Studies along such 'late Durkheimian' lines have included French Revolutionary festivals, ritual and symbolism under Fascism, nationalist movements, mass strikes, and media events.

These are the main lines of Durkheim's impact upon twentieth-century social science. I have not discussed his impact beyond the social sciences (for example, on and through such partly literary figures as Roger Caillois, Michel Leiris, and George Bataille, members of the so-called *Collège de Sociologie* in the late 1930s), or countless unacknowledged influences. More specific and acknowledged social scientific influences could also be cited, for instance, upon the work of Basil

Bernstein on sociolinguistic and educational 'codes,' drawing on Durkheim's ideal-typical polarities, and upon the so-called 'strong program' in the sociology of science, originating in the University of Edinburgh, focusing, in a relativizing vein, on the 'social' origins of 'natural' classifications (see Bloor 1976). Here, as ever, Durkheim's ideas are interpreted in accordance with locally generated concerns. The story of their reception, sketched here, confirms both their continuing attraction and their continuing power to generate alternative and invariably controversial readings.

Dynamic Decision Making

Dynamic decision making is defined by three common characteristics: a series of actions must be taken over time to achieve some overall goal; the actions are interdependent so that later decisions depend on earlier actions; and the environment changes both spontaneously and as a consequence of earlier actions

(Edwards 1962). *Dynamic decision tasks* differ from *sequential decision tasks* (see *Sequential Decision Making*) in that the former are primarily concerned with the control of dynamic systems over time to achieve some goal, whereas the latter are more concerned with sequential search for information to be used in decision making. (Dynamic decision tasks also need to be distinguished from dynamic decision processes. Dynamic decision models (e.g., Busemeyer and Townsend 1993), describe the moment-to-moment deliberation processes that precede each action within the sequence of actions.)

Psychological research on dynamic decision making began with Toda's (1962) pioneering study of human performance with a game called the 'fungus eater,' in which human subjects controlled a robot's search for uranium and fuel on a hypothetical planet. Subsequently, human performance has been examined across a wide variety of dynamic decision tasks including computer games designed to simulate stock purchases (Rapoport 1975), welfare management (Dorner 1980, Mackinnon and Wearing 1980), vehicle navigation (Jagacinski and Miller 1978, Anzai 1984), health management (Kleinmuntz and Thomas 1987, Kerstholt and Raaijmakers 1997), production and inventory control (Berry and Broadbent 1988, Sterman 1994), supervisory control (Kirlik et al. 1993), and fire-fighting (Brehmer 1992). Cumulative progress in this field has been summarized in a series of empirical reviews by Rapoport (1975), Funke (1991), Brehmer (1992), Sterman (1994), and Kerstholt and Raaijmakers (1997).

1. Stochastic Optimal Control Theory

To illustrate how psychologists study human performance on dynamic decision tasks, consider the following experiment by You (1989). Subjects were initially presented with a 'cover' story describing the task: 'Imagine that you are being trained as a psychiatrist, and your job is to treat patients using a psychoactive drug to maintain their health at some ideal level.' Subjects were instructed to choose the drug level for each day of a simulated patient after viewing all of a patient's previous records (treatments and health states). Subjects were trained on 20 simulated patients, with 14 days per patient, all controlled by a computer simulation program.

There are a few general points to make about this type of task. First, laboratory tasks such as this are oversimplifications of real-life tasks, designed for experimental control and theoretical tractability. However, more complex simulations have also been studied to provide greater realism (e.g., Brehmer's (1992) fire-fighting task). Second, the above task is an example of a discrete-time task (only the sequence of events is important), but real-time simulations have also been examined, where the timing of decisions

Figure 1
Feedback diagram for a typical dynamic decision-making task. S represents the linear stochastic dynamic system, D represents the decision policy, w is the disturbance factor, T is the control treatment, H is the output state of health, and H^* is the desired state of health

becomes critical (e.g., fire-fighting). Third, the cover story (e.g., health management) provides important prior knowledge for solving the task, and so the findings depend on both the abstract task properties and the concrete task details (Kleiter 1975). Fourth, the stimulus events are no longer under complete control of the experimenter, but instead they are also influenced by the subject's own behavior. Thus experimenters need to switch from a stimulus–response paradigm toward a cybernetic paradigm for designing research (Rapoport 1975, Brehmer 1992).

This health management task can be formalized by defining $H(t)$ as the state of the patient's health on day t; $T(t)$ is the drug treatment presented on day t; and $w(t)$ is a random shock that may disturb the patient on any given day. Figure 1 is a feedback diagram that illustrates this dynamic decision task. S represents the dynamic environmental system that takes both the disturbance, w, and the decision maker's control action, T, as inputs, and produces the patient's state of health, H, as output. D represents the decision-maker's policy that takes both the observed, H, and desired, H^*, states of health as input, and produces the control action, T, as output.

Based on these definitions, this task can be analyzed as a stochastic linear optimal control problem (Bertsekas 1976): determine treatments $T(1), \ldots, T(N)$, for $N = 14$ days, that minimize the objective function

$$F = E\{\Sigma_{t=1,N}\, \alpha[H(t) - H^*(t)]^2 + \beta T^2(t)\} \qquad (1)$$

contingent upon the environmentally programmed linear stochastic dynamic system,

$$H(t+1) = a_1 H(t) + a_2 H(t-1) + b_1 T(t) + b_2 T(t-1) + b_3 T(t-2) + w(t) \qquad (2)$$

Standard dynamic programming methods (Bertsekas 1976) may be used to find the optimal solution to this problem. For the special case where the desired state

of health is neutral ($H^* = 0$), some treatment effect takes place the very next day ($b_1 0$), and there is no cost associated with the treatments (i.e., $\beta = 0$), then the optimal policy

$$T(t) = -[(a_1/b_1)H(t) + (a_2/b_1)H(t-1) \quad (b_2/b_1)T(t-1) + (b_3/b_1)T(t-2)] \quad (3)$$

is the treatment that forces the mean health state to equal the ideal (zero) on the next day. If the cost of treatment is nonzero (i.e., $\beta > 0$), then the solution is a more complex linear function of the previous health states and past treatments (Bertsekas 1976, You 1989).

Dynamic programming is a general-purpose method that can be used to solve for optimal solutions to many dynamic decision tasks. Although the example above employed a linear control task, dynamic programming can also been used to solve many nonlinear control problems (Bertsekas 1976). However, for highly complex tasks, dynamic programming may not be practical, and heuristic search methods such as genetic algorithms (Holland 1994) may be more useful (see also *Artificial Intelligence: Genetic Programming*).

The formal task analysis presented above provides a basis for determining factors that may affect human performance on the task (Brehmer 1992). One factor is the stability of the dynamic system, which for Eqn. (2), depends on the two coefficients, a_1 and a_2. In particular, this system is stable if the roots of the characteristic equation

$$\lambda^2 - a_1\lambda - a_2 = 0 \quad (4)$$

are < 1 in magnitude (Luenberger 1979). A second factor is the controllability of the system, which depends on the three coefficients, b_1, b_2, and b_3 (Luenberger 1979). For example, if the treatment effect is delayed ($b_1 = 0$), then the simple control policy shown in Eqn. (3) is no longer feasible, and the optimal policy is more a complex linear function of the system coefficients.

Consistent with previous research, You (1989) found that even after extensive experience with the task, subjects frequently lost control of their patients, and the average performance of human subjects fell far below optimal performance. However, this is a gross understatement. Sterman (1994) found that when subjects tried to manage a simulated production task, they produced costs 10 times greater than optimal, and their decisions induced costly cycles even though the consumer demand was constant. Brehmer (1992) found that when subjects tried to fight simulated forest fires, they frequently allowed their headquarters to burn down despite desperate efforts to put the fire out. Kleinmuntz and Thomas (1987) found that when subjects tried to manage their simulated patients' health, they often let their patients die while wasting time waiting for the results of nondiagnostic tests and performed more poorly than a random benchmark.

2. *Alternative Explanations for Human Performance*

There are many alternative reasons for this suboptimal performance. By their very nature, dynamic decision tasks entail the coordination of many tightly interrelated psychological processes including causal learning, planning, problem solving, and decision making (Toda 1962). Six different psychological approaches for understanding human dynamic decision-making behavior have been proposed, each focusing on one of the component processes.

The first approach was proposed by Rapoport (1975), who suggested that suboptimal performance could be derived from an optimal model either by adding information processing constraints on the planning process, or by including subjective utilities into the objective function of Eqn. (1). For example, Rapoport (1975) reported that human performance in his stock purchasing tasks was reproduced accurately by assuming that subjects could only plan a few steps ahead (about three steps), as compared with the optimal model with an unlimited planning horizon. In this case, dynamic programming was useful for providing insights about the constraints on human planning capabilities. As another example, Rapoport (1975) reported attempts to predict performance in a multistage investment game by assuming that the utility function was a concave function of monetary value. In this case, dynamic programming was used to derive an elegant decision rule, which predicted that investments should be independent of the size of the capital accumulated during play. Contrary to this prediction, human decision makers were strongly influenced by the capital that they accumulated, and so in this case, dynamic programming was useful for revealing qualitative empirical flaws with the theory.

An alternative approach, proposed by Brehmer (1992) and Sterman (1994), is that suboptimal performance is caused by a misconception of the dynamic system (Eqn. (2)). In other words, a subject's internal model of the system does not match the true model. In particular, human performers seem to have great difficulty in discerning the influence of delayed feedback and understanding the effects of nonlinear terms in the system. Essentially, subjects solve the problem as if it was a linear system that has only zero lag terms. In the case of Eqn. (2), this yields the simplified policy

$$T(t) = -c_1 H(t) \quad (5)$$

where c_1 is estimated from a subject's control decisions. Diehl and Sterman (1993) found that this type of

simplified subjective policy described their subjects' behavior very accurately.

A more general method for estimating subjective decision policies was proposed by Jagacinski and Miller (1978). Consider once again the example problem employed by You (1989). In this case, a subject's treatment decision on trial $T(t)$ could be represented by a linear control model:

$$T(t) = c_0 + c_1 H(t) + c_2 H(t-1) + c_3 H(t-2) + c_4 T(t) + c_5 T(t-1) + c_6 T(t-2) + \text{error} \quad (6)$$

where the subjective coefficients $(c_0, c_1, \ldots, c_6)$ are estimated by a multiple regression analysis. This is virtually the same as performing a 'lens model' analysis to reveal the decision-maker's policy (Slovic and Lichtenstein 1971, Kleinmuntz 1993). This approach has been applied successfully in numerous applications (Jagacinski and Miller 1978, Kleinman et al. 1980, You 1989, Kirlik et al. 1993). Indeed, You (1989) found that subjects made use of information from both lags 1 and 2 for making their treatment decisions.

Heuristic approaches to strategy selection in dynamic decision tasks have been explored by Kleinmuntz and Thomas (1987), and Kerstholt and Raaijmakers (1997). These researchers examined health management tasks that entailed dividing time between two strategies: collecting information from diagnostic tests before treatment vs. treating patients immediately without performing any more diagnostic tests. A general finding is that even experienced subjects tended to overuse information collection, resulting in poorer performance than that which could be obtained from an immediate treatment (no test) strategy. This finding seems to run counter to the adaptive decision-making hypothesis of Payne et al. (1993), which claims that subjects prefer to minimize effort and maximize performance. The information collection strategy is both more effortful and less effective than the treatment strategy in this situation.

Finally, an individual difference approach to understanding performance on complex dynamic decision tasks was developed by Dorner and his colleagues (see Funke (1991) for a review). Subjects are divided into two groups (good vs. poor) on the basis of their performance on a complex dynamic decision task. Subsequently, these groups are compared with respect to various behaviors in order to identify the critical determinants of performance. This research indicates that subjects who perform best are those who set integrative goals, collect systematic information, and evaluate progress toward these goals. Subjects who tend to shift from one specific goal to another, or focus exclusively on only one specific goal, perform more poorly.

3. *Learning to Control Dynamic Systems*

Although human performers remain suboptimal even after extensive task training, almost all past studies reveal systematic learning effects. First, overall performance improves rapidly with training (see, e.g., Rapoport 1975, Mackinnon and Wearing 1985, Brehmer 1992, Sterman 1994). Furthermore, subjective policies tend to evolve over trial blocks toward the optimal policy (Jagacinski and Miller 1978, You 1989). Therefore, learning processes are important for explaining much of the variance in human performance on dynamic decision tasks (Hogarth 1981). Three different frameworks for modeling human learning processes in dynamic decision tasks have been proposed.

A *production rule* model was developed by Anzai (1984) to describe how humans learn to navigate a simulated ship. The general idea is that past and current states of the problem are stored in working memory. Rules for transformation of the physical and mental states are represented as condition–action-type production rules. A product rule fires whenever the current state of working memory matches the conditions for a rule. When a production rule fires, it deposits new inferences or information in memory, and it may also produce physical changes in the state of the system. Navigation is achieved by a series of such recognize–act cycles of the production system. Learning occurs by creating new production rules that prevent earlier erroneous actions, with new rules being formed on the basis of means–ends type of analyses for generating subgoal strategies. Simulation results indicated that the model eventually learned strategies similar to those produced in the verbal protocols of subjects, although evaluation of the model was based on qualitative judgments rather than quantitative measurements.

An *instance or exemplar*-based model was later developed by Dienes and Fahey (1995) to describe how humans learn to control a simulated sugar production task, and to describe how they learn to manage the emotional state of a hypothetical person. This model assumes that whenever an action leads to a successful outcome, then the preceding situation and the successful response are stored together in memory. On any given trial, stored instances are retrieved on the basis of similarity to the current situation, and the associated response is applied to the current situation. This model was compared to a simple rule-based model like that employed by Anzai (1984). The results indicated that the exemplar learning model produced more accurate predictions for delayed feedback systems, but the rule-based model performed better when no feedback delays were involved. This conclusion agrees with earlier ideas presented by Berry and Broadbent (1988), that delayed feedback tasks involve implicit learning processes, whereas tasks without delay are based on explicit learning processes.

Figure 2
An artificial neural network for learning to control a dynamic system. The current state and the goal feed into a layer of hidden units that learn to produce an action. Next the current state and the action feed into another layer of hidden units that learn to predict the consequence

An *artificial neural network* model was developed by Gibson et al. (1997) to describe learning in a sugar production task. Figure 2 illustrates the basic idea. At the bottom of the figure are two types of input nodes, one representing the current state of the environment, and the other representing the current goal for the task. These inputs feed into the next layer of hidden nodes that compute the next action, given the current state and goal. The action and the current state then feed into another layer of hidden nodes, which is used to predict the consequence of the action, given the current state. The connections from the current state and action to the prediction hidden layer are learned by back-propagating prediction errors, and the connections from the current state and current goal to the action hidden layer are learned by back-propagating deviations between the observed outcome and the goal state (holding the connections to the prediction layer constant; see Jordan and Rumelhart (1992) for more details.) This learning model provided good accounts of subjects' performance during both training and subsequent generalization tests under novel conditions. Unfortunately, no direct comparisons with rule- or exemplar-based learning models were conducted, and this remains a challenge for future research.

Another type of artificial neural network model for learning dynamic systems is the reinforcement learning model (see Miller et al. (1991) for a review). Although this approach has proven to be fairly successful for robotic applications, it has not yet been empirically tested against human performance in dynamic decision tasks.

4. *Laboratory vs. Naturalistic Decision Research*

Klein and his associates (Klein 1998) have made progress toward understanding dynamic decisions in applied field research settings, which they call *naturalistic decision making* (e.g., interview fire chiefs after fighting a fire). Field research complements laboratory research in two ways: on the one hand, it provides a reality check on the practical importance of theory developed in the laboratory; on the other, it provides new insights that can be tested with more control in the laboratory.

The general findings drawn from naturalistic decision research provide converging support for the general theoretical conclusions obtained from the laboratory. First, it is something of a misnomer to label this kind of research 'decision making,' because decision processes comprise only one of the many cognitive processes engaged by these tasks—learning, planning, and problem solving are just as important. Decision making is used to define the overall goal, but then the sequence of actions follows a plan that has either been learned in the past or generated by a problem-solving process. Second, learning processes may explain much of the variance in human performance on dynamic decision tasks. Decision makers use the current goal and current state of the environment to retrieve actions that have worked under similar circumstances in the past. Klein's (1998) recognition-primed decision model is based on this principle, and this same basic idea underlies the production rule, exemplar, and neural network learning models. Third, learning from extensive experience is the key to understanding why naïve subjects fail in the laboratory whereas experts succeed in the field—it is the mechanism that moves performance from one end of the continuum to the other.

Dynamic Mapping in Geography

Dynamic mapping summarizes various cartographic presentation methods which incorporate the dimension of time into a map. These methods can be differentiated into those used either for static presentations or for dynamic presentations. All presentation methods have their own individual characteristics and are suitable for specific applications (Fig. 1).

1. *The Term and Concept of Dynamic Mapping*

Dynamic mapping is a cartographic concept used to depict dynamic spatial phenomena or to present spatial information in a dynamic way. It is involved with the depiction of spatial processes on maps. Our world is in permanent change. If the changes are of less interest because of their relative unimportance, it is sufficient to present a specific state of our world and of the corresponding date. Yet, if the occurring changes are of great importance, the dynamic aspect of reality—the dimension of time—has to be depicted in maps. Maps, however, are static: they can depict states but they can hardly show dynamic processes. To overcome the static nature of maps, different presentation methods were developed to give an impression of the changes and movements in space (Monmonier 1990, Muehrcke 1992). Recently the concept of dynamic mapping has been expanded by computer technology. Not only is the presentation of spatial changes now a matter of interest, but so too is

Figure 1
Methods of dynamic mapping: (a) time-series maps, (b) time-composite map, (c) change map, (d) time-related chart map, (e) flow map, (f) cartographic film or animation

dynamic presentation of spatial data, such as the successive display of map objects.

2. *Methods of Dynamic Mapping in Static Maps*

One presentation method for depicting spatial processes are time-series maps. They show a particular area and subject at different points in time in a series of maps. The user has to compare the individual maps and has to understand the changes which have occurred. Time-series maps have to be arranged in a way that enables visual comparison. They have to be placed next to each other, and their content should not be too complex. Map series are applied to show the distribution of particular phenomena at certain given intervals, e.g., changes of population distribution, boundaries, or landforms, etc.

Another method is the time-composite map. Such a map depicts two or more stages of the development of a particular phenomenon in one single map. The distinct stages can be differentiated by color, pattern, isolines, or point symbols. Time-composite maps are suitable for showing the expansion or contraction of areas, linear networks, or other phenomena, e.g., the growth of a city, the development of transportation systems, or the spread of diseases. Time-composite maps succeed in presenting one-directional changes, but they fail if retrogressive developments have to be depicted as an intermediate stage.

Map series and time-composite maps show only selected stages of the entire development. The change itself has to be understood by interpretation. However, some geographical questions emphasize, above all, the change and its extent. These questions require a map which shows explicitly the change that has taken place within a certain time period. For that purpose the change map was developed. Qualitative change maps depict objects which have been added to or removed from a particular area during a relevant time period, e.g., the difference in forest cover in different years. Quantitative change maps present changes in magnitude, the change in a value such as population density or air pollution. They either show the direction of change as increase or decrease, or give the absolute values of magnitude change.

A further method of presenting changes directly is a map with time-related charts which depicts developing phenomena of areas or locations in line or bar graphs, e.g., maps with diagrams of the annual temperature curve for selected stations. This type of map is able to give a detailed impression of development in time but it has its limitations in depicting the spatial distribution of a changing phenomenon.

Geographical processes may take place at a particular location (similar to the mentioned changes of population or temperature) or they may be a sort of movement in space like the movement of people, goods, or winds. To show these spatial movements, vector or flow maps with special symbols such as

arrows or lines are applied. The position and alignment of the arrows and lines can depict the moving objects' routes and directions, and the size of the signatures can denote the objects' values. Typical examples of vector or flow maps are maps of expedition routes, commuter movements, or ocean currents.

3. Cartographic Film and Animation as Dynamic Maps

All of the presentation methods referred to above are able to produce an idea regarding the changes that take place, but they have their limitations: they fail to depict the dynamics of the process. They are snapshots and the changes in the inter-snapshot periods can only be inferred.

For this reason, cartographic films were made. Films are dynamic presentation forms which are not restricted to single stages and can therefore give an impression of the complete process. Cartographic films are created like animated cartoons. They are sequences of slightly varying maps that give the illusion of continuous spatial movement or change in the case of fast presentation (24–30 pictures per second). Early cartographic films had to be made by hand; each map of the sequence was drawn by a cartographer. They were produced for military propaganda to depict frontier changes during World War II, or as instruction material for students. Despite their advantages, cartographic films did not become a widespread presentation form because of their time-consuming and expensive creation.

The cartographic film benefited from computer animation (Thrower 1961). Computer animations are film sequences completely generated by computer. Only some initial maps of the sequence are arranged by a cartographer, the intermediate maps are constructed automatically by the computer. Computer animations have two advantages compared to traditional films. First, computers take over the time-wasting map-making process of traditional films and allow quicker and less expensive production of cartographic animations; second, computer animations can be controlled interactively by the user. At a basic level, interaction means the start, stop, and interruption of an animation. At a higher level, more sophisticated interactions are possible, such as the selection of particular time intervals or the definition of different viewpoints (Peterson 1994).

Because of the advantages of speedy production and interaction, computer animation brought great potential to cartographic visualization and expanded the concept of dynamic mapping. Computer animation is no longer used exclusively for the depiction of spatial dynamic phenomena, it is also employed for any dynamic presentation of spatial data (DiBiase et al. 1992, Dransch 1997). Examples include the successive display of map objects, the alteration of graphic presentation, or the variation of the user's viewpoint. According to this differentiation two types of cartographic animation exist: temporal animation and nontemporal animation. These are able to improve the visualization of spatial data for demonstration purposes, as well as for exploration tasks; support the understanding of spatial processes and relations; increase the users' attention; and assist graphic data exploration.

Computer animations are quite different presentation forms compared to static maps. They are dynamic and they provide plenty of information to the user in a short time. The existing cartographic rules of map-making, therefore, have to be extended and the question of suitable applications, efficient design, and also cognitive aspects has generated recent research topics in the field of dynamic mapping (MacEachren and DiBiase 1991, Monmonier 1992, Buziek 1999, Kraak 1999).

4. Future of Dynamic Mapping

Developments in computer science and technology concerning virtual reality (VR) may further expand the concept of dynamic mapping. VR technology produces virtual environments by computer (Shneiderman 1998). The user will become part of this virtual world and may interact with it via multifarious interfaces. In cartography, spatial processes could be created with VR technology to give the user a vivid and lifelike impression. In addition, VR technology could also be used to build abstract worlds in which to present spatial concepts or data in a dynamic and highly interactive way. In this way, VR technology will add more vividness and interactivity to cartography and dynamic mapping, however, it also changes the traditional cartographic viewpoint. In contrast to the traditional method of looking at a map, using VR means being in the presentation. This entails the danger of getting lost because the spatial overview that is provided by maps is missing.

Dysexecutive Syndromes

At any given moment, your brain—with its tens of billions of neurons—produces a cacophony of neural activity. Indeed, it seems amazing to think that we are able to direct our attention to any single thought or execute any particular action. Yet, somehow we manage to orchestrate this noisy world and effectively control our mind and actions. Psychologists have coined the term 'executive control' to refer to the ability to select, manage, and control one's mental abilities. Without executive control the brain acts like an orchestra without a conductor or business without a boss.

Studies of patients with brain damage have suggested a syndrome in which executive control appears to have run amok. In particular, patients with damage to the frontal lobes, the most anterior part of the brain, have problems in controlling and directing their thoughts and actions. Indeed, psychological studies have suggested that the frontal lobes are important for a variety of executive functions, including paying attention, searching for thoughts, retrieving memories, initiating actions, and even controlling emotions (Shimamura 2000, Smith and Jonides 1999). Problems often arise in these patients when they are confronted with multiple sensations or choices and must decide which one to select and which ones to ignore. In this sense, these patients exhibit a 'dysexecutive syndrome' (Baddeley 1986).

When confronted with multiple thoughts or choices, patients with frontal lobe damage are easily distracted, unable to focus attention, and have difficulty making plans and decisions. By analogy, consider the kind of control needed to direct traffic in a busy intersection. Cars are entering from all directions, and control must be initiated by preventing some cars from entering the intersection while letting others pass through. Without some control—stop sign, signal, or traffic officer—crashes are likely. Now consider the cars to be neuronal impulses that cross literally billions of intersections. Executive control helps select some impulses while inhibiting others.

1. *Paying Attention*

Paying attention requires the focusing of one's thoughts to specific features in the environment. Let's say you are conversing with someone at a party where many other conversations are occurring at the same time. To carry on your conversation, you must focus your attention on the person with whom you are conversing and attempt to block out or suppress the conversations around you. In the laboratory, a task that has been used to measure attention is the Stroop color-word test. In this task, subjects see a list of color words written in different colored ink (e.g., the word 'RED' written in green ink). They are asked to report the ink color of each word and to ignore the word itself. Thus, the task requires subjects to pay attention to ink colors and suppress the natural tendency to read the words. Our ability to suppress reading is not completely successful as it takes much longer to identify the ink color of these words compared to reading color patches (MacLeod 1991).

Patients with frontal lobe damage exhibit particularly long response latencies when asked to name the ink color of stimuli when the stimuli are themselves incongruous color names (Perret 1974). Also, neuroimaging studies (PET, fMRI) suggest that areas in the frontal lobes and areas along the inner or medial surface of the cortex (the anterior cingulate gyrus) are particularly active when individuals perform the Stroop task (Peterson et al. 1999). Thus, based on these findings there is some evidence for a role of the prefrontal cortex in selecting or initiating activation. Damage to this area produces a dysexecutive deficit in the ability to pay attention—that is, control which perceptual features to select and which to suppress (Moscovitch 1994, Shimamura 2000).

2. *Searching for Memories*

Dysexecutive syndromes include problems in the ability to attend to thoughts and memories just as it includes problems in paying attention to environ-

mental stimuli. For example, take a minute to retrieve all of the words that you can think of that begin with the letter 'A.' This task requires you to search your memories and retrieve specific items. Perhaps, you developed a strategy to control what words you retrieved. For example, after trying to come up with just any words that begin with 'A' maybe you started to cue yourself with categories, such as foods that being with 'A' or animals that begin with 'A.' Or maybe you used two-letter cues, such as 'AB,' then 'AC,' then 'AD.' Such strategies are efficient because they facilitate the retrieval of different words and prevent the report of the same words. Patients with frontal lobe damage have difficulty directing their memory searches (Baldo and Shimamura 1998). They may report only five or six different words in a minute and often repeat the same words.

Controlling one's memories is also important for learning. For example, how would you try to learn the following series of words: car, pear, truck, shirt, banana, hat, airplane, shoe, and apple. Maybe you tried to organize the words by making a story involving the words. Perhaps, you noticed that the words could be grouped by the categories: vehicles, fruits, and clothing. In fact, when learning such word lists, many people group the words in terms of category and then report the words by category saying all of the vehicles first, then fruits, and so on. Controlling our thoughts for efficient learning requires the organization of new material so that it can be retrieved easily (Stuss et al. 1994).

Consider your memory as a library. What if every time you added a new book to your library, you simply threw the book in a pile? After dozens of new books, how easy would it be to retrieve any particular book? An efficient library requires a librarian who catalogs new books and organizes them on the shelves for efficient retrieval. Learning new knowledge (i.e., adding new books to your library) requires cataloging and organizing new information. A dysexecutive syndrome is akin to a library without a good librarian. Patients with frontal lobe lesions have problems learning new information because they cannot organize their thoughts and put them in an appropriate context. That is, they do not catalog information into meaningful groupings.

3. *Making Plans and Selecting Appropriate Responses*

A third aspect of executive control concerns the ability to focus on which plans or responses to initiate. If you had many plans for the day, such as meeting friends, shopping, and meals, it is necessary to develop a strategy or scheme for ordering your actions. Some things must be done at specific times (e.g., a lunch date), whereas other actions can be done with less time constraint. Efficient organization of one's actions requires a kind of control similar to that needed to control one's memories. Strategies must be developed for efficient use of time and energy. Dysexecutive syndromes lead to poor planning, impulsiveness, and flighty behavior. Patients with frontal lobe lesions often exhibit problems in handling everyday events, because they cannot seem to control and organize their plans and actions. Instead, they seem to initiate actions that immediately comes to mind, even if the actions may be inappropriate at the time. For example, a patient with severe frontal lobe damage may enter a restaurant, sit next to a stranger having a meal and start eating. Such patients appear to be overcome with immediate needs and motivations rather than controlling and planning actions appropriate for the moment, such as having a host seat you and ordering food from a menu (Miller and Cummings 1999, Milner and Petrides 1984).

4. *Controlling Emotions*

Finally, dysexecutive syndromes can include problems in controlling one's emotions. The following passage describes the rather interesting case of Phineas Gage, a railroad foreman who incurred frontal lobe damage following a bizarre accident in which an iron rod penetrated—harpoon-like—through Gage's skull damaging his frontal lobes (Harlow 1868, MacMillian 2000).

> He is fitful, irreverent, indulging at times in the grossest profanity (which was not previously his custom), manifesting but little deference for his fellows, impatient of restraint or advice when it conflicts with his desires, at times pertinaciously obstinate, yet capricious and vacillating, devising many plans of future operation, which are sooner arranged than that are abandoned in turn for others appearing more feasible…In this regard his mind was radically changed, so decidedly that his friends and acquaintances said he was "no longer Gage" (Harlow 1868).

Patients with severe damage to the frontal lobes often fail to control their emotions. They exhibit emotional outbursts, both anger and glee, that are not often socially acceptable, such as physical aggression or inappropriate advances to the opposite sex. In this domain, it appears that most people are able to suppress their emotions when they are not appropriate to elicit. Patients with frontal lobe damage often fail to suppress their emotions.

5. *A Board of Executives*

Recent research on human frontal lobes have shed light concerning dysexecutive syndromes. Most of these investigations have centered on the role of the frontal lobes in selecting, monitoring, and controlling mental processes. Indeed, psychological studies of patients with frontal lobe lesions and functional

neuroimaging studies of neurologically intact individuals suggest that this brain region is involved in tasks that require many aspects of executive control, such as stimulus selection, working memory, memory retrieval, and set shifting (D'Esposito et al. 1995, Shimamura 2000).

In simplified terms, the prefrontal cortex is your brain's chief executive—it functions to attend to the environment, ignore irrelevant information, select memories, make decisions, and initiate actions. Without it, thoughts are disorganized, more susceptible to interfering information, and more confused. In actuality, there appears to be several supervisors, each one overseeing a particular mental capacity, such as perceptions, memories, emotions, and action. Thus, the frontal lobes acts more like a governing board of supervisors whose job it is to monitor and control many aspects of mental activity. In the case of Phineas Gage, the supervisor in charge of emotional control was dysfunctional and therefore emotions or feelings were blurted out without regard to the situation or social context. In sum, Phineas was not able to monitor and control the expression of his emotions. Other dysexecutive syndromes appear to affect the attention to perceptions and memories rather than emotions. Interestingly, different parts of the frontal lobes seem to control different aspects of mental function.

Dyslexia (Acquired) and Agraphia

1. Forms of Acquired Dyslexia

It has been known at least since the late nineteenth century that damage to the left hemisphere of the brain can specifically affect a person's ability to read—that is, can result in an acquired dyslexia. However, it was not until the seminal paper by Marshall and Newcombe (1973) that it became clear that acquired dyslexia occurs in a variety of forms, and that one can understand these forms by relating them to a model of the normal reading system. The basic approach here is to propose an explicit model of reading containing a variety of processing components, and then to seek to show how a particular pattern of sparings and impairments of these components would result in a set of reading symptoms that corresponds to the symptoms of a particular observed form of acquired dyslexia.

Marshall and Newcombe (1973) described three forms of acquired dyslexia; at least three other forms have subsequently been identified, and all six will be described here.

1.1 Phonological Dyslexia

Beauvois and Derouesné (1979) were the first to report that in cases of acquired dyslexia the ability to read nonwords aloud could be selectively impaired relative to the ability to read words aloud. They reported six cases of previously literate readers of French for whom

this was the case, and numerous other cases have been reported since then; see Coltheart (1996) for a recent comprehensive review. The most extreme of these cases was WB (Funnell 1983) who scored 0/20 correct on reading aloud very simple nonwords such as *nust* or *cobe*, while achieving scores of 85–90 percent correct in reading aloud long low-frequency morphemically complex abstract words such as *satirical* or *preliminary*.

When the ability to read aloud pseudohomophones (printed nonwords whose pronunciations are real words, such as FAKT) is compared to the ability to read aloud nonpseudohomophonic nonwords such as FANT, some phonological dyslexics show a clear advantage for the pseudohomophonic items while others clearly show no difference here (see e.g., Berndt et al. 1996). These results are not only obviously relevant for any attempts to offer a theoretical interpretation of phonological dyslexia; they also show that this condition is not a homogeneous one. Selective difficulty in reading nonwords aloud must occur for different reasons in different patients, if some patients' nonword reading shows an advantage for pseudohomophones while other patients' nonword reading does not.

1.2 Surface Dyslexia

If, after brain damage, word reading can be spared while nonword reading is selectively impaired (that is, if phonological dyslexia can occur), it is natural to wonder whether the reverse pattern might also arise: worse reading of words than nonwords. Here it is important to distinguish between *regular* and *irregular* words. Regular words are those that respect the standard relationships between letters or letter groups and their corresponding pronunciations; irregular words are those whose spelling–sound relationships violate at least one such correspondence. Thus the word *steak* is irregular because of the way the letter group *ea* is pronounced in that word; in almost all words containing this spelling, the *ea* is pronounced as in *steam* or *freak*, both of which are regular words. On all extant models of the reading system, the procedure people use to read nonwords also allows perfectly accurate reading of regular words: so all theories predict that one would never find a person with acquired dyslexia who could read nonwords but was impaired at reading of regular words.

Irregular words could be a different matter, however. According to at least some models of reading, irregular words cannot be read correctly by the procedure that is used to read nonwords—the application of knowledge about typical relationships between segments of spelling and their most common pronunciations would produce correct reading of nonwords but incorrect reading of irregular words. So one might expect to come across patients with acquired dyslexia who are good at reading nonwords but bad at reading irregular words—and such patients have indeed been described.

This form of acquired dyslexia is known as surface dyslexia, first described by Marshall and Newcombe (1973) and reviewed by Patterson et al. (1985). The most extreme cases so far reported are MP (Bub et al. 1985) and KT (McCarthy and Warrington 1986), both of whom were normal in speed and accuracy of reading regular words and nonwords while severely impaired in reading exception words.

If patients with surface dyslexia are erring with exception words because they are reading these words via the application of knowledge about typical relationships between segments of spelling and their most common pronunciations, then one would expect their reading errors to demonstrate this. Precisely this type of error is indeed very frequent in surface dyslexia, and it is known as the 'regularization error'—for example, reading *broad* to rhyme with 'code,' or *steak* to rhyme with 'meek.' Some patients with surface dyslexia are not perfect at reading regular words: at least some of these patients produce what might be called 'irregularization errors' with regular words, such as reading *hoo*t as if it rhymed with 'foot' or *hea*t as if it rhymed with 'threat' (Patterson et al. 1996).

The deficit in irregular-word reading by surface dyslexics is frequency-sensitive, with performance much worse for low-frequency irregular words than for high-frequency irregular words.

As with phonological dyslexia, there is more than one form of surface dyslexia. Reading errors such as *gauge* → 'That is something about a railway…that's as much as I've got, train,/gɔdʒ/' (Kay and Patterson 1985; patient EST) clearly show that the problem here is not in visual word recognition (since the printed word has been comprehended correctly, it must first have been recognized correctly) but instead is a failure in retrieval of stored information about the correct pronunciation of that particular word. Since the patient is being asked to read aloud— i.e., to produce a spoken response—he can only fall back on the procedure used for reading nonwords aloud, which of course will yield a regularization error with this irregular word. This is 'output surface dyslexia.'

A different form, 'input surface dyslexia,' is demonstrated when patients asked to define printed exception words produce such responses as *bear* → 'a drink, beer' (Coltheart et al. 1985; patient CD). Here the patient has not recognized the word as an orthographic whole (which is necessary for normal reading comprehension) so has had to attempt the reading comprehension task by first translating the word from orthography to phonology via the application of knowledge about typical relationships between segments of spelling and their most common pronunciations. Since *bear* is an irregular word, a regularization error (translating *bear* into the pronunciation of 'beer') will occur here. The use of this regularized phonological form to access

semantics is responsible for the specific comprehension error made here.

1.3 Visual Dyslexia

There has been curiously little research on this form of acquired dyslexia. Its characteristic symptom is the abundance of visual errors in reading aloud—responses which share many letters with the stimulus but are otherwise unrelated to it, such as reading *enigma* as 'image' or *garden* as 'anger.'

1.4 Lexical Nonsemantic Reading

Brain damage sometimes affects the semantic system and so impairs the comprehension of written or spoken words. This can happen as a consequence of head injury, but is more commonly due to a progressive brain deterioration such as dementia of the Alzheimer's type. Schwartz et al. (1980) studied the reading performance of WLP, a patient of this type. At a point in the evolution of her disorder where she could no longer understand written words reliably, she could still read aloud very well—and that included the ability to read aloud exception words such as *blood*, *shoe*, and *sweat*.

According to some models of reading aloud (Hillis and Caramazza 1991), the procedure by which irregular words can be read correctly is via a pathway from orthography to meaning and then a pathway from meaning to pronunciation. If that were so, then a severe semantic impairment would always be accompanied by an impairment in the reading of irregular words. The data from WLP, and from other reports of patients with severe semantic impairment but good irregular-word reading (Cipolotti and Warrington 1995, Coslett 1991, Lambon Ralph et al. 1995), show that this kind of model of reading cannot be correct; and this form of acquired dyslexia has come to be called 'lexical nonsemantic reading.'

1.5 Pure Alexia (Letter-by-letter Reading)

In this form of acquired dyslexia (see Coltheart (1998) for a recent comprehensive review), words and nonwords are read aloud slowly and effortfully, usually by naming each letter in left-to-right order. If all the letters are named correctly, the patient will then usually produce the whole word or nonword correctly. Latency to read aloud increases linearly with the length of the word or nonword, with slopes sometimes as shallow as one letter per five or more seconds, so that a six letter word might require 30 seconds or more before a correct reading response is produced. The term 'letter-by-letter reading' is used since it describes the characteristic reading behavior of these patients. The term 'pure alexia' (or 'alexia without agraphia') is used because writing and spelling is often intact in these patients; this is discussed further below.

Some patients with pure alexia exhibit a phenomenon known as 'covert reading.' When letter strings are presented at durations too short for the patient to be able to read them aloud—two seconds or so, for example—and the patient asked to judge whether the letter string was a word or not, or in other studies whether it was the name of an animal or not, performance on these classification tasks can be well above chance, and even sometimes perfect, even though the stimuli cannot be read aloud and the patient may even claim not to have seen them at all (see e.g., Saffran and Coslett 1998). It is argued that in pure alexia 'the right hemisphere supports performance in covert reading tasks, and…letter-by-letter reading is the product of the left hemisphere operating on information transferred from the right' (Saffran and Coslett 1998, p. 141). Here it is important to appreciate the lesion sites typically associated with pure alexia. These patients generally have damage to two distinct regions of the brain, the left occipital cortex and the splenium of the corpus callosum. The left occipital lesion means that printed words must be visually processed by the right hemisphere's occipital cortex. That in itself would not cause reading to be abnormal, however, since intact readers have no difficulty in reading words briefly presented in the left visual field (must be visually processed by the right hemisphere's occipital cortex). Normal readers read promptly under these conditions by transferring information from right occipital cortex to language systems in the left hemisphere. Pure alexics can't do that, and the reason must be that the splenium of the corpus callosum is the pathway by which such interhemispheric transfer for reading is normally done. In the patients, the splenial lesion means that some other callosal pathways have to be used for this transfer, and the use of these other pathways may impose a slow and serial letter-by-letter transfer process.

1.6 Deep Dyslexia

This acquired dyslexia is reviewed in detail by Coltheart et al. (1980). Its cardinal symptom is the semantic error in reading aloud. When single isolated words are presented for reading aloud with no time pressure, the deep dyslexic will often produce as a response a word that is related in meaning, but in no other way, to the word he or she is looking at: *dinner* → 'food,' *uncle* → 'cousin,' and *close* → 'shut' are examples of the semantic errors made by the deep dyslexic GR (Coltheart et al. 1980). Visual errors such as *quarrel* → 'squirrel' or *angle* → 'angel,' and morphological errors such as *running* → 'runner' or *unreal* → 'real,' are also seen. Concrete (highly-imageable) words such as *tulip* or *green* are much more likely to be

successfully read than abstract (difficult-to-image) words such as *idea* or *usual*. Function words such as *and*, *the*, or *or* are very poorly read. Nonwords such as *vib* or *ap* cannot be read aloud at all.

As noted above, Marshall and Newcombe (1973) proposed that different forms of acquired dyslexia might be interpretable as consequences of specific different patterns of breakdown within a multicomponent model of the normal skilled reading system. That kind of interpretation has also been offered for deep dyslexia, by Morton and Patterson (1980). However, this way of approaching the explanation of deep dyslexia was rejected by Coltheart (1980) and Saffran et al. (1980), who proposed that deep dyslexic reading was not accomplished by an impaired version of the normal skilled reading system, located in the left hemisphere of the brain, but relied instead on reading mechanisms located in the intact right hemisphere.

Subsequent research has strongly favored the right-hemisphere interpretation of deep dyslexia. Patterson et al. (1987) report the case of an adolescent girl who developed a left-hemisphere pathology that necessitated removal of her left hemisphere. Before the onset of the brain disorder, she was apparently a normal reader for her age; after the removal of her left hemisphere, she was a deep dyslexic. Michel et al. (1996) report the case of a 23-year-old man who as a result of neurosurgery was left with a lesion of the posterior half of the corpus callosum. They studied his ability to read tachistoscopically displayed words presented to the left or right visual hemifields. With right hemifield (left hemisphere) presentation, his reading was normal. With left hemifield (right hemisphere) presentation, his reading showed all the symptoms of deep dyslexia. In a brain imaging study, Weekes et al. (1997) found that brain activation associated with visual word recognition was greater in the right than the left hemisphere for a deep dyslexic, but not for a surface dyslexic, nor for two normal readers.

It seems clear, then, that deep dyslexia is unlike all the other patterns of acquired dyslexia discussed here, in that deep dyslexics do not read via some damaged version of the normal (left-hemisphere) reading system, whereas patients with other forms of acquired dyslexia do.

2. *Forms of Acquired Dysgraphia and Their Relationship to Acquired Dyslexia*

Just as damage to the left hemisphere of the brain can sometimes specifically affect reading, so too left-hemisphere damage can sometimes specifically affect spelling and/or writing. Such an impairment of writing or spelling in a previously literate person is referred to as an acquired dysgraphia; and various different forms of patterns of acquired dysgraphia have been reported. There is a selective difficulty in spelling nonwords relative to words, known as 'phonological agraphia' or 'phonological dysgraphia' (e.g., Shallice 1981). There is a selective difficulty in spelling irregular words relative to regular words and nonwords, known as 'lexical agraphia' or 'surface dysgraphia' (e.g., Beauvois and Derouesné 1981). There are cases in which semantic errors are made in spelling to dictation, and spelling of nonwords to dictation is impossible, known as 'deep dysgraphia' (Bub and Kertesz 1982). There is also 'lexical nonsemantic spelling' (Patterson 1986)

Almost all patients with acquired dyslexia also exhibit acquired dysgraphia—the only clear exception here is for pure alexia (letter-by-letter reading), in which writing and spelling are often intact. Patients with acquired dyslexia and acquired dysgraphia offer unique opportunities for learning more about the relationships between the systems intact people use to read and to spell. For example, when one sees a patient who reads *yacht* as '/jætʃt/' and spells 'yacht' as *yot*—a patient with surface dyslexia and surface dysgraphia—it is exceedingly tempting to take this as evidence that the body of orthographic knowledge we use to recognize familiar printed words is the same as the body of orthographic knowledge we use when retrieving familiar spellings. If this were so, then loss of the representation of the word *yacht* from this body of knowledge would force the word to be both read and spelled via the application of knowledge about typical relationships between segments of spelling and their most common pronunciations. This method of reading and of spelling would generate the particular erroneous reading and spelling responses just described. Here one would be arguing against the view that there are distinct bodies of orthographic knowledge for orthographic input (reading) and for orthographic output (spelling and writing) (as proposed by many (e.g., Morton 1980) and for the view that there is just a single body of orthographic knowledge used both for reading and for spelling and writing (as proposed by Allport and Funnell 1981).

But the relationships between the form of acquired dyslexia a person has and the form of acquired dysgraphia accompanying it are unfortunately much more complicated than this. Most people with surface dysgraphia also show surface dyslexia, but not all do: RG (Beauvois and Derouesné 1979) was a surface dysgraphic but a phonological dyslexic. Most people with deep dysgraphia also show deep dyslexia, but not all: MK (Howard and Franklin 1988) was a deep dysgraphic but a surface dyslexic, and JC (Bub and Kertesz 1982) was a deep dysgraphic but essentially normal at reading.

