There are two popular approaches to choosing alternatives to standard statistical procedures when one fears that assumptions are likely to be violated. One is to use robust procedures, and the other is to use nonparametric procedures. Robust procedures are designed to be less sensitive to violations of specific assumptions without sacrificing too much of the good performance of standard procedures when the standard assumptions hold. Nonparametric procedures are chosen so that their properties can be verified under fewer assumptions. For more details on these types of procedures see *Robustness in Statistics* and *Nonparametric Statistics: The Field*.

Estimation: Point and Interval

Introduction

When sampling is from a population described by a density or mass function $f(x \mid \theta)$, knowledge of θ yields knowledge of the entire population. Hence, it is natural to seek a method of finding a good estimator of the point θ, that is, a good point estimator. However, a point estimator alone is not enough for a complete inference, as a measure of uncertainty is also needed. For that, we use a set estimator in which the inference is the statement that $\theta \in C$ where $C \subset \Theta$ and $C = C(\mathbf{x})$ is a set determined by the value of the data $\mathbf{X} = \mathbf{x}$ observed. If θ is real-valued, then we usually prefer the set estimate C to be an interval. Our uncertainty is quantified by the size of the interval and its probability of covering the parameter.

1. Point Estimators

In many cases, there will be an obvious or natural candidate for a point estimator of a particular parameter. For example, the sample mean is a natural candidate for a point estimator of the population

mean. However, when we leave a simple case like this, intuition may desert us so it is useful to have some techniques that will at least give us some reasonable candidates for consideration. Those that have stood the test of time include:

1.1 The Method of Moments

The method of moments (MOM) is, perhaps, the oldest method of finding point estimators, dating back at least to Karl Pearson in the late 1800s. One of the strengths of MOM estimators is that they are usually simple to use and almost always yield some sort of estimate. In many cases, unfortunately, this method yields estimators that may be improved upon.

Let $X_1,\ldots, X_n$ be a sample from a population with density or mass function $f(x|\theta_1,\ldots, \theta_k)$. MOM estimators are found by equating the first k sample moments to the corresponding k population moments. That is, we define the sample moments by $m_j = \Sigma_{i=1}^n X_i^j/n$ and the population moments by $\mu_j(\theta_1,\ldots, \theta_k) = \mathrm{E}X^j$ for $j = 1,\ldots, k$. We then set $m_j = \mu_j(\theta_1,\ldots, \theta_k)$ and solve for $\theta_1,\ldots, \theta_k$. This solution is the MOM estimator of $\theta_1,\ldots, \theta_k$.

1.2 Maximum Likelihood Estimators

For a sample $X_1,\ldots, X_n$ from $f(x\,|\,\theta_1,\ldots, \theta_k)$, the likelihood function is defined by

$$\begin{aligned} L(\theta\,|\,\mathbf{x}) &= L(\theta_1,\ldots, \theta_k\,|\,x_1,\ldots, x_n) \\ &= \Pi_{i=1}^n f(x_i\,|\,\theta_1,\ldots, \theta_k) \end{aligned} \tag{1}$$

The values of θ_i that maximize this function are those parameter values for which the observed sample is most likely, and are called the maximum likelihood estimators (MLE). If the likelihood function is differentiable (in θ_i), the MLEs can often be found by solving

$$\frac{\partial}{\partial\theta_i}\log L(\theta\,|\,\mathbf{x}) = 0, \quad i = 1,\ldots, k \tag{2}$$

where the vector with coordinates $\frac{\partial}{\partial\theta_i}\log L(\theta\,|\,\mathbf{x})$ is called the score function (see Schervish 1995, Sect. 2.3).

Example If $X_1,\ldots, X_n$ are i.i.d. Bernoulli (p), the likelihood function is

$$L(p\,|\,\mathbf{x}) = \prod_{i=1}^n p^{x_i}(1-p)^{1-x_i} \tag{3}$$

and differentiating log $L(p\,|\,\mathbf{x})$ and setting the result equal to zero gives the MLE $\hat{p} = \Sigma_i x_i/n$. This is also the method of moments estimator.