Thus the relationships between acquired dyslexia and acquired dysgraphia are simply not understood at present. But as has been documented above acquired dyslexia itself is rather well understood. Various types of acquired dyslexia have been clearly delineated, as have subvarieties of each type, and we have very clear ideas about how to interpret these patterns of impaired

reading in relation to an information-processing theory of the normal reading system.

3. Computational Cognitive Neuropsychology of Reading

Currently a number of information-processing theories of reading aloud are expressed as computational models—that is, as executable computer programs which turn print into phonology and do so by using the specific information-processing procedures posited by the particular theory. Some of these models are in the connectionist tradition and are built up via connectionist learning algorithms such as backpropagation (Plaut et al. 1996, Zorzi et al. 1998). Others are nonconnectionist, with their architectures specified by the modeler rather than by a learning algorithm (Coltheart et al. 2001). This is an area of much ongoing theoretical development.

One way to test such models is to investigate their ability to simulate different patterns of acquired dyslexia. The way this is done is to try to 'lesion' particular components of the program so as to cause the computational model to exhibit the same kinds of errors as do patients with particular forms of acquired dyslexia—to cause the program to make regularization errors with irregular words, especially low-frequency ones, for example, whilst still being good at reading nonwords (thus simulating surface dyslexia) or to cause the program to be poor at reading nonwords while still being able to read words (thus simulating phonological dyslexia). The computational cognitive neuropsychology of reading is currently being pursued both in the connectionist tradition (Plaut 1997) and in the nonconnectionist tradition (Coltheart et al. 2001)

M. Coltheart

Dyslexia, Developmental

Developmental dyslexia can be characterized as a specific problem with reading and spelling that cannot be accounted for by low intelligence, poor educational opportunities, or obvious sensory or neurological damage. Children with developmental dyslexia often appear to have good spoken language skills and extensive vocabularies. Accordingly, the first theories of developmental dyslexia postulated underlying deficits in visual processing ('word blindness'). Recent evidence from developmental psychology, genetics, and brain imaging increasingly suggests, however, that the central deficit in developmental dyslexia is a linguistic one. In particular, dyslexic children appear to have difficulties in the accurate specification of phonology when storing lexical representations of speech.

1. The Normal Development of Lexical Representations

A schematic view of a lexical representation is shown in Fig. 1. Researchers in child phonology have shown that, in the normal course of development, the phonological aspects of children's lexical representations become increasingly segmental and distinctly specified in terms of phonetic features. When vocabulary size is small, there is no need to represent words in a systematic or detailed manner, and so early word representations are thought to encode fairly global phonological characteristics (e.g., Jusczyk 1993). As vocabulary grows, these holistic representations are gradually *restructured*, so that smaller segments of sound are represented (Metsala and Walley 1998). Developmentally, children appear to first represent syllables (a word like *wigwam* has two syllables), then onsets and rimes (the onset in a syllable corresponds to the sound/s before the vowel, the rime corresponds to the vowel and any subsequent sounds, e.g., *p - it*; *scr - ew*), and ultimately, phonemes (phonemes are the smallest units of sound that change word meaning, e.g., *pit* differs from *sit*, *pot*, and *pin* by the initial, medial, and final phonemes, respectively). According to this 'emergent' view of segmental representation (Metsala and Walley 1998), the phoneme is not an integral aspect of speech representation and processing from infancy onwards (as was once thought), but rather emerges as a representational unit via *spoken language experience*. The degree to which segmental representation has taken place is in turn thought to determine how easily the child will become phonologically 'aware' and will learn to read and write.

Figure 1
Schematic depiction of a lexical representation, showing cognitive tasks tapping input and output processes

Dyslexic children appear to have specific difficulties in the representation of segmental phonology. Most of the evidence for this 'phonological deficit' has come from 'phonological awareness' tasks, in which children are asked to make judgements about shared phonology or to manipulate phonology (e.g., the *rhyme oddity* task, in which the child is asked to distinguish the odd word out from a triple like *man*, *pat*, *fan*, and

the *phoneme substitution* task, in which the child is asked to substitute the initial phonemes in words, so that Bob Dylan becomes Dob Bylan). A large number of studies carried out in many languages has shown that dyslexic children perform poorly in such phonological awareness tasks (see Goswami in press, for review). Importantly, such deficits are found even when dyslexic children's performance is compared to that of younger children who are reading and spelling at the same level as them (the methodologically important *reading level match* research design, which holds reading level constant rather than chronological age and thus gives a mental age advantage to the dyslexic children). A phonological deficit seems to characterize dyslexia across languages. Whether the child is learning to read a nontransparent orthography like English, or a transparent orthography like German, phonological awareness deficits are consistently found. This suggests that an important causal factor in dyslexia is an underlying difficulty in developing segmentally well-specified lexical representations of speech.

2. *The Abnormal Development of Phonological Representations in Dyslexia*

The cognitive profiles of developmental dyslexics show fairly specific linguistic deficits that are related to phonology rather than semantics. For example, developmental dyslexics have poor phonological memory skills. They find it difficult to remember verbal sequences, and they show poor performance on standardized tests of phonological memory (such as repeating nonsense words like *ballop* and *thickery*). Repeating nonsense (novel) word forms requires the child to set up new phonological representations. Developmental dyslexics are also slower to recognize familiar words on the basis of acoustic input. For example, they require more acoustic-phonetic information than age-matched controls to recognize familiar words in speech gating tasks, in which incremental segments of speech from word-onset are presented through headphones. On the output side, developmental dyslexics show deficits in fine-grained measures of speech production such as the distinctness of vowel articulation. They also show problems in confrontation naming tasks (in which simple pictures must be named on demand), even though they are very familiar with the items in the pictures. Their problems are particularly marked when the familiar names are long and of low frequency, and thus correspond to phonological forms that have been encountered less frequently and that also require the accurate specification of more phonological segments. Developmental dyslexics find rapid 'automatized' speeded naming tasks difficult. These tasks require the child to name familiar items presented in lists (such as digits) as quickly as possible, thereby accessing and outputting what should be well-practiced and so well-specified phonological forms ('nine, two, five,…').

3. *Auditory Processing Problems*

Studies that have attempted to uncover basic auditory processing deficits to explain this apparently selective difficulty in representing phonological forms in memory have so far produced mixed results. Typically, a basic processing task will show dramatic impairments for some dyslexic children, and no apparent impairment for others, despite extremely careful subject selection. Thus, some dyslexic children have great difficulty with 'minimal pairs' tasks that require the discrimination of similar-sounding words (e.g., *smack–snack*), yet others do not (Adlard and Hazan 1998). Some dyslexic children find phoneme categorization and repetition tasks very difficult (e.g., discriminating between or repeating /b/ and /d/), and others do not (e.g., Manis et al. 1997). Some dyslexic children find temporal order judgements very difficult. Typically, such tasks require them to decide whether a high tone preceded a low tone or vice versa. Accordingly, it has been proposed that dyslexia is caused by temporal processing deficits (e.g., Tallal 1980), but this view is quite controversial. For example, Mody et al. (1997) have shown that dyslexic children who find it difficult to discriminate phonemes like ba/da show no deficit with a nonspeech analogue task that makes the same temporal processing demands (sine wave speech). Thus far, most auditory processing deficits that have been found appear to be specific to linguistic stimuli. However, the lack of uniformity across subjects is puzzling. One possibility is that the primary basic processing difficulty has not yet been discovered. A second is that the difficulty lies not in perception *per se*, but in *representing* the segments that can be detected in the input, as discussed above. A third is that sensory deficits in basic auditory processing and phonological deficits are not causally related, but arise from the dysfunction of a neural system common to both (Eden and Zeffiro 1998). Finally, it is logically possible that there may be a variety of causes of dyslexia, with some children's primary problems lying outside the auditory realm.

4. *Phonological Processing Deficits in Dyslexia: Brain Imaging Studies*

Nevertheless, evidence from brain imaging work is consistent with the view that the key difficulty in dyslexia is a weakness in the representation of phonological information. The phonological processing system spans a number of cortical and subcortical regions in the brain, including frontal, temporal, and parietal cortex. Studies of aphasia long ago revealed the importance of Broca's area (frontal cortex) and

Wernicke's area (posterior superior temporal gyrus) for the motor production and receptive aspects of speech, respectively, and the lateralization of language-related processes to the left hemisphere is equally well documented.

Interpretation of functional neuroimaging studies of dyslexia is complicated by the fact that only adult developmental dyslexics can be scanned, which means that the brain's compensatory responses to any initial disorder may account for some of the patterns of task-related activity that are found. Nevertheless, despite seemingly inconsistent results in early studies, localization of phonological mechanisms in the temporo-parietal junction and abnormalities in activation surrounding this junction in adult developmental dyslexics during phonological processing tasks have been documented by a number of research groups (see Eden and Zeffiro 1998 for review). When performing tasks like rhyme judgement, rhyme detection, and word and nonsense word reading, dyslexic subjects show reduced activation in temporal and parietal regions, particularly within the left hemisphere.

5. *Genetics of Developmental Dyslexia*

The heritability of dyslexia has been demonstrated by a number of family and twin studies (e.g., Gayan and Olson 1997). More recently, linkage studies have been used to try to determine where in the human genome the critical genes for dyslexia are located. The most promising findings so far concern the short arm of chromosome 6, and sites on chromosome 15 (e.g., Grigorenko et al. 1997). These studies depend on definitions of the dyslexic phenotype that are based on deficits in phonological awareness tasks and single or nonsense word reading. Thus there is evidence that individual differences in phonological processing are to some extent heritable. Of course, there cannot be a 'gene' for dyslexia in the sense that there is a gene for eye color, as reading is a culturally determined activity. Individuals at genetic risk for dyslexia who develop in a favorable early environment as far as reading is concerned (for example, children who have carers who stimulate their linguistic awareness via language games, nursery rhymes, and so on, and who read books to them and model and encourage literacy activities by reading and writing extensively themselves) may be able to compensate to some extent for their genetic predisposition to dyslexia. Other individuals with a lower degree of risk but relatively adverse early environments may be more handicapped.

6. *Developmental Dyslexia Across Languages*

As noted earlier, the degree to which the segmental representation of phonology has taken place is thought to determine how easily the child will become phonologically 'aware' and will learn to read and write. Phonological awareness is usually defined as the ability to recognize and manipulate subsyllabic units in spoken words. It has been shown to be an important predictor of reading and spelling progress in a vast number of studies of normally developing children in many languages, and follows the developmental sequence syllable–onset/rime–phoneme across all the alphabetic languages so far studied (Goswami in press). Nevertheless, it is also the case that learning to read itself affects the representation of segmental phonology. In particular, attainment of the final developmental stage of full phonemic representation is highly dependent on being taught to read and write an alphabetic language (see Goswami and Bryant 1990 for a review).

For example, adults who are illiterate show the same difficulties with phonological awareness tasks at the phoneme level as prereading children, and Japanese children (who learn to read a syllabary) show relatively poor phoneme level performance in comparison to American children.

Given the close relationship between the development of phonemic awareness and learning to read and write, the difficulties faced by developmental dyslexics would be expected to vary to some degree with linguistic transparency, even if the underlying problem in all languages concerns phonological representation. This is in fact the case. Dyslexic children who are learning to read and spell transparent orthographies like German show the confrontation naming deficit characteristic of English dyslexic children, suggesting that their phonological representations of speech are compromised. However, they do not show accuracy deficits in nonsense word reading tasks, although they do show marked speed deficits (e.g., Wimmer 1993). When nonsense words are carefully matched across languages, German dyslexic children are much better at reading nonsense words than English children (Landerl et al. 1997). This presumably reflects the consistency of grapheme–phoneme relations in German compared to English. The German child, even the child with a linguistic difficulty, is learning a less variable orthographic code.

7. *Subtypes of Developmental Dyslexia?*

Some researchers have argued strongly for two subtypes of developmental dyslexia: 'surface' dyslexia and 'phonological' dyslexia (but see Oliver et al. in press). Phonological dyslexics are thought to have problems in assembling sublexical phonology (reading using abstract spelling-to-sound 'rules'). Surface dyslexics are thought to have problems in using stored lexical knowledge to pronounce words (they seem to have difficulty in directly addressing orthographic representations). This 'double dissociation' model of de-

velopmental dyslexia has been drawn from patterns of adult pathology (the 'acquired' dyslexias).

The subtyping argument has depended critically on the use of regression procedures, in which performance relationships between the use of lexical and sublexical phonology characteristic of normal children are used to derive confidence limits for assessing the same performance relationships in dyslexic populations. These regression procedures typically depend on the use of *chronological* age-matched normal readers. As processing tradeoffs between the reliance on lexical and sublexical phonology may depend on the overall level of word recognition that the child has attained, *reading level* matched controls are more appropriate. Stanovich et al. (1997) demonstrate clearly that when reading level matched controls are used to define processing tradeoffs, then almost no 'surface dyslexic' children are found, even in the original samples used to support the notion of subtypes of developmental dyslexia. They conclude that the 'surface' dyslexic profile arises from a milder form of phonological deficit accompanied by exceptionally inadequate reading experience.

8. *Towards a Phenotype of Dyslexia*

Neurodevelopmental disorders are not discrete syndromes, but most typically have a graded character. They are also seldom highly specific, and rarely involve a single deficit. Although a difficulty in representing segmental phonology appears to be the core symptom of developmental dyslexia, many researchers have noted a number of associated deficits that more or less frequently accompany the phonological deficit. For example, dyslexic children can be clumsy, they can have attentional problems, they may display mild cerebellar signs such as slow motor tapping, and they may have subtle abnormalities in visual processing such as poor motion processing when visual stimuli are of low contrast and low luminance. At present, the most widely accepted phenotype of developmental dyslexia depends on deficits in performance on a battery of cognitive tasks that tap the integrity of the child's phonological representations of speech. This battery most typically includes phonological awareness tasks, single word and nonsense word reading tasks, and rapid 'automatized' naming tasks. Developmental dyslexia is thus currently best conceived as a subtle linguistic deficit that involves an impairment in the representation of the phonological segments of speech in the brain.

Dyslexia: Diagnosis and Training

Developmental dyslexia, a childhood disorder characterized by 'unexpected' reading and spelling difficulties, became the subject of serious scientific enquiry in the 1970s. This article discusses how the definition of dyslexia is critical to its diagnosis and considers the implications of research on dyslexia for the assessment and teaching of dyslexic children.

1. The Definition of Dyslexia

Since the landmark Isle of Wight studies, it has become conventional to distinguish children who have specific reading difficulties (dyslexia) from children who have reading difficulties in the context of more general learning problems (reading backwardness). A child is considered to have a specific problem with reading if their reading attainment is significantly below that predicted from their general cognitive ability on the basis of the correlation between reading and IQ in children of the same age (a discrepancy between expected and actual attainment). However, a limitation inherent in the 'discrepancy-definition' of dyslexia is its dependence on IQ because the verbal IQ of poor readers is likely to decline as a consequence of their limited reading experience. Thus, diagnosis using this definition of dyslexia runs the risk of missing true cases of dyslexia either in children whose verbal IQ is lowered, or in those who have overcome their reading problems but may have significant difficulty with spelling and written work.

2. Dyslexia as a Core Phonological Deficit

The most widely accepted current view of dyslexia is that it is part of the continuum of language disorders and reflects phonological (speech) processing difficulties (Share 1995). These include problems with phonological awareness, verbal short-term memory, naming especially in speeded tasks, phonological learning, speech perception and nonword repetition. Current theories suggest that dyslexic children have difficulties first in establishing, and later in accessing, adequate phonological representations (see *Dyslexia, Developmental*). The strong evidence of phonological deficits in dyslexia has led to the definition of dyslexia as a core phonological deficit, irrespective of IQ (Stanovich and Siegel 1994). This definition makes sense in terms of what is known about normal reading acquisition; phonemic skills are critical to the development of the alphabetic principle that allows children to decode words they have not seen before. Dyslexic children typically have difficulty reading words that are not part of their sight vocabulary, such as non-words.

3. Subtypes of Dyslexia

Most systematic studies of individual differences among dyslexics have revealed variations in their reading skills. As well as dyslexic children who have difficulties using phonological strategies for reading and spelling, it is possible to identify others who appear to have mastered alphabetic skills and can use these proficiently; at least when there are no time demands. Such children have been referred to as developmental 'surface' dyslexics. These children rely heavily upon phonological strategies for reading and spelling. Thus, they tend to pronounce irregular words as though they were regular (e.g., island—izland), they have particular difficulty distinguishing between homophones like pear-pair, and their spelling is usually phonetic (see *Dyslexia (Acquired) and Agraphia*).

A number of recent studies have suggested that individual differences in the reading skills of dyslexic readers might be explained by differences in the severity or developmental status of underlying phonological skills. Thus, children with phonological dyslexia appear to have a disorder of reading development whereas surface dyslexics are developmentally delayed in their acquisition of reading skills (Snowling 2000).

4. Dyslexia Across the Life-span

A second advantage of the core phonological deficit hypothesis of dyslexia is that it accounts well for the changing profile of dyslexia across the life span. While reading problems are the key symptom of dyslexia in the early school years, adults with a childhood history of dyslexia often become fluent readers though few overcome their spelling problems. Adult dyslexics also have difficulty decoding words they have not seen before (i.e., nonwords) and with phonological awareness, speeded naming and verbal short-term memory tasks.

At the other end of the age spectrum, preschool children with a genetic risk of dyslexia show phonological difficulties in the context of slower than expected vocabulary development (Gallagher et al. 2000). Indeed, problems of phonological awareness, together with limitations of letter knowledge presage reading difficulties in high-risk children (Byrne et al. 1997, Lefly and Pennington 1996).

5. The Assessment of Dyslexia

The convergence of evidence from studies of the normal development of reading and from dyslexia enables practitioners both to identify children at risk of dyslexia and to provide early intervention. Children who have a family history of dyslexia and children who have a history of speech-language difficulties appear to be at risk, although the nature of the speech-language impairment is an important factor in determining outcome. By school entry it is possible to identify with some certainty, children who will go on to have difficulties with reading by assessing their performance on tests of phonological awareness and letter knowledge. With young children in the age range of four to five, tests of syllable and rhyme awareness seem the most suitable, while from six years onwards, tests requiring awareness of spoken words at the level of the phoneme are the most sensitive.

In spite of the attractions of the core phonological definition of dyslexia, the whole-scale abandonment of general cognitive ability in the diagnosis of dyslexia would be hazardous. For children who have already failed to learn to read, the starting point of the assessment should involve an assessment of general cognitive ability. This form of assessment is important in diagnosing whether dyslexia accompanies a broader language disorder (Bishop 1997) or the syndrome of nonverbal learning disabilities (Rourke 1995). However, the assessment will be most useful if it proceeds to assess the phonological skills that underlie reading development and the reading strategies the child is currently using with a view to prescribing appropriate intervention (Snowling and Stackhouse 1996). From the point of view of diagnosis, a limitation of the core phonological definition of dyslexia is its focus on phonology and the development of decoding skills. Whilst there is a consensus that automatic decoding skills are critical to reading development, proficient reading is the product of both decoding and linguistic comprehension skills. Although dyslexic readers have basic level decoding difficulties, many have normal linguistic comprehension that can afford them a number of advantages; they tend to comprehend what they read relatively well and they can monitor their comprehension processes.

6. *Comorbidity and Compensation*

Some of the variation among dyslexics seen at the behavioural level may be due to comorbidity between dyslexia and another disorder. A substantial body of research suggests that many dyslexic children have low level impairments of the transient visual system (Hogben 1997). Although there is no conclusive evidence that these are causally linked with dyslexic children's reading impairments, such problems may affect the ability of children who have phonological difficulties to compensate. Similarly, some dyslexic children have motor impairments and others problems of attention control (Pennington et al. 1993).

Arguably, the course of reading development followed by a particular dyslexic child will be determined not only by the severity of their phonological processing problem, but also by their other cognitive skills (Snowling 2000). For dyslexic children who have good semantic skills and poor phonology, it is likely that their word recognition will improve in the face of decoding deficits because they rely heavily on context. In contrast, dyslexic children who have milder phonological difficulties or poorer general language skills will tend to show delayed development along normal lines. Furthermore, the environmental variables impinging upon the dyslexic child are critical to eventual outcome. Cross-linguistic studies are beginning to reveal that the manifestations of dyslexia depend on the orthography in which a child learns to read (Frith et al. 1998). More generally, print exposure, a measure of the extent to which a child reads, is an independent predictor of reading attainment.

7. *Interventions for Dyslexia*

There is now a considerable body of literature pointing to the benefits of phonological awareness training to subsequent literacy development (Toija 1999). Training in phonological skills is particularly effective when it is combined with highly structured reading tuition. However, it is also becoming clear that dyslexic children and children at risk of dyslexia respond relatively less well to these techniques than normally developing readers (Byrne et al. 1997). Indeed, initial phonological skill is one of the best predictors of responsiveness to intervention in such training regimes (Hatcher and Hulme 1999). For children who do not respond to such treatments, more intensive therapies may need to be designed and special school placement considered.

Dyslexia, Genetics of

Dyslexia is a developmental language disorder which mainly affects the acquisition of reading and spelling skills. Dyslexia is an interesting example of the intersection between an evolved behavior (language) and a cultural invention (literacy). While there cannot be genes for reading or other relatively recent cultural inventions (consider agriculture, banking, and football), there can be genetic influences on evolved cognitive and behavioral traits necessary for proficiency in such cultural inventions. Because there is now extensive evidence of genetic influences on individual differences on most domains of cognition and behavior, it is not surprising that there are genetic influences on reading and spelling skills. In what follows, we will first consider how the dyslexia phenotype is defined, then consider genetic studies of dyslexia, and conclude with how these genetic discoveries will help us understand the development of this disorder.

1. *Definition of the Phenotype*

In the case of complex behavioral traits like dyslexia, careful cognitive analysis is often needed before the genetic dissection begins. Without such analysis, the phenotype utilized in genetic studies will be much coarser and more likely to be influenced by numerous genes and environmental influences. Genetic studies of dyslexia have built upon extensive research on the psychology of reading. This research has pinpointed which of the many cognitive components of skilled reading are most important for individual differences in reading proficiency. Some of the cognitive components of skilled reading include eye movements, visual perception, language processing, reasoning, and memory. In neuroimaging studies of skilled reading, many parts of the brain 'light up,' including parts associated with the cognitive components just listed. The key question then is whether all of these cognitive components are equally important for individual differences in learning to read or whether a cognitive explanation of most of reading difficulty can be provided by a much smaller set of components. If the former situation were the case, we would want to divide individuals with reading difficulty into many different cognitive subtypes before undertaking genetic studies. On the other hand, if the latter situation obtains, genetic studies would be more feasible.

Dyslexia was first described 100 years ago by Pringle-Morgan (1896), but real advances in our understanding of its cognitive phenotype have only come in the last 20 years (see Shaywitz 1996 and Snow et al. 1998 for reviews). Earlier theories of dyslexia focused on the reversal errors made by individuals with dyslexia, such as writing **b** for **d** or **was** for **saw**, and postulated a basic deficit in visual processing. Orton (1925) termed this deficit 'strephosymbolia,' which means 'twisted symbols.' The recent advances in our understanding of the cognitive phenotype in dyslexia have built upon basic research focused on both human speech and skilled reading. Although the goal of reading is comprehension, which depends on many higher cognitive processes such as reasoning and memory, it turns out that a very substantial proportion of the variation in reading comprehension can be accounted for by individual differences in the accuracy and speed of single printed word recognition. So, most poor readers have a primary problem with recognizing individual printed words, not with reading comprehension. Not too surprisingly, problems with printed word recognition are almost inevitably accompanied by problems with spelling, since both word recognition and spelling depend on understanding the relations between letters and sounds. Poor readers with these primary problems in word recognition and spelling that are not due to a vision or hearing problem, or a lack of instruction, are called dyslexics. The smaller subset of poor readers with a primary problem in reading comprehension and not in word recog nition are thus not included in the definition of dyslexia.

Single word recognition skill is highly related to phonological coding skill, the ability to pronounce letter strings that have never been seen before (usually measured by having a subject read pseudowords). A reader who can pronounce pseudowords demonstrates an implicit understanding of the quasi-regular correspondences that exist between written letters and spoken sounds. Without this implicit understanding, a reader would have to depend on pure rote memory to read or spell a very large number of seemingly unrelated items (about 100,000 or more in the case of a reader of this encyclopedia). Of course, the pronunciation and spelling of some exception words, such as *yacht*, have to be memorized. The ability to learn word-specific pronunciations and spellings is called

orthographic coding skill. Extensive research has documented that dyslexics are less accurate in reading pseudowords (phonological coding) than even younger, normal readers matched on single, real word reading accuracy. While the majority of developmental dyslexics also have deficits in orthographic coding skill, it is not clear that there is a subtype of dyslexia with only a selective deficit in orthographic coding. So, the vast majority of dyslexics have a deficit in phonological coding that at least partially explains the key defining symptoms of their disorder, slower and less accurate single word recognition and spelling.

But what are these speech sounds that the phonological code represents? A skilled reader knows that the spoken word *bag* is spelled with three letters and that these letters correspond to the three 'speech sounds' in the spoken word. However, a sound spectrograph of this or other spoken words will not reveal discrete speech sounds because of the phenomenon of coarticulation: the articulatory gestures for each speech sound overlap in their production, allowing us to talk much faster than would be the case if we produced each speech sound separately. Linguists call these speech sounds 'phonemes,' explicit awareness of which is called 'phoneme awareness,' which can be measured by tasks which require a subject to count or manipulate the phonemes in a word. Interestingly, one can learn to talk without phoneme awareness, because spoken language can be processed in larger 'chunks,' such as words or syllables. But one cannot learn to read, unless the language one is learning to read is a syllabary, like Japanese Kana. Linguistic theory predicts, and extensive empirical research has confirmed, that the ability to segment these phonemes in spoken speech is a prerequisite for learning to read an alphabetic language like English. If the alphabet is a code and if the letters correspond to phonemes, then how could one understand that code without phoneme awareness? Thus, one might expect deficiencies in phoneme awareness to underlie dyslexia. Indeed, numerous studies have found that dyslexics across the lifespan have deficits in phoneme awareness, which appear to have their origin in sometimes subtle problems with early language development. However, deficits in phoneme awareness are not uniquely predictive of later dyslexia, since other measures of phonological development predict about as well (Snow et al. 1998). Finally, it should be acknowledged that the relation between reading and phoneme awareness is a reciprocal one; while phoneme awareness is a prerequisite for normal reading, reading experience also facilitates phoneme awareness.

In sum, contrary to intuition, individual differences in reading skill have more to do with speech than with vision, and at least as much to do with single word processing as with the processing of connected text. Once we focus on poor readers with primary problems in word recognition, the vast majority are found to have problems in phonological coding and phonological development. So, the cognitive explanation of most of reading difficulty involves many fewer cognitive components than those involved in skilled reading. These facts about the dyslexia phenotype have facilitated genetic studies which have built on this cognitive science understanding of normal and abnormal reading. If these linkage studies of dyslexia had used letter reversals, or even reading comprehension, as the phenotype, it is unlikely that as much progress would have been made.

It is important to emphasize that few of the complex behavioral phenotypes now being tested for linkage have an equally mature cognitive science analysis to build on. For example, other substantially heritable childhood disorders, such as autism and attention deficit hyperactivity disorder, and most adult psychiatric disorders, are less well understood than dyslexia at the cognitive level of analysis. How much of a barrier this will prove to be for genetic studies remains to be seen, but it could be a substantial one.

2. *Genetic Mechanisms*

In the last two decades, our understanding of the etiology of dyslexia has increased considerably due to advances in both behavioral and molecular genetics. For fifty years after it was first described by Pringle-Morgan (1896) evidence for recurrence in families was repeatedly documented in case reports, leading Hallgren (1950) to undertake a more formal genetic epidemiological study of a large sample of families. Besides conducting the first test of the mode of transmission, his comprehensive monograph also documented several characteristics of dyslexia that have recently been rediscovered: (a) the sex ratio is nearly equal, about 1.5 M:F and (b) there is not a significant association between dyslexia and non-right handedness. Hallgren also documented that dyslexia co-occurs with other language disorders; however, the degree and basis of this comorbidity has not yet been fully worked out, although it fits with the view that dyslexia is a developmental language disorder.

Although Hallgren and his predecessors provided considerable evidence that dyslexia is familial, it has taken modern twin studies (see DeFries and Gillis 1993 for a review) to demonstrate that this familiality is substantially genetic and modern linkage studies to actually begin to locate the genes involved. Unlike the situation in Hallgren's time, we now have very strong, converging evidence that dyslexia is both familial and heritable (see Pennington and Gilger 1996 for a review). We can also reject the hypotheses of classic, X-linked or simple recessive autosomal transmission, at least in the vast majority of cases. We also have evidence that dyslexia is genetically heterogeneous. Perhaps most importantly, we have evidence that supports Hallgren's observation that what looks like autosomal dominant transmission occurs in many

dyslexic families. So there do appear to be effects of loci with sizable effects, acting in a dominant or additive fashion, on the transmission of reading problems.

However, we can place several important constraints on Hallgren's hypothesis of a single autosomal dominant gene influencing dyslexia. First, it is very unlikely to be one gene, because of the evidence for genetic heterogeneity. Second, it may not be a gene influencing dyslexia *per se*, since the familiality, heritability, and transmission results for normal variations in reading skill are not clearly different from those for dyslexia. Hence, the same *loci* may be involved in the transmission of both normal reading skill and dyslexia. If this is true, then dyslexics would just have more of the unfavorable alleles at these loci and/or more environmental risk factors, such that their reading scores are pushed beyond the cutoff for dyslexia. In this case, the locus (or loci) is not a necessary 'disease' locus, but is instead better conceptualized as a susceptibility locus. A susceptibility locus, unlike a disease locus, is neither necessary nor sufficient to produce the disorder in question. If a susceptibility locus influences a continuous (as opposed to categorical) trait, then it is called a quantitative trait locus (QTL). Complex behavioral traits are more likely to be influenced by several QTLs than a single Mendelian locus.

So instead of a classic, autosomal dominant 'disease' gene, which is rare in the population and which is by itself necessary and sufficient to produce the disorder of dyslexia, we are likely dealing with several, more frequent quantitative trait loci (QTLs), which are involved in the transmission of both dyslexia and normal variations in reading skill. No one QTL is likely to be necessary to produce dyslexia. Whether one QTL has an effect size sufficient to produce dyslexia is an empirical question which only linkage methods can answer.

In summary, several hypotheses about the transmission of dyslexia can be rejected on the basis of available data reviewed in Pennington and Gilger (1996). (a) Dyslexia is not an X-linked disorder, and there is little evidence of parental sex effects on transmission. There is converging evidence for sex differences in penetrance, which would produce the slight preponderance of males (1.5 M:F) that is observed. (b) Simple polygenic/multifactorial transmission can be rejected because there is a major locus effect in several samples. This major locus effect acts in an additive or dominant, but not in a recessive fashion. (c) A monogenic hypothesis can be rejected because dyslexia is genetically heterogeneous. (d) A necessary 'disease' allele hypothesis can be rejected because there is evidence for a major locus effect on the transmission of normal variation in reading skill. A remaining hypothesis that fits the empirical data considered here is that a small number of QTLs underlie the transmission of both dyslexia and normal variations in reading skill.

Given the strong possibility that the loci contributing to dyslexia are QTLs, and given the evidence for genetic heterogeneity, traditional linkage analysis (of large extended dyslexic families) is not the most appropriate method to identify these loci. Instead, sibling pair linkage analysis is more appropriate. By selecting sibling pairs in which at least one sibling has an extreme score, one can perform linkage analyses which screen for genetic loci influencing extreme scores on a continuous measure.

Using such a method, evidence for a QTL on the short arm of chromosome 6 was found across two independent samples of sib pairs and across two sets of genetic markers (Cardon et al. 1994). Each sample gave significant evidence of a quantitative trait locus located in a two centimorgan (2cM) region of 6p22.3-21.3.

This finding has now been replicated in three other samples and by two other laboratories (Fisher et al. 1999, Gayan et al. 1999, Grigorenko et al. 1997), although a fourth laboratory using a different phenotype definition did not replicate this result (Field and Kaplan 1998). The Grigorenko et al. study also found some evidence of differential genetic effects as a function of which cognitive component of reading was used to define the phenotype. However, Fisher et al. and Gayan et al. both found that the QTL on chromosome 6 was linked to deficits in both of the two main cognitive components of word recognition, phonological and orthographic coding. This result is consistent with behavioral genetic analyses of these two components, which have found that they have a large, although not complete, genetic overlap (Olson et al. 1999). Work is now under way to identify the actual gene in this region, to screen the remainder of the genome to identify other QTLs that influence dyslexia, and to test whether they differentially influence cognitive components of reading, such as phonological and orthographic coding.

3. *Implications of the Genetic Findings*

These exciting linkage findings may eventually allow us to address how much variance in reading scores these genetic loci account for, and eventually how frequently unaffected siblings have unfavorable alleles at these loci. If a similar, sib pair linkage study were conducted using probands selected for extremely high reading scores, we could determine whether different alleles at the same loci influence exceptionally good reading. If so, we could conclude that the same quantitative trait loci are affecting reading scores across the whole distribution. If they are, then our speculation that the same genes are influencing normal and extreme individual differences in reading would be supported. If not, then we would have direct evidence that dyslexia is etiologically distinct. Once we have a better understanding of these genetic mechanisms, we

can also conduct much more revealing studies of environmental factors, both risk factors and protective ones, which are also undoubtedly operative in the transmission of both abnormal and normal reading skill.

These linkage results also permit a direct test of the etiology of the comorbidity of dyslexia with other developmental disorders, such as attention deficit hyperactivity disorder and speech and language disorders. Most importantly, once these genes are clearly identified, we can begin to trace the dynamic, developmental pathway that runs from gene to brain to behavior.

Finally, it is important to discuss how the finding of moderate genetic influence on dyslexia and the approximate location of some of the genes involved influences how we treat this common disorder. Here it is important to emphasize that the issues of etiology and treatability are separate ones. Traits under a high degree of genetic influence can nonetheless be quite malleable because the reaction range of the genotype is broad. Many non-geneticists are resistant to genetic explanations because they fear that a genetic etiology means that the disorder is immutable. Instead, exactly the opposite is often the case; understanding the genetics of a disorder can lead to fundamental advances in its treatment. Although we do not currently know whether the linkage results for dyslexia will lead to changes in its identification or treatment, we already know that the phenotype is malleable and that training can significantly improve the educational outcome of children with dyslexia.

Early Childhood: Socioemotional Risks

Socioemotional development in early childhood pertains broadly to the quality of children's evolving participation in relationships, with the parent–child relationship serving as a primary focus in early childhood. Socioemotional development takes into account normative achievements in emotional and cognitive developmental domains, and parental and child characteristics that contribute to individual differences in the quality of children's emotional functioning and social behavior. This article is concerned with individual differences in the quality of young children's socioemotional functioning, and selected risks to such functioning from the vantage point of attachment theory and research. Indeed, security of attachment represents a central means of conceptualizing and assessing socioemotional functioning in early childhood.

1. *Quality of Attachment and Socioemotional Functioning*

The reader is referred to *Attachment Theory: Psychological* for detailed treatment of the emergence of attachment theory and description of attachment classifications in infancy. Mary Ainsworth's (Ainsworth et al. 1978) identification of the three basic attachment patterns in infancy (secure: group B; insecure-avoidant: group A; and insecure-ambivalent: group C), and Main and Solomon's (1986) addition of the insecure-disorganized/disoriented category (group D), significantly revolutionized thinking about the roots of socioemotional functioning in childhood. Whereas sensitive parental care has been found to predict group B classifications, rejecting, intrusive caregiving has been linked to group A classifications, and inconsistent and/or noncontingent caregiving has been predictive of group C attachments (Cassidy and Berlin 1994, Main 1981). Group D attachments have been linked to highly pathological caregiving such as child abuse and other forms of severe parental inadequacy resulting from parental psychopathology or drug and alcohol abuse (Solomon and George 1999). Among the insecure attachment groups, group D may represent the most insecure and the most at risk for the development of serious behavior problems in later childhood. In low-risk samples, 60–65 percent of infants are typically classified as secure, 15–20 percent as insecure-avoidant, 10 percent as insecure-ambivalent, and 10–15 as insecure-disorganized.

2. *Quality of Attachment and Later Relationships*

Central to attachment theory is the development of internal working models of relationships, which emerge with the advent of more sophisticated cognitive and memory capabilities as children move from sensorimotor to representational modes of functioning. Internal working models are believed to exert a powerful organizational influence on the manner in which information from the social environment is processed and interpreted, and on one's behavior toward attachment figures and peers. Significant predictive relations are thus expected between quality of attachment in infancy and the quality of children's subsequent relationships with peers. Secure children, who are likely to experience a history of caregiving empathy, warmth, and sensitivity, should be more likely to manifest such characteristics in interactions with peers and adults than children experiencing a history of caregiver rejection or inconsistency. Further, because of their history with a sensitive, responsive caregiver, secure children will be more likely than insecure children to organize their behavior around caregivers, and to enter into positive, cooperative relationships with them. Indeed, children classified as secure in infancy have later been found as toddlers and preschoolers to be more empathic and socially competent with peers, more compliant and cooperative with mothers, and more sociable with unfamiliar adults than children classified in infancy as insecure. Among the four Ainsworth–Main infancy classifications, the insecure-disorganized category appears to be particularly associated with more severe relationship disturbances in older children. Children classified as disorganized in infancy have been found to show heightened levels of disruptive behavior toward peers, and role-reversing, controlling behavior toward caregivers at age six. These findings are consistent with work finding disorganization in infancy to be linked with significant caregiving pathology. The extent to which early attachment security can predict the quality of later relationships with parents and peers is likely to depend on the stability of parental care over time (Lamb et al. 1985). Few would argue, however, that early security is inconsequential. Indeed, a basic tenet of attachment theory is that children who enjoy a secure relationship with the

primary caregiver are better equipped psychologically to negotiate and resolve subsequent developmental challenges (e.g., establishing a sense of independence and mastery in the preschool years) than children who are insecure.

3. Risks for Insecure Attachment

Given the connection between quality of parenting and security of attachment, it follows that specific threats to the quality of parenting will place young children at risk for insecure attachment and, in turn, for socioemotional difficulties in the wider world. The following section identifies risks as derived from three domains: the parent, the parent's social-ecological niche, and the child. What follows is by no means an exhaustive list. Indeed, it is reasonable to conclude that any stressor that compromises parents' ability to provide adequate care places children at socioemotional risk. The following section highlights factors that have been repeatedly identified either theoretically or empirically as threats to attachment security in early childhood.

3.1 Parental Risks

3.1.1 Nonautonomous working models of attachment. Attachment theory proposes that working models of relationships continue to be revised and updated as older attachment relationships evolve and as individuals develop new attachments over time. The most significant development in the assessment of working models of relationships in adulthood is the Adult Attachment Interview (AAI) (George et al. 1985), a semistructured, autobiographical interview that inquires about adults' perceptions of their early relationships with mothers, fathers, and other attachment figures. The AAI classification system places great emphasis on the manner in which past and present attachment relationships are described and the overall coherency of the narrative. The AAI yields four attachment groupings—autonomous, dismissing, preoccupied, and unresolved—which are viewed as reflecting one's current state of mind with respect to attachment, and which map conceptually onto the Ainsworth–Main infancy classifications of secure, insecure-avoidant, insecure-ambivalent, and insecure-disorganized. Autonomous (secure) adults evaluate attachment relationships as meaningful and important, provide convincing supportive evidence for perceptions of their early attachment relationships, and take an open, balanced, and forgiving stance in portrayals of untoward experiences with caregivers, past or present. Dismissing adults tend to idealize their parents, using very positive descriptors to describe their relationships with them without convincing supportive evidence. Lack of memory, or providing accounts of experiences that belie the very positive descriptors given for parents, is characteristic of dismissing adults. Preoccupied adults are actively or (less commonly) passively preoccupied with their attachment figures. Their narratives are entangled, angry accounts of past and present experiences with caregivers, with excessive focus on perceived parental slights and transgressions, and parental character 'flaws.' Finally, unresolved adults show conspicuous lapses in the monitoring of reasoning and discourse in discussion about loss or abuse, indicative of significant mental disorganization vis-à-vis these experiences.

In a meta-analysis, Van Ijzendoorn (1995) reported that nonautonomous mothers were less sensitive and supportive in interactions with their young children than autonomous mothers. In this same report, 75 percent of infants had an attachment classification that corresponded with the analogous AAI classification of the mother. Autonomous mothers were likely to have secure infants, dismissing mothers were likely to have insecure-avoidant infants, preoccupied mothers were likely to have insecure-ambivalent infants, and unresolved mothers were likely to have insecure-disorganized infants. Thus, autonomous mothers' ability to respond to infants with sensitivity, dismissing mothers' proclivities to reject infant bids, preoccupied mothers' tendencies toward inconsistency, and unresolved mothers' frightened/frightening behavior function to organize infant attachments that are complementary to those of the parent. These findings suggest that parents with nonautonomous working models of attachment may place their children at risk for insecure attachment.

3.1.2 Parental psychopathology. There is a large literature on the debilitating effects of parental psychopathology on children's emotional well-being. Most commonly assessed has been maternal depression, probably because it is so widespread among women with small children, and this work consistently demonstrates that children of depressed mothers have elevated rates of internalizing (e.g., depression, anxiety) and externalizing (e.g., oppositional, 'acting-out' behavior) symptoms than children of nondepressed controls (Gelfand and Teti 1990).

Depressed mothering has been described as hostile, critical, disengaged, and intrusive, and thus it is not surprising that theoretical explanations for the transmission of psychopathology from depressed parent to child target the depressed parent–child relationship. Indeed, depression in mothers is associated with elevated rates of insecure attachment in infants, particularly when the depression is chronic and moderate to severe. Teti et al. (1995) found that 80 percent of infants of depressed mothers were classified as insecure (with 40 percent insecure-disorganized), compared to only 30 percent (10 percent insecure-

disorganized) in the nondepressed group. That high rates of attachment disorganization were found among infants of chronically depressed mothers is consistent with the premise that unpredictable, frightened, or frightening behavior, which has been theoretically linked to disorganization, is more probable among parents with psychiatric disturbance.

3.2 Social-ecological Risks

3.2.1 Marital discord. Much has been written about the debilitating impact of marital discord on the socioemotional well-being of young children. High levels of marital stress are associated with reduced parental sensitivity and responsiveness, and with higher rates of insecure attachment. Presumably, marital discord affects attachment security indirectly, via its impact on quality of parenting, although Davies and Cummings's (1994) emotional-security hypothesis proposes that young children's emotional security with parents is impacted directly by repeated exposure to marital conflict. Recent work has emphasized the importance of distinguishing between marital conflict that is resolved, versus unresolved marital conflict, with the latter being especially problematic for children.

3.2.2 Parental social supports. The quality of support parents receive from their broader social networks also relates to quality of parenting, although evidence for a linkage between social support and security of children's attachment to parents is not as clear as it is for marital quality. Like marital discord, low social support has been associated with unresponsive, insensitive parenting, although its relation to insecure attachment is most clearly discernible in higher-risk samples. For example, Crockenberg (1981), in her study of relations of infant temperament and parental social supports to security of infant–mother attachment, reported an association between low support and insecurity only among temperamentally irritable infants. Social support may function most clearly for parents as a buffer against the ill effects of specific life stressors, such as difficult infant temperament.

3.3 Child Risk: Difficult Temperament

Although there is no universally accepted definition of temperament, most students of temperament would agree that it refers to a set of trait-like predispositions that are genetically based, that present themselves relatively early in infancy, and on the basis of which infants can be reliably distinguished. Typical 'core' constructs of temperament include emotionality (e.g., positive vs. negative mood), activity level, reactivity to stimuli, adaptability to changes in routine, and, possibly, sociability. Intuitively, it is reasonable to expect that infants who are negative in mood and highly reactive and unadaptable to new situations would present unwelcome challenges to parents, and in turn to their developing attachment security with the parents, in comparison with infants typically positive in mood, generally adaptable, and low in reactivity. Despite research since 1980, however, the role of infant temperament in the development of infant–parent attachment remains controversial. Temperament-attachment associations are, at best, modest, suggesting that quality of attachment and temperament are not redundant constructs. It is likely that temperamental predispositions do indeed influence the development of attachment security, but indirectly, via a more direct impact on parent–child relations and parental feelings of efficacy. Parents are likely to find difficult infants more challenging and potentially stressful than easier infants, and those parents who can engage successfully with and adapt to difficult infants are theoretically more likely to foster infants' security than parents who withdraw from or overreact to these difficulties.

4. Attachment Security, Cumulative Risks, and Protective Factors

Studies of the impact of risk factors on development in older children consistently indicate that development is increasingly compromised as the number of risk factors to which a child is exposed increases. Such research, focusing on the socioemotional functioning of young children, is less common. However, Belsky (1996) recently demonstrated such a cumulative relation in a study of attachment security in infancy, which included the risk factors of parental psychological maladjustment, marital discord, difficult infant temperament, low parental social supports, high levels of work and family stress, and low social class. Studies of this kind illustrate the point that development takes place against a backdrop of risks and protective factors, the latter serving to buffer the child against the adverse effects of risks, and that both should be considered together in attempts to predict development. Interestingly, factors that are considered 'protective' are frequently at the opposite end of the same spectra as the risk factors (e.g., nondepressed vs. depressed parent, marital harmony vs. marital discord, easy vs. difficult temperament).

5. Future Directions

The specific manner in which risk and protective factors in early childhood interact to impact parenting and early attachment is poorly understood. However,

such questions are at the forefront of the field. For example, how might an easy temperament in infancy buffer the negative impact of maternal depression on socioemotional functioning? Do an easy baby's positive mood, low reactivity, and adaptability elicit less negative (or more positive) parenting from that parent, which, in turn, increases the likelihood of a secure attachment? Alternatively, does easy babies' generally high adaptability lead them to more adaptable developmental outcomes even in the face of parental inadequacy, within limits? Answering such questions should help to elucidate important mechanisms of influence on development.

Early Concept Learning in Children

Coverage of concepts in this article is restricted to objects. Concepts are part of our explicit knowledge; they are the ideas we bring to mind when planning, thinking, and recalling; that is, they involve more than just recognizing an object as familiar or knowing how to interact with it. Over the course of a lifetime we accumulate a huge amount of explicit information about objects such as dogs and spoons, including what they look like, what kind of thing they are, what they do or is done with them, locales in which they are found, materials of which they are composed, and so forth. However, the core of a concept of a given object consists of the kind of thing it is, which means that concepts are fundamentally classificatory. For example, the core of a concept of dog is that it is an animal and the core of a concept of spoon is that it is an eating utensil. The broader concepts of animal and utensil are in turn defined in terms of what they do or is done to them. Concepts at this abstract level of animal or utensil begin to be formed early in life.

1. Traditional Views of Concept Formation

Due to the writings of the Swiss psychologist, Jean Piaget (e.g., 1936), for most of the twentieth century it was assumed that children do not begin to form concepts until late in the second year. Piaget claimed that infants know about objects only in terms of sensorimotor activity; they were thought to be able to recognize objects and to know how to interact with them, but not to be capable of classifying them or

thinking about them in their absence. Because this view was so widespread little research on the foundations of concepts in infancy was conducted. Typically, research on early concept formation was carried out on newly verbal children, which meant that concept learning and language acquisition were often confounded.

The most common words for objects in daily speech are at what is called the 'basic level' (Mervis and Rosch 1981), that is, words such as 'dog' and 'spoon' as opposed to 'animal' and 'utensil.' Because these common words for objects are the ones that children most often hear, they are the first object words that children learn. However, it was then assumed that the language reflects fairly closely their level of conceptualization. Thus, children were said first to form *basic-level concepts* such as dog and spoon and only later to form more difficult *superordinate concepts* such as animal and utensil. However, although young children do not often use superordinate words, they often overextend words such as 'dog' to refer to all animals, which does not fit well with the notion that they do not have some concept of animal.

2. Current Theory and Research

2.1 Methods of Study

As preverbal infants have come to be studied, the traditional view of concept formation has begun to change. Infant research not only removes the confound between learning concepts and learning language, it also enables examination of concept formation at a younger age, thus providing information about the earliest foundations of the conceptual system. This research effort is still young and there is a great deal yet to be discovered about the first concepts. However, several useful techniques have been developed. These include the *object-examination task*, in which infants are given a series of little models of objects from one class to examine, for example a series of animals, and then an object from another class, for example, a car.

If infants examine the car longer than still another animal, it indicates the infants think that a car is different. Using this task it was found that by nine months of age infants differentiate animals, vehicles, plants, and furniture, but make relatively few distinctions within these classes. For example, they do not distinguish dogs from cats or rabbits nor tables from chairs or beds (see Mandler 1998 for a summary). Other research showed that even younger infants are sensitive to the differences in physical appearance of different kinds of land animals as well as different kinds of furniture, so the failure to categorize them on the object-examination task indicates a failure to make conceptual divisions within these domains. Thus, even though young infants are able to perceptually categorize dogs as different from cats, they do not at first treat them as if they were different kinds of things.

The object-examination task is suitable for testing infants as soon as they begin to manipulate objects (about six months). Another test, suitable from about twelve months, is the *sequential-touching task*. This task is an instructionless version of the standard classification test in which children are instructed to put together objects that are the same kind of thing. In the sequential-touching task, infants are presented with a number of objects from two classes simultaneously, and encouraged to play with them. The number of times infants touch objects from the same class in a row (run length) is measured and compared to chance run lengths. This test provides data similar to that from the object-examination test, indicating that even in the second year infants are not making many subdivisions in the large classes of animals, vehicles, furniture, and utensils.

A particularly useful test of early concept formation is the *generalized imitation task*, suitable from about ten months of age. Infants are shown an event acted out with little models, such as a dog being given a drink from a cup. They are then encouraged to imitate what they have just seen, but are given the cup and two different objects (for example, a different dog and a cat, or a rabbit and a car). Their choice of object to use to imitate drinking is recorded. This technique, by using the generalizations that infants are willing to make, is useful to test the breadth of early concepts. It is also useful to determine how preverbal infants have interpreted the events they observe. By varying the choices provided for infants to use for their imitations, one can narrow in on what they have understood. For example, if one-year-olds are shown a little model of a dog drinking and then given a different dog and a rabbit, they are equally likely to choose the rabbit as the dog as their first choice of animal to give a drink. On the other hand if the infants are given another dog and a bird, they are more likely to use the dog first for their imitations and only later give the bird a drink. This kind of finding suggests the infants interpreted the dog as a land animal, rather than as a dog or more generally as an animal. However, their willingness to give the bird a drink as a second choice, indicates the breadth of the generalizations they have made about drinking (Mandler and McDonough 1998).

2.2 Some Early Object Concepts

These different techniques converge in showing the global nature of the early concepts that have been studied. By nine months of age (and perhaps earlier) infants make distinctions among the domains of animals, vehicles, plants, and furniture, but within these domains make few distinctions at the basic level. For example, infants generalize any animal behavior to all other animals (including drinking and sleeping

to fish), and generalize car keys as applicable to any vehicle (including forklifts and airplanes). Near the end of the first year they have learned some of the functions of ordinary household objects, but still at a global level. For example, they have learned something about the function of containers (Baillargeon 1995) but they interpret both cups and frying pans as appropriate containers from which to drink (Mandler and McDonough 1998).

Gradually during the second year infants begin to narrow down their concepts of common household objects until they begin to approximate basic-level concepts. In the studies to date, the earliest differentiation of broad concepts into subclasses occurs in the vehicle domain, followed by household artifacts, with differentiation of animals and plants occurring at a much slower rate. This ordering seems likely to be culturally determined, but this remains to be studied. In any case, by the time they are about three, children are more apt to base their generalizations on basic-level classes rather than on larger ones and in that sense they are approaching adult functioning. However, right from the beginning inductive inferences are determined by conceptual meaning, rather than physical appearance. The main difference between these early concepts and those of later years is the sophistication of the theories that underlie them (see Carey 1985).

Overall, the general principle on which the conceptual system is built in the first two years is that broad concepts gradually become subdivided into finer ones (even though there may be a few more individualized concepts from an early age). This principle explains why the conceptual system (in so far as objects are concerned) is strongly hierarchical. Every time a new distinction is learned it is done on the basis of forming a subdivision in a more inclusive class. This order of acquisition may also partly determine the order of breakdown of the conceptual system following brain damage, in which basic-level concepts disappear before more foundational ones (Patterson and Hodges 1995).

2.3 The Nature of the Earliest Concepts

Relatively little is yet known about the kinds of information infants use to form their first concepts. It is known that infants parse the world into coherent objects, and make a distinction between animate and inanimate objects at least from two to three months of age. It seems reasonable to assume that the basis for this distinction lies in some appreciation of the different roles that animate and inanimate objects play in events. Infants are sensitive to the difference between caused and noncaused motion and to the contingent movements that characterize interactions among animates. Hence, the earliest concept of animal is likely to be something like an object that begins to move by itself and that interacts with other objects contingently and/or from a distance. Similarly, the earliest concept of artifact or inanimate thing may consist of an object that either does not move at all or, if it moves, only does so when another object comes in contact with it, and which does not interact with other objects from a distance. This distinction presumably forms the initial conceptual division of the world into two kinds of objects, from which the further division into more detailed concepts proceeds. In this sense the construction of the conceptual system lags behind the perceptual system, which is capable of making very fine distinctions from quite early in infancy. The conceptual system begins with a few crude, and probably event-related, distinctions and only gradually subdivides these into finer categories.

Early Education and Care in the World Regions

Introduction: a New Understanding of Early Childhood

It is hardly too strong to say that societies in the past sometimes behaved as if young children under three did not engage in learning and cognitive activity.

Today, the phrase 'learning begins at birth' (Jomtiem World Conference of Education for All) conveniently sums up a sea-change in public knowledge and attitudes toward young children. There is now an increasing recognition among researchers, educators, social policymakers and the public at large that the early years constitute a critical period in the human development cycle. What was seen almost exclusively as a care period is now recognized as an important moment in the human life-cycle for brain and cognitive development (Lindsey 1998). As a result, public authorities now tend to intervene more readily in the period, either by supporting parents in their child rearing or by investing in early childhood services across the age range 0–6 years.

Countries differ widely, however, in their response to these research findings. In many countries, the care of young children is still seen as a private matter, or, from a gender perspective, considered in practice to be the responsibility of women. Young children may be included with other beneficiaries in generalized health, welfare and labor policies, but little help is given to parents either to improve the quality of private care arrangements or to reconcile work with the responsibilities of family life. In other countries, e.g., the USA, public day-care exists, but it is often of a traditional, social welfare nature, focused mainly on the health, hygiene and protection of children from low-income backgrounds. In yet others e.g., the Nordic countries, explicit policies and systems are in place to cater for all young children as a distinct group with their own specific needs and rights. Excellent early care and education services are available, organized by the public authorities on the assumption that 'professional caregiving and interaction with children can provide an environment that supports the social, emotional and cognitive development of the child,' (Swedish Ministry of Education 1999).

1. *Definition*

In its narrowest sense, early education is defined as the initial stage of organized instruction, designed primarily to introduce young children to a school-type environment' (ISCED 1999). In this definition, it is understood as a center-based (often school-based) program carried out by adequately trained staff, designed to meet the educational needs of children over 3 years of age, and prepare them for school.

For several reasons, the definition is unsatisfactory. With its emphasis on formal education and the age-group 3–6 years, it excludes most programming for young children throughout the world. It is more realistic to define early childhood education and care as any systematic intervention aiming at the development of young children in the age-group from birth to 6 years (the beginning of formal schooling in most countries). Though day-care and preschool programmes immediately come to mind, early childhood programming in this broad sense would also include interventions with strong health and nutrition components, or embrace non-formal programs and play groups with a developmental focus. In this article the term 'early education and care' will be interpreted in this broader sense.

2. *An Overview of Early Education and Care Programs in the World Regions*

2.1 *Minority High-income Countries*

In most of the high-income countries of Europe, North America, Asia, and Oceania, early education and development has been a part of government policy for decades. Provision of educational services for children over 3 years of age has predominated, but today, public or private investment in childcare services for the under-3s is increasing rapidly. The increase is generally attributed to the greatly augmented participation of women in the labor market, and, in some countries at least, to the new awareness of the importance of child development and learning.

Pre-school provision for children over 3 years of age is likewise expanding, and from the age of 4 years, ranged in coverage from 55 percent to 98 percent across the OECD countries (OECD, 1999). In a number of countries, e.g., in Belgium and increasingly in France, entitlement to a place in pre-school begins at the age of 30 months. In the year—and frequently in the 2 years—immediately preceding the age of compulsory schooling, provision in excess of 90 percent is common in high-income countries.

Significant differences exist, however, between countries in terms of how early education is conceptualized. A basic difference concerns the separation or integration of care and education. In countries where separation is practised, e.g., Australia, Greece, Ireland, Italy, Netherlands, Portugal, UK (until recently), and USA, early education predominates, with higher coverage rates, and better training and renumeration of personnel in the education sector. Preschool is considered to be the initial stage of organized instruction, while early care is relatively underdeveloped. Programs for young children are formal and institutional, organized according to the school model, although subject based teaching is generally not encouraged. Formal quality control—registration, regulation, control of curriculum, centralized staff training and inspection—is usual. France and Belgium also fit into this model, although it should be noted that in these countries public child care is well-developed and preschool begins, in general, around the age of 30 months.

In other countries, e.g., the Nordic countries, Spain, and parts of Italy, a more social and integrated

approach to care and early education is adopted. There is greater decentralization of administration and services to regional or municipal levels. Unified policies are generally formulated for children from birth to six years, and there is more mixing of ages within groups than in the education tradition. Personnel are generally trained to a satisfactory level, have adequate career paths and enjoy a professional status. Staff–child ratios are favorable and centers can rely on stable public funding. Emphasis is placed on providing a caring and stimulating environment for children, rather than on preparation for school.

The province of Reggio Emilia in Italy provides a successful illustration of integrated early childhood services. In-service training policies that reach across traditional boundaries, and the creation of centers with integrated age groups, are among the strategies used to bridge education and care. Municipally-funded advisory services, professional training, and staff development are made available to all services, whatever their target group or sponsoring body. The pedagogical approach of Reggio Emilia is even more renowned. It seeks to foster the cognitive and social development of young children through a systematic focus on symbolic representation and expression (language, movement, sketching, painting, mathematics, media…). Young children are encouraged to explore their feelings thoughts and environments through different modes of expression natural to them—'the hundred languages of children' (Edwards et al. 1993). The Reggio approach emphasizes the autonomy and self-direction of children. Within mixed age groups, children choose, negotiate and participate in long-term pedagogical projects that are often extremely challenging. There is also continuous assessment and documentation of the progress of each child, and well-developed strategies for teacher development and parental participation.

In countries in which early care and education is not seen as a right of young children, compensatory programs for young children may receive significant government subsidies, e.g., 'Head Start' in the USA, 'Sure Start' in the UK. Research has shown that early childhood education helps, in particular, children from disadvantaged backgrounds to acquire social skills and integrate effectively the early primary school classes (Schweinart et al., 1993, NICHD 1997). Targeted programs are often based on a mixed rationale that may include: the preparation of disadvantaged children for school; social intervention toward 'at risk' populations; reduction of unemployment among mothers and, hence, savings in direct welfare payments. Despite the real benefits brought by such programs, the approach may have negative effects, e.g., stigmatizing disadvantaged groups, giving the impression that they and their children are problematic and in need of educational 'intervention.' In addition, the compensatory approach may place too great an emphasis on education as an agent of social change. It can be forgotten that poor neighborhoods may need—in addition to education—significant investments in the housing stock, local industry, training and employment policies. In sum, to see early education as a sufficient response to social ills may be to divert attention from other more necessary inputs and from the equity obligations of government.

2.2 Former Soviet Eastern European and Central Asian Republics

In the immediate postwar period, after the Eastern European and Central Asian Republics were absorbed or became part of the Soviet sphere of influence, there was a rapid expansion of fullday day care, kindergarten and preschool facilities. Under communist governments, child care was organized as a state-funded, supply model. Early childhood education was seen as a means of inculcating the new values of communist society and of forming the 'socialist personality.' Enrolment rates in daycare centers and kindergartens soared, reaching, for example in former Czechoslovakia, high levels of coverage. In addition, work leave permissions were given to parents—almost always taken up by women—during the first year or 2 years after the birth of a child. However, since 1990, these countries have gained independence and undergone profound social and economic change.

The transformation has had beneficial effects on children and families, in particular, through the adherence of states both to the European Human Rights Charter and the United Nations Convention on the Rights of the Child. However, it may be suggested that from a gender perspective and the funding of early education services, the trend has been less positive. As economies struggle, unemployment has grown. The response of a number of countries has been to extend parental leave, which, in practice, takes women disproportionately out of the labor market. In addition, a marked reduction of state expenditure on early care and education may be noted. During the transition period, early childhood services were devolved to the municipalities or local authorities, and state budgets to the sector drastically reduced. The reduction has hit hardest early childhood services in rural areas, where the former rural cooperatives no longer function. Thus, in the space of 10 years, Bulgaria went from almost full early education coverage of young children in 1988, to 70 percent coverage in 1998.

Moreover, in the former socialist republics, early-years teachers and child care personnel (almost all women) suffer from low status. Wages are so meagre that many leave the profession or are obliged to seek supplementary earnings elsewhere. From a gender perspective, the low status of the profession indicates an underestimation of child-rearing and of the contribution that women make to society through this

work. In addition, the dependence of services on increased contributions from families has led to inequality of access, the poorest families being no longer able to afford services. Even when the state has waived fees for disadvantaged categories of children, e.g., for minority or Roma children, cultural expectations about education hinder participation by these groups in preschools, and reinforce weak performance in primary school. The situation has led, in Central Europe and the Balkans, to the segregation of many of these children into special education.

Signs of a reversal of the situation are now apparent in several countries. Despite recurring difficulties, Hungary, for example, is now making special efforts in favour of Roma children through the preschool system. Likewise, Romania has actually been able to expand its early childhood services over recent years, and effective efforts are being made to improve the previously disastrous situation of poor and institutionalized children. In the Czech Republic, after an initial down-sizing, the government is now making an important effort to reorganize services for young children and to improve their quality.

2.3 *The Majority World*

In the majority world, expansion is greatest for the age group 4–6 years, especially for the children in the year preceding compulsory school (UNESCO 2000). Yet, the growing need for child care should not be underestimated. Extended family help is diminishing in majority world countries, in a situation where many mothers in the rural areas are fully occupied in the rural economy or in meeting the survival needs of older children. In the cities too, in order to provide for their children, mothers are obliged to seek paid work or engage in exchanges of services, while young women, like their counterparts in the industrial world, see a career as part of their social identity. During their periods of work, often irregular, mothers must entrust the daily care and education of young children to other family members, to informal private arrangements or, where they exist, to community, voluntary, or for-profit services.

In several countries, especially in Latin America, governments now receive significant aid from the international organizations and the major development banks to provide early childhood programs (World Bank Human Development Network 1999). These agencies see early childhood programming as an integrated set of activities (including nutrition, immunization, health, care, development activities, preschool education, parent programming, reproductive health, prenatal and postnatal care, community building) spanning the whole age range from conception to the beginning of compulsory school, and including a strong family outreach. When accompanied by equitable economic and social policies, integrated early childhood programming is perceived as a promising means of tackling the poverty cycle (Sen and Brundtland 1999).

2.3.1 Sub-Saharan Africa. Tackling poverty is also part of the early childhood agenda in sub-Saharan Africa, but the challenges are infinitely greater. Due to national debt repayments and an AIDS pandemic, poverty and illness are pervasive in many African countries. Moreover, governance, macroeconomic management, basic infrastructure and public accountability are weak in many countries, and need to be radically improved before any permanent progress can be made in the educational and social fields (Oxfam 1999). Because of the crisis, early childhood intervention must take the form, in many instances, of food supplementation, primary health, and family support programs.

Yet, some governments and the international donors see the field from a broader perspective, that is, in terms of the holistic development of children and of their basic human rights. Much attention is given in the Sahel countries, for example, to investing in reproductive health care for girls and women, and to making it possible for girls to begin education as young as possible. A few countries have also made remarkable progress in the numbers of children being reached through regular preschool programs. South Africa, for example, progressed from an enrolment rate of 10 percent in 1985 to a 28 percent preschool enrolment rate in 1995, while both Senegal and Kenya have now reached an enrolment rate for preschool children of 40 percent. In addition, Kenya has trained almost half its preschool teachers, and established national training centers for preschool staff in several provinces (UNESCO 2000). Major problems remain, however: acute lack of resources and stable funding; inequitable access to services (rural populations generally do not have services); poor quality of services as many service providers have little understanding of child development; and a general absence of trained personnel.

2.3.2 Arab States. Though enrolment figures continue to rise throughout the region, the rate of coverage across countries remains extremely varied, ranging from 1 percent in Yemen, to 8 percent in Egypt, to 63 percent in Morocco, and over 70 percent in Lebanon. As in the rest of the developing world, provision is concentrated in the urban areas, and only a few governments take a leading role in funding and supporting services. The burden of early childhood programming is still borne by the international donors, the NGO sector and local

communities. In several countries, including in sub-Saharan Africa, religious leaders have successfully developed early childhood programmes, e.g., in parallel with traditional Koranic classes.

2.3.3 Asia and the Pacific. As the region is extremely diverse (with three-quarters of the world's children), generalization are difficult to sustain. Enormous contrasts exist with respect to government investment in early childhood policies. The OECD countries of the region—Japan, Korea, Australia, and New Zealand—and Singapore, have policies, coverage figures and system structures comparable to the Western European countries. In contrast, many other countries are still engaged in broadening or improving their primary education systems, leaving it to the voluntary sector—religious institutions, NGOs, and communities—to engage in early childhood programming. In consequence, great inequalities of access continue to exist. Some notable progress in the region can be seen, however, in the enrolment of 4 to 6-year-olds, especially in Malaysia (90 percent), Vietnam (ca. 70 percent) and in China (ca. 50 percent). The other large, high-population country in the region, India, has an enrolment rate of only 17 percent for children aged 3 to 6 years but a number of far-reaching food supplementation and early stimulation programs, such as the Integrated Child Development Services, exist.

2.3.4 Latin America and the Caribbean. During the last decades in Latin America, initial (preschool) education has been the fastest growing sector in education. A number of countries have now reached over 80 percent enrolment rates for children aged 4 years and upward: Barbados, Costa Rica, Chile, Cuba, Jamaica, Mexico, Peru, Uruguay. Another characteristic of the region is its broad developmental approach to early care and education, which contrasts favorably to the didactic approach found in primary education. Much emphasis is placed on nutrition, health, and the developmental needs of children, e.g., in the countrywide programs of Colombia. The approach has proven to be effective, leading to the prevention of stunting, improved health, better physical and mental performance, and enhanced educational achievement. However, as in much of the majority world, children from better-off families are more likely to be enrolled than children from families with few resources or belonging to minority groups. Urban programs still predominate, and entire rural or indigenous populations, e.g., along the Andes, have, in general, extremely weak access. Poverty, too, is a huge barrier to the meaningful participation of children in early care and education programmes in Latin America. Unlike the major countries in Asia, child poverty has actually increased in the continent over the last decade.

4. Conclusion

In summary, the situation of early childhood programming worldwide may be expressed as follows. Research consistently shows that services for families and young children have positive impacts on child development, in particular, on children from disadvantaged backgrounds. Through early intervention, early disability and learning difficulties are more readily diagnosed and prevented. Again, longitudinal research from over 20 countries shows that regular attendance by young children at organized developmental programs, before they begin compulsory schooling, enhances social and cognitive development, and influences positively later educational outcomes, such as reading ability and retention in grade (OECD 1999).

In terms of volume, early childhood services have expanded steadily in almost all countries in the world in the last ten years. Eastern Europe and Central Asia stand out as temporary exceptions, when, with the economic recession in these regions, early childhood services were reduced. In other regions, and in particular, in the industrialized world, early education and care has emerged from the private, domestic sphere. As the foundation stage of life-long education, it has become a legitimate focus of state intervention. The challenge for the coming years will be to unify care and education, and the conceive appropriate policies for the whole age-group from birth to 6 years.

East Africa: Sociocultural Aspects

After more than a half century of modern scholarship, it is unnecessary to reconfirm the historical and cultural complexity of East African societies now encompassed by the independent nations of Kenya, Tanzania (including Zanzibar), and Uganda. From the maritime civilizations of the Indian Ocean islands and coast which have traded with the external world for at least two millennia, to the more archaic forms of economic adaptation, including the still extant gathering and hunting societies in the interior, this region displays an exceptional range of social and cultural forms. In addition to Swahili as a regional Bantu language, branches of all the other African linguistic families, Nilotic, Cushitic, and Khoisan, are also represented.

1. *Prehistory and History*

Based on finds at Kobi Fora in Kenya and Olduvai Gorge in Tanzania, generally it is now accepted that the earliest hominids emerged in East Africa some six to four million years ago. Although permanent agricultural settlements have existed for at least 10,000 years, historical records on the area extend back only to the first century of the Christian era. The original Greek manuscript, *Periplus of the Erythrean Sea*, describing the trade routes from Alexandria on the Red Sea in Egypt and then south along the East African coast, mentions Rhapta, a settlement assumed to have existed somewhere on the now Tanzanian shore line. Arabic documents from the eighth century onward are more prolific and exact, indicating the existence of the still occupied trading sites of Lamu in southern Kenya and Kilwa in southern Tanzania. This land of 'Zinj' is described as inhabited by a population engaged primarily in a maritime trade in animal skins and horns and some slaves, but particularly ivory, as well as subsisting on agriculture and domesticated herds. Subsequent Arab influence, including Islamization, comes to a halt for a time at least with the arrival of the Portuguese in the late fifteenth century and their partial conquest of the then more numerous city states dotting the littoral. However, these first Europeans were themselves expelled from the area by a resurgent Afro–Arab coalition directed from Oman on the Arabian peninsula which in turn failed to establish suzerainty over the entire area.

Subsequent European incursions, primarily British and German, which included penetration of the interior in the latter half of the nineteenth century hindered the now more extensive slave trade supporting the off-shore, particularly Zanzibari, plantation economies based upon the export of spices. This era culminates in 1885, with the Berlin Treaty that partitioned all of Africa, excluding Ethiopia, among the European powers, and in the case of East Africa between Britain and Germany. The results of World War I brought the entire area under British control until Independence in the early 1960s.

2. *Social Forms*

The existing subsocial formations in recent and contemporary East Africa can be classified in the usual manner as either mercantile or agricultural states, less politically complex agricultural chiefdoms of varying scale, noncentralized agricultural and pastoral societies, and the few remaining gathering-hunting groups. However, these categories are heuristic and ideal as most, if not all, the economies were mixed and interdependent prior to the colonial era. In addition, there was also fluidity in economic forms over time as the archaeological data indicate that some gathering/hunting peoples may have resorted at times to agriculture and then reverted to their previous mode of adaptation on numerous occasions. The same flexibility characterized pastoral peoples. Such adaptive shifts in more recent times have involved simultaneous alterations in ethnic identities that are often labels based primarily upon livelihood. Thus, for example, indigent Maasai who no longer kept cattle were reclassified by others as *il torrobo* (Maasai for the poor or hunters) or Nderobo, while in another instance a whole segment of Maasai who took up agriculture as their primary occupation in the nineteenth century

were redefined as Arusha. Thus, in addition to the complexity of social forms, the fluid basis of ethnic identities, often assumed to be fixed 'tribal' isolates, was a constant feature of the region's social history. Although there were and are cultural differences, in some instances a matter of degree and in others of kind, a more rigid colonial mentality and policies often helped to bring into existence these so-called tribes.

2.1 City States and Kingdoms

Prior to the advent of European incursions, complex economic and political entities existed at both extremes of the East African region. The coast, as noted, was intermittently dotted with numerous city states while the western-most interior, some 800 miles away, featured a series of large-scale polities referred to as the Interlacustrine Bantu Kingdoms due to their clustering around the lakes, such as Victoria and Tanganyika, in the Great Rift Valley. Most notably these included Baganda, Banyoro, Basoga, and Batoro, in contemporary Uganda, as well as Rwanda and Burundi that eventually fell under Belgian colonial control and re-emerged as separate nations with independence. These two regional extremes were linked by a long-distance commerce, including, by the early nineteenth century, some managed by interior middle-men groups, allowing all concerned to expand and flourish with the exchange of valued trade goods. The Bantu kingdoms were early on the subject of academic scholarship. However, in part due perhaps to its less romantic and more complex 'un-tribal' or 'detribalized' condition the coastal region failed to receive serious scholarly attention until after the colonial era.

Although these ancient city states, extending 1,000 miles along the coast north to Somalia and south to Mozambique, never formed a single political unit, they were linked by a common civilization. In addition to a shared maritime mercantilism, marriage alliances, and patrilineal descent, other commonalities included by the eleventh century Islam and a related life-style, as well as Swahili as a *lingua franca*. This term 'Swahili' eventually emerged as a complicated and wide-spread ethnic category on and beyond the coast as the language and Islam spread throughout East Africa before and after the colonial period. The word Swahili itself is derived from the Arabic *sahel* for coast. The language has a modicum of loan words from this source but otherwise it is Bantu in all of its essential grammatical features. As it was adopted as a first or second language by others in the region, many also identified themselves as an *mswahili* or *waswahili* (a Swahili person or people respectively), which implied not only language usage but also a form of modernization involving the adoption of Islam or even Christianity, migration to other areas of the country for a livelihood, and a modified Arab or European lifestyle, including forms of dress and architecture. Among themselves in the towns and cities they inhabit, the *Waswahili* may also admit to another ethnic affiliation reaffirming the plasticity of this sort of identification.

The agricultural bases of the interior states situated in fertile highland areas with the banana (originally from Indonesia) as a staple may have been the historical outcome of an incursion of northern cattle-keeping peoples into an area inhabited for at least a thousand years by Bantu-speaking agriculturalists. The high population densities, in the case of Baganda close to two million people, and social complexity resulted in what has been described as semifeudal states involving unequal control over resources including land and cattle, concomitant social stratification (though no caste system) and in most instances, a series of patron-client relationships spanning economic and political divides. These kingdoms which shared a host of cultural similarities in addition to the economic and social ones, competed with each other for more extensive control over the region. At the apex of the highly centralized political systems stood a king advised by a prime minister and other councilors who appointed chiefs over large districts who in turn delegated authority to headmen in villages. Although often popularly viewed as a despot, it is unlikely that the king could have achieved this level of power and authority until the introduction of firearms in the early nineteenth century via trade from the coast. The stability of the entire political/economic system was further solidified with colonialism and its application of indirect rule that permitted little if any challenges to established authority, or radical changes in the system. Although these were not the only centralized political systems in East Africa, as others of varying degrees in other highland areas existed beyond the coast (such as the Shambaai and Chagga of Tanzania), the vast majority of the population in the less watered lowland savanna and woodlands of the region, shared with pastoral peoples, were organized into smaller political units.

2.2 Agriculturalists and Pastoralists

Among the agriculturalists the principle traditional crops were millet, sorghum, and maize. In the more abundantly watered areas, relying in some instances on complex irrigation systems as among the Sonjo of Tanzania, rice and bananas were also cultivated. Cattle which play such a significant cultural role in the entire area, including among agriculturalists, and smaller live stock such as sheep and goats, were also maintained when and wherever possible. Politically this is the classic 'Tribes Without Rulers' region as termed by one of the classic anthropological volumes of the colonial period and the 'golden age' of East African ethnography. This vision of much of the social

landscape was influenced in no small part by the prior researches of E. E. Evans-Pritchard among the acephalous pastoral Nuer of the neighboring Southern Sudan, an area now racked by a civil strife pitting the Islamic Northern and more traditional Southern peoples against each other. In light of the range of societies in East Africa proper and their variability they are best represented by a limited number of examples which also reflect the interests of the ethnographers at different points in the history of East African scholarship.

The quarter of a million Sudanic-speaking agricultural Lugbara who live along the Nile–Congo divide on both sides of the Uganda–Congo border are characteristic in that they had no political offices until chiefs and subchiefs were appointed by the colonial authorities. This lack of a formal political system was somewhat unusual in light of the relatively high population density which exceeded 100 people per square kilometer in some areas in the early twentieth century but explicable in light of the absence of nucleated settlements. The basic social unit was the homestead of various sizes composed of patrilineally related kin residing in their own dwellings surrounded by their fields. This family cluster recognized the authority of a senior male elder with ritual significance due to his control over shrines dedicated to the lineage ancestors. Thus, at its core this social group had both a descent and a related religious ideology.

The Lugbara themselves conceive of their social structure in terms of clans originally historically associated with specific territories despite the dispersal of their members over time. As such, principles of descent provided an ideological rather than actual form of social organization as is the case for many other East African peoples. These recognized territories or 'tribes' may have a 'rain-maker' with ritual authority in certain matters but as indicated no formal leader. Order was maintained by compromise and conciliation among the resident elders. Disputes among members of different territorial groups were difficult to mediate and as such could result in violence and a state of feud. On the other hand, since clan kin were dispersed among the various Lugbara tribal units and marriages were also effected across these lines resulting in affinal relationships, violence was not entered into easily, especially among contiguous territories. More distant Lugbara tribal sections presented less opportunity for conflict and if a state of feud did exist, it was difficult to act upon as the result of spatial separation. Thus, there was a political order, despite anarchy in the technical sense of the term, among these people who recognized a common moral code supported by the ritual authority of elders and ancestors.

The manner in which social order or stability was maintained among a people lacking a well-defined political system was one of the driving research concerns during the colonial era, while change became a principal interest of postcolonial scholarship. This shift in orientation is exemplified by the situation and description of the Iteso, Nilotic-speaking sedentary cultivators residing in this instance on both sides of the Kenya–Uganda border. By the time of their analysis the Iteso were almost all Christians, and their expansionist tendencies, as well as the former political system which had permitted this process, had been radically altered by the often violent imposition of colonialism. According to historical reconstruction, prior to European intervention the Iteso were organized into a number of territorial sections under the leadership of a single individual or 'war leader.' These units were broken down into a number of subsections that tended to correspond with the residence of patrilineally related males who also recognized a local leader for political as well as ritual purposes. These locations undertook common defense, the peaceful settlement of disputes, and collective religious activity. Typical of Nilotic speakers, the territories were crosscut by an age-grade system including a warrior class which had facilitated Iteso incursions into the land of other ethnic groups. During the colonial period appointed chiefs replaced the former leaders and the territorial units dissolved as neither expansion nor defense were relevant concerns. These aggregations were replaced by diffuse neighborhoods of a smaller social scale composed of cooperating but individual households now engaged in the cash economy. The resulting process generated a typical East African society brought into being by the colonial presence. Similar processes of ethnic consolidation and consciousness among the more numerous Kikuyu and Luo peoples of Kenya during the colonial era had a significant impact on postcolonial politics.

The primarily pastoral Nilotic-speaking peoples inhabiting a grassland expanse in both arms of the vast Rift Valley in eastern Uganda, western Kenya, and north-central Tanzania provide a striking alternative to agricultural societies in more than economic fashion as many of the representatives of this language family have preserved their traditional cultural system to this day. Included in this category are the Jie, Karimojong, and Turkana of Uganda, the Kipsigis, Nandi, and Samburu of Kenya, and the Barabaig of Tanzania. However, the quarter of a million Maa-speakers or Maasai who have occupied the central plains of both Kenya and Tanzania for the past 400 years are best known to travelers, tourists, and scholars of the region for the persistence of their traditional ways despite impositions placed on their life style by both the colonial and independence regimes during the twentieth century.

The enormous expanse of Maasailand is divided into numerous large and politically autonomous named territorial sections in some instances covering thousands of square kilometers including tens of thousands of individuals. Within these sections, social order is maintained at the local level by male elders with either ritual authority derived from membership

in a particular clan, seniority in the age grade, or local community of kin. Although patrilineal in terms of descent principles, kinship ties of various types are a significant factor only at a settlement composed of a number of usually polygynous households that herd their animals together under the direction of a senior male. The most striking feature of the social system is the age grade system bisecting the entire expanse of Maasailand which includes the moran, formerly a warrior class of young men but now primarily responsible for cattle herding.

For the Maasai, cattle are not only the basic foodstuff in the form of milk, meat, and blood but also the most important cultural idiom. The animals are valued in and of themselves as esthetic items, the object of admiration, discussion, song, and dance, but they also mark both existing social relations through their exchange, and the passage of time through inheritance. They are circulated as bride-wealth and blood-wealth, in compensation for violence, and loaned out to establish herding partnerships over wide areas. Finally, these animals are the primary means for communicating with the supernatural world as sacrificial offerings to the creator in religious ceremonies. Thus, this single item in all its capacities links humans both to each other and to their deity in a manner unavailable to cultivators. In more practical economic terms the ability of the Masaai and other pastoralists to sell off some animals for cash to meet the demands of the state in the form of taxation has permitted them to avoid further integration with the wider society and in doing so conserve existing cultural patterns. However, the alienation of their former land by both the independent and colonial regimes for the sake of agriculture and agriculturalists, as well as for the creation of national parks for tourism, has had a severe impact on these people.

2.3 Foragers

Scattered among the pastoralists and agriculturalists in both forests and plains are pockets of hunters and gatherers, such as the well-known Mbuti Pygmies of western Uganda and the Congo. Other foraging groups, though physically distinct from the Mbuti, include the Okiek of Kenya, the Ik of Uganda, and the Sandawe and Hadza of Tanzania. The forest-dwelling Mbuti and related populations generally are considered to be descendants of the first residents of this and other parts of Africa who have adopted the languages of their later arriving and now Bantu neighbors, while the Okiek and Ik speak the related Nilotic languages of their pastoral neighbors. However, Sandawe and Hadza bear some phonetic similarities to the tongues of hunters and gatherers in Southern Africa. Despite the traditional academic classification on the basis of foraging, there are also variations among these peoples including the tendency to mix this adaptive strategy with agriculture and herding when feasible. Thus, a portion of the few hundred Hadza residing in a desolate region of Northern Tanzania unsuitable until recently for either agriculture or herding are interesting in that they maintained a foraging lifestyle in pure form, as well as a significant degree of economic independence, from surrounding groups and the state, even after Independence.

Although seemingly inhospitable to others, the Hadza territory of over a thousand square miles, open to any member of the group as their are no recognized territories, is replete with natural resources harvested on a nomadic and individualistic basis. Although the area is heavily populated with game, the Hadza rely mainly on wild vegetable matter for food in the form of roots, berries, and fruit gathered daily by both males and females, the latter with their small children. These nutrients usually are consumed immediately rather than being collected for later distribution. Traditional bow and arrow hunting, however, is exclusively a male activity. If the kill is small it is also eaten on the spot, while some of the remains of a larger animal may either be transported back to camp or simply abandoned. Thus, there is almost complete economic independence even among the Hadza themselves. As such, it would be misleading to characterize their local aggregations as bands in the sense of groups recognizing a common territory or cooperative bonds. Beyond the nuclear family, based on relatively unstable monogamous unions, the larger and only unit is a camp, occupied for no more than a few weeks, and on average by a dozen or more adults. This aggregation does not have a recognized leader nor form a stable unit, as some members will depart and others join it on a constant basis. At other times it may split off into independent units or merge with other camps for a period of time. This organizational fluidity of foraging societies is perhaps their characteristic feature in both East Africa and other parts of the world.

3. Cultural Concerns

This overview of East Africa in terms of economic, political, and social forms in no way suggests a paucity of equally, if not more, complex cultural systems including beliefs, values, myth, history, and literature both oral and written. These integrated systems of thought, often shared over a wide area, even in terms of particulars, defy simple categorization into a number of ideal types. In general, the peoples of this region, regardless of their form of economic adaptation must be considered highly spiritual, whether in terms of their adherence to the local religions or the world religions that have supplanted them. In turn, these cosmologies have been transformed by local beliefs and practices. As in other parts of the world, the traditional ideological systems took a great interest

in notions of good and evil and thus acceptable standards of interpersonal morality guarded by the living as elders and/or the deceased as concerned ancestors. The 'problem of evil' in society was often represented (by agriculturalists in particular) as a matter of witchcraft or sorcery responded to by recourse to diviners to identify the culprit in order to restore a harmonious social order through confession and reconciliation.

As indigenous philosophies these systems of thought also reflected on the meaning and passage of life and the significance of death, occasions usually marked by elaborate ritual gatherings and activity. Communication with their creator, most often viewed as a more distant and less knowable figure than in world religions, traditionally was maintained through prayer and sacrifice. Indeed as this review of primarily social forms suggests, it was and is often best to view many East African peoples at the local level and in the most meaningful sense as composed of ritual communities concerned with the spiritual and social welfare of their members.

East Asia: Environmental Issues

1. Human Beings and the Environment

Environment means what surrounds human beings on the outside. It can be divided into the natural and the social environment. The natural environment is the air, water, mountains, the sea, soil, plants, animals, and the earth as a whole. The social environment is the family, the school, the firm, the community, the social stratification, the market, the state, and global society as a whole.

When we say the 'environmental problem,' the central interest is of course on the natural environment. While human beings have, since ancient times, utilized the natural environment as a resource, the degree to which they exploit natural resources increased rapidly after the Industrial Revolution, during which they obtained the industrial technology through which to transform nature as they wished. The other side of the coin of this industrial technology, however, was to break the natural environment of unanticipated consequences. Thus, today human beings are confronted with the environmental problems such as pollution of the air, water, soil, and sea, destruction of the ecosystem of the plants and animals, ozone layer depletion, and global warming.

On the other hand, however, the social environment has always something to do with it. This is because it is the human social action of production and consumption that deteriorates the natural environment, unless it is caused by earthquake, volcanic eruption, or typhoon. In this sense the destruction of the natural environment is connected closely with the ways in which human social actions are organized by the social environment. The social environment is, sociologically speaking, of importance as the socializing agent that brings people to conform to environmental ethics. This means that the degree to which the natural environment is polluted is controllable through the ways of the working of the social environment.

2. The Beginning of the Industrialization in East Asia

The history of the 'environmental problem' is not necessarily new, in the sense that even in the pre-industrial age there was deforestation, land exhaustion, and urban spoilage. However, the development

of modern industrialism brought a new stage of environmental problems from the pollution of land, water, and the air to car fumes, waste disposal, global warming, ozone depletion, and so on. The result is the recent issue of 'sustainability.'

Industrialization was originated by the Westerner in the second half of the eighteenth century. Non-Western countries, more than 100 years later, began to industrialize through cultural diffusion from the West. The beginning of industrialization in the East Asian countries was toward the end of the nineteenth century. In East Asian countries, as the beginning of the industrialization was late, the beginning of the environmental problem was of course late, too. But once industrialization started, it advanced very rapidly, so that the destruction of environment came so intensively.

Among East Asian countries, Japan's start to the industrialization was the earliest. Japan's industrial revolution was between the 1890s and the economic boom after World War I (1914–18). While the Japanese economy of the 1920s was in depression, there was an economic recovery after the Manchurian War (1931–3). However, the defeat in World War II (1941–5) made the Japanese economy degenerate to the level before 1920, so that the Japan's industrialization was interrupted between 1945 and 1955. It was the result of unprecedented high rate of economic growth period (1955–73), in which more than 10 percent in the yearly growth rate continued during 18 years, that Japan reached the economic level of the Western advanced countries in terms of per capita GNP. The other side of the coin, however, of this rapid economic growth was the peak in the unprecedented occurrence of pollution in this period.

The countries or the areas in East Asia that achieved the industrialization after Japan were Singapore, Hong Kong, Taiwan, and Korea (which are known as the 'Four Little Dragons'), as well as the advanced area of China (the coast area along the Yellow Sea and the East China Sea, and the basin area along the River Yangtze-Jiang). Among them the most advanced is Singapore which was a British colony before the World War II and is now the most successful international city state consisting of mainly overseas Chinese. The second most advanced is Hong Kong, which has developed as an international financial center until 1997 as British colony, but is now a part of China. The third is Taiwan, which has achieved success in economic development through an export market strategy since the latter half of the 1970s. Korea, similar to Taiwan, has achieved economic success since the government began to take the development strategy through export market in the 1960s and the 1970s.

The economic development of the Four Little Dragons is important, although they are small countries, because the industrialization of the East Asia was once a 'point' (Japan) but now it spreads to a 'surface' by them. In this surface the three points (Taiwan, Hong Kong, and Singapore) are Chinese in ethnicity, and it is important in that they effectively promoted the industrialization of the advanced area of mainland China. In the 1980s the surface including Japan, the Four Dragons, and China changed the image of the East Asia drastically from stagnation to development. However, from the point of view of the environmental problem, the other side of the development was the peak of the pollution.

3. *Economic Development of Japan and the Problem of Environment*

The first big industrial pollution in Japan was the contamination of rice fields by spill of the slag of copper mines into rivers. There were several such events, among which the biggest was the case of Ashio Copper Mine Co. Ltd. of Tochigi Prefecture beginning from 1885. Slag that spilled into Watarasegawa River in every flood polluted rice fields of the lower villages irrigated from the polluted river, so the victims were farmers whose rice fields became impossible to cultivate. Shozo Tanaka, a member of the Diet represented from the district, having decided to devote himself to the opposition movement of the victim farmers, not only interpellated government in the Diet, but also made a direct appeal to the Emperor Meiji by presenting a petition written by an anarchist Shusui Kotoku, but in vain.

Japan's Industrial Revolution was centered on light industries of silk and cotton spinning, and was followed by heavy industries of steel and machines after World War I. All of them used coal as energy, so that the sky of Osaka and other industrial cities were covered by soot and smoke. As these were regarded as a symbol of economic prosperity, however, there was no recognition that they were harmful for residents' living.

Between war defeat in 1945 and the beginning of high rate of economic growth in 1955 there were no environmental problems because Japanese industries had not recovered from the war damage.

At the starting point of the events of the industrial pollution after the war stood the case of Minamata disease of 1956 caused by methyl mercury included in the waste water of Chisso Co. Ltd. located in Minamata City, Kumamoto Prefecture. The Company threw the waste away into the Shiranuhi sea and polluted fish seriously, so the victims were fishermen who caught the polluted fish. The symptoms of the victims were terrible: paralyzed limbs, convulsed bodies, dribbling, sight and speech impediment, muddled senses, mental derangement; more than half died within 3 months. The cause was not known at the outset but was clarified gradually by the physicians of the medical department of Kumamoto University. Until 1968 the government did not acknowledge that

the liquid waste of Chisso Co. Ltd. was the cause, as there was a difference of opinion between the Ministry of Trade and Industry, which took the side of the Company and the Ministry of Health and Welfare that took the side of the Kumamoto University physicians. Because of this delay it was in 1973, 17 years after the event, that some of the victim's families won compensation by winning the case.