If we instead have samples $X_1,\ldots, X_n$ from a binomial (k, p) population where p is known and k is unknown, the likelihood function is

$$L(k\,|\,\mathbf{x}, p) = \prod_{i=1}^n \binom{k}{x_i} p^{x_i}(1-p)^{k-x_i} \tag{4}$$

and the MLE must be found by the numerical maximization. The method of moments will give the closed form solution.

$$\hat{k} = \frac{\bar{x}^2}{\bar{x}-(1/n)\Sigma_i(x_i-\bar{x})^2} \tag{5}$$

which can take on negative values. This illustrates a shortcoming of the method of moments, one not shared by the MLE. Another, perhaps more serious shortcoming of the MOM estimator is that it may not be based on a sufficient statistic (see *Statistical Sufficiency*), which means it could be inefficient in not using all of the available information in a sample. In contrast, both MLEs and Bayes estimators (see *Bayesian Statistics*) are based on sufficient statistics.

1.3 Bayes Estimators

In the Bayesian paradigm a random sample $X_1,\ldots, X_n$ is drawn from a population indexed by θ, where θ is considered to be a quantity whose variation can be described by a probability distribution (called the *prior distribution*). A sample is then taken from a population indexed by θ and the prior distribution is updated with this sample information. The updated prior is called the *posterior distribution*.

If we denote the prior distribution, by $\pi(\theta)$, and the sampling distribution by $f(\mathbf{x}\,|\,\theta)$, then the posterior distribution, the conditional distribution of θ given the sample, $\mathbf{x}$, is

$$\pi(\theta\,|\,\mathbf{x}) = f(\mathbf{x}\,|\,\theta)\pi(\theta)/m(\mathbf{x}) \tag{6}$$

where $m(\mathbf{x}) = \int f(\mathbf{x}\,|\,\theta)\pi(\theta)\,\mathrm{d}\theta$ is the marginal distribution of $\mathbf{x}$.

Example Let $X_1,\ldots, X_n$ be i.i.d. Bernoulli (p). Then $Y = \Sigma_i X_i$ is binomial (n, p). If p has a Beta (α, β) prior distribution, that is,

$$\pi(p) = \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} p^{\alpha-1}(1-p)^{\beta-1} \tag{7}$$

the posterior distribution of p given y, is

$$\begin{aligned} f(p\,|\,y) &= \frac{f(y, p)}{f(y)} \\ &= \frac{\Gamma(n+\alpha+\beta)}{\Gamma(y+\alpha)\Gamma(n-y+\beta)} p^{y+\alpha-1}(1-p)^{n-y+\beta-1} \end{aligned} \tag{8}$$

which is a beta distribution with parameters $y+\alpha$ and $n-y+\beta$. The posterior mean, a Bayes estimator of p, is

$$\hat{p}_{\mathrm{B}} = \frac{y+\alpha}{\alpha+\beta+n} \tag{9}$$

2. Evaluating Point Estimators

There are many methods of deriving point estimators (robust methods, least squares, estimating equations, invariance) but the three in Sect. 1 are among the most popular. No matter what method is used to derive a point estimator, it is important to evaluate the estimator using some performance criterion.

One way of evaluating the performance of a point estimator W of a parameter θ is through its mean squared error (MSE), defined by $\mathrm{E}_\theta(W-\theta)^2$.

MSE measures the average squared difference between the estimator W and the parameter θ. Although any increasing function of the absolute distance $|W-\theta|$ would serve, there is a nice factorization

$$\begin{aligned}\mathrm{E}_\theta(W-\theta)^2 &= \mathrm{Var}_\theta W + (\mathrm{E}_\theta W-\theta)^2 \\ &= \mathrm{Var}_\theta W + (\mathrm{Bias}_\theta W)^2\end{aligned} \tag{10}$$

where we define the bias of a point estimator as $\mathrm{Bias}_\theta W = \mathrm{E}_\theta W-\theta$. An estimator whose bias is identically (in θ) equal to zero is called *unbiased*.