Following the Minamata case, pollution events occurred in many places of Japan during the high rate of economic growth period. In Niigata Prefecture, Niigata Minamata disease occurred in 1965 by the pollution of the Aganogawa River caused again by methyl mercury included in the waste water of Showa Denko Co. Ltd. The victims were fishermen again. In Toyama Prefecture, *itai-itai* disease occurred in 1955–60, caused by cadmium pollution from Mitsui Metal Mine Co. Ltd. into Jinzugawa River. The victims were farmers whose rice fields were irrigated from the polluted river. In Yokkaichi City, Mie Prefecture, once a harbor city with beautiful coast, a large-scale petrochemical complex was built in the latter half of the 1950s. Yokkaichi asthma occurred there, beginning in 1960, caused by sulfur oxide emission into the air from the complex. In Tagonoura Coast, Shizuoka Prefecture, in which the beautiful Mt. Fuji scenery of the Tokaido Line has been well known since the ancient Manyo poem, the coast was polluted by waste fluid discharged from the many paper manufacturing factories into the sea. Polluted sediment accumulated at the coast, was reported by photos in newspapers, and provoked national indignation.

Though these many cases of industrial pollution intensively occurred in the high rate of economic growth period, public opinion that was formerly permissive to the behavior of business firms came to severely watch them. Neighborhood protest movement against industrial pollution came to be organized in many districts. Under these backgrounds of rising public opinion and protest movement, the Basic Law for Environmental Pollution Control was enacted in 1967. In the so-called 'Pollution Diet' in 1970 this law was revised more rigorously and the 14 antipollution Laws were established at a stroke. In 1971 the Environment Agency started. Between 1969 and 1975 a series of environmental standards for sulfur oxide, carbon monoxide, nitrogen dioxide, water pollution, floating particles of dust, factory noise, airplane noise, and Shinkansen noise were settled.

Against the pollution for which industrial enterprises are responsible, these governmental anti-pollution measures under the background of public opinion and protest movement were very effective. After the latter half of the 1970s no enterprise discharged untreated wastewater or soot and smoke into rivers, sea, or air. This fact is also related to the change of the Japanese industrial structure into the 'postindustrial' stage, the border of which was again in 1975.

Thus, after 1975, the character of the environmental problem in Japan changed totally from the problem of pollution by factory to that of the 'global environment' such as the pollution caused by automobile gas and by family garbage for which all the residents in general who were once victims of the factory are responsible. The sort of targets with which the environmental problem must wrestle changed to, for example, saving energy and resources, separating and recycling garbage, regulating automobile gas, preventing global warming, preventing ozone layer depletion, stopping acid rain, and protecting nature.

Confronting these changes in environmental problem, the ways of the environmental administration as expressed in the 1967 Basic Law for Environmental Pollution Control came to be changed. In 1993 the enacted Fundamental Law of Environment altered the new environmental policy. The direction of this policy change was basically from regulating pollution to making a society in which sustainable development is possible.

4. Economic Development of China and the Problem of Environment

The People's Republic of China under the Mao Zedong regime (1949–76) pushed the Soviet Russian type of heavy industrialization until 1957, but after that the industrialization policy was discarded in adopting the People's Commune from 1958 and the Great Proletarian Cultural Revolution from 1966. After the death of Mao Zedong in 1976, Deng Xiaoping took political power and the Cultural Revolution came to an end. Deng Xiaoping, succeeding Zhou Enlai's policy of 'four modernizations,' promoted China's industrialization, on the one hand, by bringing up many small-scale industrial firms in rural villages after the abolition of People's Commune, and on the other hand, by introducing joint companies with Japanese and Western capitals by setting up in big cities of the 'Economic Special Areas' for that purpose.

As the economic development of Taiwan, Hong Kong, and Singapore progressed in this same period, Fujian as the root of Taiwanese, Guangdong as the root of Hong Kong people, and Taiwan, Hong Kong, and Singapore were unified into the 'Chinese People's Economic Area' beyond borders. The impact of this Chinese People's Economic Area, being extended to the whole advanced area of mainland China (the coastal area along the Yellow Sea and the East China Sea including 'Economic Special Areas,' and the basin area along the River Yangtze-Jiang), had the effect of promoting the industrialization of the advanced area of China as a whole. The average figures of GDP growth rates in real terms of 8 years from 1990 to 1997 are: China 9.9 percent, Singapore 8.0 percent, Korea

7.4 percent, Taiwan 5.5 percent, and Hong Kong 4.5 percent (the data are partially deficit for Hong Kong and Taiwan). In sum, China and the Four Little Dragons are now the area of highest economic growth in East Asia.

However, from the point of view of environmental problem, the other side of the coin of the high rate of economic growth in this area is the big deterioration of the environment of the East Asia. Let us look at this problem on mainland China.

The first point is air pollution. As the industrial as well as domestic energy in China depends overwhelmingly on coal, the sky in Chinese cities, especially in winter, is, even in clear weather, always darkened by sulfur dioxide, nitrogen oxide, soot, and smoke. When these melt into moisture, acid rain falls, and seasonal wind carries them to Korea and Japan.

The second point is deforestation. The River Yangtze-Jiang, the longest river in China, was once blue if not clear, but is now of yellow ocher color and there was a big flood in 1998, as the result of deforestation in the upper reaches. The Chinese government, though it announced that deforestation is prohibited, is unable to control offenders. This is the result of deforestation, based on the expanding difference between advanced and underdeveloped areas.

The third point is the problem of water shortage. In the Yellow River, the second longest river in China, water in the dry period disappears halfway, partly by the worsened condition in the upper reaches, but mainly by the increased use of water in the middle districts. Disappearance reaches 427 km and 107 days on the average in the 1990s. This brings big problems in agricultural and industrial production as well as in civil life in the middle and lower reaches.

The fourth point is the shortage of the facilities for the disposal of factory waste water and sewage. While the role of the many small industries in rural villages is important in the economic growth of contemporary China, they are mostly in primitive condition with no facilities of wastewater disposal. In cities, too, drainage and sewage disposal facilities are not enough.

The fifth point is the spread of desert. Mongols live in the dry area as nomadic tribes. Industrialization of China brought higher demand for wool, and the result an increase in breeding sheep. Because of the limited supply of grass in the dry area, the increasing number of sheep brought about the desert. Now it approaches the west side of Beijing.

In China, the environmental policy of the government started late after entering this period of high-rate economic development. The Vice Prime Minister Li Peng announced in 1983 for the first time that the environmental problem must be the basic policy goal. The Environment Protection Law was, although begun in 1979, enacted, after revision, in 1989. The administrative organization of the Bureau of Environment Protection started in 1974 as a section in the Ministry of the State.

In Korea, the environmental policy started earlier than in China. The Pollution Protection Law in Korea was enacted in 1965 and it was revised as the Environment Conservation Law in 1977. As the administrative organization, the Environment Agency started in 1980 and became the Ministry of Environment in 1994.

When the UN Conference on Environment and Development (Earth Summit) was held in Rio de Janeiro, Brazil in 1992, and the Rio Declaration on Environment and Development as well as 'Agenda 21' was adopted, China made 'Agenda 21 of China: White Paper on Population, Environment and Development in the 21st century China' and established the environmental standards in quantitative terms toward the sustainable development, such as the rate of diffusion of sewage disposal facilities in cities, the rate of reutilization of solid industrial waste, the rate of forest to total national land in area, and the rate of nature protection districts to total national land in area.

5. *The Significance of the Environmental Problem in East Asia*

While many of the East Asian countries are now in a stage of high rate of economic growth in industrialization, there are big differences among them in terms of the level of per capita GNP in US Dollars in 1998: Japan 32,350, Singapore 30,170, Hong Kong 23,660, Taiwan 12,265, Korea 8,600, China 750. The figures for Southeast Asian countries are: Malaysia 3,670, Thailand 2,160, Philippine 1,050, Indonesia 640. We can say that Japan and the Four Little Dragons achieved the industrialization, but others are still at the level of developing countries. Unlike Western European countries, in which industrialization is already complete and economic levels are not very different, in Asia the many countries have different industrialization levels.

As was shown in the process of COP3 Kyoto Convention (UN Framework Convention on Climate Change) in December 1997, there is opposition of interest between the advanced and the developing countries around the measures against environmental pollution, as the developing countries want to develop more rapidly. While this is also the case among the Asian countries, in East Asia, not only Japan and the Four Little Dragons, but also the advanced area of the mainland China have already achieved industrialization. In this sense East Asian countries, together with the Western countries, must take the responsibility for the global environmental problems with which now the entire world is confronted.

East Asia, Religions of

Comprising China, the Korean peninsula, Taiwan, and Japan and containing a sizeable proportion of the world's population and home to some of the oldest and most advanced cultural systems in the world, East Asia has produced a number of major religious traditions such as Taoism, Confucianism, and Shinto, as well as developing its own distinctive regional forms of Buddhism. Besides these religions there exists also a pervasive folk religious tradition linked to customs, practices, and beliefs that forms the underlying bedrock to the entire religious structure of the region. Especially since the nineteenth century, too, numerous new religious movements have developed in the region, in response to rapid social change and modernity, but often reasserting many of the themes of folk religion and of the traditional religious environment within new forms adapted to the modern age. The region has also developed its own scholastic traditions which are essential for any understanding of its religious dynamics and that provide important new perspectives and alternative voices from those derived from Western academia.

1. *East Asia in Religious Contexts: an Overview*

East Asia represents a problematic area of analysis because of its size, vast and varied population, historical and social complexity, the differing historical and social experiences of each country, and its multiplicity of religious forms. This, and the existence of religious expressions associated with particular countries of the region, raises questions about how far one can talk about the region as a whole in religious or cultural terms. An example here would be Shinto, which is specific to the Japanese cultural sphere and which raises questions about the use of religious ideology in the formation of nation states, about cultural identity, and about the relationship between religion and politics. However, while Shinto provides meaningful examples relating to such questions, it cannot necessarily be considered as an exemplar of the patterns of East Asian religion in general, given that no similarly identifiable national religious traditions exist in other countries in the region. Similarly, the religious responses to rapid social change and modernity, which have seen the formation of new religious movements in different parts of the region, cannot necessarily be considered as indicative of a region-wide commonality. Many of the new movements that have arisen in Korea, e.g., draw heavily on evangelical Christian themes as well as the shamanic beliefs and practices which are central to the Korean tradition, while Japanese new religions have drawn much more heavily on Japanese cultural traditions based on Buddhism, Shinto, and folk religion. Indeed, scholars from the region have been reluctant to draw many parallels between the countries of East Asia. Japanese scholars, e.g., prefer to discuss the Japanese new religions in the comparative context of new religions in the West rather than in the Asian context. Rather than expressing similarities and commonalities, indeed, the academic traditions of each country in the region tend to emphasize concepts of cultural uniqueness and difference and where they have sought a comparative focus have looked outside the region.

2. *Religious Traditions of East Asia: Buddhism, Confucianism, Taoism*

The East Asian religious spectrum includes historical religions that have influenced the whole region and localized traditions that are influential in some, or one, area but that cannot claim cross-border significance. Three major historical traditions have been influential across boundaries and formed part of the religious constitution of the region as a whole: Buddhism, which although coming from outside, has taken on particular regional characteristics in China, Korea, Taiwan, and Japan, and Taoism and Confucianism, both of which originated in China but have also been influential in Korea, Taiwan, and Japan.

2.1 Buddhism

Buddhism entered East Asia along the major trade routes, supported by the patronage of ruling elites who saw it as a means of strengthening the ethos and power of the state. This was particularly so in Japan, where it was adopted as an arm and pillar of the state from the seventh century onwards. While its growth and development of an extensive monastic system owed much to its promises, expressed in popular Buddhist texts such as the Lotus Sutra, of spiritual emancipation for all, and while it has developed monastic forms and meditative traditions (most famously Zen in Japan) with a primary orientation towards renunciation and spiritual transcendence, Buddhism's main orientation in East Asia has been social, familial, and mundane. As elsewhere, it has used magical symbols and rituals for the amelioration of the living, both individually and in social contexts, and operated as a religion dealing with death and the after-life, offering an eschatological framework of other-worldly salvation through a range of memorial and funerary services which aid the dead spirits in their journey to the other world. It has been through Buddhism that the spirits of the dead have been transformed into ancestors who guard over their living kin and in this way it offers solace to the bereaved while reinforcing the solidarity and continuity of the household.

2.2 Confucianism

While the thoughts of Confucius (551–479 BC) may be regarded as the foundations of a moral and philosophical tradition emphasizing filial piety and the moral duties of rulers and subjects, Confucianism has developed into a broader cultural and religious form that has influenced the development of all East Asian societies. While Confucianism has taken on overt religious manifestations in the ritual veneration of Confucius, its primary influences have been ethical and relating to the affirmation of social codes that underpin the existing order of society. Confucianism, besides emphasizing classical learning and the veneration of tradition, affirms the basic goodness of human nature and asserts that the ways individuals conduct themselves affects the basic social order at familial and wider social levels. This notion of individual spiritual responsibility for one's actions, and of the individual as a microcosm, in spiritual terms, of society at large has been central also to many of the East Asian new religions.

2.3 Taoism

Although originally a mystical tradition of meditation and passive withdrawal from worldly affairs, Taoism became associated with the search for longevity and the overcoming, through ritual and mystical practices, of the physical limitations of the body. Taoist practitioners in China sought, through the study of alchemy, to find the elixir of life, and they formed cults venerating that deities symbolized longevity. Taoism also developed complex systems of divination and fortune telling which were central to its appeal beyond China. Taoist ideas spread across the region in tandem with other Chinese cultural influences, including Confucianism, Buddhism, and the Chinese writing system. In Japan, Taoist influences were subsumed within the broader cultural sweep of continental culture and it never assumed its own distinct religious form there. However, its influences were pervasive, especially in terms of divination and magical practices. The early Japanese Imperial Court, e.g., developed a Bureau of Divination using Taoist techniques to predict and govern state affairs, while popular divination practices derived from Taoism remain widespread in Japan.

3. Indigenous Traditions: The Case of Shinto

Although Shinto, literally 'the way of the gods,' is often termed an indigenous Japanese religion, it is more accurately considered as a localized tradition that developed in conjunction with and in antithesis to the foreign religion of Buddhism which entered Japan from the sixth century onwards. The native religious tradition of Japan prior to the entry of Buddhism centered around the worship of local gods such as clan tutelary deities who were guardians of communities and clan lineages. This loose-knit local tradition acquired a specific identity with the entry of Buddhism. Even the term Shinto first came into existence after the incursion of Buddhism, as a means of differentiating the local from the imported tradition. Shinto is, thus, an example of a tradition that developed in response to (and hence in conjunction with) another, external religion, a point that has been emphasized consistently by influential Japanese scholars such as Kuroda Toshio.

Shinto is based in concepts relating to the *kami*—a term usually translated as god or deity, but implying a spiritual life-giving force. *Kami* may be associated with specific natural phenomena or landscape (for in Shinto, the entire world of Japan is considered to be the creation of the *kami* who give life to and animate it) but they may be spiritual entities that embody particular virtues or capacities and that can, if suitably beseeched and venerated, bestow blessings. The Shinto pantheon contains many thousands of *kami* from localized deities to ones of national influence. *Kami* may also be the spirits of humans of note or special accomplishments, such as Sugawara no Michizane, the ninth century scholar whose spirit is venerated as Tenjin, the *kami* of learning.

3.1 Shinto, Buddhism, and Religious Integration in East Asia

Interaction rather than conflict between Buddhism and Shinto has been a core theme in Japanese religious history. Buddhism's strategies of assimilation and accommodation have been nowhere more striking than in its dealings with Shinto and its *kami*. Since the *kami* were the guardians of the earth and the landscape, Buddhism adopted them as spiritual protectors of Buddhist temples: the striking vermilion Shinto gateway, representing entry to the *kami*'s sacred area, is rarely absent from Japanese Buddhist temple courtyards and, especially up to the nineteenth century, many religious centers were not so much Buddhist temples or Shinto shrines, but shrine–temple complexes combining both traditions. Many deities are also shared between the traditions, while this complementarity is manifest also in the roles Shinto and Buddhism play in the life cycles of individuals and communities. While Buddhism deals with death rituals and the memorialization of ancestors, Shinto is associated with beginnings and growth. The Shinto gods guard over the beginnings of life and are called upon for protection and support when babies are born and as infants grow: the *miyamairi* rite in which newly born children are taken to shrines to be placed under the protection of the Shinto gods, remains widely followed in Japan, as is the *shichigosan* festival in November when children of seven, five, and three are given further ritual blessings.

This functional integration, in which Shinto deals with birth and life and Buddhism with death and the hereafter, has strengthened both traditions in the Japanese system. It is not a pattern limited only to Japan, for a dominant characteristic of the religious structures of the entire region has been that of integration of a number of traditions in the lives of the people. Thus, a state official in premodern China might be involved in Confucian rituals at work, Taoist divination rites and practices in his family life, and Buddhist funerary rituals when someone died, while in Korea, too, similar patterns (Confucian public rituals, the use of shamans and diviners for personal concerns, and Buddhist death rituals) could be discerned. It has only been in recent times, with the emergence of exclusive religious groups, such as the evangelical Korean protestant sects and a number of Japanese new religions that refuse to condone traditional religious practices, that this integrative pattern has been challenged. For the majority, however, it remains dominant.

3.2 Festivals and the Ritual Calendar

Shinto illustrates the close interaction of religion, festivity, and the calendrical cycle—a theme that permeates much of East Asian religion. Its festivals (*matsuri*, meaning both prayer and celebration) were traditionally a central element in the lives of local communities, and in modern Japan they remain a colorful and vibrant element in the calendar, involving a mixture of sacred ritual and spectacular festive entertainment that may include processions, dances, fairs, tourist attractions, and much celebratory eating and drinking. The most widespread of all such festivals is New Year when people make a first visit of the year to a shrine (*hatsumôde*) to thank the gods for blessings received in the past year and for protection and good fortune in the coming year. Many people also visit Buddhist temples at this time. *Hatsumôde* is highly popular and, since the 1970s, has been performed by a growing number of Japanese: numbers have risen from around 30 million in the late 1950s to around 85 million (out of a population of 120 million) in the 1990s. The growth of *hatsumôde* numbers is not isolated: Japanese scholars have noted a growth in participation in customary religious ritual activities between the 1950s and the early 1990s, and this has led them to question the validity of secularization theories and to show that these do not necessarily have universal validity.

However, such growth masks a shifting pattern within Shinto, in which small, rural shrines have declined due to rural depopulation and because people have preferred to visit better known and more identifiably national shrines further afield. Partially this has been a result of the development of an advanced transportation system but also because, as localized community structures have broken down or been transformed due to changing life patterns, people have sought their primary focus of identification in the national community. Hence, while they once would have performed *miyamairi* and *hatsumôde* at local shrines, tying themselves to local communities and deities, they now do these at shrines of national significance, an act that confirms their identification with the wider national community and reaffirms, in an age of internationalization in which the primary forms of comparison in terms of identity are across national rather than regional or local lines, their sense of Japanese identity. Many nationally well-known shrines receive many millions of worshippers at festival times: Meiji shrine in Tokyo, for instance, receives around four million visitors at New Year.

3.3 Shinto, Mythology, National Identity, Nationalism, and the State

The connection between Shinto and national identity indicated by recent patterns of shrine visiting points to a deep-seated characteristic of religion in the region: the close connection of religion, state, and identity. Here, again, Shinto is a striking (if particularized) example. Its myths attribute the creation of Japan and the origins of the Japanese people and its Imperial dynasty to the *kami*. In these myths the Imperial family are ordained divinely to oversee the nation, as

they are descended from Amaterasu, the Sun Goddess, who is venerated at the great shrines of Ise, the most important shrines in Japan. The *kami* are the procreators of Japan and its people, who thus exist in a special, unique relationship to their gods and land. This special relationship is central to Japanese concepts of identity and has been associated closely with Japanese nationalism since the Meiji Restoration of 1868, when Japan developed a modern-style sense of nationhood by using Shinto and its mythological links to the Emperor as a focus of national unity and as a means of emphasizing national uniqueness as a chosen people and land. The association of Shinto and the state helped create a myth of racial superiority which legitimated Japan's colonization of Taiwan and Korea, involved the suppression of other religions and played a major part in Japan's fascism and war mongering in the first half of the twentieth century.

In the postwar era, official links between Shinto and the state have been barred under the Constitution, Japan has become a secular state, and Shinto exists predominantly as a shrine-centered tradition based around life cycle and other rituals and festivals. Nevertheless, there remain many people (especially of right-wing persuasion) and many Shinto priests who aspire to a return to a formal association between Shinto and the state. Many of the discussions of Shinto in the modern age thus center around issues of religion, nationalism, and politics.

4. *Underlying Structures and Common Themes—Folk Religion*

Although the above-mentioned religions are the most visibly identifiable older traditions of the region, they are underpinned by a pervasive folk tradition. It is a common argument of scholars from the region (e.g., Miyake Hitoshi in Japan) that this amorphous folk religion of shared customs, attitudes, beliefs, and practices deeply rooted in everyday lives and concerns of the people, forms the foundational religious structure of the region. Indeed, many of the ideas and themes that are central to the new religions derive directly from these folk religious foundations, while the new religions themselves have been analyzed widely as modern articulations of the folk tradition. The folk tradition has also been the filter through which the historical religions of the region have been adopted by and adapted to local cultures. Those religions that have best developed strategies to accommodate or work with this tradition have been the ones which have transplanted most successfully to or developed in the region: examples include Buddhism, whose strategies and doctrines of accommodation have enabled it to absorb and work with local customs, and (in a reverse case) Christianity, whose inability to accommodate or accept folk religious beliefs and customs, notably relating to the ancestors, has proved a major impediment to its growth in much of the region.

The importance and vitality of this folk tradition is such that it has been a major focus of academic study in the countries of the region. Folk studies (or folk religious studies) are a primary academic discipline in Korea (where shamanism, as the cornerstone of the folk and native religious structure, has received especial attention) and Japan, and is generally accorded greater weight as an academic discipline than in the West. It is not just concerned with the indigenous traditions of folk religion; Japanese scholars such as Sakurai Tokutarô (shamanism), Miyake Hitoshi (mountain religion), and Shinno Toshikazu (pilgrimage and legends) have been concerned to map out and discuss the interactions of folk religion and Buddhism, and to demonstrate that 'folk religion' as manifest in Japan should not be discussed solely in Japanese terms but placed in a wider context. Making use also of Western academic studies of religion, scholars such as Miyake have demonstrated the potential universality of folk religious models, as well as broadening the comparative and potentially universalizing dimensions of Japanese scholarship of religion.

4.1 *Themes of East Asian Folk Religion*

The varying elements associated with the East Asian folk religious tradition(s) include emphases on calendar and ritual cycles relating to individuals and communities, the prevalence of shamanic beliefs and concepts relating to the role of spirits (including the spirits of the dead), spirit possession, healing, and the analysis of misfortune and provision of healing, the veneration of ancestors, and various this-worldly beliefs and customs relating to seeking assistance and amelioration in this world.

All these exist alongside or interact with the major traditions or are manifest in and expressed by them. Concepts relating to the spirits of the dead and the ancestors are deeply rooted in the folk religious arena, but the ritual services related to death and the ancestors are most commonly performed through the medium of Buddhism, whose success in East Asia has depended greatly on its ability to adapt to and accommodate folk beliefs in this area. The importance of the ritual calendar and the notion of the yearly cycle of festivals and rituals, originally based in the folk tradition and centered around agricultural rites, has already been mentioned in the context of Shinto in Japan, but it extends throughout the region in differing forms.

Perhaps the most predominant beliefs in the folk tradition relate to psychic interpretations of causation (of illness, misfortune, and, indeed, good fortune). Beliefs that this world does not exist in isolation but is influenced by other realms, and that those living in this

world can be affected by the actions of spirits, mean that, in folk terms, any problem or event may be seen as having spiritual as well as physical causes. Thus, an illness may have psychic causes (e.g., the actions of an unhappy spirit) as well as physical (e.g., the effects of germs) ones, and hence solutions to problems require spiritual attention (e.g., ritual performances, acts of penance) to deal with its spiritual aspects. A strong shamanic tradition has existed throughout East Asia, in which spiritual healers (very often female, and with claims to be able to either travel between this and the spiritual world, or to make contact with it and find ways of appeasing the spirits who are afflicting the living) play a major role. This shamanic tradition is perhaps the most ubiquitous element in the Korean religious universe, but it also remains important in the rest of the region. Studies of Japanese religious behavior in modern times show that people are far more likely to turn to a local healer or diviner than to a Buddhist priest when they have personal problems. This loose-knit tradition of healers and diviners serves also as a counterbalance to the formal religious systems of Buddhism and Shinto, whose priesthoods are almost entirely male, and provides a mode of religious expression for spiritually inclined females, who have remained marginalized in the formal traditions. By contrast, the vast majority of shamanic spiritual healers in Korea and Japan are female.

5. *Millennial Themes in East Asian Religious Culture*

An important theme in East Asian religion that shows how religious ideas may be expressed across the various traditions and cultures of the region relates to millennial beliefs and expectations of future worldly salvation. These are found throughout the region, articulated through the folk religious traditions, Taoism, Buddhism, and, more recently, the new religions. Expectations of a new dawn, the arrival of a spiritual kingdom on earth, and/or the appearance of a celestial or spiritual savior who will bring justice, redeem the sick, punish the unworthy, and transform or renew the world have been especially potent in China, sometimes with Taoist influences but often associated with Buddhism, but they have emerged in Korea and Japan as well. In China, various Taoist-inspired movements such as the second century CE Way of Great Peace movement have rebelled against the state in the hope of establishing a new paradise on earth, while Buddhist-inspired movements have also been inspired by the concept of imminent salvation on earth, often centered on the future Buddha Maitreya (whose cult also inspired similar millenarian impulses in Japan). In China, too, there have been repeated uprisings of the millennial White Lotus Society, which combined Pure Land Buddhist ideas along with folk, Taoist, and other elements, while the Pai Shan-ti Hui movement, which incorporated Christian ideas and sought to create a heavenly kingdom of eternal peace on earth, caused the bloodiest and most dramatic of all such millennialist uprisings, the Tai Ping rebellion of 1849–64 which claimed millions of lives.

Millennial themes are prevalent in many of the new religions. In Korea, numerous religious movements have fused extreme forms of evangelical Protestantism with dramatic millennial visions. The Tami Church (known also as the Mission for the Coming Days) attracted attention when it announced that the apocalypse would begin on October 28, 1992 and that its members would be raptured up to heaven. While this case of failed prophecy damaged the Tami Church, it has not dampened the emphasis on apocalypticism, which remains a central theme in much of Korean Protestantism, and which forms one of its cardinal attractions for the local populace.

The most striking manifestation of millennialism in Japan has been in the new religions that have arisen since the mid-nineteenth century, initially through the actions of charismatic female religious leaders such as Nakayama Miki (1798–1887) of Tenrikyô and Deguchi Nao (1837–1918) of Ômotokyô, but most recently among the 'new' new religions of the late twentieth century, many of which have emphasized that the world is at a critical turning point in which the old, materialist civilization will be swept away as a new spiritual world dawns. While many of the adherents of earlier millenarian movements were poor and disadvantaged, and the thrust of their movements was initially towards seeking social justice, the beliefs of the latest wave of new religions have been conditioned more by concerns that this world is facing extinction because of nuclear or environmental problems, and that a spiritual revolution is essential in order to avoid destruction. The most dramatic and famous of these later millennial movements was Aum Shinrikyô, which believed that a final war between good and evil was inevitable and in which the vast majority of humanity would be wiped out prior to the advent of a more spiritually oriented world.

6. *New Departures: The New Religions*

Since the mid-nineteenth century massive economic development, the impact of Western influences, and immense social change and population movement have produced recurrent tensions between traditional social, cultural, and religious structures, and the individualizing patterns of modernity. In religious terms, the most striking sign of such tensions and developments has been the emergence of new religious movements throughout the region. This phenomenon has been most pronounced in Japan but is discernible also in the rest of the region.

The new religions have generally been eclectic, drawing on the primary religious inspirations of the

societies in which they have emerged: Korean new religions, e.g., might draw on Buddhism, shamanism, and Confucianism, while Shinto (along with Buddhism and the folk tradition) is a source of inspiration for many Japanese new religions. In very recent times, influences have come from outside the region as well, with evangelical Christian movements especially prominent in Korea and new-age themes appearing in the most recent new religions in Japan.

The new religions have been especially effective in dealing with the tensions between modernity and tradition, through their articulation of many aspects of traditional folk religious belief (e.g., concepts of psychic causation) in ways that fit with the needs of individuals in the modern world. They have flourished mostly in the growing conurbations of East Asia, providing a new sense of belonging and community identity for populations that have moved from rural areas to the cities for work reasons. While providing individual solutions to problems and focusing on understandings and definitions of the self in modern terms, they have equally emphasized tradition, reaffirming many of the social parameters of traditional culture and morality. The solutions they pose to individual problems center around shamanic concepts of spirit possession and magically-charged healing rituals, but combined also with reaffirmations of traditional moral structures and obligations, notably Confucian ethical values of filial piety. A typical example taken from a new religion in Japan might be that a personal misfortune or illness is the result of having neglected to perform appropriate rituals for one's ancestors and of causing their wrath: this breach of ritual propriety is a moral lapse which needs to be rectified through repentance and self-reflection, as well as participating in healing rituals. As such many of the new religions display a pronounced interweaving of magical practices alongside affirmations of morality; as various Japanese scholars have noted (e.g., Shimazono 1992), rather than magical practices decreasing as ethical and moral considerations become more strongly emphasized, the Japanese new religions show that the two often operate in tandem, the latter increasing and being articulated more pronouncedly as magical practices become more widespread.

The region's new religions almost invariably owe their origins to the charisma and inspirational leadership of individuals who claim to have direct contacts with other realms or to bring new revealed truths to the world. While serving as a medium for a newly revealed deity, however, a common pattern is that the charismatic leader gradually displaces the deity as a source of inspiration, authority, and worship, often becoming regarded as living deities and venerated accordingly. Their charisma, however, may continue after death, a point often emphasized by Japanese scholars interested in the study of charisma: authority and succession to the leadership generally (following traditional East Asian familial patterns) passes through the family lineage to a son or daughter, suggesting that charisma is in part related to the concept of blood and lineage, and the deceased founder becomes an even more central figure of worship, with their mausoleum often becoming a pilgrimage center for the religion.

6.1 Aum Shinrikyô: New Religions and Violence

In 1995 world attention was directed towards the millennial Japanese new religion Aum Shinrikyô and its blind charismatic leader, Asahara Shôkô, because of its nerve gas attack on the Tokyo subway. While Aum was not the first or only religious movement in East Asia in modern times to commit acts of violence the sensational nature of the subway attack, Aum's use of chemical weapons, and the subsequent evidence showing that it had engaged in a protracted series of crimes emanating from its religious activities and beliefs, caught the attention of defense and law agencies as well as scholars world wide.

The Aum affair has special significance for the sociological study of religion for many reasons. It showed similarities with patterns of violence that manifest in other religious movements in the West (e.g., the Peoples Temple, the Rajneesh movement, and the Order of the Solar Temple) and appeared, in an extreme form, to fit into a wider pattern of the production of violence within certain forms of newly formed charismatic, world rejecting millennial movements. It provides a dramatic case study for those interested in the relationship between religion and violence, and several of those who have studied Aum have interpreted it as an example of the violence-producing dimensions of religion (e.g., Shimazono 1997, Reader 2000). As an example of how new religions can produce violence primarily because of their doctrinal orientations and internal dynamics, the case of Aum provides a significant counter-example to the arguments widely held by many scholars of new religions in the West, that movements that engage in violence do so primarily in response to excessive external pressures placed on them by a hostile society.

7. Scholarship on the New Religions and the Problem of East Asia

Mention has been made of the scholastic traditions in the region, especially of Japan, and some of the analyses and ideas they have transmitted. The new religions of Japan provide a case in point where work done by Japanese scholars has added to the wider understanding of new religions across the globe. Japanese scholarship generally has examined the 'new' new religions in the context of late twentieth century

urban society and modernity, and as such has thus recognized, either explicitly or implicitly, the parallels that could be drawn between Japan as a first-world, modern, and technological society, and Western countries. Western scholars specializing in new religions have also been drawn to comparative studies of the Japanese new religions because of these recognizably common influences and factors. Much of the best Japanese scholarship on the new religions of Japan has taken account of Western theoretical perspectives, while many of the scholars in Japan have worked closely with Western scholars of new religions, mutually influencing and being influenced by them.

This has placed contemporary Japanese scholarship on the new religions in an international framework, and has made Western scholars more than ever aware of the importance, when seeking to develop comprehensive or universal models and categories in the study of religion, of the Japanese situation. Certainly no sociologist of religion concerned with the rise of new religions in the modern world can ignore the work being done in this field in and relating to Japan, just as no student of religious violence or of millennial movements could afford not to take note of Aum Shinrikyô. However, the corollary of this development has been to separate out Japan from the rest of East Asia in terms of the study of new religions: rather than viewing parallels within the region, e.g., Japanese scholars (and Western scholars working on Japan) have tended to examine Japanese new religions in the comparative context of Western new religions. This, however, means that the (potential) parallels between Japanese new religions and those of the rest of East Asia are focused on less clearly.

In other words, the problematic question raised earlier about how far one can discern or discuss the region in broad terms, is in some areas being answered in practical terms by contemporary scholastic work in and centered on Japan, which associates Japan far more with the industrialized West than, and thereby draws implicit boundaries with, the rest of geographical East Asia. While this does not invalidate the conceptual category or notion of East Asian religions, it does indicate the problematic aspects of talking of the region in any uniform sense. Not only do the traditions themselves take on different guises in the different parts of the region, but the manner in which they may be studied and the lessons that may be drawn from them may also highlight questions of difference rather than commonality. To what extent future studies will further add emphasis to the issue of difference and challenge the viability of treating the region as an entity is a moot question of great interest and significance to the field as a whole.

East Asian Studies: Culture

'East Asian Studies' is a well-established area studies program with a long and distinguished tradition of studying the peoples of East Asia and their lives. 'East Asia' appears to be a fairly well demarcated geographical area, consisting at present of the People's Republic of China (mainland China, now including Hong Kong), the Republic of China (Taiwan), North and South Korea, and Japan. However, shifting political boundaries—even at the start of the twenty-first century—and recent epistemological and theoretical questions in various fields have reminded us that 'East Asian Studies' is a highly complex undertaking. Building on excellent studies of the peoples of East Asia and their cultures, the field is now invigorated by fresh insights and perspectives. Historically the Chinese, Korean, and Japanese 'civilizations' have had much in common, due mainly to the diffusion of the Han and Tang civilizations from China to the rest of the area. Linguistically, the Sino-Tibetan languages, all of which are characterized by the tonal system (whereby tones give distinctive meanings to the same sound types), belong solely to the Chinese; the Korean and the Japanese, together with the Ainu and Gilyaks, come from an altogether different, non-tonal linguistic stock. Yet the Chinese writing system was adopted and imposed on the spoken languages of the Korean and the Japanese, although both later added their own system.

1. *Recent Developments—'Non-socialized Culture'*

Given Japan's indebtedness to Chinese civilization, Japan has had a long tradition of Sinology, attracting scholars of China—including Chinese—to study there. Asian peoples themselves, along with scholars, used to view their country primarily in relation to 'the West'. However, at least since the mid- to late nineteenth century, there have been vigorous dialogues on and by Asians and Asianists on the relationships—cultural, political, economic, etc.—among Asian peoples. Representations of Japan, for example, to the rest of the world have, until recently, been made primarily by Western scholars alone, but Chinese, Koreans, and other Asians—and not exclusively the elites as in the past—are now taking part in the study and representation of the Japanese. Conversely, Japanese scholars have greatly shifted their focus to other Asian peoples, especially Koreans (Shima and Janelli 1998). A new Pan-Asianism, distinct from the one imposed by the Japanese during their imperial period, is a product of renewed recognition of cultural, social, economic, and political relationships of long standing among Asian countries and peoples.

Recent changes of emphasis and perspective in East Asian Studies derive from criticisms of, and even some frontal attacks on, the concept of *culture*—a cherished or, some would argue, the most fundamental concept in anthropology. Today, the term culture is in increasingly common use outside of anthropology, and in fact flourishes in Cultural Studies and various other disciplines, while becoming widely used in the mass media. At the same time, anthropology remains divided on this issue. Those who advocate to do away with 'culture' altogether have been accused of not offering alternatives to deal with collectivity, that is, 'society' or 'culture.' Even those sympathetic to the criticisms of the culture concept feel it is hard to discard it altogether, or, '[W]hatever the infirmities of the concept of 'culture' ('cultures,' 'cultural forms' …) there is nothing for it but to persist in spite of them' (Geertz 1995).

We are now increasingly aware that the *concept* of culture, if used as a hermetically-sealed entity, fails to explain the very *dynamics* of culture, always in the process of transforming at the confluence of internal/local historical development and external/global historical forces. Almost all major foundational features of Japanese culture and political economy came from the Asian continent, usually via Korea. They include the 'wet-rice economy' in early times, and later—during the fifth and sixth centuries—the imperial ritual, the writing system, city planning, metallurgy, and a host of other activities. The draft of the Meiji constitution, promulgated in 1889, was drawn up by German and Austrian legal scholars and many of the key articles were adopted almost verbatim. Japan's modern army and navy were modeled after the French and German army and navy. In fact the modernization in Japan, as in other Asian countries, was, to a great extent, Westernization. No society is an island in history. Hybridity is a *sine qua nom* of any culture. Recent emphasis on globalization makes us keenly aware of the basic nature of culture as a dynamic, unending process of the interpenetration between the local and global.

2. *Dynamics Within*

A powerful critique of the notion of culture as a 'totalizing' and 'essentializing' representation of a people or a culture led our studies in several productive directions. One such direction is the further emphasis on *diversity*, multiple voices within an artificially demarcated unit of our study—be it a people, a culture, or a society—resulting in a plethora of research on social groups other than the dominant ones. These groups include not only the so-called minorities but also the homeless, school dropouts, etc. This move is a corrective to representation in the past, for example, of the Chinese by the Han Chinese, or the Japanese as the agrarian Japanese: the emphasis on the latter led to a label, 'rice paddy courses,' refering to introductory courses on Japan. The recent research on minorities places these social groups not as isolated groups but in

relation to dominant social groups, especially but not exclusively in regard to power inequality between the dominant and marginalized social groups.

In the case of Japan, wet-rice agriculture, which originated somewhere as yet unidentified within tropical Asia, reached northern Kyūshūsome time around 350 BC, supplanting the hunter-gatherer economy of the first occupants of the archipelago, who had arrived around 200,000 BC. It laid the foundation for the political economy of the Yamato state and the imperial system. Gradually the segment of the population engaged in rice agriculture—or, more accurately, who reaped the economic/financial crop from wet-rice economy—became the dominant social group, representing 'the Japanese'. The agrarian cosmogony and cosmology became those of the Japanese, whereby the rice agrarian seasonality governed all Japanese and rice paddies came to represent the Japanese space.

There is an increasing awareness now among scholars that the other side of the development of 'Agrarian Japan' was the marginalization of 'the Japanese' in nonagrarian sectors. They included those people whose livelihood derived from the resources of the sea and the mountains. In particular, this included what later became known as the '*hisabetsu burakumin*' (settlement people under discrimination). These were people who engaged in nonagrarian occupations such as the performing arts, architecture, and trading, plus itinerant religious specialists, who, from late medieval times—when the notion of impurity received radical negativity—became increasingly marginalized, until 1582 when they were codified as two categories of 'outcasts.' The marginalization of the Ainu, who continued to engage in hunting, fishing, and plant gathering well into the nineteenth century, was similarly based on the yardstick of agrarian values, which placed emphasis on plant domestication. In addition, the assignment of 'primitiveness' to them was a byproduct of the Japanese, who tried to 'modernize' their nation according to the model of Western modernization (Ohnuki-Tierney 1987, 1993).

A related development is the shifting of focus among scholars from males to females—their voices, their life experiences, and women as social agents who actively carve out or change the courses of their lives. The issue of gender preferences, both institutionalized and culturally sanctioned as well as individual, has also received considerable attention. Gender-related issues often address the question of gender inequalities, which are in turn juxtaposed with the power inequalities between classes within society, on the one hand, and between the colonizers and colonized, on the other, breaking new ground for various disciplines (Watson and Ebrey 1991).

3. *Transnationals, Diasporas*

Another major critique of culture is how it was presented in the past as being spatially tied. The non-isomorphic nature of the cultures, locality, and peoples of East Asia was realized early by scholars of East Asia, who have contributed to the studies of 'overseas communities'—numerous 'Chinatown' studies, Brazilian Japanese, and the like. 'Emigrant communities' are a native category of villages from which people regularly emigrated to overseas communities, while closely maintaining ties with their home villages (Chen 1939, Watson 1975). Building on this distinguished tradition, scholars of 'transnationalism' study emigration, the resultant overseas communities (some diasporic), and especially transnationals with 'flexible citizenship' in the contemporary context of globalization which created a unprecedented flow of population across borders of nation-states (Ong 1999). The recognition of the non-isomorphic relationship between a political unit—such as a nation-state—and a people/culture became more than obvious in East Asia when 'the Chinese' were divided into those in the People's Republic of China, those in Hong Kong—first under the British and then the People's Republic of China—and those in the Republic of China (Taiwan) across the Formosa Strait. Likewise, 'the Koreans' were split into North and South. Japan, which has been stereotyped as homogeneous in terms of demographic composition, has been a multi-ethnic nation throughout history. But, to give one example, in 1940 the then prime minister of Japan, Konoe Fumimaro, delivered a now infamous speech that 'one hundred million Japanese with one soul' be dedicated to the service for the Emperor. This figure included 30,000,000 Koreans, Chinese, and others who resided in Japan and its occupied territories, who were given an equal right to death, that is, from 1944 they were forced to become Japanese with the Japanese soul in order to be drafted to fight for imperial Japan. This is not to mention the diversity within, with the Ainu to the north, and the Okinawans to the south, who were once thought of as distinct from those on the main islands, and 'Westerners,' including the 'white Russians' and Jews.

The political mosaic in East Asia offers a fertile ground for studies of 'identities' and conflicts among social groups within a nation-state and between nation-states. Within a nation-state, the majority vs. minorities are interlaced with the question of what makes a social group 'ethnic' (the Okinawans in Japan 'used to be' ethnic); whereas the two Chinas and two Koreas present a different situation—the question of two nation-states consisting of one people. In other words, East Asia offers a microcosm of what we see in the world in which collective identities form flexible circles, some of which overlap with each other.

4. *Nationalisms, Colonialisms, Imperialisms*

At the level of nation-states, the identity of a people could be expressed through peaceful 'cultural

nationalism' which defines and represents a people of a nation-state as distinct from another, often those who, physically or symbolically, press at the 'border'—figuratively and politically. Thus, when the Japanese began to emerge from their total immersion in the Han and Tang civilizations of China, they began to assert their own culture, switching from embracing the Chinese aesthetics of plum blossoms to that of cherry blossoms as their flower. Since the mid-nineteenth century Japan's nationalism, both cultural and political, has been informed by paradoxes and ambivalence of the Japanese's own identity, which was formed in part by rejecting Western political imperialism—while at the same time eagerly emulating Western civilization—and in part by rejecting their own Asian identity—while seeking it in order to establish a difference from the West.

Research on the complex problem of identities in East Asia will join the now burgeoning field within social science of ethnicity, nationalism, and ethnonationalism. Ethnonationalism is 'the politicization of ethnicity,' related to 'the generation of regional or subnational reactions and resistances to what is seen as an overcentralized and hegemoic state' (Tambiah 1996, p. 16).

Colonialism in East Asia is another genre of research in which interest is growing, and which promises a rich source of comparative work. Studies of Western colonializations have yielded rich fruit for scholars in the past. The Opium War (1839–1942) and the resultant cessation of Hong Kong became the symbol of the power of Western (British) colonialism over Asia, whereas the Boxer Rebellion (1899–1900), crushed by the combined forces of Western and Japanese powers, foreshadowed not only Western but Japanese imperialism. Another growing field of interest concerns the histories and cultures of Japanese colonialism during its military period, as in the colonization of Korea (1910–1945) (Duus 1995), and the building of the puppet state of Manchukuo (1931–1945) (Young 1998). These studies offer important comparative bases for Western and non-Western colonializations in Africa, the Americas, and other parts of the world.

A genre which is similarly regarded as important, although it has not yet received systematic attention, is cultural imperialism, especially of Western European cultures over many parts of Asia, and also of the world—how political domination by other, primarily Western European nations (but also Japan to a lesser degree) nonetheless became the cultural mirror to emulate. Western cultural imperialism has been at the center of modernization processes in Asia, with the often eager adoption of Western science, technology, and capitalism leading to almost everything from the 'West' being revered, including the body esthetics. Even before affluence led the Japanese to seek out designer names such as Gucci, Bally, and Louis Vuitton, American Revlon lipsticks and Ivory soap were far more expensive than their domestic counterparts and were preferred as gift items.

This is an important area of study, not only because it offers us a valuable window onto the other side of political colonialism but also because it constitutes a significant dimension of the current globalization, in which the notion of brain death, organ transplantation, human rights, environmental conservation, and the like, which involve concepts and values that are predominantly Western in origin, are considered outside their areas of origin. Medical high technologies, saluted as the golden achievement of Western biomedicine, brings prestige to those in another society who embrace them as being 'progressive,' although such technologies may require not only radical reconceptualization about the death in relation to the body but also mortuary rituals, with beliefs, values, kinship, and a host of other important dimensions of a people needing to be considered and, where necessary, renegotiated.

5. *Global Forces and East Asia*

Another category of studies that offers an approach to study people not as an enclosed entity is 'global studies,' or studies of transnationality—there are a wide range of approaches within this field. Those at the forefront of the study of globalization consider the twenty-first century as a new era marked by an unprecedented flow of people, goods, and signs. Others urge us to compare the present with the past when spice trades, capitalism, colonialism, features of Western High Culture, etc. spread throughout the world. The present globalization is marked by the spread of high technology and market economy of late capitalism. The global flows of people are studied as research on tourism, diaspora, and transnationals. The flows of goods and signs/symbols are studied through research on global dissemination of youth fashion, fast food, television programs, films, pop music, and a host of other things that are engulfing the globe. Most originate in the West, but some, such as reggae, do not. Reassessments of the claims for 'McDonaldization' or 'CocaCola-ization' are underway, for example, in Watson (1997), which offers a close examination of the fast food industries in Beijing, Hong Kong, Taipei, Seoul, and Japan. These studies of the introduction of McDonald's—a symbol of postmodern fast-lane life in the USA and an epitome of Americana for peoples elsewhere—show a simultaneous transformation of the locale, which in turn transforms the fast food in significant ways.

6. *Cultural, Social, Political Institutions*

East Asian studies continue to produce distinguished scholarship on: kinship and social organiz-

ation; religions (beliefs and rituals); educational systems; arts and performing arts; and healthcare systems. Excellent studies of the institutionalized religions of Buddhism and Confucianism, shared by most Asian societies in variant forms, and of Shintoism in Japan describe how they have impacted on sociopolitical organizations as well as arts and science. They also tell us how people experience these religions in their daily lives. The emphasis on the impact of religion in individual lives receives the focus of attention in the studies of 'ancestor worship' shared by most peoples of East Asia (Ahern 1973, Watson and Rawski 1985, Janelli and Janelli 1982, Smith 1974). 'Ancestor worship' is a misnomer but refers to the practice of taking care of the souls of deceased family members and relatives through a long series of rituals. Despite profound changes that such worship underwent in each society, it remains perhaps the most important aspect of religious beliefs and rituals in these societies.

Shamanism and other religious beliefs and practices that have been regarded not to belong to institutionalized religions are also well studied in relation to the day-to-day lives of contemporary peoples. In contemporary Korea, for example, Shamanism is of exceptional importance and recent studies highlight the role of women in Korean shamanism (Harvey 1985, Kendall 1985). Although their pervasive influence is less recognized, Taoism and geomancy, as practiced in China and spread to Japan, constitute important dimensions of cosmology comprising symbolic oppositions (expressed in *yin-yang*) and remain important in the daily lives of people in East Asia.

In addition to these traditions—large and small—of religions that are considered to be 'indigenous' or of long standing in East Asia (Buddhism originated in India), we witness recent studies on Muslims and Christians in East Asia, again showing the recent view of culture as not localized or hermetically sealed. Indeed, Protestantism is quite a strong force in contemporary Korea, while many influential intellectual and political leaders of Japan since the Meiji 'restoration' in 1868 have been devout Christians, some of whom were presidents of the University of Tokyo, taking on important roles as intellectual and moral leaders.

The academic study of healthcare has a long tradition in East Asia. 'Chinese medicine' in particular has received attention from distinguished scholars such as Joseph Needham, who explicated how their medicine constitutes a science distinct from Western science (Needham 1969), and Manfred Porkert, who later produced a similarly distinguished work (Porkert (1974). A compiled work by Arthur Kleinman (1976) focuses on doctors, patients and their interactions, rather than medicine as a system.

East Asian Studies: Economics

The East Asian economies can be divided roughly into three groups—the advanced industrial economy of

Japan, the newly industrialized economies (NIEs) of Taiwan, South Korea, Singapore, and Hong Kong, and the transforming planned economy of China. Dramatic changes have reshaped East Asia as a regional economy since the early 1970s. The rapid development of the NIEs and the early success of China's transforming economy have made this region one of the most dynamic in the global economy. However, the economic difficulties wrought by the economic downturn in Japan in the 1990s, the Asian financial crisis of 1997, and the considerable challenges still facing the Chinese reform effort have shown the vulnerabilities of this regional economy.

1. East Asian Economic Development

In East Asia, the second half of the twentieth century was a period of strong economic development in one form or another. The newly industrialized economies of South Korea, Taiwan, Singapore, and Hong Kong were viewed as the most dynamic economies in the world, having leapt, in the postwar period, from the status of poor underdeveloped to strong industrialized economies (Clark and Roy 1997). The last two decades of the century also saw great success in the economic transformation of the Chinese economy. The patterns and trajectories of change within these nations have challenged conventional wisdom about how developing nations modernize and industrialize, and about the role of the state in these processes of change.

1.1 The Newly Industrialized Economies

The three decades following World War II were a period of enormous enthusiasm about the economic prospects for developing countries. These were the years when a large number of such countries embarked on ambitious projects of agricultural and industrial modernization. Indeed, it was this effort that gave rise to 'development economics,' and more broadly, 'development studies,' as new disciplines in the social sciences. In the halcyon years of development planning, most eyes were focused on the larger or more industrialized countries such as India, Brazil, Mexico, and Egypt. Few expected very much, if anything, from East Asia, large areas of which had been colonized by Japan in one way or another in the first half of the twentieth century, and parts of which seemed hopelessly backward. Taiwan had a minuscule industrial base in 1950, Hong Kong and Singapore were tiny city-states, and South Korea seemed to be sinking in a morass of corruption and inefficiency by the end of the 1950s. Yet, a quarter of a century later, the tables had been turned: East Asia emerged as the economic 'miracle' of the postwar period, witnessing some of the fastest growth rates of the modern epoch, while Latin America and South Asia were mired in political and economic crises. Given this regional growth phenomenon, does it make sense to talk of an 'East Asian Model'? There are some important similarities in development strategies across the cases, enough to persuade many commentators that the appellation is warranted. But there are also interesting differences that are worth noting.

Among the East Asian NIEs, South Korea and Taiwan have attracted the most attention. Over the years, two general views have emerged about the reasons behind their spectacular economic success. One, which was perhaps the dominant one for much of the 1970s and 1980s, held that the two countries were successful because of their fidelity to free-market policies, particularly an open trade regime (Lal 1985, Bhagwati 1988). But this view has come under a great deal of criticism from many quarters, and a new argument has emerged in recent years, which offers a different explanation for Korean and Taiwanese success. In some ways, the two countries achieved their remarkable economic success the 'old-fashioned' way: both started with highly successful land reforms, which immediately set them apart from much of the developing world; both managed to bring about extraordinarily high savings rates, which were then channeled into correspondingly high rates of investment. But the two countries did not simply grow by increasing the rate of accumulation. They also succeeded in acquiring, and then unpacking, technology from advanced industrial countries, so that they were able to move up the production chain into manufacturing and exporting high value-added goods. The involvement of the state was crucial to this process (Gold 1985). First, both governments launched highly effective campaigns to increase literacy rates, which accounted for a highly educated work force (World Bank 1993). Furthermore—and this has been one of the most heralded facts about their experience—the two states played a crucial role in facilitating the acquisition and transfer of imported technology. These technologies were brought in sometimes through foreign direct investment, but mostly through licensing agreements with multinational corporations (MNCs). Agreements were carefully crafted to ensure that foreign partners did not simply hand over obsolete technology, and that local engineers were able to acquire blueprints as well as the training necessary to master the technology. Firms were also encouraged, assisted, and even coerced to produce for export markets, in order to submit them to the rigors of international competition (Amsden 1989, Wade 1990). Success in export markets was used by both states as a benchmark for efficient production. Even firms producing mainly for the domestic market often had to show export success in order to be granted credit, investment licenses, and other state benefits (Aoki et al. 1997). Finally, the state was active in maintaining, for many of the crucial years of take-off, a tightly policed and powerless labor force, which added to the 'flexibility' of production.

While South Korea and Taiwan shared these elements in their development strategies, they also exhibited some important differences. Korea emphasized a reliance on the private sector, which was not only encouraged to grow, but also to become increasingly concentrated. In this, it resembled the Japanese experience: the Korean economy was dominated by a small number of highly diversified business groups, known as the Chaebol, which together accounted for the majority of the country's domestic product. The Chaebol quickly emerged as the pivot on which industrial policy turned, establishing a close working relationship with the ruling regime (Amsden 1989). The Taiwanese state, on the other hand, did not have such a close relationship with private capital. Taiwanese planners relied much more on a large agglomeration of state enterprises as the nucleus for development policy; private capital was influenced—in comparison with the Korean case—more through pricing and procurement policies than by direct negotiation. The private sector was, in turn, not actively encouraged to become highly concentrated. Taiwanese industry was, much more than its Korean counterpart, characterized by small enterprises (Wade 1990). Nevertheless, a kind of quasi-corporatist structure was used to bargain with some sectors. Indeed, in both countries, a similar structure was put to use for this: firms in targeted sectors were organized into sectoral or trade associations, which were given the right to bargain with the state (Fields 1995). The overall complexion of industrial policy, however, remained visibly different in the two cases, with Korea relying on a highly concentrated private sector, and Taiwan more on state enterprises and small firms.

Singapore and Hong Kong are usually regarded as contrasting cases to Korea and Taiwan, in that whereas the latter two are examples of state-led development, the former pair embody a free-market path—or so the story goes (Rabushka 1979). There is some measure of truth to this. Hong Kong, in particular, did not experience anything like the selective industrial policy witnessed in the larger countries. And both of the city-states were much more open to foreign direct investment than either Korea or Taiwan. But there are important respects in which the city-states converged with the experience of their larger neighbors. First, like Korea and Taiwan, both Hong Kong and Singapore actively suppressed labor rights. Second, the state was of some importance in facilitating industrialization. Singapore, despite being more open to foreign investment, relied greatly on state enterprises to facilitate the entry of MNCs by forming partnerships with them, hence reducing the risk of such undertakings; further, the domestic market was not thrown open to imports, and was protected much like that in Taiwan and Korea. Local firms were also offered carefully targeted fiscal incentives, under the guidance of an Economic Development Board. Hong Kong was, of the four, the furthest away from the interventionist model. But here, too, the state played a crucial role in solving a host of collective action problems for local firms: most directly through its considerable expenditure on infrastructure, training programs, and, perhaps most importantly, its massive socialization of wage costs through the construction of an extremely generous welfare state. Between 1949 and 1980, government expenditure in Hong Kong grew by 26 times, and expenditure on welfare by an amazing 72 times (Castells 1994). This was absolutely crucial to the success of Hong Kong exports, in lowering the wage costs to producers.

In sum, despite their differences, the four cases do exhibit certain important similarities. Perhaps the most important of these is the critical role played by the state in fostering the transition to highly productive industrialized economies. The differences lie mainly in the instruments used by the various regimes: selective intervention in the larger two countries, and more macro-level policies in the smaller ones.

1.2 China's Transforming Planned Economy

While the NIEs were executing successful development processes, the first three decades of Communist Party rule in China (1950s through 1970s) were organized around the establishment of a socialist planned economy (also called a 'command' economy). In this system, markets were eliminated and replaced by governmental plans that guided the economic decisions of enterprises and individuals. China's one-party government replaced private ownership with state ownership, established economic targets for industrial enterprises, and set up collective farming in the agricultural sector. Economic agents (whether industrial enterprises or farmers) were instructed to whom they would sell their goods and for what price. Revenues were then collected by the government and redistributed to enterprises and individuals in the economy. This system was thus more than a purely economic system; it was also the basis for the social security system in China (Walder 1986, Whyte and Parish 1984).

Without a competitive marketplace to regulate and guide economic behavior, planned economies, such as China's, are often rife with inefficiencies. In 1978, after a decade of upheaval wrought by the Cultural Revolution, the Ten Year Plan of 1976 was already faltering, and the need for some degree of economic reform was clear. Following a political struggle that pitted reform-minded Deng Xiaoping against the economically conservative Hua Guofeng, Deng Xiaoping took control of the economy in late 1978 at the Third Plenum of the Eleventh Central Committee of the Chinese Communist Party. Once in control of the government, Deng launched China on a path of economic transformation.

One of the central debates in research on transitions from planned to market economies revolves around

the extent to which privatization is a necessary part of this process. Some scholars have argued that without rapid and complete privatization—the so-called 'shock therapy' approach to reform—true economic reform is impossible (Kornai 1990, Sachs and Woo 1997). Other scholars have argued that China is the case that disproves this view: in contrast with the rapid changes that characterized the economic reforms of Russia and Eastern Europe, China's reforms have been introduced in a gradual and stepwise fashion, where the government has experimented with new economic policies and incrementally implemented the successful practices on a wide scale (Naughton 1995). Proceeding in this gradual fashion, the Chinese transition to a market economy has been unquestionably the most successful in the world. (China sustained the fastest rates of growth in the world for the first decade and a half of economic reform. Throughout the 1980s, its real GDP grew at an average annual rate of 10.2 percent, a level that was equaled only by Botswana. From 1990 to 1996, the average annual rate of growth for real GDP was 12.3 percent, the highest rate of any country in the world for that period. It has also had the highest industrial growth rate (an amazing 17.3 percent average annual growth 1990–96) and the second highest growth in services (9.6 percent per annum, 1990–96) in the world.)

In the industrial sector, often regarded as the backbone of the Chinese economy, five key changes have reshaped this system. First, the government gradually removed itself from day-to-day decision-making, effectively placing the responsibilities of economic decisions on the shoulders of industrial managers. In the early years of the reforms, enterprises were still expected to produce a certain amount of goods for the government's plan, but anything they produced above this residual plan they were allowed to sell in China's emerging markets. This transitional system was called the 'dual-track' system (Naughton 1995). Second, a private economy was allowed to emerge to compete with the state sector, a factor that was critical for the creation of a competitive marketplace. Thus, while privatization was the cornerstone of industrial reform in other transforming planned economies, Chinese firms were introduced to market economic behavior without privatization (Rawski 1994), and state firms eventually 'grew out of the plan,' producing an increasing proportion of their goods for the marketplace (Naughton 1995). The success of this transition, however, has varied in accordance with a firm's position in the former command economy: firms under township and village governments, most of them the so-called Township and Village Enterprises (TVEs), have been managed closely by local governments and thus have weathered the reforms much more successfully than those under the central and municipal governments (Walder 1995).

A third change that has defined China's economic reforms is that foreign investors were allowed in the Chinese economy for the first time since the communists expunged the foreign presence in the early 1950s. This factor has been very important for the transfer of technology and the transfer of international management practices. Fourth, the government adopted a decentralized and piecemeal approach to development regionally: in the late 1980s, the government adopted the coastal development strategy, in which the goal was 'state-directed' export-oriented growth (Yang 1991). Finally, Chinese enterprises have been relieved of their responsibilities in the provision of social security benefits to their employees and, perhaps more significantly, they are no longer required to make lifetime commitments to the workers they employ. In the agricultural sector, a similar process of change has unfolded, where farmers have been given the freedom to sell whatever they produce beyond the plan in the marketplace, until eventually the market has overtaken any vestiges of an economic plan in this sector. All of these economic changes have been formalized through the passage of some 700 national laws and more than 2,000 local laws (Pei 1994).

Transforming the planned economy of the world's most populous nation has been a complex process and is far from complete. Nevertheless, the first two decades of transition from plan to market have been impressive and, compared to the reforms in Russia and Eastern Europe, a dramatic success. For the first decade and a half of economic reform, China had the fastest growing economy in the world, sustaining double-digit growth figures for much of the 1980s and 1990s. Where it was a third-world developing economy as late as the early 1980s, by the beginning of the twenty-first century China had the seventh largest economy in the world overall in terms of gross domestic product (GDP), and it is second only to the USA when GDP is adjusted for purchasing power within the country. (For example, if a bushel of rice costs half as much in China as in the USA, then a unit of currency is twice as valuable there. GDP statistics can, when appropriate, be adjusted for 'purchasing power parity' (PPP): a statistic that adjusts for cost of living differences by replacing exchange rates with relative measures of local purchasing power.)

Among the challenges that still lie ahead are the continued reform of the state sector—the leviathan organizations that remain inefficient and insolvent after more than 20 years of reform; the continued reform and clarification of property rights; the liberalization of several critical sectors, such as the telecommunications sector, and the development of the western provinces, which have fallen far behind the development in the eastern coastal region.

2. *National and Regional Economic Crises*

It is, in part, because of the great successes of development in East Asia that recent economic crises have hit the region so hard. Two related, but distinct,

economic crises are worthy of note here. The first is the economic downturn that Japan suffered in the second half of the 1990s. The second is the Asian financial crisis, which gripped much of East and Southeast Asia in 1997 and 1998.

2.1 Japan

Japan was, for most of the postwar period, one of the fastest-growing economies of the industrial world, racking up huge rates of growth year after year until it had achieved its current position as the second largest economy in the world, with an annual GDP of more than $5 trillion. Its economy was the engine for the broader regional development of East Asia, both through its capacity as a market, and as a source of capital and technology. A more intangible, but nevertheless important, role was that it provided the model on which the two Northeast Asian 'tigers'—Taiwan and South Korea—based their economic strategies.

By the end of the twentieth century, however, the Japanese dynamo seemed to be losing its energy. It spent most of the 1990s mired in an economic recession that turned out to be the longest and most severe of its postwar history. The precipitating event behind the crisis was the collapse of the asset bubble of the 1980s, which burst in the beginning of the next decade. The bubble itself had been built up during the 1980s as the Japanese state had initiated a policy to ratchet upwards the domestic rate of investment and make the economy less dependent on external markets. Spurred on by the constant pressure by the USA to raise the value of the yen, the Japanese government moved by the late 1970s to trigger a massive investment drive by raising the value of domestic assets. At one level, it worked very well—as asset prices rose, Japanese firms launched a massive drive to retool and invest in new technology. But the flow of investment soon exceeded anything that actual returns could justify, driving up asset prices steadily into a speculative bubble. Sooner or later all speculative bubbles burst, as did this one in the 1990s. And once the bubble burst and the economy slowed, firms found themselves stuck with massive overcapacity and onerous levels of debt. Through much of the decade, business and residential investment continued to fall, throwing the economy into a downward spiral.

The Japanese downturn was one of the background factors that laid the conditions for the East Asian crisis of 1997–8, which is now regarded as the most significant economic catastrophe the world has seen since the Great Depression. As the economy slowed down, firms compensated by turning outward, in a massive wave of investment in Southeast Asia. This led, in turn, to a process not unlike that witnessed in Japan: corporations went into deep debt to pay for new investments, leading to the build-up of extraordinary industrial capacity; after a point, money also began to pour into real estate and other forms of wealth, driving up their prices until a speculative bubble was created reminiscent of the Japanese bubble.

2.2 The Asian Financial Crisis

Though much of East Asia had bounced back from the Asian financial crisis by the spring of 2000, this crisis revealed some weaknesses in the rapid development of the 'Asian Tigers.' The crisis itself was set off by currency devaluation: in the spring of 1997, as the pace of growth in the Thai economy fell below projections, currency investors began to speculate against the baht in hopes of profiting from the inevitable devaluation of the currency. When the currency devaluation came in July, foreign investors fled from Thai markets, and similar behavior spread quickly throughout the region. Stock prices plummeted, currencies went into free fall, and banks began to call in loans that their customers—many of them large corporations—could not repay. By the end of 1997, the International Monetary Fund had bailed out Thailand, Indonesia, and South Korea with $17 billion, $43 billion, and $57 billion, respectively.

Two explanations have been advanced to account for the crisis. In one view, an over-reliance on foreign capital and international institutions, changes in regional economies—namely China's and Japan's—and reliance on the dollar brought about the crisis (Ahn 2000). First, the strength of the Japanese yen in the 1980s and the dollar in the 1990s led to excessive foreign investment in the strong East Asian economies, particularly for Japanese investors. As local banks sought strong currencies, investment and lending agreements were structured to attract these foreign players, and excessive capital led to high-risk investments, many of which would prove to be insolvent when the crisis stripped the veneer of economic discipline. Second, as China's economy began to expand, it took over a large share of the export market, the centerpiece of development for many East Asian Economies. Third, when European currencies depreciated against the dollar in 1995, dollar-pegged East Asian currencies appreciated—relatively speaking—leading to a decline in exports. Fourth, as the flow of international capital increased through such institutions as hedge funds and short-term loans, speculative behavior on the part of international currency investors in these rapidly expanding financial markets led to market volatility.

A second explanation acknowledges the problems listed above, but places the blame of the crisis on the East Asian economies themselves. This explanation often veers into a cultural argument about the prevalence of 'crony capitalism' in the region. In this view, the East Asian business model, often led by government-directed investment in key industries, is also often built around implicit guarantees from the government for the liabilities of local financial institutions

(Krugman 1998). Thus, the so-called 'soft budget constraint' (Kornai 1994), which was the hallmark of planned economies, some economists argue, was also fundamental to the East Asian business model more generally. Governmental guarantees led to risky behavior on the part of financial institutions, which ultimately led to the financial crisis itself.

3. *The Balance of Power: Regionally and Globally*

Despite the economic crises experienced in the region in the 1990s, overall the second half of the twentieth century saw a dramatic shift in the economic balance of power both intra-regionally and with regard to Asia's position globally. Within the region, while Japan was far and away the economic powerhouse of the region by the end of the 1980s, at the dawn of the twenty-first century the balance of power looked very different. Partly because of the rise of the NIEs, but perhaps more importantly, because of the dramatic growth of China's economy, Japan's economic dominance in the region has unquestionably waned. It is difficult to predict what the exact economic balance of power will be within the region in the coming decades, but it is certainly clear that China will challenge Japan as the center of the Asian economy.

Globally, the economic balance of power has shifted as well. While Japan has been counted among the group of seven (now group of eight) industrialized nations since the organization's inception, during most of the twentieth century Western economies have dominated the global scene. However, with Japan and China both among the top 10 largest economies in the world and four Asian economies among the top 20 (five if we include Australia), Asia is certain to play an increasingly important role in the balance of the global economy.

East Asian Studies: Gender

1. *The Concept of 'Gender'*

Gender is an analytic term that came into common academic usage in the late 1970s and early 1980s in the United States among feminist social scientists. The widely influential historian Joan Scott urged historians to use the term gender to describe women's social and historical differences from men positively (Scott 1986).

By the early 1990s, debate over the gender concept had widely expanded. Judith Butler's theoretical work (1990) established gender to mean the cultural practices that make sexual natures of all kinds appear to be fundamental, heterosexual, and unchanging. Simultaneously a publishing boom of high-profile volumes began that, over the 1990s, has firmly secured the notion of gender into questions of national or political difference. Other volumes (e.g., Sangari and Vaid 1990, Gilmartin et al. 1994) have linked the gender concept to the problem of colonialism in what have become the fields of postcolonial studies, comparative feminism, and gendered area studies.

2. *The Policies of Gender*

Gender is modern political policy. Presently it forms an element of the post-Cold War global governance goals disseminated through the United Nations, so-called nongovernmental organizations (NGOs), and donor or civil society organizations. This post-1989 neo-liberal gender policy is juridical. It argues that all states should adopt the position that women's rights are universal human rights. Gender as state policy, however, is older and more historical than current rhetoric would have it. In the twentieth century, industrialized and late industrializing states have cast citizenship in gendered terms.

2.1 *Contemporary Gender Policy, Global Governance, Women's Human Rights, 1979–*

The importance of gender as policy emerged in the initiatives for global governance over the last quarter of the twentieth century. It is an aspect of the international human rights law movement. Its cornerstone is the Convention on the Elimination of All Forms of Discrimination against Women (CEDAW), which seeks to abolish 'gender-based violence' and is a 1979 revision of the 1948 Universal Declaration of Human Rights. The United Nations, donor agencies (like the Ford Foundation), and a newly arisen civil society sector began advancing gender-sensitive programs during the United Nations Decade for Women (1975–85) and during subsequent United Nations Conferences on Women, culminating in the 1995 Beijing Fourth World Conference on Women and its resulting 'Platform for Action.' As a whole, these institutions and the World Bank's investments promote the view that gendered difference is an important axis of inequality. Many advocates in the United States blame non-Western states for gendered inequality. They seek to use gender as a development index to force perceived noncompliant states to redress the relative poverty and vulnerability of female citizens. Loans, investment, education, and outreach into semi-official social service agencies are the instruments of global governance. Though a lack of clarity prevails about whether these attempts are effective or a US form of triumphalism, Charlotte Bunch and Hillary Clinton are the movement's best-known leaders.

3. *Historical Gender Policies of Modernizing States in 'East Asia': The 1840s to the 1980s*

The novelty of contemporary uses of the gender analytics tends to obscure the longevity of gender modernization policies throughout Asia-Pacific. Scholars working in the framework of the 'East Asia' area studies during the 1980s and 1990s have established that much. It can be said that colonialism itself advanced the rationalization of gender by bureaucratizing social modernity or (in some cases) by directly exploiting the bodies of women. During the mid-nineteenth and twentieth centuries, the forces of imperialism, colonialism, and sub-imperialism propelled late industrializing states toward expeditious efforts of political modernization and capital accumulation. States pursued this objective in various ways, although interstate relations meant that events in one state (e.g., Japanese imperialism in Korea, Manchuria, Taiwan) contributed to the shape of gender policy in other states.

3.1 *Colonial Gender Policy in Modern Korea*

Between the 1870s, when its traders arrived in Korea's overwhelmingly agricultural economy, and 1945, when Japanese colonial administration evacuated and the neo-colonial United States occupation began, the peninsula took on the classic colonial configuration of a political economy twisted to serve Japanese imperial expansionism. Japan's colonial authorities reordered Korea's rural economy, instituting modern concepts of ownership to expedite taxation. The new system placed tax gathering and relations of production in the hands of a semi-colonial and semi-feudal native elite, 'landlordizing property rights'. This industry led to a widespread shift from peasantry to tenancy as the primary relation of production. Agricultural productivity rose, but so did rural immiseration. Poverty, occupation, and assimilation policies flowered into a widespread licensed military prostitution industry (see Choi 1997). This, and particularly Japanese family law, burdened Korean gender and class relations and helped to shape a male-centered style of nationalist anti-colonial struggle, involving women and men of all classes (see Park 1998, Fujime 1997).

In divided South Korea after the Pacific War, a state-compelled development that Alice Amsden calls 'late-industrializing' (and argues is a global model) reconfigured Korean social relations of gender (Amsden 1989). The incorporated Cold War state

inherited a Europeanized, Japanese, colonial civil code. As Hyunnah Yang has shown, along with the modern legal regulation of domestic relations the civil code supported an imaginary 'Korean tradition' that naturalized female subordination. Consolidation of Japanese domestic civil statutes and modern family law into Korean jurisprudence in the Korean Republic (during and after the partition of the nation) also ratified a gendered modernity, heavily weighted to the nuclear, patrilineal, small family unit. The now constitutional doctrine of patrilineality triggered waves of feminist intervention into state-sanctioned subordination of women and women's labor power under the US-supported military regime (Yang 1998). Feminist and labor movement successes have led to revisions of the family law in 1962, 1977, and 1989. However, the fact remains that the modern state—more perhaps than the dynastic regime—consolidated domestic property, family jurisdiction, domestic labor, and legal claims in the hands of the patriline and restricted the claims of female kin. Little is known of the gendered state policy of North Korea, but it appears to be modeled on that of the People's Republic of China (PRC) during the Cultural Revolution (1966–76).

3.2 Colonial Modernity, Imperialist Economy, National Gender Policy in Modern Japan

Historians are agreed that the Meiji state (1868–1912) was preoccupied with gender policies from the outset of its drive to modernize Japan on the European model (under threat of Western imperialism) (see Bernhardt 1991, Sievers 1983). The Meiji civil code of 1898 ideologically reformulated the patriarchal family and its relation to the state, emphasizing the political obligation of scientific housewifery, or 'good wife, wise motherhood.' Severe restrictions on women's political rights were coupled with the statist argument that the labor of women should be considered a civil service to the nation. Deliberate gender policies like these persisted, toward varying ends, throughout the twentieth century. First, the new state-sponsored industrialization policy willfully and strategically regendered the household division of labor by moving men out of domestic production into heavy industry. Second, policy affecting men and children led to the official drive in the late nineteenth century to 'reshape conceptions of womanhood' (Uno 1991). Fostering smaller family formations, female education, young women's heavy participation in waged light industrial production, instituted bans on female public political participation, as well as campaigns encouraging feminine virtues in household and reproductive labor affected growing sectors of the national population. A twenty-year effort to bureaucratize the policy on women culminated in the 1898 implementation of Japan's prewar civil code.

Capital accumulation through industrial production and constitutional state formation in Japan rested on colonial expansion onto the Asia mainland, into Korea and Taiwan, and eventually throughout the Asian Pacific. Despite its best efforts, the state had never been able to contain female wageworkers from moving into the labor market. As militarization and colonial administration drained off increasing numbers of men into service, state policy began gendering the notion of national sacrifice. Men were to provide military or colonial service. Militarized policy on women sought to rework the family into a feminine sector of the public sphere. The onset of glorification of national motherhood is datable to this era. It resurfaced (in altered form) in immediate postwar policies.

After 1945, state policy sought to emphasize domestic reproduction and super-exploit male labor in an economic drive to recover Japan's regional supremacy under the umbrella of a US-dominated Cold War containment policy. Adjunct to this was an effort to limit female participation in Japan's national labor market while increasing (after 1956) women's responsibility to undertake domestic consumption responsibilities.

As in the Korea case, the history of gender and the nation sometimes precludes an emphasis on the Japanese women's rights movement, to say nothing of a transnationally influential, Japanese feminist critical theory that arose with colonial modernization and state formation. Nonetheless, as Mariko Asano Tamanoi noted in her study of rural women and nationalist ideology, the term 'national woman' is too simplistic and does not convey the full import of gendered social change in the twentieth century (Tamanoi 1998).

3.3 Sub-imperialism, Colonial Modernity, and Policies of Gender Revolution in Modern China

The Chinese record of state-mandated gender policy is intricate. That is due to its enormous size vis-à-vis other East Asia nation-states, its semi-colonial status after 1842, a full half-century of multiply sited civil wars, and the high priority which the Chinese Communist Party accorded to women's liberation. As early as the compromised Republican era (1911–49), the state was initiating gender and development policies that were later absorbed into influential Party state policies associated with Maoism and the revolutionary mobilization policies of the PRC.

National gender policy first appeared in the form of state-mandated reforms of education, female dress, and foot-binding practices. A juridical modernization indebted to both continental European and Japanese models was instituted in the 1929–31 modern civil code and, under the Nationalist or Republican Party

state (1911–49), mobilized women into participatory forms of citizenship. A further link exists between the weakly instituted republican civil code (organized around a liberal divorce law) and campaigns during the 1940s and 1950s to propagate the Chinese Communist Party's Marriage Law (Bernhardt 1994).

The ethos that infused revolutionary gender ideology came from the early twentieth-century Chinese Enlightenment: an anti-colonial, urban, nationalist movement led by modern intellectuals. The Chinese Communist movement, which incorporated feminist themes, was—relative to contemporary states—hospitable to policies that institutionalized women's liberation. But, like other states, women's liberation became an index of national modernity, particularly, perhaps, under Chinese Communism. What most distinguished the gender policy of the early Chinese communist states was their focus on mobilization as a means of institutionalizing political policy and their organization of gender revolution around a Marriage Law that put the conjugal couple at the center of jurisprudence (Gilmartin 1995).

Land reform and class war in the late 1940s and early 1950s and the state policy of rural communization in the early 1960s were no doubt two of the most transformative revolutions of the twentieth century. These revolutions consolidated the gains of Chinese state feminism by placing laws on the books that governed the social labor of women and granted women the rights to own (however briefly) land in their own names (Johnson 1983.) Socialist development policies, which were aimed at consolidation of state power and primitive accumulation for investment in late, socialist industrialization, rested on the nuclearization of family resources in the urban areas. They also proletarianized women and periodically used female labor as a reserve pool. The mobilization of peasant women into agricultural production furthered primitive capital accumulation as well as mechanisms to extract rural capital gains for use in urban development. Nonetheless, recent studies point to the ways that particularly poor peasants took advantage of the modern state institutions to further personal goals, particularly women seeking divorces. The socialist state's welfare policies had a wide-reaching impact on several issues: the gendering of labor, domesticity, sexuality, and demography; civil rights and access to public space; and avenues of upward political mobility.

4. *Economic Liberalization, the Displacement of 'East Asia' as a Region, Gender Scholarship and Transnational Flexible Economies*

Just as historically 'modernization' is usually linked to Europe and the United States in the nineteenth and twentieth centuries, neo-liberal 'globalization' is linked to Asia-Pacific in the last third of the twentieth and probably much of the twenty-first century. Asia-Pacific is a laboratory of post-Fordist flexible capital accumulation inside a post-Cold War international state system. The Asian Pacific roots of this neo-liberal globalization lie in:

(a) the Chinese economic reforms of the 1970s;

(b) the hyper-development of newly industrialized countries (NICs) and city-states (Taiwan, South Korea, Singapore, Hong Kong);

(c) Japanese capital investment in Malaysia and other South East Asian countries;

(d) the rise of flexible Chinese diasporic capitalism; and

(e) US sponsored neo-liberal policies of the World Bank and the General Agreement on Tariffs and Trade (GATT) system.

Within intra-Asian political economies, in so-called transnational gendered labor flows, and outside it in interregional global trade, policy elites in Asia-Pacific states and national corporations are scaling back modernization strategies based on a state welfare logic (see Higgott 1999, Ong and Nonini 1997).

No longer central to development are the projects that had earlier supported the public ideology of a state or nation-typical, modern woman and domestic relations, although the use of maids among the middle class is stabilizing the elite family structure in some regions. It is premature to speculate what specific gendered configurations in subregions and specific locales will emerge in the future. However, gender is becoming a central concept in writing throughout the Asia-Pacific region and the United States. Scholars globally seek to explain how liberalization of economic life affects populations that are now defined in relation to their consumption power or their capacity to be absorbed into the flexible service sector (e.g., tourism, prostitution, travel) as well as their labor power. Heightening class differentials separating consumers and service providers, surging global inequality explained in cultural terms, ethnic and race-coded discriminations, systematic preference accorded flexibility in labor migration, and capital investment patterns across state lines (but within regional cores) are all having an impact on the way that the concept 'gender' (in Chinese usage 'social gender' or *shehui xingbie*) will be employed. Transnational corporations (TNCs) now recruit and market with the concept in mind. New social movement policy strategists, networks of internationalist progressive scholars, United States feminist human rights lawyers, World Bank lending policy makers, United Nations monitors of prostituted labor and infectious diseases: all are incorporating the policy and analytics of 'gender' into their thinking.

Particularly since the finance capital crisis of 1997–8, it has been increasingly apparent to observers that a new regional production of scholarship is on the rise. Produced by diasporic scholars from Asian locales resettled in the metropole, or writing from 'new

metropolises' of Singapore, Hong Kong, Seoul, Jakarta, Tokyo, Beijing, and Sydney, 'conscientized' scholars in the First World, and expatriate Asians in the white nations of Europe and the US, this scholarship is eroding the boundaries of area studies, properly speaking. Whether we are speaking of scholarship on gender inequality which Women's Federation scholars in Beijing produce in Chinese for national circulation, or studies produced in Tokyo and Seoul in English for international dissemination, or the steady translation of mainline US feminist and gender theory to a wide number of gender studies institutes throughout Asia, the full impact of localized scholarship on US-oriented area studies has yet to be registered. The trend toward globalized scholarship is exemplified in the work of the journal *Positions: East Asia Cultures Critique* which publishes research that questions strict national divisions on which conventional area studies have rested and also injects the gender analytics into scholarship. The appearance of pan-Asian or regional cultural studies journals like *Inter-Asian Cultural Studies* (Taiwan), the *Asian Journal of Women's Studies* (Korea), and many others is also blurring the edges of area studies and area-oriented gender studies.

The effort to grasp the implications over the years 1970–2000 of re-regionalization (as well as the rise of flexible capital and gendered consumer markets) is producing significant lines of innovative global scholarship. The concepts of 'transnational Chinese capitalism' and 'flexible citizenship' allow Aihwa Ong, for instance, to propose the emergence of ethnicized capital flows which are not nationally grounded and which rest on the persistent powers of the state, opportunistically taking advantage of state forms (Ong 1999). Modern Chinese transnationalism, its distinctive strategies of capital accumulation, and gender analytics are all being studied empirically. Specialists consider gender as a significant axis among other axes, such as ethnicity, nationality, sexuality, racialization, and caste status. A special issue of the journal *Positions: East Asia Cultures Critique* (1999) on 'Asian Transnationalisms' has highlighted these dynamics in relation to ethnicity and sexuality.

Advocates and critics of liberal globalization alike recognize the enlarged opportunities for public sexual expression opening up in the new metropolises of Pacific Asia. Sexualized and commodified styles of self-presentation open fresh possibilities for new social movements of minority social groups, such as self-styled queers (Ho 1998). Minority sexual communities—gay, bisexual, non-procreative heterosexual—exist in most of the new metropolises. The centrality of the gender analytics to scholarship about these communities and cultural criticism from within them are very clear in queer social, cultural, cinema, and theoretical studies which presume trans-nationality and track how sexual expression is gendered among specific groups of queers (see Manalansan 1997, Hanawa 1994). It is premature to consider how crosscurrents between queer criticism and a retrenched or renaturalized market heterosexuality will play out. One critic has shown (in a field study of young, heterosexual, urban, upwardly mobile, Chinese women) that claims to sexual pleasure have led to enriched lives. Yet, sexual rights have proved consistent with authoritarian forms of governmentality (Erwin 2000).

Another avenue for innovation in gendered area studies of the re-regionalized Asia-Pacific has been the political economy of ethnic coding in intra-national, transnational and trans-border contexts. Diasporic ethnicities such as the Hmong are trans-Asian minorities whose communities are now globalized. Ethnic and national coding have been significant to studies of minority service work in tourism and in gendered, often sexed, labor flows of subaltern national citizens from the Philippines into the boom economies of Taiwan, South China, and Hong Kong. Ethnographers and theorists are pursuing a combined transnational and ethnic focus that promises to clarify the political complexity of the new Asia Pacific and its new social movements.

5. *Conclusion*

The analytics of gender offers increased penetration of markets as easily as it offers progressive scholars another significant index for gauging relative oppression and appropriately representing those who cannot represent themselves. Certainly advertising, cultural markets, and lifestyle expenditure in the ongoing consumer revolution refiguring the region are naturalizing heterosexual gender norms around anatomical sexual difference and the capacity to consume and produce what is appropriate to one's 'nature.' Increasingly feminist critique has taken up the problems endemic in consumer society as well as extending its traditional concern for poverty, anti-sexism, and freedom from reproductive tyranny and disease. Undoubtedly, scholarship will look increasingly at the conjugal pair, partly in order to queer commercial norms and partly to expose the political culture's reliance on a heterosexual mode of consumption.

Another task for gender analytics in Asia-Pacific area studies is to document the vast and increasing rifts that separate women in the same society, as well as the economic differentials between women and men affecting specific sectors. A related project will be to follow up on Li Xiaojiang's comment (2001) that the struggle for gender equality is a long historical struggle for all sectors and subgroups, classes, and class fragments, and should be studied as such. A further probable area of new research may be the political economy of pan-'Asianism' and the cultural production of women in transition in many of the liberalized state economies (Barlow 1998). How the

new social movements engaged in Asia-Pacific (as elsewhere) proceed in the years 2000–10 may have some impact on how the gender analytics is employed in state policymaking and that, in turn, will affect the problems taken up in academic venues.

East Asian Studies: Geography

East Asian studies seen through the prism of geographic analysis is a subset of the larger interdisciplinary field of area studies which developed during and immediately after World War II as the need for understanding foreign areas became more imperative in the US with its growing role in global affairs. Geography, with its emphasis on the study of people and places and their interrelationships, occupied an important niche, especially in East Asia, a region where extensive military operations and commitments were involved and where major perceived strategic interests of the United States were at stake.

1. Changing Views and Realities of East Asia

The study of East Asia from a geographic perspective in recent years has been strongly influenced by events in the region and the unfolding drama and trajectory of development within the regional units—China, Japan,

and the Koreas—as well as by changing approaches and methods within the social sciences. China is defined here in its greater context of the People's Republic of China (PRC), Hong Kong, Macao, and Taiwan. In addition, the shifting global geopolitical and economic trends and realities have exacerbated the challenges to the region and its national units. Meanwhile, area studies as an approach to knowledge has been undergoing far reaching changes as new conceptual trends in the social sciences and humanities have led to new ways of looking at how nations are structured and cultures operate. Thus, the nature of economic and social behavior within the national units has been reexamined in the context of the remarkable economic growth of Asia during the last 35 years and the emergence of East Asian states such as Japan and China as major global economic and political players with increased power.

Paradoxically, while political and military/security issues have made the most dramatic headlines, geography research and study of the region and its subunits has focused mainly on economic, urban, and regional development studies including trade, regional growth, urbanization, migration, and environmental issues (see, e.g., Yeung 1998). Much if not most of this work has followed a well-established and more traditional paradigm of empirically based, positivist work in the social sciences and has employed conventional quantitative and statistical methods rather than more recent postmodernist and qualitative approaches.

2. *New Methodologies and Technologies*

At the same time geographic analysis employed in regional studies of East Asia has begun to embrace emerging methodologies of GIS (geographic information science), digital cartography, and remote sensing from earth satellite and conventional aerial platforms. These emerging methodologies focus on acquiring spatial data on natural and human patterns and phenomena and storing, manipulating, and analyzing these data digitally and numerically. By such means and methods, much larger sets of data can be reviewed and analyzed, which not only permit greater knowledge and understanding, but may result in the development of new approaches to the study of East Asia's geography and new ways of conceptualizing regional and spatial arrangements.

Owing to the newness of these methodologies and data-acquisition sources, their impact and significance continues to evolve in step with ability to comprehend and harness their remarkable capacities in new and innovative ways. One significant trend associated with these technologies is their use in environmental studies and in the interface between human and environmental relations and linkages. While the effects of this trend are only beginning to be seen, given the power and utility of the new tools and methods it is likely their effect will be to encourage more studies that focus on the environment and the manner in which humans organize their economic, political, and social activities in space to respond to the environmental opportunities and realities that confront them. At the same time, given the enormous environmental changes underway and the growing challenge for local and regional environments to support the massive East Asian populations with food, fiber, water, and other essential elements for development, much remains to be done if geographic study in East Asia is to provide timely and valuable service for the social and behavioral sciences (Smil 1993).

3. *Challenge of Regional Diversity*

Another striking reality about East Asia that affects the manner in which geographic analysis is employed is the range of social and economic systems that operate across what is only a partially coherent cultural region. Thus, Japan operates a relatively open democracy and managed market economy. South Korea has followed a similar path with closer relations between government and major private enterprises or *chaebol* (large multifaceted commercial/industrial conglomerates). China, by contrast, is a massive socialist economy in transition that has undergone far-reaching restructuring, in which it has sought to rely on market mechanisms to increase efficiencies in production and output, and to increase dramatically the productivity of its land, labor, and capital resources while maintaining a high degree of political control and considerable economic control. Much recent work in geography is aimed at seeking better understanding of China and its growth and development.

3.1 *Contributions of Asian Researchers*

One of the salient trends of the last two decades in Chinese geographic study is the emergence of a large cadre of young scholars from the region—China, Taiwan, and Hong Kong—who are aggressively engaged in research and who frequently publish the results of their work in English. These young scholars are scattered through Asia, Oceania, North America, and to a lesser extent Europe, but their contributions have been very significant in bringing a Chinese and Asian view coupled with methodological and substantive training in both Asia and the West. This blending of intellectual traditions paired with training in the latest methods and fashions of Western science and social science provides creative and highly innovative approaches to study. It often results in scholars who are based in Western universities but who maintain very close contact with the East Asian setting

and point of origin, and who bring a special insight to bear on the analysis of social, political, and economic issues in the region (Chan 1994).

4. Theoretical Matters and Substantive Studies

Examples of such geographic research on China have centered on analysis of regional development and economic growth, associated with foreign investment as linked to China's recent economic growth and restructuring. Distinctive among the social sciences, economic geographers have centered their work on spatial issues and locational questions related to regional disparities in income, output, investment, and growth processes (Wei 1999). Generally empirical in nature, this work has added to the broader conceptual debate on China's approach and policy to national development and its regional dimensions (Fan 1995). As much of this work has centered on variations in regional growth, it has evolved to look at issues in local and regional development and has explored some of theoretical points that touch on the special nature of Chinese development. Geographers have been especially active in investigating south-east China and the Pearl River Delta region around Guangzhou and Hong Kong (Lin 1997). This work has moved beyond a focus on economic variables and begun to explore issues at the interface of regional and local politics, society, and economy. In this way, it has drawn from theoretical and conceptual ideas within other social sciences and even the humanities.