For an unbiased estimator we have $\mathrm{E}_\theta(W-\theta)^2 = \mathrm{Var}_\theta W$, and so, if an estimator is unbiased, its MSE is equal to its variance. If $X_1,\ldots, X_n$ are i.i.d. from a population with mean μ and variance σ^2, the sample mean is an unbiased estimator since $\mathrm{E}\bar{X} = \mu$, and has MSE

$$\mathrm{E}(\bar{X}-\mu)^2 = \mathrm{Var}\bar{X} = \frac{\sigma^2}{n} \tag{11}$$

Controlling bias does not guarantee that MSE is minimized. In particular, it is sometimes the case that a trade-off occurs between variance and bias. For example, in sampling from a normal population with variance σ^2, the usual unbiased estimator of the variance $S^2 = \frac{1}{n-1}\Sigma_{i=1}^n(X_i-\bar{X})^2$ has MSE $= 2\sigma^4/(n-1)$. An alternative estimator for σ^2 is the maximum likelihood estimator $\hat{\sigma}^2 = \frac{1}{n}\sum_{i=1}^n(X_i-\bar{X})^2 = \frac{n-1}{n}S^2$. This is a biased estimator of σ^2 with MSE

$$\begin{aligned}\mathrm{E}(\hat{\sigma}^2-\sigma^2)^2 &= \left(\frac{2n-1}{n^2}\right)\sigma^4 < \left(\frac{2}{n-1}\right)\sigma^4 \\ &= \mathrm{E}(S^2-\sigma^2)^2\end{aligned} \tag{12}$$

showing that $\hat{\sigma}^2$ has smaller MSE than S^2. Thus, by trading off variance for bias, the MSE is improved.

Measuring performance by the squared difference between the estimator and a parameter is a special case of a function called a *loss function*. The study of the performance, and the optimality, of estimators evaluated through loss functions is a branch of decision theory. In addition to MSE, based on squared error loss, another popular loss function is absolute error loss, $L(\theta, W) = |W-\theta|$. Both of these loss functions increase as the distance between θ and W increases, with minimum value $L(\theta, \theta) = 0$. That is, the loss is minimum if the estimator is correct.

In a decision theoretic analysis, the worth of an estimator is quantified in its risk function, that is, for an estimator W of θ, the risk function is $R(\theta, W) = \mathrm{E}_\theta L(\theta, W)$, so the risk function is the average loss. If the loss is squared error, the risk function is the MSE.

Using squared error loss, the risk function (MSE) of the binomial Bayes estimator of p is

$$\begin{aligned}\mathrm{E}_p(\hat{p}_{\mathrm{B}}-p)^2 &= \mathrm{Var}_p\hat{p}_{\mathrm{B}} + (\mathrm{Bias}_p\hat{p}_B)^2 \\ &= \frac{np(1-p)}{(\alpha+\beta+n)^2} + \left(\frac{np+\alpha}{\alpha+\beta+n}-p\right)^2\end{aligned} \tag{13}$$

In the absence of good prior information about p, we might try to choose α and β to make the risk function of $\hat{p}_{\mathrm{B}}$ constant (called an *equalizer* rule). The solution is to choose $\alpha = \beta = \sqrt{\mathrm{n}/4}$, yielding

$$\mathrm{E}(\hat{p}_{\mathrm{B}}-p)^2 = \frac{n}{4(n+\sqrt{\mathrm{n}})^2}$$

We can also use a Bayesian approach to the problem of loss function optimality, where we would use the prior distribution to compute an average risk $\int_\Theta R(\theta, W)\pi(\theta)\mathrm{d}\theta$, known as the *Bayes risk*. We then find the estimator that yields the smallest value of the Bayes risk. Such an estimator is called the Bayes rule with respect to a prior π.