For example, research in recent years in other social sciences has examined the social/cultural notion of *guanxi* (Chinese for social relations or connections) and its role in commerce and politics. Much has been written on this topic and its more broad and related subject, what the sociologists Granovetter (1985) and Wank (1999) call the 'embeddedness' of private business in social networks and political power. What is this *guanxi* and how does it work? How does it interplay with commerce and politics and where did it originate? Can it be used and linked ideologically with Chinese and Asian thought to create a larger theoretical framework and context associated with Confucian and Asian values? Do these values and patterns vary in different parts of China, and is there a definable geography or spatial pattern of such matters? Related to this is the larger question of the role of the central state in development versus the role of local players and forces, and geography researchers are writing increasingly on the role of local forces and operatives.

Geographic study on this has largely been empirical, and some scholars have taken the difficult path of seeking to understand the commercial linkages between the PRC and Taiwan that transit the Taiwan Straits (Hsing 1998). On the surface such transactions would appear to be straightforward enough—the desire of Taiwan capitalists to minimize labor costs and thereby remain competitive in world markets for their manufactured goods that have a high labor content. Yet the relationships are complex, even among Chinese confrères who speak the same Fujian regional language. The political and commercial systems between Taiwan and mainland China have operated differently for a century if we include the previous period of Japanese colonial rule of Taiwan (1895–1945), and the subtle outward variation in behavior belies the complexity of culture and its interface with commerce and politics. Geographic research on shoe manufacturers, for example, who seek to bridge the gap between Taiwan and the PRC mainland reveals some of the difficulty and offers probing insight into the spatial complexity and significance of regional variation in what Wank (1999) has called the 'commodification of communism'. Such work confirms the murky and conflated relationships of Taiwan foreign investment in China and the linkages between business and politics in Taiwan as well as in neighboring Fujian on the mainland.

Similar work on the Pearl River Delta of the Hong Kong–Canton Region reveals the significance of a political-economy approach to understanding how intimate and intertwined are relationships among foreign investment, economic development and growth, technology and information transfer, and local and regional politics (Leung 1993). Seeking answers and understanding to such processes of economic, social, and political behavior requires a combination of conceptual approaches that may range from the local ethnographic and qualitative to the statistical and quantitative. The resourceful investigator will employ all that have utility and value in achieving better understanding of the particular processes of social, political, and economic change underway in the time and place of her/his study.

Geographic study of Japan and Korea has paralleled some of the same themes discussed for China while also exploring some topics that relate to economic trends associated with Japan's economic growth and global financial role. Geographers have written extensively about Japan's increasingly global economic ties, and much of this work has focused on the tactics and policies of Japan's foreign investment especially as directed toward North America, Europe, and Oceania. At the same time work has been done on the evolving industrial and corporate networks in Japan with reference to small businesses and the dynamics of local, regional, and national forces that drive location and growth. Such research originates in the past growth and emergence of Japan as a global player in the world's economy, and one whose decisions play a mighty role in determining world patterns of manufacturing. Thus, this work links events and trends in Japan to a larger world space economy, and its thrust comes from scholars who have a perspective that extends beyond a commitment to the analysis of Japan as a regional object of study.

Such research provides a more intellectually viable and catholic framework for contemporary area studies (Watters and McGee 1997).

Urban studies on Japan continue to be an important focus of study, and these include more traditional historic studies of cities and their economic and social processes as well as a number of recent studies of specific cities such as Tokyo and Yokohama (Cybriwsky 1998). Similar work is found in Korea. Seoul, as the nation's primate city, dominates as an object of study where the approach of urban biography has been used. This direction builds on traditional approaches in urban geography and continues an important qualitative dimension in urban related research. Knapp (1990) and Gaubatz (1996) have done extensive work in cultural geography that draws inspiration from the landscape and builds upon the intimacy of human activity and landscapes in China, although this is a minor theme in recent Japanese geographic studies. Related to this and historical geography is continuing work on the history of cartography of China, Japan, and Korea.

5. *Geography and East Asian Studies, a Continuing Successful Blend?*

Is geographic research and analysis on East Asia, as a branch of the social sciences, serving its purpose well, and providing creative and thoughtful answers and expositions on salient and significant issues, and matters that should benefit from spatial and geographic approaches to knowledge? In some specialized areas such as aspects of space economy, urban and migration studies, some specific cultural studies, and human–environmental studies, the answer is yes, and there are many good examples of high-quality work done in recent years in China, Japan, and Korea for evidence. On the other hand, social themes and gender studies are few, and geographers have largely ignored urgent political and security issues in East Asia. Are the current approaches, tools, and interests of contemporary geographers sufficient to meet the intellectual as well as policy challenges of contemporary East Asia as an increasingly important component of the world equation for the twenty-first century? Until geographers confront the key issues of geopolitics as well as political economy, it is likely their influence will be muted among social scientists and beyond in the broader arena of academic and policy oriented scholarship. At the same time, given the new tools of GIS and remote sensing that should enable a much more aggressive approach to environmental studies, geographers would do well to exploit that advantage and blend it with related studies in the social sciences to meet the many new challenges of the twenty-first century, as people everywhere cooperate and compete to make the fullest and best use of their environments and resources.

East Asian Studies: Politics

'East Asia' in this article refers to the northeastern section of Asia, known also as 'Northeast Asia,' that embraced the five polities of China, Taiwan, North Korea, South Korea, and Japan in early 2000. For the sake of economy, this article discusses the study of politics in Taiwan as part of Chinese studies and that

of North Korea as part of Korean studies. 'Politics' is a category of human activities concerned with the determination and enforcement of rules governing the assignment of rights and duties to variously classified members of an organization, such as the state. The article discusses, on the basis of a survey of scholarly works published mainly in English, how specialists studied post-World War II politics in the abovementioned five countries.

1. *The Evolution of the Studies of Politics During the Cold War Period (1945–89)*

Several patterns and tendencies, four of which in particular stand out, have characterized the studies of politics in postwar East Asia. First, they have been led by landmark political events and developments, especially in Chinese and Korean studies. Second, American scholars and their scholarship have dominated the field. Third, the majority of the studies have been descriptive rather than theoretical. Moreover, even the few theoretical works have tended to place greater emphasis upon empirical accuracy than theoretical relevance. Fourth and last, studies of politics in one East Asian country have tended to be undertaken without much attention to studies of politics in another country, especially until the mid-1980s. These characteristics are particularly conspicuous in the works published during the Cold War period.

1.1 *The Evolution of Chinese Studies*

For a decade following the end of World War II, there were few social scientists anywhere in the world who were seriously interested in, much less knowledgeable about, modern Chinese politics. In Europe, scholarly interest in China was limited largely to a few British and Dutch philologists and historians, commonly known as 'sinologists.' Chinese politics was a serious concern only to a very small number of social scientists in Japan and the United States.

Japan did have a tradition of social science work on aspects of contemporary Chinese society, including surveys of rural society and economy dating back to the 1930s. The bulk of such work was, however, economic studies by economists in government and academia with only limited and indirect relevance to the study of contemporary Chinese politics. Even in the United States, the amount of scholarly work produced in the early postwar years was quite meager and owed mainly to sinologists and historians, such as John King Fairbank and Karl A. Wittfogel.

Interest in and research on Chinese politics grew rapidly in the subsequent years, propelled by a series of headline-catching events and developments: the unfolding Cold War (1947–89), the Cultural Revolution (1966–9), the emergence and evolution of the Reform regime (1978–present), and the Tiananmen Square incident (1989). These events, especially the Cold War and the Cultural Revolution, gave rise to as highly ideological, and often explicitly partisan, discussions of Chinese politics among social scientists as among policymakers.

In the United States, the Cold War inspired studies with ideological overtones of the doctrinal basis, organizational forms, and political and economic impacts of Chinese communism under Mao Zedong's leadership, often in comparison to Soviet communism. In Japan, ideological concerns divided nearly all China specialists into friends and enemies of the Maoist regime and its policies. In Europe, where the traditional sinological approach was stronger, and in Australia where there was no tradition of East Asian studies, ideological divisions among China specialists were neither as evident nor as serious.

The Cultural Revolution, however, introduced as sharp, or even sharper, ideological divisions among European, especially French, China specialists as among their American and Japanese counterparts. A good portion of American scholarship on the Revolution and related topics was, in fact, deliberately nonideological and analytical. Some works applied concepts associated with modernization theory or elite and faction politics models. These works helped to lay conceptual foundations for future studies of Chinese politics to build on.

The reforms undertaken by the Deng Xiaoping regime in the late 1970s and 1980s led to the 'opening' of China to investigations by foreign scholars, encouraging less ideological and more analytical studies of Chinese politics. This was true for works by European as well as American and Japanese scholars.

Changes in American scholarship were particularly notable. First, the range of topics chosen for investigation vastly expanded. Elite and faction politics continued to attract scholars' attention, and so did work on political culture in the tradition of modernization theory (e.g., Pye and Pye 1985). Such studies, however, were no longer the mainstream of American scholars' work on Chinese politics but were increasingly overshadowed by works on the Chinese bureaucracy and policy making (e.g., Lieberthal and Oksenberg 1988), local politics, rural industrialization, special economic zones, and the military.

Some scholars borrowed terms and concepts from works on Eastern European politics of the period, such as civil society, public sphere, and the state. This practice paved the way for more explicit and systematic comparisons of political and economic reforms in China and Eastern Europe to be undertaken in the 1990s. Also worth noting are the several revisionist studies of Chinese–United States relations in the early phases of the Cold War that relied on newly available archival and biographical sources.

Many of the changes in American scholars' work noted above were replicated in those of Japanese

scholars. Above all, the heavily ideological and partisan overtones that had characterized much of the work done in the heyday of the Cold War dissipated, as more and more Japanese social scientists began not only to visit China for fieldwork but also to collaborate with Chinese scholars.

Even more dramatic and significant was the change in the way Chinese intellectuals thought about and discussed Chinese politics. This was an integral part of the sweeping transformation of the intellectual environment of Chinese society, especially in Beijing and other large cities. Pro-reform, pro-democracy scholars, writers, and journalists set up clubs, salons, and seminars some of which began to publish journals and books, such as the *Journal of Dialectics of Nature* and *Towards the Future* book series, both edited by Jin Guantao and his colleagues (Gu 1999). The book series featured translations of Western social science works by, for example, Max Weber, Robert Merton, Kenneth Arrow, Cyril Black, and Alex Inkeles. The activities of these groups presaged the emergence in the 1990s of a new generation of Chinese students of Chinese politics who were mentored in Western-style social science theories and methodologies.

The process of the democratic transition in China, however, was abruptly interrupted in 1989 by the Tiananmen Square incident. The sensational event generated a spate of studies of the nature and problems of the democratic polity and civil society that had emerged under the Reform regime. In the United States alone, some two dozen books on the subject were published in the decade immediately following the event.

The glare on goings-on in mainland China had left 'the other China,' or Taiwan, nearly totally in the shadow throughout the Cold War period. The only notable exception was a modest amount of work on Taiwan's 'economic miracle.' It was not until the mid-1990s that serious scholarly work on the reform and democratization of Taiwan (which lagged behind mainland China studies by nearly a decade) began to appear in print in the United States and elsewhere.

1.2 The Evolution of Korean Studies

Having been under Japanese colonial rule since 1910, Korea had no viable native academic community at the end of World War II. Moreover, the peninsular state was immediately divided into antagonistic halves amidst the rising tide of the Cold War, each governed by a highly authoritarian government. While a Korean Political Science Association and a Korean Association of International Studies were founded in South Korea in the mid-1950s, it was mainly United States-based scholars who pioneered studies of South Korean politics until the early 1980s.

Most of these scholars focused on topics related to one of three broad subjects: the Korean War and South Korea–United States relations, the authoritarian regime and the democratization movement, and the rapid development of the South Korean economy. The first type of work is represented by Cumings' two-volume study (1981, 1990) of the origins of the war, the second type by Henderson's work (1968), and the third type by Amsden's (1989).

In the 1980s, studies of Korean politics by Korean scholars began to be published in South Korea. Most were historical and normative accounts of Japanese colonial rule and post-independence politics under military rule. The historical and normative emphasis in the studies of politics in the post-independence period reflected the frequent, and almost wanton, amendments of South Korea's constitution and electoral laws. Apparently for similar reasons, Marxist and other radical theories, such as dependency theory, were popular among Korean scholars.

Little was done on politics in North Korea, obviously due to the nearly total absence of reliable information on the subject. Suh's study (1988) of the lifelong leader, Kim Il Sung, was one of the few valiant attempts to understand and explain the politics of the 'hermit kingdom' of this period.

1.3 The Evolution of Japanese Studies

Unlike either China or Korea, Japan entered the post-World War world with a substantial community of social scientists with its origins dating back to the late nineteenth century. The Japanese Political Science Association (JPSA) was founded as early as in 1948. The best known among its early members turned their attention to the causes and consequences of prewar and wartime Japanese 'fascism.' Maruyama's work (1963) exemplifies this line of investigation.

By the mid-1950s, some Japanese political scientists began to study Japanese politics during the Allied Occupation (1945–52) and early post-Occupation periods. The subjects of these studies included the evolution of the Occupation authorities' policies, the Japanese government bureaucracy, parliamentary and local elections, public opinion, and social movements. The first major fruit of these efforts was a symposium published in 1958 under the title *Gendai nihon no seiji katei* (Political Processes in Contemporary Japan).

By comparison, studies of Japanese politics in the early postwar period by American and other foreign scholars were more narrowly focused on particular Occupation policies, such as the revision of the Meiji constitution, the purge of war criminals, and the land reform. By the early 1960s, however, the field of Japanese studies had come to be dominated by works based on and espousing modernization theory, as exemplified by the half-dozen edited volumes published by Princeton University Press in the mid-1960s to the early 1970s under the rubric of the theory. From this point onward, American scholars and their works inspired and guided studies of Japanese politics by Japanese scholars.

Research on Japanese voting behavior, for example, relied largely on theories and methods developed by American political scientists, notably by the so-called Michigan school. The Japan Election Studies Association, founded in 1981, inherited and perpetuated this tradition. The dominant influence of American scholarship was also evident in the study of the Japanese bureaucracy and policy making that gained great popularity following the publication of an edited volume on the subject in the United States in the late 1970s (Pempel 1977).

A major landmark in this line of work was the publication of Johnson's (1982) detailed study of the Japanese industrial and trade policy bureaucracy. This work triggered an international controversy on the nature and role of 'industrial policy' and the 'developmental state,' and inspired a series of case studies on related subjects. These included works on the relevant experiences of other East Asian countries, looked at deliberately and systematically in comparative perspective, thus giving rise to a new field of 'East Asian' studies (e.g., Haggard 1990, Wade 1990).

2. *Studies of East Asian Politics in the First Post-Cold War Decade*

The four tendencies or patterns that characterized studies of politics in East Asian countries during the Cold War period generally continued into the last decade of the twentieth century. The descriptive and interpretive emphasis, however, somewhat diminished and gradually began to yield to a more analytical and theoretical concern, consistent with a trend in American political science in general.

2.1 *The State of Chinese Studies*

There was a global shift in the study of Chinese politics in the post-Cold War decade from ideological and normative to empirical and theoretical interest and concerns. Foreign scholars now had and availed themselves of opportunities to visit and engage in fieldwork in China. Even Russian scholars began to study and write about aspects of Chinese domestic politics and foreign policy, although much of their work remained historical and philological rather than analytical and theoretical. Nonetheless, American scholars and their work not only continued to dominate the field but to do so more thoroughly than before.

American scholars' interest in elite and faction politics at the top of the Chinese political hierarchy held up during the 1990s (e.g., Baum 1994). So did their interest in Chinese-style bureaucratic politics that had emerged in the 1980s. The scope of their interest, however, substantially widened in the 1990s. Detailed and systematic investigations began to touch the politics of economic development and industrialization, the environmental crisis, and the military establishment and security policy.

Particularly noteworthy was the rapid growth of a theoretically informed empirical literature on regional and local politics and political economy. In addition to a number of detailed case studies undertaken by independent scholars, collaborative research projects jointly sponsored by Chinese and American organizations began to appear by the early 1990s. The Shandong Field Research Project of the Shandong Academy of Social Sciences and the Committee on Scholarly Communications with China is a good example. The University of Michigan–Peking University project is another.

The use of large-scale surveys to collect sets of data amenable to systematic statistical analysis was another new and significant development in Chinese studies of the 1990s. The Michigan–Peking joint project mentioned above, for example, involved such a survey and generated such a data set (Jennings 1997, Manion 1996). Moreover, Chinese scholars participated increasingly in the design, as well as the implementation, of a survey project and the analysis, as well as the collection, of the data.

More often than not, 'collaboration' between American and Chinese scholars was apprenticeship of the latter to the former in practice. It occurred in the context of a rapid increase in the number of Chinese scholars and students at American universities and in that of publications co-authored by 'senior non-Chinese and junior Chinese scholars' (Unger 1994, p. 181). By the end of the decade, however, some of these Chinese scholars began to engage in independent research and publish its results in sole-authored works, often in English.

Consistent with one of the four tendencies of East Asian studies in general noted earlier, the reversion of Hong Kong to China in 1997 spawned a spate of works on the event by both Chinese and foreign scholars. Most works predicted a gloomy future for the economy and, especially, politics of the island after the reversion, some based on elaborate theoretical models (e.g., de Mesquita et al. 1996). The reality, however, turned out to be more complex and mysterious than could be predicted by currently available social science models.

Studies of Taiwan politics in the 1990s were also characterized by increasing numbers of native scholars apprenticed to American scholars. Both the mentors and students tended to focus on the marketization of the island's economy and the democratization of its politics and publish increasingly sophisticated studies of the subjects.

2.2 *The State of Korean Studies*

American and other foreign scholars' interest in the Korean War, democratic reform, and economic development in South Korea continued well into the

1990s. In addition, North–South relations and the prospects of reunification became subjects of serious academic interest following Kim Il Sung's death in 1994 and, especially, the election of Kim Daejung as the South Korean president in 1997.

By far the most remarkable development in Korean studies in the 1990s was, however, the emergence of a substantial number of Korean specialists of Korean politics. Even more than its Chinese counterpart, this new generation of Korean political scientists was under the powerful influence of American political science. A 1995 survey of the Korean Association of International Studies' 1300 or so members revealed that nearly half had earned their doctoral degree at North American universities, as compared to about one-third who had done so at Korean universities. By the late 1990s, American-trained scholars had come to dominate Korean political science, including the field of Korean politics, not only numerically but also in setting research agendas and defining what was good research. The American influence was especially great in works with a strong theoretical and/or methodological bent.

North Korea remained as closed to and hidden from scholars' scrutiny even after Kim Jong Ill took over the country's political leadership as it had been under his father's iron-fisted rule. There was no genuinely academic research on its politics, or even its economy and society, inside North Korea itself. There was some outside, especially in Japan and the United States, but it remained, as the reviewer of an edited collection of research papers (Suh and Lee 1998) commented, a practice 'reminiscent of medieval scholasticism or ancient Chinese oracle-bone divining' (C. K. Armstrong 1999 in *The Journal of Asian Studies* **58**: 224). North Korean politics in the last decade of the twentieth century thus remained as inaccessible as before to scholars either inside or outside the country.

2.3 The State of Japanese Studies

Research on the Japanese national bureaucracy and policy making that began to attract concentrated academic attention in the 1980s continued to expand in the 1990s. The objects of detailed investigations were no longer limited to industrial policy, as in Johnson's (1982) study, but expanded to include many others, such as fiscal, construction, telecommunications, health, welfare, science and technology, environment, and defense policies. Attention expanded also to include, in addition to the role of the central and local government, those of labor, the mass media, and ethnic minorities.

Moreover, work by Japanese and foreign scholars became increasingly theory-conscious and methodologically sophisticated. Nearly all such work, however, relied on theories, models, or methods developed by American scholars, such as rational choice, new institutionalism, agency, and path dependence (see *Political Science: Overview*). Among those studying Japanese electoral politics and voting behavior, for example, the use of not only the least squares and maximum likelihood methods but multinominal probit and logit models became increasingly commonplace.

Some American comparative politics scholars with expertise in the field of American or European politics undertook research and published results on one aspect of Japanese politics or another (e.g., Katzenstein 1996). Theoretical and methodological Americanization was thus well advanced even among Japanese political scientists, the overwhelming majority of whom, unlike their South Korean counterparts, not only did not hold a doctoral degree from an American university but, in fact, did not hold one from any university.

2.4 The State of Comparative Studies of East Asian Politics

During the 1990s, the economic and political reforms and transitions in China began to be systematically compared to those in Eastern Europe. Hungary in particular was chosen as China's European counterpart. Some studies attempted also to compare transition processes in Eastern Europe on the one hand and East and Southeast Asia on the other. Yet others compared reforms in mainland China with those in Taiwan and Russia or those in Taiwan and South Korea. One study compared the relationship between mainland China and Taiwan with that between North and South Korea.

Aspects of Japanese politics were often compared to those of American politics. For example, one edited book compared policy processes in the two countries from a rational choice theoretical perspective, while another compared the parallel processes of globalization and decentralization in them. More commonly, however, Japan was subject to multilateral, rather than bilateral, comparisons, especially with other advanced industrial countries. For example, the causes, processes, and consequences of market liberalization and deregulation in Japan were compared in one study with those in the United States and Western European countries and, in another, with those in France, Spain, South Korea, and Mexico. Likewise, Japanese environmental policy, labor politics, and judicial system were compared with those in North America and Western Europe.

Studies of international relations in East Asia became theory- and methodology-conscious more slowly than comparative studies of domestic politics. By the late 1990s, however, there had appeared some work that applied a sociological evolutionary model to Chinese foreign policy, a model of linked international–domestic negotiations, known as two-level

games, to Japanese–United States trade negotiations, network analysis to Japanese relations with its Asian neighbors, and so on. Some work on security relations among East Asian and, more broadly, among Pacific Rim nations used the international regime model that had gained considerable popularity among American international relations scholars in the mid-1980s.

At the turn of the millennium, the impacts of unexpected events on the study of politics in East Asia did not appear to have diminished or to do so in the foreseeable future. Nor did the pace-setting role of American scholars, especially in theoretical and methodological innovations. On the other hand, the pull of the empirical in studies concerned with the development of empirical theory of politics did seem to have diminished somewhat, while the pull of the theoretical had become somewhat stronger, in large measure as a result of the powerful influence of American political science. There was also growing interest in comparative studies of selected aspects of politics in two or more East Asian countries or those in them and in other areas of the world. These features of the field are likely to persist into the first decade of the new millennium.

East Asian Studies: Society

For most of the past 1,500 years East Asia has consisted of three principal societies—China, Japan, and Korea. Each developed with little impact from outside until the 1840s, except frontier conquerors such as the Mongols and Manchus, who remade the state somewhat but the society very little. Japan and Korea borrowed from China as their model, but interaction was irregular. Distinct domestic forces, including Japanese community orientation and samurai loyalties, evolved independently. With strong state traditions and complex organizations, East Asian societies retained their independence and national identities despite powerful influences of the more developed West in modern times. Except for the interval in the first half of the twentieth century, when Japan imposed colonialism and the 'East Asian Co-Prosperity Sphere' on the rest of East Asia, it was not until globalization in the 1990s that economic, political, and even cultural barriers fell sharply in this region. After Japan reformed under the US Occupation and China borrowed from the Soviet socialist model, both societies turned away from their mentors and even basked in claims of uniqueness. Although such claims hid the universal effects of modernization, state-led efforts to sustain idealized social practices lasted a long time and, to a degree, continue. The past still weighs heavily amidst new commitments to internationalize to meet global competition.

The study of societies in East Asia crosses disciplinary boundaries. Given the importance of state policies, it is not surprising that political scientists often play a large role, treating values through political culture, social change through campaigns and policy initiatives, and civil society through state controls. Historians are notable too; after all, links between past and present figure in many explanations of social

problems and successes. Anthropologists are in the foreground in the many analyses of family and community, often central even in discussions of modernization. While sociologists until recently have counted as but one part of a large mix of researchers, they have gained prominence at the extremes: articulating the models of development that have worked in the region and exposing the serious social problems that threaten further development. Their research, along with historians in the 1960s–1970s, highlighted preconditions for modernization, along with political scientists in the 1980s and 1990s, analyzed social movements and values, and together with anthropologists of late has focused on the social exchange and networks that allow informal ties to prevail over formal institutions.

Transformation in East Asia rarely was imposed from outside or reflected domestic class struggle. Administrative continuity under Confucian principles allowed top-down change to dominate. Over time, three transformative forces began at the top and were redirected from below. Bureaucratization occurred as at first itinerant officials such as Confucius in the sixth century BC offered their services and later powerful emperors or shoguns built multilayered staffs. This process drove the spread of male literacy and examinations in China and Korea, as public service became the source of honor and often wealth. It also transformed feudalism in Japan as vassals learned to serve their lords in administrative tasks. Yet, leaders relied on moral suasion and community self-administration, keeping the size of the bureaucracy down.

Urbanization spread, beginning with Chinese walled cities as outposts of administration. The role of these cities changed as they gradually reorganized within regional networks of cities linked by numerous rural periodic markets and legally unfettered migration. Controls in Japan were tighter, but when *daimyo* accelerated the concentration of samurai in castle towns as warring states gave way to economic competitors, Japan's urbanization after 1600 far overtook that of China. Eased by coastal transportation, a national market ensued. While intra-regional ties as well as global ties were curtailed in East Asia, strong state support and growing commercialization made Edo (Tokyo) and Beijing the world's largest cities in the eighteenth century (Rozman 1974).

Confucianism also was embraced at the top and then spread widely through education and family-based rituals, guiding mass as well as elite social practices in scattered communities. There was no religious hierarchy. Although rice cultivation required village cooperation, the family was relatively free to pursue opportunities in landownership, commerce, or education except for limitations in Japan on social class mobility. In China, the population climbed to 400 million or nearly a third of the world's total in 1850. In Japan, with about one-tenth as many people, decentralized rule through more than 250 domains spurred regional competition, allowing some domains to move ahead in development. Four led in seizing power soon after the US forced open the country and in centralizing Japan under the emperor through massive reforms that resulted in rapid modernization. A social transformation came from part of the old elite inspired by a new nationalism. Studying which of the leading industrial countries excelled in each area, they borrowed widely, abolishing closed social classes, pursuing universal education, and building a national bureaucracy based on a modern university system with rigorous entrance examinations. Free of the rigid imperial Confucianism in China, Japan could draw on tradition flexibly to meet the challenge of the West (Rozman 1991).

As precocious as East Asian societies had been—with China in the forefront of global development from 500–1500 AD, and Japan and Korea gaining in dynamism—they lacked some forces that enabled the rise of the West (Rozman 1981). In long-lasting dynasties, each was ruled for continuity and stability with little impetus from foreign trade or thought, religious minorities, or intellects that questioned Confucianism. Once obliged to change, however, Japan and later China and Korea could tap some promising traditions. Bureaucracies of the educated elite were useful in latecomers to modernization catching up via reforms from the top. Urban and commercial traditions nurtured an entrepreneurial spirit. Family initiative and paternalistic organization reached across the population despite traditions of deference to the state, respect for elders, and subservience of women that limited the scope of change. In Japan, habits of loyalty to lords proved convenient when new leaders pursued reform. In China it took longer to activate and unite challengers to authority.

Japan's transition was fastest, relying on more intense bureaucratization, higher rates of urbanization, and a combination of Confucianism and the samurai code of obedience and honor (Black et al. 1975). While Japanese society experienced most of the changes usually associated with development, there were important differences (Dore 1967). Administrative guidance at crucial times accelerated modernization and left society more vertically organized and dependent. Recitation of the imperial rescript on education inculcated a sense of duty rather than a questioning civil society. The decision in 1898 to model the civil code on samurai family ideals reinforced a patriarchal family intended to restrain deviance. The state took a harsh stand in the face of social problems such as tenant disputes and urban riots, stressing an ideology of harmony and reliance on go-betweens in conflict resolution. It turned to repression to counter the popularity of socialist ideas. As nationalism fueled wars and colonialism, the state asserted new powers, for instance, organizing ward associations for surveillance and mobilization. Loyal conscripts and diligent workers made success possible

in building a centralized, industrial power able to dominate Korea and move ever more aggressively against China. Yet, an emerging middle class was ready for reform.

As the imperial center in Beijing's Forbidden City retarded reform, Chinese society failed to modernize. It took much longer for alternative power centers to emerge, and they were left divided by warlordism across a vast country. After imperial examinations were ended in 1905 literacy rates stagnated despite the appearance of modern schools. Treaty ports and the sudden rise of Shanghai as the leading city gave foreigners high visibility, but failed to spur urbanization. Criticisms of Confucianism as a cause of backwardness reinforced attacks against female foot-binding, elite cultural aloofness, and growing inequality in the villages. Japanese aggression plunged the country into war, exacerbating social problems. Accustomed to regarding their country as the center of the world, Chinese searched for a new source of pride. Communists rode the coat-tails of nationalism and land reform to power.

The period of 1945–55 shifted the direction of social change in each of the East Asian societies. Defeat exposed the falsity in wartime rhetoric to Japanese and brought support for many of the reforms imposed by the US Occupation. Policies to create a democratic society included land reform, coeducation, increased equal rights in the family, decentralization, and freedoms for the society in dealing with the state. Although Japanese ways of implementation soon limited the impact of some of these changes and elements of wartime centralization led in the recovery, the results were far-reaching and favorable for social harmony and national development. China's communists were far more radical, aggressively targeting reputed class enemies in land reform and urban reorganization. They stifled traditional society and sprouts of capitalism as the reach of the state extended downward. Yet, the enormous scale of the society and the limited modern resources available to the state forced compromises. At first, these were promises of gradual application of the Soviet model such as collectivization. Later, even after many excesses of radicalism, they were impatient calls for more extreme changes to compensate for what was missing.

Postwar development started as top down in all of the East Asian states except Hong Kong under British administration. Taiwan started with tension between the newly arrived mainlanders and the local residents who had fared better than Koreans under Japanese rule. Yet, reforms gave scope to a dynamic society as entrepreneurs expanded family enterprises and US-educated professionals brought high-tech exports to the fore. In South Korea a strong state at first stymied the business community, but then colluded with a small number of *chaebols* to promote rapid growth. Of course, the top-down approach went furthest under communism: in China, where the Soviet model was applied in the 1950s, and in North Korea, where more extreme social mobilization and isolation remained unchanged.

The Japanese postwar model of modernization inspired the rest of the region to double-digit growth. Three types of 'Confucian capitalists' rose to the fore. First, were the elite officials chosen after examination competition to the best universities and working long hours while their wives devoted themselves to a supportive home and education of the next generation. Second, were the salarymen whose entry into large corporations rested on a similar background. Companies fostered lifetime employment through seniority wages, small work groups that socialized together, and inculcation of identity to company rather than to profession. Third, were small family enterprises, which even in Japan employed a disproportionate number of people. This model succeeded as long as young people gave up their adolescence for rote memorization, women accepted brief working careers as office girls before marriage, and salarymen gave priority to company over family and leisure (Rohlen 1989, Brinton 1993). It benefited from widespread belief in the fairness of exams for social mobility and in the existence of a middle class seen as embracing 90 percent of Japanese.

As rates of growth slowed and productivity became increasingly dependent on creativity, Japanese lost confidence in their model. Young people became engrossed in pop culture, the burden of one of the world's most rapidly aging populations raised new demands for social welfare, women sought careers, and men preferred leisure. Society was converging with the West. The Japanese media touted the urgency of a third wave of reforms comparable to those of the Meiji era and the Occupation. Yet, vested interests blocked decentralization as well as other means to far-reaching reform. 'Internationalization' remains an elusive ideal for people used to all-encompassing in-groups rather than individualism (Sugimoto 1997).

Under communist rule, life in China was jolted by a quarter of a century of social experimentation. Starting with land reform, all citizens were assigned class labels that determined their opportunities in life and left them vulnerable to periodic campaigns and collective punishment. In the Great Leap Forward, people's communes for a time even threatened family life with collective day care and mess halls. Extreme forms of thought control relying on Mao's little red book and on sending officials and intellectuals to the countryside for re-education accompanied the Cultural Revolution. The result was a dossier society, where criticism and self-criticism in small groups politicized daily life. Yet, despite forced relocation of millions of teenagers from the cities and the havoc in education from attacks on experts, conditions of life and work were mostly frozen. Workers were assigned an organization claiming broad control over all aspects of life with little hope for mobility (Walder 1986). Peasants could not

leave the commune after urban–rural differences became fixed. Some indicators such as life expectancy and literacy improved rapidly, but urbanization stalled. Ideological claims to be building a pure socialist society in contrast to Western capitalism and Soviet revisionism were based on concealment of social problems and arbitrary authority. When Red Guards were unleashed to beat their teachers and denounce their parents, it appeared that campaigns against Confucianism were in fact reversing Chinese traditions. In fact, most people coped with pressures from above by turning to family for support. Without much modernization of life or, in rural areas, support from the state, Chinese retained many traditional attitudes (Parish and Whyte 1978).

From 1978, the Chinese mainland turned to a different model of development already successful in Taiwan, Hong Kong, and Singapore (Orru et al. 1997). To some extent, this resulted from the pragmatism of leaders who had suffered through Mao Zedong's radicalism and were now bent on winning popular support and catching up. Even more, it was a tribute to the resilience of Chinese society. As commune controls were relaxed, villagers reinvigorated the family farm, then seized opportunities to develop township and village enterprises, and finally flocked to the cities as the 'floating population' ready for any onerous job even if the state forced them to accept a temporary status without ordinary benefits. The state favored coastal areas, initially in the Southeast, with special economic zones (Solinger 1999). Not only did inequalities across China widen abruptly, many social groups felt unfairly treated. Personal connections, including bribery, determined life chances for many. Eager to sustain the monopoly of the communist party and hostile to a free press and independent judiciary, China's leadership failed to address problems of corruption. As society became increasing materialistic, it also lost more of its spiritual moorings. While some flaunted their new wealth, others searched for new values in the West or in religion. The state had some success in countering this with nationalism, portraying China as long humiliated by the West and newly contained by US hegemonism.

After social class labels were dropped and millions were rehabilitated, Chinese regained many freedoms despite some significant limitations. With the end of rationing and easier movement, urbanization doubled. Authorities sought to channel part of the influx into small cities or townships. With the return of competitive examinations, a meritocracy re-emerged and bureaucracies became more technocratic; yet power in some localities rested with party leaders who behaved as petty tyrants. Barriers to markets were dropped, and entrepreneurship flourished. Workers could now move from one job to another, but the state continued to provide loans to state-owned enterprises deeply in debt in order to limit layoffs and demonstrations by workers and pensioners whose housing and other benefits depended on these firms. The state sought to channel interest groups, authorizing professional associations and trade unions subject to its influence. Scared by the large demonstrations led by students in 1989 and by the example of the Soviet Union, China's communist party allowed more safety valves in popular culture and materialism while putting the lid on a civil society. Ethnic minorities, which were concentrated mostly in the west and south, were not much assimilated. Outnumbered ten to one by Han Chinese, they were no longer subject to the decimation of the Cultural Revolution and allowed to revive many customs as long as no political organization posed a challenge. Contradictions mounted between rising middle class aspirations in coastal urban areas and local corporatism in which networks linked to officials protected business arrangements.

Hong Kong, Taiwan, and Korea influenced China not only by their own ascent as middle-class societies, but also by their transfer of business practices through direct investment to nearby regions of the mainland. Foreign firms spread new management practices—a sharp shift from the inefficient socialist egalitarianism and clientelism in the factory. For many young migrants, exploitation in the form of long hours and few benefits took its toll quickly, but an endless supply of surplus labor from the countryside was ready to replace them. Multinational corporations spread high-tech business as well, drawing many urban professionals into the information age. After television had spread rapidly and popular culture was bringing Taiwan and Hong Kong together with the mainland in Greater China, the Internet became the new force of internationalization. Yet, in a population nearing 1.3 billion in the year 2000, over 80 percent remained well removed from a modern lifestyle. For most of rural and inland China, state-controlled television provided the main source of internationalization. A wide gulf still separated urban and rural. Despite stringent family planning since the 1970s when the state imposed a one-child policy, later relaxed to permit two children in some rural families, the workforce continued to grow so fast that only a high economic growth rate could meet the need for jobs. A return to household and community control of labor exposed the inferior status of women. So, too, did the struggle to have a son in the countryside. While all over East Asia aging populations and low birth rates were threatening to impose a great cost in social welfare, the costs in China would come later but with even less of an economic cushion from national pension and healthcare systems.

In the year 2000, contrasts abound in East Asia. In North Korea years of famine and total isolation from the outside leave a totalitarian society in desperation. In the Pacific coast megalopolis dominated by Tokyo high incomes bring many of the problems of affluence. Except for Koreans brought to Japan before 1945 and ex-patriots in Hong Kong after it was transferred from British rule, few foreigners live in any of the East Asian

societies. While guest workers on a small and regulated scale have begun to come to Japan, Taiwan, and South Korea to fill the dirtiest jobs, they are outsiders. Disparities slow regionalism as well as globalization. Calls for a common identity based on Confucian heritage or Asian values confront distrust left by Japan's insensitive handling of its legacy of war crimes and China's nationalist pressure to regain Taiwan and expand its power without assurances of democratic evolution.

Recent research explores the impact of accelerated globalization on East Asian societies. On Japan and Korea, domestic and foreign experts warn that a new model of development is required. They show limitations in educational creativity, bottom-up entrepreneurship, and competition free of administrative guidance. On China, foreign specialists are split between those who recognize the unexpected adaptability of a communist-led system still able to achieve high growth rates after the Asian financial crisis and those who point to mounting frustration among farmers and workers in an era of unbridled exploitation over much of the country. Both sides have come to recognize a model of family-based enterprise through 'Greater China' challenged by both the larger-scale and more transparent operations of a new era and the lingering fetters on initiative left in West China and other areas bypassed by the recent dynamism.

On the one hand, borderlessness should bring high-tech urban agglomerations such as Beijing through Seoul to Tokyo or Taipei-Hong Kong-Guangzhou. On the other hand, civil societies remain weak, and state power combines with deep historical scars to make nationalism strong. New-age materialists are succeeding older generations socialized to forego self-gratification in times of far less modernization. As dating and divorce spread, single-child families are challenging traditional solidarity. Organizational paternalism with lifetime employment is fading. Still trying to guide social change, states face a powerful combination from bottom-up social forces inspired by global information and linked to the global economy. While many Confucian elements endure in social life, the challenges to top-down control are greater than ever. The need for deeper research on what occurs behind formal institutional facades is also greater than ever. While scholars have extended empirical studies and are armed with more theoretical models, there is still a dearth of research that reveals the hidden mechanisms in societies still not known for their transparency.

Eastern European Studies: Culture

Culture can be treated as a distinct object of study. For instance, literature and art are usually understood as expressions of 'high culture,' while the economy is typically studied as something apart from culture. Culture also is used to differentiate groups. Nations are not only political categories, but they are distinguished by language, ways of life and interpretations of the past. Some argue that to explain social life at all, one must understand meanings in everyday life, or the culture of a place and time. Finally, culture is fundamental in social inquiry itself. It is embedded in the constitution of the objects of our inquiry (Calhoun 1995, pp. 61–6). All of these meanings of culture inform this entry, but the final sense of culture shapes its overall architecture.

The notion of 'Eastern European Studies' should be understood as a regional theme in the more general enterprise called 'area studies,' that interdisciplinary

study of a region's languages, cultures, histories, and institutions. This particular form of scholarship achieved great prominence in the USA during the Cold War, during which a new linkage between Western geopolitics and scholarship was cultivated. The American government sought expertise about other parts of the world in order to aid its struggle against communism's spread. Consequently, it subsidized research and training in area studies across the world's regions.

Combining Western geopolitical aims with scholarly work was relatively more compatible in studies of Eastern Europe and the Soviet Union than of other world regions. During and after World War II, the Soviet Union expanded its borders to include Estonia, Latvia, Lithuania, Western Ukraine, and Belarus, while communists took power in other parts of Eastern Europe—East Germany, Poland, Hungary, Czechoslovakia, Romania, Bulgaria, Yugoslavia, and Albania. Many political émigrés from these countries could be found among the West's experts in Eastern European Studies. Despite the political associations of exile and state sponsorship, Eastern European Studies enjoyed relative autonomy and scholarly growth through its location within various disciplines. After communism's collapse throughout the region, Eastern European Studies no longer faces such a direct and obvious political implication. It does, however, face a challenge of coherence and other problems associated with culture's place in disciplinary practices.

1. *Eastern Europe as Cultural Category*

Eastern European Studies has its antecedents in various forms of civilizational study, most notably 'Orientalism.' Like Orientalism, area studies expertise tends to be organized through networks of knowledge production grounded outside the region. While the Cold War inspired American area studies projects, an East European focus could build on an earlier West European invention. During the Enlightenment, West Europeans understood this region, then including Russia, as neither Orient nor Western, a place filled with contradictions whose coherence a 'European' gaze could not recognize (Wolff 1994, Gal 1991).

This combination of Western proximity and 'backwardness' has shaped much of Eastern European Studies. One enduring debate asks whether Eastern Europe's indigenous social relations or its trade relations explain its economic underdevelopment over the last 400 years (Chirot 1989). Despite its economic trajectory, East European art, music, architecture, and literature have thrived, leading some to identify modernity's disarticulation as a regional distinction (Wandycz 1984). These accomplishments lead others to argue that Europe itself should be understood as much from its east and especially its center as from its west (Sayer 1998).

Eastern European Studies has not only been cultivated in the West. For instance, the Soviet Union had its own complement of area studies. Eastern Europe was particularly important in this array given the role post-World War II Eastern Europe played, until *perestroika*, as a *cordon sanitaire*. Within Eastern Europe, however, the region's area study is not well developed; the region is rarely articulated as a category of cultural imagination. East European diversity has invited much finer breakdowns.

Most significantly, the region's imperial heritage is diverse—with the Ottoman, Habsburg, Russian, and Prussian empires shaping the region's long nineteenth century, with enduring effect. The 'Balkans,' territories of the former Ottoman Empire in Southeastern Europe, have remained an important regional category throughout the twentieth century; with war in the 1990s, the term gained new cultural power (Todorova 1997). Those from the Western-most parts of the region also took the area's diverse imperial legacy as a starting point for their contemporary critique of Soviet domination, arguing that communism ill suited East Central Europe, with its more developed civil societies (Szücs 1988). Some resist Cold War categories altogether and argue that East Central Europe's boundaries should move into Soviet space, to include the lands of the fifteenth- and sixteenth-century Polish-Lithuanian Commonwealth (Magosci 1993).

There is no simple cumulation of scholarly competencies in Eastern European Studies. There has been no regionally hegemonic language, like Russian was in the Soviet Union. Depending on the boundaries one invokes, and the time one imagines, different languages have been more and less dominant and numerous. For example, in 1900, Germans, Poles, and Ukrainians were the largest ethno-linguistic groups in Magosci's (1993, pp. 97–8) East Central Europe, but Romanians, Hungarians, Czechs, Belorussians, Serbs, Greeks, Bulgarians, Croats, Slovaks, Lithuanians, Slovenes, Albanians, Macedonians, Bosnian Muslims, and Montenegrins were all dominant in particular places across the region. Beyond these groups who then had, or who would eventually have, East European states in their name, there were significant numbers of Jews, Turks, Gypsies/Rom, Italians, Carpatho-Rusyns, Szekelys, Friulians, Armenians, and other ethno-linguistic groups.

There also is no principal religious tradition in Eastern Europe, whose status Islam occupies in the definition of Middle Eastern and North African studies. Islamic and Orthodox, Roman Catholic, and Protestant Christian religions dominate various parts of the regional landscape. Judaism was demographically and culturally significant before the Holocaust, and even after genocide, Judaism remains critical to understanding the region's cultural politics. Thus, while Eastern Europe is itself a profoundly important

cultural category, it is not based on the region's cultural homogeneity. Eastern European Studies is, however, profoundly shaped by the culture of nations and nationalism.

2. *The Significance of the Nation*

Cultural analysis in Eastern European Studies draws upon an indigenous scholarship, but one organized through national fields rather than across the region. For instance, Polish sociologies of the intelligentsia, both before and after World War II, had the nation as their field of reference (Chałasinski 1997). Hungarian ethnographies of the countryside, while foundational for Western anthropology's study of Transylvania and elsewhere, were focused on the making of the Hungarian nation (Hofer 1968). Musicology or literary criticism also has been organized within national fields, around leading figures like Béla Bartók or Witold Gombrowicz, whose complicated expressions of their nation through music and literature form leitmotifs of their cultural interpretation. Consequently, the nation is one of the region's most important cultural formations. It shapes other cultural studies and is an object of study itself.

Studies of the nation are themselves framed within larger cultural formations. Many studies of the nation in Eastern Europe are set up within a narrative of civilizational distinctions. For instance, national historiographies tend to depict the Ottoman Empire's expansion through the 1600s and its retreat from the Balkans during the nineteenth and beginning of the twentieth century in terms of the contest between Islam and Christianity, on which more recent stories of civilizational clash draw. Romanian national historiographies identify their civilizational alternatives with Western and more autochthonous (indigenous, native) traditions (Verdery 1991). Estonian social science around ethnicity portrays a 'civilizational' difference between the West and Russia (Kirch 1997).

In contrast to those who demonstrate enduring cultural oppositions, others have emphasized the process of establishing national identity and difference, asking, for example, how intellectuals articulate nations (Suny and Kennedy 1999). Those who focus on 'historic' nations (Walicki 1982) and nations that had to '(re) awaken' (Rudnycky 1987) have different emphases. The latter tend to ask how peoples come to recognize themselves as nations and how they mobilize to realize political ambitions including the formation of nation-states out of imperial states (Hroch 1985). Those who focus on historical nations are more influenced by narratives of loss, whether of sovereignty, territory, or tolerance. For instance, how should one theorize the condition of Jews in a nation-state rather than an empire (Hertz 1988)? How did nationalism learn to hate (Porter 2000)? How do diasporas beyond the homeland's state boundaries figure in the nation's membership (Brubaker 1996)?

Nationalism and its study are not limited to Eastern Europe, but its significance in Eastern European Studies has been elevated by the region's distinctive experience with communist rule, which in turn has come to define the region as a whole, and to organize most of its cultural social science.

3. *Culture in the Social Sciences*

Czesław Miłosz's *The Captive Mind* (1951) is one of the best-known works detailing how communist rule shaped high culture. His portraits were based on particular Polish writers' responses to Stalinism, but they also could be understood as ideal typical portraits of authorial responses to communist rule. Jeffery Goldfarb (1981) developed this concern for cultural freedom, identifying communism's constraining and enabling properties for artistic expression and audience appreciation in Polish theatre and other cultural productions. While political censorship certainly constrained cultural expression, it also made artistic expression broadly valued and independent of culture's commodification.

Many treatments of the intelligentsia were as concerned with power and privilege as cultural expression *per se*. In one of the most influential and controversial works assessing the intelligentsia, György Konrád and Iván Szelényi (1979) argued that communist rule's maturation allowed this class to shape the conditions of distribution in its own favor. Underwritten by a principle of teleological knowledge that privileged their own system of 'rational redistribution,' the intelligentsia was poised to come to power. With the aid of monetarist ideology, Eyal et al. (1998) argued this finally came to pass in communism's collapse. This formulation of the intelligentsia has also been helpful in understanding how communism's institutional politics of redistribution escalated nationalist politics among Romania's cultural producers (Verdery 1991).

Studies of class, stratification, and inequality under communist rule were mostly unconcerned with culture, but Stanisław Ossowski's (1963) emphasis on ideology in inequality's study opened the way for 'subjective' assessments of class and stratification. A number of Polish researchers asked about the popularity of gradational, functional, and dichotomous visions of inequality in the social consciousness (Zaborowski 1986). Class consciousness was complicated by the authorities' appropriation of that discourse, but other sensibilities of work and labor could inform peasant and worker identities (Lampland 1995). Perceptions of 'us' and 'them,' based on political distinctions were found to be quite widespread through survey research, and became especially powerful in Poland after the formation of the Solidarity movement in 1980 (Adamski 1993).

A substantial body of scholarship has been developed to address each period of communism's systemic crisis—1956, 1968, 1980, 1989 (e.g., Ekiert 1997). Rock music has been analyzed as a contributor to these transformations of communism, but the explicitly cultural analysis of political crisis is not so common. Culture rather performed as the obvious background, most notably in terms of a nation's fit with communist rule imposed by the Soviet Union. The Hungarian Revolution of 1956, the Prague Spring of 1968, the Solidarity movement of 1980–81, and the end to communist rule throughout the region in 1989 all implied a mismatch between the nation and communist rule. Studies of political culture were typically organized, in fact, to explain the conditions under which the political cultures of some nations would or would not resonate with communist political culture. More recent studies tend to break down the assumption of opposition between nationalism and communism and rather study how opposition and authorities construct the nation in their own terms. For instance, instead of treating official communist discourse as simply illegitimate and therefore unworthy of serious scholarly engagement, Kubik (1994) explains how Polish communist rulers tried to appropriate the national imaginary. He also explained Solidarity of 1980–81 as 'oversymbolized,' or laden with more images and meanings than that single social movement could manage. This oversymbolization in 1980–81 also helps to explain postcommunist Poland's political divisions (Ekiert and Kubik 1999).

Not every nation developed a political regime under communist rule that could produce easily imagined dichotomies of 'us' and 'them.' Ceausescu's Romania generated a social consciousness organized around duplicity and complicity. With symbolic violence the norm, and physical violence the backup, self-censorship and dissimulation became intrinsic features of the socialist habitus; the public sphere was based on the production of lies and regulation so profound as to destroy the meaning of public/private distinctions (Kligman 1998). Civil society and the public sphere, rejuvenated in the West alongside its mobilization in Eastern Europe (Keane 1988, Cohen and Arato 1992), could not find a home in Romania. It did, however, find an important place, if in different forms, across the region.

The discourse of civil society found modes of expression, and even optimism in various cultural products and forms of social organization—in Vaclav Havel's *Power of the Powerless* (1986), or Adam Michnik's (1977) notion of 'new evolutionism.' Civil society's culture was argued to be tolerant, pluralist, and progressive.

The very spaces opened up in these advocacies could also produce nationalist expressions that threatened others and even led to war (Bunce 1999). This was most clearly seen in the nationalist mobilizations within civil society around Yugoslavia's breakup. Memories of oppression by others, rekindled by polyvalent symbols, could become the cultural stock for civil society's mobilization to hate. Alternative narratives of the war's making seemed to deny the possibility of panoptic stances from which to explain Yugoslavia's dissolution. Different vantage points, shaped by variable appreciation for the survival of a united Yugoslavia and for different national narratives, have organized competing stories about the war's making, and charged the field of their interpretations (e.g., Woodward 1995 vs. Ramet 1999).

4. *Culture in Transition*

Studies of the nation and of nationalism after communism's collapse were not restricted to those in war. Communism's end offered peoples new opportunities to redefine their nation, and this invited substantial scholarly engagement. These transformations were apparent already in 1988, when for instance the polysemy of Béla Bartók was played out in the last summer of communist monopolistic rule in Hungary (Gal 1991). Some scholars shaped claims to national distinction with their own expertise, clarifying the ways in which proximate languages were related to one another and could distinguish nations, leading others, further removed, to explain the complexities and sources of these arguments. Some utilized less culturally reflexive approaches like rational choice or game theory, but the cultural field and historical legacies of places and peoples continued to shape scholarly approaches to national identification (e.g., Laitin 1998). While the nation demanded some attention to historical legacies and cultural formations, other subjects were more tolerant of distancing cultural analysis.

In the first years after communism's collapse, most studies of transition to markets and democracy were rather formal and structural, as more and more scholars without contextual expertise identified Eastern Europe as the natural laboratory for testing their generalizing theories. This led to significant debate, especially in political science, about the relative value of area studies. Much of the contest hinged upon how much one needed to know about culture and history in order to produce good explanation, but it did not attend to the global cultural formation of transition itself (Kennedy forthcoming). Of course methodology also matters in this variable attention.

Ethnographies of transition were more likely to put into question the guiding concepts of transition, especially by noting the hermeneutic gap between transition's key concepts and their everyday meaning (Burawoy and Verdery 1999). For instance, these inquiries help us appreciate money's magical powers and land's elasticity in transitional economies (Verdery 1996), and the difficulty of distinguishing private from public ownership (Stark and Bruszt

1998). Sometimes ethnographies even challenge the framework in which the transition is envisioned. Ought postcommunist capitalism be conceived as merchant, and not bourgeois, capitalism (Burawoy and Krotov 1992)?

A similar range of questions has emerged around gender studies. As in most transition studies, some gender analysts have kept culture at a distance. By treating gender more as a variable—asking, for instance, whether women's employment chances have been disproportionately hurt by economic transition—cultural analysis is less obviously necessary. But when gender serves as a lens for interpreting social change, as Watson (1993) suggests in her characterization of 1989–92 as a 'masculinist revolution,' gender studies engage profound cross-cultural questions. For instance, terrific debates have occurred over the measure of cultural imperialism involved in Western feminism's categories and modes of inquiry in regard to Eastern Europe (Gal and Kligman 2000).

5. *Culture and Discipline in Eastern European Studies*

As a field of inquiry, Eastern European Studies has been organized through culturally constituted geopolitical categories. During the Cold War, the field was driven by questions of fit between nations and communist rule. After communism's collapse, the field has been reconstituted around questions of transition and nationalism's threat. At the same time, however, communism's collapse has also invited a transformation of the field's methodological premises. With open borders to scientific collaboration, social scientists without area expertise can work with indigenous scholars to produce important findings, bracketing culture as extraneous to the scholarly enterprise in ways that area studies could never manage. More open borders have also meant, however, greater room for ethnographies and other direct qualitative fieldwork, and more intimate portraits of everyday life and assessments of its fit with the larger frameworks guiding global visions of Eastern Europe and its trajectory. This opening to methodological variety has transformed Eastern European Studies, simultaneously making more cultural analysis possible, and making culture more invisible through fusions of scientific horizons across the world.

To the extent disciplines treat culture as a variable, and therefore something that may or may not be incorporated in analysis, the meaning of Eastern Europe as a region tends to be lost, and expertise in its history, institutions, languages, and cultures can be devalued. To the extent scholars engage the 'double hermeneutic' in their work, or explore meaning on the ground and in the cultural relationship between scholarship and the places under study, area studies expertise and cultural theory are more likely to be valued. Indeed, the extensive engagement between social science and the design of change in postcommunist Eastern Europe suggests that culture could become more, rather than less important, in social science about Eastern Europe.

Economists advise market transition, political scientists and sociologists debate democracy's making, linguists articulate nations, and historians adjudicate responsibility for past crimes. Not all of these disciplines are so deeply involved in engaging that double hermeneutic, however. For many, as Žižek (1993, p. 200) has observed, Eastern Europe becomes the mirror in which the West's generalizability can be recognized. In that reflection, Eastern European Studies poses little challenge beyond extension for Western social science. But for those who take up the challenge of difference (Calhoun 1995), the category of Eastern Europe and the translation of inquiry across that space remains part of the question with which not only Eastern European Studies, but also the social sciences themselves, could be culturally reconfigured. What would Eastern European Studies look like if the privilege of nations, men, and global integration through markets became the object of reflection rather than the point of departure for social science about, and out of, the region?

Eastern European Studies: Economics

The changes in the Eastern European economies during the first decade of the transition to capitalism have been, without exaggeration, momentous. Beginning in the late 1980s, the countries in the region emerged from a system based on communist party rule, state ownership, and central planning, and adopted in its place a system based on multiparty democracy, private ownership, and markets. Although the break with the past was radical, and notwithstanding that the region is poised for period of rapidly improving living standards, the first decade of transition was difficult. Most countries suffered deep recessions, experienced massive redistributions of income and wealth, and struggled with the slow process of building supporting institutions for a market economy. And even for the countries that have advanced furthest, the transition is not over. The next

decade will bring further momentous changes as countries prepare for accession to the European Union.

Transition has been a challenge for economists. Never before had industrial countries attempted to adopt abruptly the institutions of capitalism. New tools had to be developed to understand such phenomena as transitional recession, mass privatization, and the political economy of institutional reform. Transition has also provided a great opportunity to understand the role of the many background institutions of capitalism. By observing the long list of institutions that had to be put in place, and by observing how economies performed when these institutions were lacking, the economics profession has attained a deeper understanding of how even established market economies work.

1. Initial Conditions

By the end of the 1980s, a number of communist countries, including the Soviet Union, had gone through a period of *reform socialism* (Kornai 1992). Among other changes, these reforms allowed greater autonomy for state enterprises, permitted some small-scale private enterprise, and increased the use of prices in allocating economic resources. However, these reforms did not alter the one-party rule and a preponderance of state ownership that were the foundation of the communist system. So the pathologies of the *classical socialist system* remained (Kornai 1992). Resources were allocated according to the dictates of central planners rather than household needs. Production methods were inefficient. And lacking the long-term profitability constraint faced by enterprises on market economies, socialist enterprises with *soft budget constraints* retained insatiable demands for inputs. Together with the continuing reliance on price controls, these demands made shortages pervasive.

Reform socialism led, in fact, to a slackening of the financial discipline on enterprises. And this in turn led to an increase in macroeconomic imbalances. At prevailing prices, the aggregate demand for goods and services exceeded the supply. In the years prior to the transition, communist governments dealt with these imbalances in three ways. They engaged in large foreign borrowing to increase the availability of goods and services; they repressed the inflationary pressures with price controls and rationing of the available goods; and they allowed open inflation.

At the outset of transition, then, reforming governments inherited economies with combinations of large debts, long queues, and high inflation rates (Lipton and Sachs 1990). They also inherited a distorted industrial structure, most notably an over-reliance on heavy industry, and a badly developed service economy. From a longer-term perspective, perhaps the most adverse part of the inheritance of all was the absence of key marketing supporting institutions, such as an established code of commercial law or a supervisory apparatus for market-oriented financial institutions. With this mix of macroeconomic imbalances and microeconomic deficiencies, the path to a market economy must have appeared daunting to the first postcommunist governments.

2. Transition

It is common to put the main steps in postcommunist transition under three rather ugly headings: liberalization, stabilization, and privatization. Much of the subsequent work the economics of transition has concentrated on these processes.

2.1 Liberalization

The first, and arguably the easiest, steps in the transition are the removal of most government controls (see Sachs 1993 for an account of the Polish experience). For example, the government simply stops controlling prices, allowing them to jump to their market levels, or ends prohibitions on new private businesses. In a related step, the government decentralizes decision-making authority to enterprises, in effect dismantling the central planning apparatus.

On the external front, the government moves to allow for freer trade and factor movements. Complicated permission requirements for exporting, high tariff and nontariff barriers to imports, and severe restrictions on foreign ownership are relaxed. In addition to gaining access to foreign markets, goods, and capital, opening up the economy to the rest of the world increases competition and exposes the population to best practice in technology and organization.

2.2 Stabilization

As noted before, postcommunist governments inherit severe macroeconomic imbalances. Even with price controls, the inflation rate typically is already high prior to the transition. Price liberalization is associated with an upward jump in prices as they reach market-clearing levels, ending the previous situation of chronic excess demand. These jumps can also have a longer-lasting impact on inflation to the extent that they cause expectations of higher future inflation.

The most important cause of the high inflation, however, is the underlying growth in the money supply. This has two main sources. First, there is the government's budget deficit. Under communism, governments relied heavily on taxes on enterprise turnover to fund their spending. They also delegated much of the responsibility for social spending directly to the enterprises. Transition has been associated with a fall

Table 1
A decade of transition

	Year transition began	Starting date of stabilization program	Real output 1995 % of 1989	Real output 1999 % of 1989	Average inflation 1989–1999	Private sector % of GDP mid-1999
EU Accession Countries (excluding Baltics)						
Bulgaria	1991	Feb-91	75	67	68.4	60

in revenues and increased spending demands on governments. For many countries, the result has been large budget deficits that are financed in part by printing money. Second, there is the financing of enterprise losses. Although the enterprises attain much greater autonomy, budget constraints remain soft. In other words, their losses are bailed out through support from the government or (more likely) 'soft' loans from the (government-controlled) banking system. In turn, the banks' losses are bailed out by 'soft' support from the central bank, which they finance by printing money.

Since a stable price level is an essential feature of a market economy, one of the most urgent tasks for the post-communist government is to bring down inflation toward single-digit levels. Table 1 provides dates for the beginning of major stabilization efforts in various countries. Given the underlying sources of money supply growth, true stabilization requires reducing the size of the government's budget deficit (or at least reducing reliance on monetary financing of those deficits), and the ability to impose hard budget constraints on enterprises. Each step is difficult as it imposes additional hardships on the population. Thus, for many countries, stabilization has been a slow and indeed a continuing process. As Table 1 shows, average inflation rates for the decade of the 1990s were high by established market economy standards.

For economists, the nature of the post-communist stabilization challenge was not especially novel. The nature and causes of high (and even hyper) inflation were well known, with the most recent experience

being the hyperinflation episodes in Latin America following the debt crises of the 1980s. Some of the challenges were more novel, including the massive and often sudden decontrol of prices, and the mass introduction of new currencies in the countries of the former Soviet Union. By and large, however, economists were able to use their accumulated wisdom on such matters as the importance of ending the printing of money to finance budget deficits, and the usefulness of exchange rate pegs to anchor inflationary expectations in the early stages of a stabilization program. (For an overview of research on postcommunist inflation and the stabilization experience, see Boone and Horder 1998.)

2.3 Privatization

In theory it is possible to have a successful market economy while retaining extensive state ownership. In practice, state ownership is associated with the politicization of enterprise decision-making (Shleifer and Vishny 1994). It is easier for politicians to control firms when the state is the owner. Moreover, politicians will use their control to pursue political ends—say, preserving jobs for constituents—rather than to maximize profits. Thus continued state ownership is an impediment to restructuring enterprises and reallocating resources. Political control is also associated with soft budget constraints, as politicians are willing and able to bail out the losses incurred while pursing their political objectives. Success with stabilization can thus depend on success with privatization.

There are a number of methods for achieving privatization: Sales to the highest bidder; restitution to pre-communist owners; voucher privatization; manager–worker buyouts, etc. Whatever the method, it might be thought that privatization is easy politically. After all, the government is transferring assets to the private sector, potentially at a large discount. In practice, groups seeing themselves as losing from privatization, or not gaining as much from the transfer of assets as they could, often have the power to block an unfavorable privatization proposal. For example, the management of state enterprises might thwart attempts to sell the enterprise to outside owners. Where such blocking power exists, the blocking groups may have to be bought out by the government, possibly by buying access to shares at steeply discounted prices.

A good example of such 'buy-offs' is the early stage of Russian privatization. Then, enterprise insiders—managers and workers—received excellent deals on their companies' shares. While this allowed privatization to proceed, and helped to depoliticize enterprise control, it might have led to excessive insider control (see Boycko et al. 1994). When insiders control a firm, they are likely to use their power to achieve objectives that run counter to efficiency, such as prolonging overstaffing. As outsiders recognize insider power to appropriate the valued added of the enterprise, high insider control makes it difficult to raise outside finance, and thus acts as an obstacle to restructuring and new investment (see Blanchard 1997). Moreover, preferential privatization has led to quite unequal distributions of previously state-owned assets, a topic returned to in Sect. 3.2 below.

The theoretical literature has concentrated on the political economy of mass privatization as well as the various channels for efficiency gains when shifting from state to private ownership (see Roland 2000, for a survey.) There is an even larger empirical literature the records the privatization strategies pursued and investigates the impact of the resulting ownership forms on restructuring behavior. Although this literature does not speak with one voice, the balance of evidence suggests that ownership by enterprise outsiders with large ownership stakes leads to most restructuring (for a flavor of the results and the empirical methods used, see the papers by Estrin 1998 and Frydman et al. 1999).

3. The Transition Experience: Pain and Progress

3.1 Transitional Recession

All the transition economies experienced severe and, for many, long-lasting recessions (Layard 1998). Table 1 shows the level of real GDP in both 1995 and 1999, each as a percentage of output in 1989. The table makes for grim reading. In 1995 all countries had measured real output levels that were below levels achieved in 1989. The picture had brightened by 1999, with Poland, the Slovak Republic, and Slovenia surpassing their 1989 output levels, and a number of other countries approaching this benchmark. In the countries of the former Soviet Union, however, the picture remained bleak. In Russia, for example, real output in 1999 was just 55 percent of the 1989 level.

These real output statistics almost certainly overstate the true output contractions. Much of the lost output had little value—and perhaps even negative value—as valuable raw materials were destroyed in irrational production processes. Nonetheless, the recessions were real, with sharp reductions in employment and expansions of unemployment.

Why did the transition economies suffer these transitional recessions? After all, if the communist system was so inefficient, should we not expect that real output would increase as countries adopt market systems? The early hope of experts on communist systems was that the postcommunist economies would move from a situation of generalized excess demand (or shortage) to macroeconomic balance, without tipping into a situation of generalized excess supply (Kornai 1995). Various explanations for the sharp contractions have been given in the literature.

Early explanations focused on the impact of the sharp postliberalization price jumps, and on Keynesian-type explanations of insufficient demand. The sharp jump in prices was thought to have limited real working capital severely, forcing enterprises to cut their production (see, e.g., Calvo and Coricelli 1992). On the demand side, a general lack of consumer and investor confidence, combined with tight government fiscal and monetary policies, was initially thought to be responsible for pushing real output below the economy's potential to produce. As time passed, and the transition economies failed to recover, or recovered very slowly, these explanations were revised. Economists began to look for more systemic explanations. One important explanation focused on the 'disorganization' that results in the no-man's-land between systems (Blanchard and Kremer 1997, Roland and Verider 1999). For a time after a central planning apparatus has been destroyed, but before market coordination is properly established, the ability to coordinate economic activity is severely impaired. Supply disturbances in one part of the economic system tend to cascade through the economic system, impairing severely the economy's potential to produce.

A related explanation focuses on the inherent unemployment bias present in market systems. When unemployment falls below the *natural* (or structural) *rate of unemployment*, inflation tends to rise. Thus, stable inflation is only consistent with what can be a relatively high rate of unemployment. (That this structural unemployment rate can be quite high is demonstrated by the high rates of unemployment in many Western European economies, even in the expansion phases of their business cycles.) In contrast, under communism, unemployment was negligible, and inflation was controlled by fiat. As an economy goes through a postcommunist transition it can no longer sustain its previously high rate of activity without suffering accelerating inflation. Over time it is expected that the superior efficiency of market coordination will lead to superior output performance, but in the short-run the loss of ability to run a high-pressure economy dominates, and output falls.

Lastly, a number of authors have stressed the impact of the large reallocations that must take place during the transition (see, e.g., Gomulka 1998). Some enterprises, and even entire industries, decline rapidly as there is little demand for their products in the newly liberalized economy. The result is a large but temporary decline in output as it takes time for the displaced resources to find productive employment in expanding sectors.

3.2 Large Redistributions of Income and Wealth

Transition is associated with substantial changes in household incomes and balance sheets. Factors affecting the income relativities include the large rise in unemployment and falls in (especially female) participation, the shift in resources from heavy industry to lighter industry and services, and hardships faced by older workers with specific skills in adjusting to the new pattern of labor demands.

In addition to the large income gains and losses for particular households, there has also been a large increase in overall income inequality. For the mid-1990s, Milanovic (1998) reports substantial increases in inequality as measured by the Gini coefficient for income per capita compared with the late 1980s, with particularly large increases for the countries of the former Soviet Union. The Gini coefficient for Russia increased to a staggering 48 in the period 1993–5 from 24 in the period 1987–8. This compares with much smaller increases for more advanced reformers, with the Gini rising to 28 from 26 for Poland, and to 23 from 21 for Hungary for the same periods.

There have also been very large shifts in wealth distribution (although reliable numbers are hard to come by). Under communism, price controls and generalized shortages forced people to accumulate undesired liquid wealth holdings, creating a *monetary overhang* of latent spending power. With price liberalization, people were able to spend down these undesired balances, contributing to the large price jump. However, this price jump also reduced the purchasing power of all (nonindexed) nominal wealth, causing substantial but unequal wealth losses.

Privatization has also affected wealth distribution, although given the low value of much of the communist-era capital stock, the amount of wealth available for distribution should not be exaggerated. The distributional impact of privatization depends on the privatization method pursued. At one extreme, sales at reasonably fair prices (as in Hungary) should have rather minor impacts on wealth inequality, while at the other, extreme giveaways to the politically well-connected of valuable energy-sector assets (as in the second wave of privatization in Russia) must have had a major impact.

If we take a broader view of wealth to include the value of assets such as entitlements to pensions and job incumbency, the impact of transition on wealth distribution has obviously been great.

3.3 Supporting Institutions for Capitalism

For economists and political scientists, one of the unanticipated benefits of the transition experience is that it has given us a deeper understanding of the role of institutions in the capitalist system, and the difficulties involved in their establishment (Roland 2000). An incomplete list of the institutions that facilitate economic activity in a private ownership economy includes the following: Regulatory and supervisory authorities for financial intermediaries and securities

markets; company laws that protect the interests of outside shareholders; a body of contract law that facilitates long-term contracting; an independent judiciary; etc.

Reformist governments can liberalize and stabilize relatively quickly, and even privatization can be well advanced in a few years with the necessary will. Institutional development takes more time. The Czech government provides a good example of a country that pushed ahead quickly with price decontrol, disinflation, and sales of state assets, but the inadequacies of its background institutions were shown in a series of scandals related to insider dealing (see LaPorta et al. 2000). These failures undermined investor confidence, and clearly hurt the performance of the Czech economy.

On the research front, a great deal of attention has been given to the economics and politics of large-scale institutional change. One of the most debated questions is the relative merits of 'shock therapy'—the rapid movement along as many fronts as possible to the desired institutional configuration. Lipton and Sachs (1990) and Sachs (1993) provide early arguments for moving quickly. In the gradualist camp, Roland (2000) outlines models that suggest the merits of a more phased approach, particularly when the outcomes of the reform process are uncertain.

4. *The Road Ahead*

In highlighting the difficulties of transition, the momentousness of the achievement must not be missed. Political and economic freedoms have been restored; the state has largely withdrawn from the ownership and control of productive resources; and markets have been allowed to exist and to flourish. The capitalist political–economic system, though not flawless, has proven its capacity to generate growth and improvements in living standards (see Maddison 1995). In contrast, the communist system brought repression, and eventually stagnation. The future should be bright for those countries that continue to advance down the road to a free economy (see Kornai 1990).

At the outset of transition, Eastern European politicians said their goal was 'to return to Europe' (Sachs 1993). The ultimate expression of such a return would be accession to the European Union (EU). For the more advanced reformers, this goal should be in reach within the first decade of the twenty-first century. The process of accession will be difficult, of course, forcing combinations of further liberalization and the adoption of often-costly EU regulations. Meeting the convergence criteria for joining the Economic Monetary Union (EMU), and thus the right to adopt the euro currency could be especially painful. Moreover, easy immigration to the richer countries to the west could drain the Eastern European of talent needed to rebuild their economies. Nonetheless, accession would be a remarkable achievement, given where these economies started from at the beginning of the 1990s. It would also mark a clear date for the end of transition.

J. McHale

Eastern European Studies: History

The collapse of communism in 1989 unleashed a flood of articles and books in political science, sociology, and international relations. The primary aim of this work was to identify and explain the causal forces and teleology propelling the region's 'transition' from communism to free-market democracy. When comparisons with Latin America, Greece, and Iberia are added to the mix, it becomes possible to speak of an entire genre of 'transitionology' whose main source of sustenance has been the history of Eastern Europe in the late twentieth century. While some historians did seek to draw usually problematical parallels between the interwar period and postcommunist developments, as a whole the discipline of history tended to remain immune to the fixation on the present. The wars of Yugoslav succession form the one notable exception, since they spawned substantial literature dedicated to elucidating the perceived connections between nationalism's role among the south Slavs in the past and the present.

And yet the underlying importance of 1989 for history far exceeds its significance for the other social sciences, for it has given birth to the need to reconceptualize Eastern European history in an entirely new framework. 'Never has an ideology and a system of power built on such vast pretensions and still greater human tragedies,' it has been noted in reference to 1989, 'fallen so ignobly as did the red star that sought to unite the lands from the gray shores of the Baltic to the azure coves of the Adriatic within a single allegiance' (Banac 1992, p. ix). Although the degree of *de facto* control varied widely from country to country, one of the communist system's greatest pretensions was its stated intent to impose a uniform way of viewing and interpreting the past.

In the short term, from the historian's standpoint, the single most noteworthy aspect of the collapse of communism in Eastern Europe is the opening of previously closed archives. Unlike in Russia, where the old way of doing things continues to erect obstacles to archival access, the archives of Eastern Europe are now available to researchers with few if any restrictions. Formerly taboo topics from the interwar period can be studied fully. To take Czechoslovakia as an example, the result has been a monograph on the Republican (Agrarian) Party's critical place in the democratic Czechoslovak political system between the wars (Miller 1999), a study of the Slovak nationalist movement's place in the interwar state and society (Felak 1994), as well as the first English-language study of Czechoslovak diplomacy during this period to be based on archival sources (Lukeé 1996). The thorough coverage afforded to Czechoslovak interwar history is a model that could be applied easily to the history of the Baltic States, Bulgaria, and Romania (Hungary, Poland, and Yugoslavia have received better treatment already, especially in their own national historiographies).

Unlike the study of the interwar period, which more often than not entails grappling with traditional themes, the collapse of communism has cleared the way for new approaches to World War II and its immediate aftermath. Instead of simply positing the war as a prelude to the communist seizure of power in Eastern Europe, the attempt is made to draw a more nuanced picture. The gray hues produced first by collaboration with the Nazis and then by retribution against those deemed guilty of this sin make the conventional story of anticommunist struggle more complex and ambiguous (Deak et al. 2000).

Above all, the immediate post-1945 period, when communists seized power throughout Eastern Europe, and the four decades of communist rule itself can now be empirically researched in a manner that is free from ideological distortions. Not surprisingly, these years have attracted the greatest attention from Eastern European historians themselves. There have also been original and meaningful English-language contributions to the study of the post-1945 period (Kenney 1997, Connelly 2000). While there have been no great revelations from the archives that would fundamentally alter our understanding of the communist period, it is now possible to document just how diverse Eastern Europe became while remaining under Soviet influence. When narrating the history of Polish–East German relations, one historian aptly speaks of a 'cold war in the Soviet bloc.' While this is certainly the most extreme such case, the basic model obtains for all of Eastern Europe, where, after 1945, individual states sought to realize their own national aims within a common ideological framework (Anderson 2001). The concept of 'national communism' was first developed

by political scientists to explain the variations that emerged in the Eastern European states following the death of Stalin in 1953. In the aftermath of 1989, this concept has acquired new relevance and salience. Thus, it is also now possible to explain, with the aid of source material, the similarities as well as the differences between the Eastern European communist states during the period of so-called high Stalinism, which stretched from 1948/49 to 1953 and witnessed the creation of something that, at least on the surface, approximated a monolithic, Moscow-controlled bloc. (The best source for English-language material on post-1945 Eastern Europe is the *Cold War International History Bulletin*.)

Independently of the topics addressed above, newer methodological trends have also made their mark on Eastern European history, though, for the time being anyway, they are less prominent in this field than elsewhere (Porter 2000, Todorova 1997).

Over the long term, the lasting impact of 1989 will lie close to the agenda of historians who are interested in the role of language and in the changes experienced by language over time. The collapse of communism has initiated a process that promises ultimately to render the very concept of Eastern Europe passé in any meaningful political and thus contemporary sense. The mix of factors driving the distinction has often changed from period to period, whereby foreign domination and perceived 'backwardness' have always played a central role. But the fundamental distinction between Eastern and Western Europe has been in existence since the Enlightenment, i.e., since the birth of modern notions of nationhood and statehood. As an Enlightenment thinker, Johann Wolfgang Herder stood out because he argued that the rights and prerogatives of modern nationhood should be extended to the stateless and usually 'small' Slavic nations of Eastern Europe.

Reminiscent of Herder's understanding of self-determination, the demise of communism has opened the way for these same nations to define their statehood within the context of an expanding European Union, which represents an unprecedented supranational pooling of resources, as well as an expanding NATO, which brings with it an unprecedented Western security guarantee for Eastern Europe. Furthermore, the extension of state-creating nationalism into Byelorussia, Ukraine, and Central Asia means that the very notion of what constitutes Europe is now confronting a new and novel environment. Since all of the states sandwiched into the vast region between Germany and Russia will, presumably, one day join the European Union, the old East–West dichotomy may remain in place in civilizational and cultural terms for some time to come, but the stark political distinction between the two halves of Europe is already beginning to fade.

What does all of this portend for the field of Eastern European history? First of all, it confronts a growing need to formulate and answer questions that can be fit into a broader European framework. This is a tricky proposition, because it denotes a challenge to previously dominant assumptions about the region's peculiarity. Second, the very concept of Eastern European history will, in all likelihood, fall by the wayside completely. In keeping with the trend towards regionalization within the European Union, the individual subcomponents of Eastern Europe, East-Central and Southeastern Europe, together with the Baltics and Ukraine, will retain their usefulness as broader categories of historical research and thinking. However, the general decline in the number of monographs devoted to Eastern European historical subjects shows no sign of abating, just as interest in area-studies and linguistic training continues to diminish.

Eastern European Studies: Politics

Eastern European studies has been the stepchild of Slavic Studies, Sovietology, or a number of research centers and projects that endeavored to study 'actually

existing socialism,' command economies, communist ideology and culture, informal markets, social movements, Marxist–Leninist theories, or other specialized topics in the political economy of the region. Prior to 1989, political scientists were likely to characterize the region as a cluster of satellite states, largely marginal to the political and economic institutions of the West, except as systemic prototypes. The fascinating histories of the region and the debates about the sources and cause of 'backwardness' were not widely read. The 1990s have transformed the intellectual terrain as much as the political.

Since 1989, there has been a veritable avalanche of material—reports, evaluations, diagnoses, prognoses, disputes, re-evaluations, chronicles, and other descriptive accounts. The academic literature has expanded at least as dramatically as the popular literature, and thus far shows few signs of waning. Virtually every major journal in the social sciences has had at least one special issue entirely devoted to the demise of communism; many have had five- and 10-year retrospectives as well. Professional associations have organized special workshops and conferences; foundations have funded seminars both here and abroad; study groups, dissertations, and research projects have proliferated. In due course, these scholarly convocations have translated, edited, and published a host of material. To this day, annual meetings include thematic panels and plenary sessions on the Transition. The sheer amount of intellectual activity and interest in and on Eastern Europe has been overwhelming. Even ignoring work that is journalistic or blatantly ideological, the research archives are flooded.

Area specialists were, of course, deeply involved in this process. Journals that focused on Eastern Europe, on socialism or communist political systems, or on the comparative analysis of institutions were deluged with requests for symposia, reprints, reviews, and manuscripts. Several new journals were established; a surge of newsletters, bulletins, and e-journals entered the scene, providing a wealth of information on current events. It is fair to say that the bulk of the work produced to date has yet to be absorbed or even thoroughly reviewed by regional specialists.

One intriguing aspect of the collapse of the socialist system was the fact that it was largely nonviolent, even harmonious—typically a 'bloodless coup' or a 'velvet revolution.' In academic circles, however, the debate has been more contentious. For Eastern European specialists, the fall of communism meant a dramatic change of government and a host of domestic problems and challenges specific to the new governments. A common response among empirical scholars was to add Eastern European and the Balkan countries to the existing pool of countries that had successfully negotiated regime change and democratization. The temptation to apply carefully crafted theories of the transition from authoritarianism to democracy, based on Latin America or Spain, for example, was nearly irresistible. For area specialists, such generalizations were clearly premature. Democratization was a fragile process, and not a foregone conclusion. Scholars with comparative interests in building democratic institutions were typically newcomers to this region; they could not claim the cultural knowledge and experience of these countries as broad and as deep as that enjoyed by resident scholars or area specialists. Moreover, Eastern Europe had produced a considerable number of homegrown activists and intellectuals as well as political commentators. After decades of repression, the crumbling Wall was greeted with a surge of publications and collaborative projects aimed at the West.

For the vast majority of Westerners, the events of 1989 were completely unexpected. The 'man on the street' was typically euphoric or incredulous. Political scientists were, however, shocked by the 'embarrassing failure' of theory to predict or explain the sudden end to the Cold War. An auxiliary issue became deciding which experts if any might have alluded to the possibility. Efforts to understand and explain the 'revolution' have proliferated, with the most successful involving scholars from the region working with scholars from the West. The work is largely multidisciplinary, rather than interdisciplinary. Few analysts could ignore the implications of combining economic and political reform. Such collaboration seems to have given rise to a whole new field of inquiry, labeled somewhat facetiously 'Transitology' or 'Consolidology.'

As a result, the 'revolution' invited a whole new debate on the most appropriate methods for studying political change. This debate centers on, 'What questions can be fruitfully approached using comparative analysis?' and 'How much emphasis should be placed on unique, country-specific aspects of political change?' These debates have tended to be louder, more vociferous, and far more colorful than is customary in methodological matters.

1. *The Big Questions*

Given the enormous amount that has been written about socialism, democracy, and economic development, revising social theories was a growth industry. After the seismic events of 1989, virtually all perspectives on and approaches to political theory required rethinking. Did socialism fail, and if so, why? Have markets been successfully introduced? Why have they failed to meet popular expectations? Has 'market socialism' proved to be an oxymoron? Is it possible to initiate 'dual track' transformations, modernizing economic and political institutions simultaneously? Or, to paraphrase one text: is it possible to rebuild the ship of state at sea? And where could one find an appropriate blueprint for such an endeavor? Needless

to say, these questions have ignited more heat than light. They do, however, promise to provide fertile ground for future theorizing.

At least since Schumpeter, analysts have argued that modern democracies emerge from capitalist processes. There are authoritarian countries that have market-oriented economies and authoritarian countries that have nonmarket economies; there are countries governed by popular elections with market economies. However, there are no countries that have both popularly elected leadership and state-controlled economies. Although there were undeniable tensions between democracy and capitalism, the conventional wisdom linked them irretrievably.

Comparative work on the transition to democracy was well established. Beginning with Portugal in 1974, a wave of successive democratic upheavals had swept several European and then Latin American countries. Analysis and theoretical work on these countries had produced a number of exemplary comparative studies. Not surprisingly, these authors were keen to add cases and test and validate their previous conclusions with new data from Eastern Europe; to create, in short, a laboratory for studying the processes involved in nation-building, democratizing, converting economies, creating and legitimating the rule of law, and nourishing civil society.

2. *Redrawing the Boundaries*

When territorial boundaries change, maps must of course be redrawn; but in Eastern Europe, the very notion of what constitutes an 'area' or 'region' of the world also needs to be redefined. The collapse of communism created some 15 new nations, and still counting. Although contiguous geographically, the primary quality these countries share is 40 or more years of Soviet domination. Culturally, linguistically, and ethnically, the postcommunist states are quite diverse. Moreover they seem to be differentiating rather than converging. Should the area be subdivided, merged, or treated as separate states. Creating new nations is a difficult process: new governments are formed; new constitutions are written; new treaties are made. For specialists on Europe or for political scientists generally, the number of units to be studied—whether defined as states, localities, urban centers, trading partners, electoral districts, monetary unions, or bilateral agreements—has burgeoned. Such entities, and the divisions among them, constitute the most basic elements of political and social inquiry.

The borders between East and West, both *de facto* and *de jure*, have obviously changed. But even more fundamentally, our conceptual boundaries have shifted and these are much harder to detect or to map. It is not yet clear whether the partially reborn countries of Eastern Europe and the Balkans will join (or rejoin) Europe or fall back into authoritarianism and fevered nationalism.

In almost every subdiscipline of politics, there have been calls for revising the theoretical agenda. Like other fields, International Relations had neither anticipated nor could explain the transformations underway. Both the European Union and NATO expanded. Ideally, the end of the Cold War should have signified a substantial lessening of security concerns. In practice, however, the focus moved to terrorism and subnational groups. Instead of a bifurcated world, the risk today seems to be a proliferation of nuclear weapons and regional arms' races.

Macrohistorical approaches were also suspect. Historical materialism and the Grand Experiment had both fizzled. The world system seemed about to topple and it was all but impossible to identify the matrix of power relations in place. Eastern Europe was liberated from the Soviet Empire, decolonized, and eager to join the banquet of Europe—an altogether different place in the world.

3. *Policy Issues*

At the outset of transition, reforms involved moving toward a market economy and a democratic state. Two competing theories were put forth to assess the speed and effectiveness of economic reform: Gradualism and Shock Therapy. At present, there is still little agreement about which strategy works best. A host of important but less urgent policies were also reviewed. Experts in comparative law, business and management, the role of the media, privatization, nation-building, social safety nets, gender relations, and institutional reform of all sorts descended on these fledgling democracies, to investigate and advise. Specialized studies on poverty and social welfare, migration, pension reform, health care, and unemployment were conducted, some for the first time. Public opinion polling and even focus groups became very frequent occurrences.

Among academics, transitology was flourishing, even if the contours were imprecise. Was transitology a branch of comparative politics or an uncharted new field? Did it apply to all forms of change, or primarily political transitions. Schmitter traced the earliest theoretical propositions in the field to Machiavelli, who argued that introducing any new system implies that all those who profited from the former state of affairs are now enemies, while those who might stand to gain from a change become at best lukewarm allies. The fundamental premise of transition is uncertainty about the outcome; in contrast, democratic consolidation appears to develop in consecutive steps.

What many comparativists did not seem to realize was that the wall separating European Studies from Eastern European studies had disappeared long before

the collapse of the Berlin wall. Political theory and comparative politics had crossed the Oder considerably before the arrival of 'democracy,' let alone transitology or consolidology. Efforts to locate these aspiring democracies in terms of their institutions, their standard of living, or their expectations for the future were certain to be off the mark.

A number of theoretical treatments of the course of transition seem to have promise. In comparative terms, the 'paths' chosen were quite different and not necessarily predictive of success. However, the point of departure tended to be enormously important. Economic and political transitions seemed to be path dependent. They were not universal, however. The legacies of socialism persisted throughout the region; however, they were mediated by unique cultural features specific to each country. Nationalism was widespread in the region; however, its effects and consequences differed enormously. Economically, virtually all of the countries have progressed; politically the future is less clear. Liberal political theory privileges concepts of citizenship that are inclusive if not universal. Yet the politics of transition seems to mean that nationalist figures were more likely to endorse democratic politics, if only for the majority. A free and unfettered market economy meant joining or rejoining the prosperous West, a prospect that European governments either shunned or deferred, a reunified Germany being the obvious exception. In short, a great many theoretical ideas have been redefined.

4. *Gender*

A fairly sizeable literature has developed on questions of gender and political transitions. With respect to politics, the number of females elected or appointed to public office has declined compared to the numbers during the *ancien regime*. Unemployment, in contrast, has climbed relative to the rate for males, excepting only Hungary. Historically, women were better educated than men on average; women were concentrated in the professions and the service sector under communism. Since these are the sectors most in demand, it is ironic that women are being displaced. In medicine, for example, one finds that men are quick to hang a shingle, while women physicians remain in depressed clinics in the public sector.

Gender inequality has become a large issue in the West; unraveling the sources and consequences receives a great deal of academic attention. Historically, communism attempted to insure gender equality through equal rights and labor market participation, although the evidence suggests these efforts were short-lived. The corollary proposition of why socialism failed to 'liberate' women despite the ideology and the rhetoric is still perennially fascinating. Analyzing trends becomes a method for proving or disproving macro-historic issues such as the reasons for segmented employment and gendered markets.

5. *Elites*

A related topic concerns the composition of elites, and in particular how to account for the persistent advantages enjoyed by the *nomenklatura*. Under communism, the top leadership in both the party and state enterprise were carefully screened for ideological consistency and rewarded for loyalty to the regime. A recurring critique was that class stratification under socialism was based on privileges instead of property, but that otherwise little had changed. Whether based on ideology ('Reds') or skills and education ('Experts'), the communist system had certainly not banished inequality.

To date, the research suggests that in Eastern Europe, there have been changes, although perhaps not as dramatic as those that occurred immediately after World War II. In Hungary, the economic elite has changed the most; in the Czech Republic, political power has clearly shifted; and in Poland, the cultural elite is composed of recent recruits. However, in other parts of the Communist bloc, managers became owners with little need for new blood.

6. *Social Protest in Eastern Europe*

Despite peaceful roundtable agreements that initiated transitions, most of the countries of the region had relatively large opposition movements and dissidents who had been more or less silenced. These groups were often involved in deliberations, pact-making, and electoral victories. The origins and activities of groups such as Charter 77 and Solidarity were of considerable interest, even though neither group had been active recently.

Political activity during the early transition period varied by country in terms of both magnitude and duration. Not surprisingly, a variety of groups and organizations contested the policies and austerity imposed by the new regime; moreover, citizens were more acquainted with protest activity than with compromise and negotiation. Comparing the patterns in East Germany, Hungary, Poland, and Slovakia between 1989 and 1993, Ekiert and Kubik (1998) conclude that relative deprivation, whether measured in objective or subjective terms, was unrelated to forms of contention. The extent of protest is best explained by institutional and resource mobilization theories. Moreover, democratic consolidation was not undermined by a high degree of protest activity. In fact, when collective demands are moderate and the strategies orderly, then protest may actually contribute to the development of robust democratic institutions.

An enormous number of research questions have been turned topsy-turvy; many eternal verities have been challenged. Rational choice theorists have been forced to include civil society and social contracts to make sense of political change. Post-communist ballots tend to be long, filled with political parties that come and go; indeed, despite the 'overthrow' of communism, socialists and social democrats are still an organized and powerful force. Predicting winning candidates or votes cast has become difficult. With little variation in economic position, at least at the outset of the transition, it is not surprising that citizens neither recognized nor voted as their economic interests dictated. Parties were not more cohesive after successfully overthrowing the communists; in fact, this was usually the point when political fragmentation began in earnest.

7. *Conclusion*

The political changes in Eastern Europe have clearly opened a wealth of social science theory and data. Thus far, there has been an unprecedented number of productive projects, both theoretical and practical. Area specialists have been indispensable to this work. In the process, they have helped to refine and define the most pressing questions drawn from a venerable literature. To be sure, there are still more questions than answers, but progress is readily apparent.