To find the Bayes decision rule for a given prior π we write the Bayes risk as

$$\begin{aligned}&\int_\Theta R(\theta, W)\,\pi(\theta)\,\mathrm{d}\theta \\ &\quad = \int_\chi\left[\int_\Theta L(\theta, W(\mathbf{x}))\,\pi(\theta\,|\,\mathbf{x})\,\mathrm{d}\theta\right]m(\mathbf{x})\,\mathrm{d}\mathbf{x}\end{aligned} \tag{14}$$

where the quantity in square brackets is the expected value of the loss function with respect to the posterior distribution, called the *posterior expected loss*. It is a function only of $\mathbf{x}$, and not a function of θ. Thus, for each $\mathbf{x}$, if we choose the estimate $W(\mathbf{x})$ to minimize the posterior expected loss, we will minimize the Bayes risk.

For squared error loss, the posterior expected loss is minimized by the mean of the posterior distribution. For absolute error loss, the posterior expected loss is minimized by the median of the posterior distribution. If we have a sample $X_1,\ldots, X_n$ from a normal distribution with mean θ and variance σ^2, and the prior is $n(\mu, \tau^2)$, the posterior mean is

$$E(\theta \mid \bar{x}) = \frac{\tau^2}{\tau^2+(\sigma^2/n)}\bar{x}+\frac{\sigma^2/n}{\tau^2+(\sigma^2/n)}\mu \qquad (15)$$

Since the posterior distribution is normal, it is symmetric and the posterior mean is the Bayes rule for both squared error and absolute error loss. The posterior mean in our binomial/beta example, $\hat{p}_B = \frac{y+\alpha}{\alpha+\beta+n}$, is the Bayes estimator against squared error loss.

We can loosely group evaluation criteria into large sample or asymptotic methods, and small sample methods. Our calculations using MSE and risk functions illustrate small sample methods. In large samples, MLEs typically perform very well, being asymptotically normal and efficient, that is, attaining the smallest possible variance. Other types of estimators that are derived in a similar manner (for example, M-estimators—see *Robustness in Statistics*) also share good asymptotic properties. For a detailed discussion see Casella and Berger (2001), Lehmann (1998), Stuart et al. (1999) or Lehmann and Casella (1998, Chap. 6).

3 Interval Estimation

Reporting a point estimator of a parameter θ only provides part of the story. The story becomes more complete if an assessment of the error of estimation is also reported. Informally, this can be accomplished by giving an estimated standard error of the estimator and, more formally, this becomes the reporting of an interval estimate. If $\mathbf{X} = \mathbf{x}$ is observed, an *interval estimate* of a parameter θ is a pair of functions, $L(\mathbf{x})$ and $U(\mathbf{x})$ for which the inference $\theta \in [L(\mathbf{x}), U(\mathbf{x})]$ is made. The *coverage probability* of the random interval $[L(\mathbf{X}), U(\mathbf{X})]$ is the probability that $[L(\mathbf{X}), U(\mathbf{X})]$ covers the true parameter, θ, and is denoted by $P_\theta(\theta \in [L(\mathbf{X}), U(\mathbf{X})])$.

By definition, the coverage probability depends on the unknown θ, so it cannot be reported. What is typically reported is the confidence coefficient, the infimum of the coverage probabilities, $\inf_\theta P_\theta(\theta \in [L(\mathbf{X}), U(\mathbf{X})])$.

If $X_1,\ldots, X_n$ are i.i.d. with mean μ and variance σ^2, a common interval estimator for μ is

$$\mu \in \bar{x} \pm 2\frac{s}{\sqrt{n}} \qquad (16)$$

where $\bar{x}$ is the sample mean and s is the sample standard deviation. The validity of this interval can be justified from the Central Limit Theorem, because

$$\frac{\bar{X}-\mu}{S/\sqrt{n}} \to n(0, 1) \qquad (17)$$

the standard normal distribution. We then see that the coverage probability (and confidence coefficient) of Eqn. 16 is approximately 95 percent.

The above interval is a large sample interval since its justification is based on an asymptotic argument. There are many methods for constructing interval estimators that are valid in small samples, including these.

3.1 Inverting a Test Statistic

There is a correspondence between acceptance regions of tests (see *Hypothesis Testing in Statistics*) and confidence sets, summarized in the following theorem.