Eastern European Studies: Society

'Eastern Europe' is as much a historically shaped sociocultural concept with contents and connotations that have changed markedly over time, as a reality of

recurrently shifting geopolitical divisions. The standing aspiration of the region's nations has been their full integration into a unified Europe driven by Western values and norms. After looking at the perennial societal experiments for reaching this fundamental goal, the article outlines the major dilemmas of closing down the East–West divide in our times, and gives an overview of contemporary social science research in reflecting and assisting these attempts.

1. *Eastern Europe: A Region with Clear Contours, but Opaque Borders*

Customarily, Eastern Europe as a geographical concept is understood to denote the region positioned east from the River Elbe and west from the Ural Mountains. Such a geographical definition meets, however, insurmountable difficulties when translated into societies, nations, and states. As to the western border of the region, the River Elbe runs through Germany. Does this mean that German society is sharply divided into a 'Western European' and an 'Eastern European' segment? Similarly, the eastern border of the region—the Urals—cut through Russia; does this mean that one half of Russia belongs to 'Eastern Europe,' while the other is part of the 'non-European East'? Further, if such faultlines divide one or more countries of the region, what are the implications of their presence: do they simply carry sociocultural differences of historical and ethnographical interest, or, does their persistence endanger the stability of the affected states, and, beyond, that of the continent itself? In short: if not simply a tool of geographical orientation, what then is the function of making the East–West differentiation within Europe?

As is well known, certain sociocultural differences on regional grounds can be observed in all societies. Still, despite the remarkable differences between Northern Italy and Sicily, nobody in our times would question Italian unity, and the belonging of the entire country to the core of the West. Likewise, even the linguistic division of countries like Belgium or Switzerland would not inspire anybody to doubt the integrity and genuinely Western character of these societies. Thus, the ambiguities in identifying the borders between Western and Eastern Europe arise from deeper layers of differentiation. Their essence is neither a neutral geographical classification according to the magnetic poles, nor a definitive and value-loaded gesture of clearly circumscribing 'togetherness' as opposed to 'otherness.' The concept of 'Eastern Europe' represents a mixture of the latter two, and carries the inherent ambivalence of such a combination. With the very same momentum, it signals undivided 'Europeanness,' and also some reservations toward it. Although the societies embraced by the concept all are 'European,' they do not come up 'fully' to the standard of what 'Europeanness' implies. In this ambivalent classification, the implicit norm is the West, and Eastern Europe remains as much Eastern, as it maintains its 'other than Western' character. Thus, the concept has always been deeply imbued with politics. On the part of Eastern Europeans, its inherent political character has manifested itself in continuous attempts to close the East–West divide through adaptation to the Western norms of a given time; on the part of the West, the same politicized attitude expressed itself in the interest-driven recognition/refusal of the Eastern attempts, having immediate consequences on the (re)drawing of the invisible political, economic, and military map of the continent of Europe.

The doubtfulness of the borders—both in the harsh physical and the more subtle sociopsychological sense of the term—has inspired recurrent attempts to refine the geographically founded geopolitical classifications by denoting important and 'meaningful' subunits within the region (Todorova 1997). Probably the most important of such attempts has been the repeated separation of 'Central Europe' from the rest of 'Eastern Europe.' The concept of Central Europe as a more 'Westernized' entity with coherent sociopolitical and cultural meanings on its own appeared mainly in nineteenth/twentieth-century public debates by writers, political thinkers, and philosophers (Kundera 1984), but attempts at the political realization of togetherness and simultaneous separation from the rest of the region's nations also came to the surface among the goals of the sweeping political movements of 1848, 1918, and the late 1980s.

However, the ideas of 'Westernizing' Eastern Europe certainly are not the fresh production of modern times. Various grandiose experiments for their realization date back as far as the time after the fall of the Roman Empire. Since those distant days, the history of the region has been accompanied by heated debates over the 'belonging-issue,' which, in turn, has gradually become a decisive aspect of the self-perception and identity struggle of the people living on its territory. The East–West divide, despite its opaque character, has proved extremely strong during the past 1000 years of European history, serving a variety of social, political, military, and economic interests both within and between the countries of the European continent. With this historically elaborated comprehensive political meaning of the concept, 'Eastern Europe' has been as much a point of departure for Western self-identification as for the shaping of programs to combat those 'historic illnesses' which have hindered certain societies from becoming parts of Europe proper. In other words, up to the time of writing, 'Eastern Europe' has been considered the embodiment of the major historical failures of the European continent. It has symbolized the stone-hard limitations of creating a Europe without any subdivisions, and has also represented the accompanying feelings of discomfort and frustration. In the

course of the century-long failed efforts, these feelings have grown to become self-perpetuating mutual prejudices, which have exhibited an ever stronger influence on shaping politics of the East–West cohabitation. The persistence of these prejudices cannot be ignored when attempting to understand the difficulties that the current program of European integration (see Sect. 3) has to face in the course of its day-to-day realization.

2. *The Historical Roots of Eastern Europe's One-sided Development*

Historians, political thinkers, writers and philosophers seem to be in full agreement on identifying the emergence of 'the three historical regions of Europe' (Szücs 1988) in the aftermath of the Barbarian conquest against the late Roman Empire, which resulted in the division of the occupied territories between Europa Occidens, Byzantium, and a distinct transitional territory in between. This latter region—the historical forerunner of Eastern Europe—occupied a halfway position in all senses of the term. It was neither 'Western,' nor 'Eastern,' but an ever-changing mixture of the two. First, the region's geographic placement exposed it to frequent attacks from both of the neighboring big powers, each of whom regarded themselves the genuine heirs of the late Roman Empire—the Frank Empire and Constantinople. Second, the shaping of the region's decisive religions, traditions, and ethos was put also under dual pressure from the West and the East alike. As pointed out by the influential work of medievalists and historians of political ideas (Gerschenkron 1962, Said 1978, Szücs 1988, Wolff 1994), although the people of Eastern Europe took up Christianity early enough in their history, but the subsequent lasting Mongol, Ottoman, and Russian invasions revitalized a number of 'Eastern' features in their social relations, institutions, faith, and the running of their daily life. Third, as it has been demonstrated amply by recent studies in comparative history and historical anthropology (Gerschenkron 1962, Said 1978, Konrád and Szelényi 1979), the states of the region as potential actors of modernization played an ambivalent role in the premodern era: Though the late Medieval centuries brought about absolutist reigns similar to those in the West of the time, the actual function of the Eastern European absolutist rule was to reinforce the estate-based power of the landed nobility, while their Western counterparts prepared the soil for the take-off of capitalism, democracy and modern bourgeois development. The repeated events of military occupations, wars, mass uprisings, and the subsequent hurried efforts at reconstruction recurrently blockaded the crystallization of fundamental institutions of statehood and administration. Instead, these events usually concluded in hasty and forceful attempts of the conqueror to employ central power to eliminate the 'historic losses,' at all social and political cost. Such attempts at forced and inorganic modernization, however, caused lasting deformations in the sociopolitical order that have had a far-reaching impact on the development of the affected societies. In assessing the potential and limitations of corrective societal actions, the most dramatic consequences shaping both politics and societies in modern times were discussed extensively by sociologists and political scientists in the 1980s and 1990s (Kochanowicz 1997, Garton Ash 1993, Arato 2000). According to the virtually unanimous conclusions of these studies, the historically informed and persistent deformations of Eastern European societies can be summarized in three main features which clearly distinguish them from their contemporaneous Western counterparts. These are: the one-sided development of nationhood and national identity (which led easily to repeated waves of radical populism and irredentist nationalism); the underdeveloped nature of civil society (which recurrently has provided natural justification for the states' inclination to gain oppressive power over people's needs); and, finally, the periodic disappearance, at best, weak institutionalization of democratic governance (which has been the cause of loose public control over administration and economic management, and which also can be seen as being responsible for the lasting symptoms of social disintegration in the region).

These historic deformations became sources of dangerous political conflicts around the beginning of the twentieth century. After the failed revolutions of 1848 which, for a century to come, represented the last heroic attempts of the nations of the region to (re)gain national independence and create their state which would guard civil rights, law and order, and free capitalist development, the societies of Eastern Europe faced exclusion from Europe proper, and reacted accordingly—in a frustrated and hostile manner. As historical research has demonstrated convincingly (Konrád and Szelényi 1979, Schöpflin and Wood 1989), the outbreak of World War I cannot be explained without considering the preceding unhealthy nationalist rivalry within the borders of the increasingly ineffective, but still oppressive Austro-Hungarian monarchy, and the deep tensions between the cultural–political formations of the communities and their governing states in all the surrounding societies. Again, the outbreak of World War II cannot be explained merely in terms of the clashing political and economic interests of the leading powers of the European continent; the picture remains disturbingly incomplete without taking into account the extremist aspirations of Hitler's Germany and its allies to find a 'final solution' for the century-long diseases of confused cultural and national identity, and also without considering their deeply embedded attempts to claim new territories and borders for their historically 'stolen' nation states (Bibó 1991). However, not only

the two world wars, but also the 'invention' of the two, diametrically contrasting ways of totalitarian ruling originate from the same roots. As argued in Arendt's and Bauman's studies that have become classics of postwar social science, one can find in their creation the same forms of traumatized, oblique, frustrated, and confused nationalism, and the unstable institutions built on them (Arendt 1958, Bauman 1989). While the Nazi way of totalitarian rein put the superiority of race and nationhood at the center of its legitimizing ideology, communist totalitarianism—with its aim of radically transcending the past—denied the role of nationhood as such, and attempted to substitute it with values of internationalism and enforced equality. However, despite the viciously different responses of the two forms of totalitarianism, the emotionally heated attitudes toward nationhood and national identity, the conflictive relationship between the state and people's spontaneously formed communities, the weak observance of rights and law, and, consequently, the enduring harm done to individual freedom, remained key problems of Eastern European societies until the end of the twentieth century. True, the modernization of the economies and societies of the region, and the ultimate closing down of the East–West divide belonged to the core of the communist program of the four decades following World War II. However, the domino-like collapse of the Soviet-type regimes in 1989–90 testified sharply to the failures of these attempts, and drove back the societies in question towards the lost track of classical capitalism. Perhaps the principal evidence of the failures is the fact that, with the sweeping events of the late 1980s, the allegedly abolished problems of the interwar years have come to the surface with dramatic intensity: Widespread poverty, intense racism, extreme social marginalization, sharp inequalities of income and wealth, pervasive corruption, and weak legal protection of defenseless communities and individuals are among the most disturbing troubles of Eastern European societies at the time of writing. In order to understand the unfolding of these problems, a brief examination has to be made of the legacy that the communist systems of Eastern Europe have left behind.

3. *Eastern European Societies: From Where to Where?*

As a number of recent studies in social and political history have shown, despite the steps taken throughout the 1970s and 1980s toward economic and political liberalization in different countries of the region, the fundamental features of the communist system of Eastern Europe remained unchanged until the late 1980s (Kornai 1991, Garton Ash 1993, Arato 2000). Backed by the military, political, and economic monopoly of the all-embracing Soviet force in the region, the communist party-states of the affected countries maintained their power over all the segments of the economy and society, including people's most private matters of career choice, marriage, child-bearing, daily consumption, or cultural taste. Aside from the tools of enforcement solely in the hands of the ruling communist parties, the bases for such an extraordinarily extended power were provided by two major deeds: the concentration of 'people's property' in the hands of the party-ruled state, and the institutionalization of the day-to-day control over society through compulsory full employment. As comprehensive studies on the working of the socialist economy have demonstrated (Kornai 1991, Sik 1991), the concentration of all the means of production was intended to induce economic rationality through the centrally prescribed production commands driven by the Plan, while compulsory employment was seen as the base for fair shares from distribution and, simultaneously, as an effective means to combat poverty. However, such a structure turned against the initial goals rather quickly: from the early 1960s onwards, the Eastern European communist regimes, one after the other, had to face recurrent deep economic crises, and an increase in social tension originating from the 'dictatorship over needs' (Fehér et al. 1983) that led to nothing else but the equality of poverty on an unparalleled scale. Thus, the mere maintenance of the regimes required certain concessions: the most important among them were the rehabilitation of the family as a legitimate sphere of people's undisturbed privacy, and the tacit acceptance of the slow evolution of a second, informal economy.

However, these concessions proved powerful tools in societies' hands slowly to erode, then effectively to decompose the oppressive structures above them. Eastern European sociological, social-historical and economic research of the 1970s and 1980s provided a rich literature of these multifaceted processes which, in retrospect, can be regarded as the direct ascendants of the radical social upheavals after 1989–90 (Vajda 1988, Staniszkis 1991, Szalai 1991, Kochanowicz 1997). The move away from classical socialism was unstoppable. First, ever-spreading participation in the informal economy gradually took a lead in determining the standard and forms of consumption for substantial layers of society; thus, the tacit acceptance of people's informal work and their partial withdrawal from party control, even in the strictly regulated socialist workplaces, were also in the immediate interest of those in power—otherwise, the communist parties would have risked unmanageable crises in production and consumption that could have led to the swift fading of the justification of their 'blessing rule.'

Second, the family-based framework of the informal economy provided a forum for learning a number of market-related skills and thus assisting the underground continuation of the interrupted embourgeoise-

ment process. Such an underground preservation of officially denied values, attitudes, skills, and socio-economic arrangements later proved crucial in the post-1989 systemic changes of returning to a capitalist/bourgeois track. Third, the informal economies of Eastern Europe complemented the ever-impoverishing state-run welfare provisions with community-based social services, and with slowly elaborated forms of secondary redistribution. Thus, they had a role in correcting the inadequacies of the distribution of incomes driven from the 'first' economy, and also in developing those market-conforming forms of social protection, which then, effectively, assisted the transition process amid the rapid withering away of state-distribution some decades later.

In short, the informal economy and the social relations around it gradually became a second—mostly hidden—regulator in the functioning of the communist regimes, and an important second pillar in organizing the daily life, well-being, aspirations, and life-careers of substantial groups of Eastern European societies.

However, the emergence of this second system had also serious deficiencies. As sociological research on the malfunctions of the 'socialist' welfare states has evidenced it (Deacon-Szalai 1990, Kochanowicz 1997, Atal 1999, Lessenich 2000), those who, for a range of varied reasons, could not participate, became increasingly dependent on the state that gradually intensified their defenselessness, instead of mitigating it. With the spreading and tacit acceptance of the regulatory role of the informal economy, the nonparticipating groups were designated as 'misusers' of the public resources, and cuts in assistance for them were approved on a mass scale. Thus, the spreading of participation in the informal economy gave rise to serious social divisions which, amid the troublesome economic conditions of the post-1989 years, eventually became an open war between the 'nondiligent' poor and the 'industrious' nonpoor.

A further shortcoming of the dual system was its weak institutionalization: any claims for the formal acknowledgement of informal work-collectives, service-providers, interest-representations, and the like were seen as open attacks against the principles of the prevailing order, and were treated as political crimes. On these grounds, the informal economy became a battlefield for freedom, but at the same time, the political connotations of participation further hindered its institutionalization. The negative consequences of such a development came to light mainly after the collapse of the old rule. As in-depth studies of the democratic potentials of Eastern Europe have pointed out convincingly (Staniszkis 1991, Berend 1993, Arato 2000), despite widespread earlier practices, civil society has proven to be extremely weak, and the new system hardly could count with its provisions, protective associations, and community-run services amid the deep 'transitional crisis' of the 1990s.

The weakness of civil society has given rise to serious crisis phenomena amid the two intertwined major processes of postcommunist transition: the decomposition of the formerly unlimited power of the central states, and the privatization of the earlier anonymous 'people's properties.' Paradoxically, the earlier resistance to the state as oppressor is now quite clearly being reversed, and while the various corporate bodies and interest alliances only clung to the state distribution policy out of fear and defenselessness, they now make angry claims on it. Behind the opposing principles of privatization intended to 'regulate' the plundering of public assets, one finds intensely competing demands for compensation. Having the arguments justifying these claims accepted and embodied in the legislation is a question of raw political force. As comparative economic studies in the region have demonstrated with ample empirical evidence (Róna-Tas 1994, Stark 1996), in this way, privatization and the creation of a bourgeoisie is the direct function of the latent bargaining positions established over past decades. Hence, the process of privatization has led to a jump in uncontrolled and unregulated inequalities of income and wealth, and to the emergence of a new. prosperous elite with little legitimization. At the same time, the process has produced masses of victims at the other end of the scale. Besides depriving them of any access to the newly distributed properties, the easiest compromise to find resources to meet the hunger of the vocal groups has been to cut back sharply on state expenditures on welfare and social services. With these steps, however, Eastern European transition societies have produced vast numbers of chronic poor, whose fate has been extreme social marginalization. Thus, despite the initial hopes of 1989–90, massive poverty and the accompanying syndromes of dramatic social disintegration have not disappeared with the recovery from the crises of the early 1990s, but have become the decisive indicators of a still non-Westernized path of current Eastern European development. The conflicts that arise from this situation have further consequences. The still excessive presence of the state in most of the region's economies, as well as the understandable open aspiration of the earlier overblown state bureaucracy to reinforce its own position of power, at most only help broad strata of societies to reach the recognition that the creation of a private market in the Western sense is a 'foreign' prescription for the process of embourgeoisement in the region—their 'genuine' path still leads through nationalized modernization. Thus, it is hardly surprising that Western and Eastern economists, sociologists, and political scientists analyzing the major sociopolitical processes of postcommunist transition arrived at largely consensual conclusions by the late 1990s (Kochanowicz 1997, Standing 1997, Arato 2000). There seems to be a general agreement that the spreading of anti-West feelings provides a fertile soil

for heated nationalism, aggressive racism, and the re-emergence of authoritarian tendencies; hence, these recent tendencies in the changes of popular attitudes endanger seriously the once vivid hopes of creating a Europe without boundaries. However, these unanimous warnings have little impact on actual politics: at best, social science reflects and informs the ongoing attempts of European integration, but can hardly influence it.

4. *Eastern Europe's (Re)turn to Europe: As Social Scientists See It*

With the collapse of communism in 1989–90, both Western and Eastern social scientists investigating Eastern Europe had to face a number of new challenges. It was not only the 'subject' of their research which suddenly changed its framework, but the formerly prevailing concepts and methods of scientific analysis had also to be reevaluated. Such a simultaneous change of 'subject' and 'approach' is a rather rare development in the history of the social sciences. However, the collapse of communism swept away a sociopolitical reality together with its prevailing ideological reflection: the death of communism put an end to the scientific lead of Marxism, and forced this powerful worldview into the background of the history of philosophy. Marxism as a frame of reference ceased to function as an adequate and applicable conceptual model for postcommunist scientific research.

Among the multifaceted consequences of these changes—that have affected as much the structure and content of higher education, as the composition of the academic community, or the financing of research and its accessibility to the broader public—there are two major aspects of the profound renewal of scholarly work that have to be underlined here. First, as an immediate outcome of the fall of communism, certain areas of research once so important in characterizing Eastern European social science have disappeared completely, while formerly nonexistent approaches and strands of thinking have gained substantial influence. It is enough to refer here to the utter disappearance of 'scientific socialism,' or 'socialist political economy' on the one hand, and the impressive rise of 'political science,' 'constitutional studies,' or 'microeconomics,' on the other. Second, due to the radical switch in the politics of science, one can record a remarkable shift in the topical composition of research, together with a fundamental institutional reorganization of academic work. Due to the preceding monopoly of Marxism as the official stand of the social sciences in Eastern Europe, previously suppressed intellectual strands demanded their well-deserved institutional acknowledgement after 1989–90, bringing to the forefront the 'underground' culture of formerly nonaccessible research on 'forbidden' subjects such as the history of the Gulags, the persistence and reproduction of poverty, the critical analysis of the planned economy, or the sociology of the hidden embourgeoisement process in societies under Soviet rule. With the now formal acknowledgement of these areas of research in the 1990s, marked shifts of emphases as well as an increased pluralism of approaches to issues at the core of social science interest were registered. However, one has to remark: these developments signal more a 'back to normal' state of affairs in research than the appearance of a genuinely new voice that one could call 'Eastern European social science.' It is better to characterize the situation as Eastern Europe's reintegration to the universal world of the academia. True, the paths to this scholarly universe have had markedly different histories in the West and the East. As to the East, the potentials of the current surprisingly quick reintegration have to be identified in the widespread underground movements of 'flying universities,' samizdat publications, and secret mass-events of the so-called 'secondary public' under communism, which not only formed the bases of strong national communities of social scientists, but also embraced a great number of cooperating groups of dissident intellectuals from Moscow to Warsaw, and Prague to Sofia. After the lifting of the political barriers, the preceding long history of such extensive underground experimentation and the simultaneous preservation of the critical stand of social science have provided a rich foundation to a strong theoretical orientation, as well as to the internationally acknowledged high qualities of empirical research in Eastern Europe.

Given the major aim of the postcommunist transition in closing down the East–West divide within the shortest possible timespan, it is understandable that the bulk of social science research in and about Eastern Europe has addressed issues of the greatest political importance of the time: marketization, democratization, issues of institution-building, and Eastern Europe's integration into an undivided Europe are in the forefront of the ongoing investigations. Following predominantly the theory of neoliberal economics, research on the changes in property relations, the institutional conditions of transition from the command ruled economy to a market regulated one, the creation of a banking system from scratch, and Eastern Europe's participation in the processes of globalization have served mainly to provide assistance to the newborn governments in the region, to orchestrate the difficult processes of transformation with the least possible social and political conflict. With such a shift toward applied research, little has yet been done, however, toward the establishment of an original economic theory which would provide ample concepts and explanations to one of the most disturbing puzzles of the late 1990s: though the neoliberal prescriptions of transformation have been followed in practically all of the 28 countries of the former Soviet empire,

their markets rarely resemble those of the Western societies.

The dominance of descriptive empirical studies and applied research is perhaps even more characteristic in other areas of the social sciences. True, the relatively unstable political processes in the region require a close follow-up of party affiliations and social movements, and a regular monitoring of people's political attitudes. Similarly, the success of institution building has to be measured against people's use/misuse of the new institutions. The list of examples can be followed with equally justifiable descriptive studies on the restructuring of people's value orientations and daily consumption, or their evaluation of the old–new institutions of public administration. Although one can hardly question the usefulness of any such research from the point of view of administrative and political decision making, as at the time of writing, it has made little contribution either to the building of a richer theory of capitalist societies, or to the deeper understanding of the still prevailing marked differences between the two halves of Europe.

Some steps toward a more thorough analytical examination of the peculiarities of contemporary Eastern Europe have been made, however, in a few novel comparative studies on state–society relationships, the characteristics of the welfare states, and the features of 'old' and 'new' poverty in both the West and the East. These studies have been initiated mainly by huge international organizations (ILO, OECD, the World Bank, UNESCO), and were run on principles of equal participation by Eastern and Western European scholars. Though it is perhaps too early to arrive at definitive conclusions, the lessons of these recent studies indicate unanimously the persistence of a sharp East–West divide, much in accordance with the sociocultural faultlines that have been explored by the historical studies on earlier centuries. It seems that in their post-1989 development, Eastern European societies have taken a lead toward increasing social disintegration between their adaptive majorities and the extremely marginalized minorities in long-term poverty. The states of these new democracies are squeezed between the contradictory challenges of accomplishing marketization and combating social disintegration at the same time; due to the weakness of their civil societies, they have postponed repeatedly the addressing of the latter problem by creating the required strong welfare systems. As a result, the current social map of Eastern Europe resembles more some Latin American societies than those of the neighboring Western Europe.

5. *Summary*

Though meant also as a geographical classification for denoting the region between the River Elbe and the Ural Mountains, the concept of 'Eastern Europe' is used mainly to express certain historically informed sociocultural differences within the European continent. It carries heavy layers of ambivalence: although the societies embraced by it all are regarded as 'European,' they do not come up 'fully' to the standard of what 'Europeanness' implies.

Such historically informed ambivalence characterizes deeply as well as the current efforts to unite Europe. Besides, they leave their mark on the internal social development of the region's societies, and also have serious consequences for the endurance of their post-1989 as the crisis.

Social science research of the past decades has centered around the historical origins and perpetuating factors of the East–West divide. Nevertheless, following the collapse of communism, it has turned more toward investigating the potentials and limitations of closing it down. The necessary shift toward the dominance of descriptive research in assistance of the politics of integration has slowed down, however, the in-depth exploration of those aspects of recent Eastern European development which carry the potential of repeated diversion from the Western path.

Eating Disorders: Anorexia Nervosa, Bulimia Nervosa, and Binge Eating Disorder

Two major eating disorders have been defined and operationalized: anorexia nervosa (AN) and bulimia nervosa (BN). In recent years preliminary definitions have been given for a third eating disorder: binge eating disorder (BED). Anorexic and bulimic eating disorders usually begin in adolescence and young adulthood and more than 90 percent of the cases of AN and BN are female. Eating and food intake can have very different functions: eating fulfills the biological necessity of keeping us alive, but it can also be a source of pleasure and joy. Food intake plays an important role when we relax or celebrate with other human beings (festivities). For a person who hungers unvoluntarily this can be bothersome or painful. On the other hand, an anorexic patient who has achieved reducing weight considerably to a pathological level will be proud of the result. Refusal to eat on the level of society can be used as a means of political pressure (hunger strike). Within a family system the refusal to eat of an anorexic girl can—in the lack of other possibilities of expression—be an attempt to find and define herself; it can be a sign of inner resistance and defense against the intrusion of others. The anorexic patient avoids confrontation with the increasing demands of the role of an adult person (sexuality, relationships, profession, achievement) and regresses to an earlier more infantile stage. Eating too much as well as eating too little can be damaging to mental and physical health.

1. Clinical Features (Diagnoses and Differential Diagnoses)

1.1 Anorexia Nervosa

Anorexia nervosa is characterized by a refusal to maintain body weight at or above a minimally normal weight for age and height, an intense fear of gaining weight or becoming fat even though underweight, a disturbance in the way in which one's body weight or shape is experienced with undue influence of body weight or shape on self-evaluation. Frequently the seriousness of current low body weight is denied or hidden. In postmenarcheal females, amenorrhoea is the fourth diagnosic criteria; its usefulness has, however, been questioned by some research groups; anenorrhoea largely is secondary to low body weight and the starvation syndrome. Laboratory tests are usually of little help for diagnosing AN. Diagnosis is made primarily on the basis of a thorough psychiatric examination in which it is a task of the examiner to find out the motives behind being underweight. According to the *DSM-IV* criteria of the American Psychiatric Association (1994) two subtypes of AN can be distinguished: (a) the restricting type and (b) the binge eating/purging type.

AN is frequently associated with social withdrawal, irritability, insomnia, depressed mood, and diminished interest in sexuality. In part, these depressive features are secondary to starvation and disappear with weight restoration. Preoccupation with thoughts about food, collecting recipes, and hoarding food are frequently seen in AN patients. In more than a third of AN cases obsessive compulsive features unrelated to food and eating are also present. Associated with AN can also be an exaggerated need to control one's environment, concerns about eating in public, feelings of ineffectiveness, inflexible black and white (dichotomous) thinking, an overly restrained initiative, and emotional expression. AN patients of the binge eating/purging type (in comparison to restricting anorexics) more frequently have problems in impulse-

[a]Resulting from vomiting. [b]Resulting from laxative abuse. [c]Resulting from starvation.

control, abuse of alcohol or other drugs, lability of mood, and they are sexually more active.

Starvation and/or inappropriate compensatory behaviors (vomiting, use of laxatives, etc.) have a variety of effects on most organ systems. Table 1 lists a number of laboratory findings usually found in starving AN patients. Except for hypokaliemia, hypochloremia, and metabolic alcalosis which are secondary to vomiting and metabolic acidosis resulting from laxative abuse, most laboratory findings are secondary to the state of starvation and the peculiar eating behaviors and eating patterns. Clinically the reduced activity of the sympathetic nervous system goes hand in hand with bradycardia, the development of fine downy body hair (lanugo), low blood pressure, constipation, cold intolerance, petechiae in the extremities, and peripheral edema during weight restoration.

1.1.1 Differential diagnosis. Occasionally general medical conditions (gastrointestinal disease, occult malignancies, brain tumors, unclear infectious diseases) associated with weight loss are misdiagnosed as AN. When diagnosing AN it is important not to focus primarily on the emaciated state but rather on the psychological features explicated in the diagnostic criteria for AN. For the physician it is important to search for a psychological motive for reducing weight. In psychiatric disorders such as depression or schizophrenia, weight loss may occur, which, however, is secondary and not resulting from a drive for thinness as in AN.

Compulsive disorder, body dysmorphic disorder, and social phobia concur with AN not infrequently. AN of the binge eating/purging type can be very similar to BN and the differentiation is (rather artificially) based on current body weight.

See *Anxiety and Anxiety Disorders*; *Obsessive–Compulsive Disorder*.

1.2 Bulimia Nervosa

Bulimia nervosa (BN) also occurs like AN predominantly in adolescent girls or young women. Its essential features are binge eating and inappropriate compensatory behaviors to prevent weight gain. In these patients usually self-evaluation is excessively influenced by body shape and weight. According to the *DSM-IV* criteria, a binge is defined on objective grounds (rather than subjective) as 'eating in a discrete period of time an amount of food that is definitely larger than most individuals would eat under similar circumstances.' Continuous snacking (eating small amounts of food throughout the day) which may also occur would not qualify as a typical (objectively defined) binge. Diagnosis of BN according to *DSM-IV* criteria requires that binge eating and inappropriate compensatory behaviors both occur on average at least twice weekly for three months.

Associated laboratory findings are very similar to those reported for binge eating/purging AN. Fluid and electrolyte abnormalities (hypokaliemia, hyponatremia, hypochloremia), metabolic alcalosis with elevated serumbicarbonate resulting from vomiting or metabolic acidosis from laxative abuse, dentrocavities, enlargement of the parotid glands, and rarely but potentially fatal esophageal tears, gastric rupture, and cardiac arrhythmias.

1.2.1 Differential diagnosis of BN. Disturbed eating behavior can be present in certain neurological or general medical conditions such as the Kline–Levin syndrome; however, certain key features of BN such as overconcern with body shape and weight are lacking. Also, a multi-impulsive form of BN has been described in which several impulsive behaviors are observed (impulsive stealing, impulsive drinking, impulsive suicidal acts, impulsive self-damaging behavior). Prognosis for this subgroup seems to be worse than for BN in general.

1.3 Binge Eating Disorder

Binge eating disorder (BED) is defined as being very similar but not identical to nonpurging BN. Main features of BED are binge eating at least twice weekly over a period of six months, associated with marked distress. However, in BED no inappropriate compensatory behavior to prevent weight gain, such as self-induced vomiting, use of laxatives, diuretics or other medication, is present. Many but not all BED patients are overweight. Overweight BED patients have the usual risks associated with obesity (hyper-

tension, orthopedic problems, diabetes, etc.). They do not have the risks of purging behavior observed in binge eating/purging AN and BN (electrolyte imbalance, alcalosis/acidosis from laxative abuse, sialadenosis from vomiting, severe dental problems from vomiting, renal failure). New research indicate that BED has many similarities with BN but that BED is quite dissimilar from AN. Very few anorexics later develop BED and very few BED patients later develop AN.

As in BN, neurological and other general medical conditions associated with bingeing and weight gain must be differentiated from BED.

1.4 Eating Disorders—Not Otherwise Specified

The eating disorders—not otherwise specified (EDNOS) category is for disorders of eating that do not meet the criteria of any specific eating disorder such as AN, BN, and BED. In *DSM-IV* six examples are given. Usually one criteria of a major eating disorder (AN, BN) is not met. One of several examples for EDNOS is: all of the criteria of BN are met, except that the binge eating and inappropriate compensatory mechanisms occur at a frequency of less than twice a week and for a duration of less than three months.

2. Epidemiology, Course and Prognosis

2.1 Anorexia Nervosa

A number of studies indicate that the prevalence of AN has increased over the decades of the twentieth century—especially since the 1960s. Research among females in late adolescence and early adulthood have revealed rates of 0.4–1.1 percent for presentations that meet full criteria for AN according to *DSM-IV*. Less than 10 percent of all treated cases with AN are male. Mean age at onset for AN is 16–18 years. Onset very rarely occurs in individuals over age 40 years. The onset of illness is frequently triggered by life events which increase uncertainty, cause anxieties, and put new demands on the individual. The mortality rate of patients with AN is only second to that of politoxicomanic drug use and dependence and it is much higher than for schizophrenia or depression. Over the long-term course of 20 years, 10–15 percent of patients with AN die from starvation, suicide, or electrolyte imbalance (which can cause cardiac or renal failure (Ratnasuriya et al. 1991). First-degree relatives of patients with AN have an increased risk for that disorder. Mood disorders have also been found to be more prevalent in the biological relatives of individuals with (binge eating/purging type) AN.

2.2 Bulimia Nervosa

Among adolescent and young adult females the prevalence of BN is about 0.8–3 percent. As in AN, the disorder is usually found in pubertal girls or young adult women; less than 10 percent of the cases of BN are men. The onset of BN is usually in late adolescence and early adult life. Although patients with BN at times can be very tough to treat, the course over a time is not as malignant as it can sometimes be in AN. Frequent and excessive dieting may trigger the start of binge eating. In a high percentage of clinical samples the disturbed bulimic eating behavior persists over several years and the course can be chronic or intermittent or with remission. In the last few years several studies have reported on the six- to 10-year course of BN (Fichter and Quadflieg 1997a). The outlook for BN patients is not quite as pessimistic as for AN patients: although about a third of treated cases show a more or less chronic course; the majority at six-year follow-up no longer fulfill the criteria for a major eating disorder. This, however, does not mean that all are free of eating disorder symptoms which in some way interfere with their everyday life.

2.3 Binge Eating Disorder

The prevalence of BED is roughly the same as for BN (1.5 percent among adolescent and young adult females). Although BED is predominantly found in females, the proportion of males is higher than in AN or BN. The short- and medium-range course of BED appears to be equivalent to that of BN (Fichter et al. 1998). Research indicates that besides BED there are other eating disorders associated with overweight not fulfilling criteria for BN or BED. Psychiatrists have carried out very little research on obese patients with atypical binges (continuous snacking throughout the day) and mental problems resulting from getting obese on the basis of a general medical condition (endocrinological disturbance) or medication which increases appetite and body weight (neuroleptics, certain antidepressants, lithium, etc.).

3. Etiology and Pathogenesis

For the pathogenesis of anorectic and bulimic eating disorders the following factors must be taken into consideration: (a) sociocultural factors (mediated through family, school, and mass media), (b) biological factors (genetic, neurochemic), and (c) life events and chronic difficulties.

See *Mental Illness, Etiology of.*

3.1 Sociocultural Factors

Eating disorders are fairly prevalent among young women in industrialized countries where the ideal of body thinness exerts considerable pressure especially on adolescent girls and young women. Most young

women have dieted once, several times, or many times—some successful, many not. In industrialized countries food exists in abundance. Studies in Third World countries have shown that anorexic and bulimic eating disorders are seen rarely there and if they occur the patient was usually from a well-to-do family. Among persons who migrated from a Third World country to an industrialized country and who were thus exposed to ideals and pressures to be slim, anorexic and bulimic eating disorders are seen more frequently than among those who remained in the country of origin.

The ideals of body slimness (especially for women) and the ideal of body fitness (especially for men) are very prevalent in industrialized countries and exert pressures on individuals. We do not know exactly why these ideals exist and how they came about but some interesting explanations exist. From an anthropological–evolutionary perspective, it is important to note that mankind never in its history has had an abundance of food in such a large proportion of the population over such a long period of time. During the evolution of mankind, food at times was scarce and our predecessors would not have survived if they had not developed special biological adaptations to periods of hunger and starvation. When we reduce our food intake and lose body weight many adaptive physiological adaptations take place which help us save energy (bradycardia, hypotension, lowering of T3, hypercortisolism, and temporary loss of reproductive functions). Mankind, however, is biologically very ill-equipped for dealing with food abundance over very long periods of time. The abundance of food appears to be a necessary but not sufficient factor contributing to the etiopathogenesis of these eating disorders. See *Psychiatry and Sociology*.

3.2 Biological Factors

A number of twin studies have shown relatively high concordance rates among monozygotic compared to dizygotic twins especially for AN but also for BN. Currently large studies using the techniques of molecular genetics are underway but the results are not yet available. AN and BN frequently have an onset around puberty, the time when, due to hormonal changes, the body undergoes considerable changes. Starting at puberty, luteinizing hormone (LH) and follicle-stimulating hormone (FSH) are secreted regularly, inducing the secretion of gonadal hormones which have an impact not only on our body but also on our brain. Also, body fat is not distributed the same way in men and women. There exists a sexual dimorphism: the fat deposits of men are predominantly in the abdominal region and those of females are primarily observed on the trunk, buttocks, and the extremities.

The hypothalamus plays an important role in the regulation of eating behavior. Simplifying a highly complex regulation, one can speak of an 'eating center' in the lateral hypothalamus and a 'satiety center' in the medial hypothalamus. Electrical stimulation of the 'eating center' or making a lesion in the 'satiety center' results in excessive eating. Stimulating the 'satiety center' or putting a lesion into the 'eating center' results in loss of appetite, loss of weight, and finally death.

3.2.1 Control of food intake. The following substances secreted in the human body have been shown to reduce hunger or food intake: (a) corticotropin-releasing hormone (CRH) which is secreted in the hypothalamus, (b) certain peptides secreted centrally or peripherally such as cholecystokinin (CCK), glukagon, bombesin, gastrin-releasing peptide, somatostatin, neurotensin, and leptin, and (c) the monoamine serotonin. Other substances increase food intake, such as the neuropeptide Y and the peptide YY, galanin, beta-endorphine, dynorphine, growth-hormone-releasing-hormone, and the monoamine epinephrine. In animal experiments it has been shown that overeating can become a conditioned response to stress.

3.2.2 Hormonal adaptations. Most if not all hormonal changes observed in AN and to some extent also observed in other eating disorders (BN, BED) are a sign of adaptation to a temporarily reduced food intake or low body weight. In emaciated patients with AN (as in healthy starving individuals), hypercortisolism and insufficiently suppressed cortisol response following application of dexamethasone are observed. During starvation the hypothalamo–pituitary–gonadal system is shut down so that reproduction cannot take place. The 24-hour secretory pattern of the luteinizing hormone (LH) and the follicle-stimulating hormone (FSH) regress to a pubertal or infantile pattern. Plasma levels of estradiol and progesterone are practically down to zero in emaciated anorexic patients, resulting in amenorrhoea. Normal-weight bulimic women show ovary dysfunctions. About 50 percent of them have unovulatory cycles and 40 percent show defects in the lutal phase (Fichter 1992). Underweight anorexic patients show increased levels of insulin and glucose following a test meal. When body fat is metabolized during starvation, free fatty acids and ketone bodies are increased in the plasma. They can serve as state markers for a negative energy balance. In emaciated patients with AN, the activity of the sympathetic nervous system is reduced, resulting in bradycardia, hypotension, and dsregulation of body temperature. These are also mechanisms for saving energy during starvation. Emaciated anorexics also appear to have lower levels of serotonin and its metabolites. Starvation in healthy subjects as well as starvation in AN

Table 2
Goals and interventions in the therapy of AN and BN

Areas of deficit	Aims and areas of intervention
Information	**Giving relevant information to patient and relatives (psychoeducation)** ● nutrition: eating wide variety of foods; no 'forbidden foods' ● effects of specific stress/pressures on behavior ● possibilities and limitations of therapy ● consequences of anorexic and bulimic behavior ● importance of taking responsibility oneself (self-help)
Disturbance of interoceptive, proprioceptive, and emotional perception	**Enhancing perception in different ways** ● self-monitoring exercises to improve body perception (movement, touch) ● exercises to enhance enteroceptive perception (satiety, hunger, feeling pressures, pain) ● improving the perception of emotions
Problems in emotional expression and lack of social skills	**Training the expression of emotions** ● understanding the 'antecedents-behavior-consequences chain' ● exercises in catharthis ● how to express emotions appropriately (at the right time to the right person in the overall most effective way) ● social skills training in role play sessions
Dysfunctional, irrational thoughts, beliefs, and values	**Cognitive behavior therapy (CBT)** ● functional analysis of 'antecedents-behaviors/thought-consequences' ● identifying dysfunctional, irrational thoughts, beliefs and values ● 'Socratic dialog' questioning irrational thoughts, values and dysfunctional beliefs ● designing new and more appropriate 'software' (rational thoughts and functional beliefs)
Chronic difficulties or stress in social environment	**Reducing pressures and stress** ● by making changes in the environment (e.g. move to own flat) ● through focusing on interpersonal relationships (IPT) ● Sessions with parents or partner when indicated
Pathological eating behavior	**Nutritional counseling and behavior therapy** ● structure for 3 main meals and 1–2 snacks; no food consumption outside the structured meals ● eat every food (no banned food, no food selection) ● learning about the nonsense of dieting ('weight cycling') ● identify antecedents of binges; eating outside structured meals
Body weight deviations	**Body weight control and management** ● eat when feeling hungry but not when under pressure ● if underweight: stepwise increase of body weight in behavioral weight increase program ● if overweight: slow decrease in food intake and body weight over long period of time (behavioral program); in several cases very low calory diet (VLCD) combined with behavioral program; in very severe cases consider surgery
Passivity, hesitance to take responsibility and make personal decisions	**Activation of patient's own initiative and responsibility** ● encourage patient to make his/her own relevant and necessary decisions ● supporting reasonable self-help groups

Table 2
Continued

Areas of deficit	Aims and areas of intervention
Medication	**When indicated:** ● supplement potassium and other electrolytes and vitamins ● in BN and BED consider prescribing serotonin-receptor-inhibitor especially when fading out (behavioral) psychotherapy
Fear of failure and of relapse following therapy	**Maintenance program** ● find solutions for problems which can be anticipated ● gradual exposure to 'daily hassles' ● Further support necessary (outpatient treatment, self-help group) ● learning to cope efficiently with everyday stress

subjects results in brain atrophy demonstrated in CT and MRT studies.

3.3 External Factors

Life events and chronic difficulties may over time make an individual vulnerable to later develop an eating disorder or may trigger its onset. During the time of adolescence not only bodily changes occur but also the individual is confronted with new demands. They are now expected to have more responsibilities and they are increasingly confronted with contacts and relationships with the other sex. Especially during adolescence, feeling left out or rejected by others can hurt deeply and increase vulnerabilities. Developing an eating disorder is a way of avoiding failures in everyday life because a wide range of important things in life are reduced to a small area of shape and weight concerns. In controlling her weight an anorexic girl can succeed. In some families with an anorexic patient, family relationship interactions cause problems. Research in this area, however, is difficult because what we see in clinical cases can be the reaction of a family to the illness rather than its cause (Russell et al. 1987). More solid research is needed in this area.

4. Treatment of Eating Disorders

4.1 General Aspects

Details on the treatment of eating disorder are given in the practice guidelines of the American Psychiatric Association (2000) which can be obtained through the internet (http://mentalhealth.uca.edu/apa.scpg/eating-disorders). Antidepressants such as serotonin re-uptake inhibitors can be beneficial in the therapy of BN and BED. Their efficacy in AN has not clearly been established.

4.2 Psychological Therapies

There exists a wealth of data on the efficacy of cognitive behavior therapy (CBT) in BN (Agras et al. 2000). CBT has also been shown in some studies to be effective in BED. Although there are several controlled studies on the therapy of AN, research in the past two decades has focused on BN and BED and further controlled studies on the treatment of AN are needed. Table 2 shows major areas of intervention for anorexic and bulimic eating disorders. Most controlled trials on psychological therapy have focused on dealing with dysfunctional, irrational thoughts and beliefs using cognitive behavior therapy or have focused on directly modifying the eating behavior. However, it has also been shown that other forms of therapies such as nutritional management or interpersonal therapy which are completely different can be effective treatments for BN.

See *Cognitive and Interpersonal Therapy: Psychiatric Aspects*.

4.3 Specific Aspects for the Therapy of AN

When a patient is severely emaciated, psychological therapies alone will not lead very far; motivating the patient to eat more and gain weight is then very important. Some patients gain weight when they are encouraged and supported to do so; others need structured behavioral programs with strong incentives for weight gain. In a few patients both these approaches will fail and tube feeding will at least for a certain period of time be necessary. Weight increase of about 150 grams per day is desirable. Other focuses of the treatment of AN are listed in Table 2 (enhancing perception, training of the expression of emotions, enhancing social skills, cognitive restructuring of dysfunctional thoughts and beliefs, normalizing eating behavior, dealing with anxieties, and encouragement to take on new responsibilities).

Most controlled treatment studies with BN patients use cognitive behavior therapy (CBT) with some variation of it. Some studies have shown the usefulness of behavioral management of eating behavior, interpersonal therapy, nutritional counseling, and guided self-help. Little attention has been given by researchers

to assess treatment, focusing on disturbances of interoceptive, proprioceptive, and emotional perception which according to Hilde Bruch (1973) is a central feature of all eating disorders (Laumer et al. 1997). For dysfunctional behaviors such as bingeing it is of importance to identify antecedent events which trigger the dysfunctional behavior of the patient. In the next step when antecedence, behavior, and consequences are clearer, behavioral interventions such as social skill training can be employed to improve coping in future problem situations.

In addition to the other areas listed in Table 2, body weight control and management is of special importance for the treatment of patients with BED if they are overweight or obese.