Theorem *For each $\theta_0 \in \Theta$, let $A(\theta_0)$ be the acceptance region of a level α test of H_0: $\theta = \theta_0$. For each $\mathbf{x} \in \chi$,* define a set $C(\mathbf{x})$ *in the parameter space by*

$$C(\mathbf{x}) = \{\theta_0 \colon \mathbf{x} \in A(\theta_0)\} \qquad (18)$$

Then the random set $C(\mathbf{X})$ is a $1-\alpha$ confidence set. Conversely, let $C(\mathbf{X})$ be a $1-\alpha$ confidence set. For any $\theta_0 \in \Theta$, define

$$A(\theta_0) = \{x \colon \theta_0 \in C(\mathbf{x})\} \qquad (19)$$

Then $A(\theta_0)$ is the acceptance region of a level α test of H_0: $\theta = \theta_0$.

Example If $X_1,\ldots, X_n$ are i.i.d. $n(\mu, \sigma^2)$, with σ^2 known, the test of H_0: $\mu = \mu_0$ vs. H_1: $\mu \neq \mu_0$ will accept the null hypothesis at level α if

$$\bar{x} - z_{\alpha/2}\frac{\sigma}{\sqrt{n}} \leqslant \mu_0 \leqslant \bar{x} + z_{\alpha/2}\frac{\sigma}{\sqrt{n}} \qquad (20)$$

The interval of μ values, $[\bar{x} - z_{\alpha/2}\sigma/\sqrt{n}, \bar{x} + z_{\alpha/2}\sigma\sqrt{n}]$, for which the null hypothesis will be accepted at level α, is a $1-\alpha$ confidence interval for μ.

3.2 Pivotal Inference

Perhaps one of the most elegant methods of constructing set estimators is the use of pivotal quantities (Barnard 1949). A random variable $Q(\mathbf{X}, \theta) = Q(X_1,\ldots, X_n, \theta)$, is a *pivotal quantity* (or pivot) if the distribution of $Q(\mathbf{X}, \theta)$ is independent of all parameters. If we find a set C such that $P(Q(\mathbf{X}, \theta) \in C) =$

$1-\alpha$, then the set $\{\theta: Q(\mathbf{X}, \theta) \in C\}$ has coverage probability $1-\alpha$.

In location and scale cases, once we calculate the sample mean $\bar{X}$ and the sample standard deviation S, we can construct the following pivots:

Form of pdf	Type of pdf	Pivotal quantity
$f(x-\mu)$	location	$\bar{X}-\mu$
$\frac{1}{\sigma} f\left(\frac{x}{\sigma}\right)$	scale	$\frac{\bar{X}}{\sigma}$
$\frac{1}{\sigma} f\left(\frac{x-\mu}{\sigma}\right)$	location-scale	$\frac{\bar{X}-\mu}{S}$

(21)

In general, differences are pivotal for location problems, while ratios (or products) are pivotal for scale problems. See also *Fiducial and Structural Statistical Inference*.

Example Suppose that $X_1, \ldots, X_n$ are i.i.d. exponential (λ). Then $T = \sum_i X_i$ is a sufficient statistic for λ and $T \sim$ gamma (n, λ). In the gamma pdf, t and λ appear together as t/λ and, in fact the gamma (n, λ) pdf $(\Gamma(n)\lambda^n)^{-1} t^{n-1} e^{-t/\lambda}$ is a scale family. Thus, if $Q(T, \lambda) = 2T/\lambda$, then

$$Q(T, \lambda) \sim \text{gamma}(n, \lambda(2/\lambda)) = \text{gamma}\,(n, 2)$$

which does not depend on λ. The quantity $Q(T, \lambda) = 2T/\lambda$ is a pivot with a gamma $(n, 2)$, or χ^2_{2n}, distribution, and a $1-\alpha$ pivotal interval is

$$\frac{2T}{\chi^2_{2n,\,\alpha/2}} \leqslant \lambda \leqslant \frac{2T}{\chi^2_{2n,\,1-\alpha/2}}$$

where $P(\chi^2_{2n} > \chi^2_{2n,\,a}) = a$.

3.3 Bayesian Intervals

If $\pi(\theta \mid \mathbf{x})$ is the posterior distribution of θ given $\mathbf{X} = \mathbf{x}$, then for any set $A \subset \Theta$ the posterior probability of A is

$$P(\theta \in A \mid \mathbf{x}) = \int_A \pi(\theta \mid \mathbf{x})\, \mathrm{d}\theta$$

If $A = A(\mathbf{x})$ is chosen so that this posterior probability is $1-\alpha$, then A is called a $1-\alpha$ *credible set* for θ. If $\pi(\theta \mid \mathbf{x})$ corresponds to a discrete distribution, we replace integrals with sums in the above expressions.

The interpretation of the Bayes interval estimator is different from the classical intervals. In the classical approach, to assert 95 percent coverage is to assert that in 95 percent of repeated experiments, the realized intervals will cover the true parameter. In the Bayesian approach, a 95 percent coverage means that the probability is 95 percent that the parameter is in the realized interval. In the classical approach the randomness comes from the repetition of experiments, while in the Bayesian approach the randomness comes from uncertainty about the value of the parameter (summarized in the prior distribution).

Example Let $X_1, \ldots, X_n$ be i.i.d. Poisson (λ) and assume that λ has a gamma prior, $\lambda \sim$ gamma (a, b), where a is an integer. The posterior distribution of λ is

$$\pi(\lambda \mid \textstyle\sum_i X_i = \sum_i x_i) = \text{gamma}(a + \sum_i x_i, [n + (1/b)]^{-1}) \tag{22}$$

Thus the posterior distribution of $2[n+(1/b)]\lambda$ is $\chi^2_{2(a+\Sigma x)}$, and a $1-\alpha$ Bayes credible interval for λ is

$$\left\{\lambda: \frac{\chi^2_{2(a+\Sigma x),\,1-\alpha/2}}{2[n+(1/b)]} \leqslant \lambda \leqslant \frac{\chi^2_{2(a+\Sigma x),\,\alpha/2}}{2[n+(1/b)]}\right\} \tag{23}$$

We can also form a Bayes credible set by taking the highest posterior density (HPD) region of the parameter space, by choosing c so that

$$1-\alpha = \int_{\{\lambda: \pi(\lambda \mid \Sigma x) \geqslant c\}} \pi(\lambda \mid \Sigma_i x_i)\, \mathrm{d}\lambda \tag{24}$$

Such a construction is optimal in the sense of giving the shortest interval for a given $1-\alpha$ (although if the posterior is multimodal the set may not be an interval).

4. Other Intervals

We have presented two-sided parametric intervals that are constructed to cover a parameter. Other types of intervals include (*a*) one-sided intervals, (*b*) distribution-free intervals, (*c*) prediction intervals, (*d*) tolerance intervals.

One-sided intervals are those in which only one endpoint is estimated, such as $\theta \in [L(\mathbf{X}), \infty)$. Distribution-free intervals are intervals whose probability guarantee holds with little (or no) assumption on the underlying distribution. The other two interval definitions, together with the usual confidence interval, provide us with a hierarchy of inferences, each more stringent than the previous.

If $X_1, \ldots, X_n$ are i.i.d. from a population with cdf $F(x \mid \theta)$, and $C(\mathbf{x}) = [L(\mathbf{x}), U(\mathbf{x})]$ is an interval, for a specified value $1-\alpha$ it is a:

(a) *confidence interval* if, for all θ, $P_\theta[L(\mathbf{X}) \leqslant \theta \leqslant U(\mathbf{X})] \geqslant 1-\alpha$;

(b) *prediction interval* if, for all θ, $P_\theta[L(\mathbf{X}) \leqslant X_{n+1} \leqslant U(\mathbf{X})] \geqslant 1-\alpha$;

(c) *tolerance interval* if, for all θ and for a specified value p, $P_\theta([F(U(\mathbf{X})\,|\,\theta) - F(L(\mathbf{X})\,|\,\theta) \geqslant p] \geqslant 1-\alpha$.

So a confidence interval covers a mean, a prediction interval covers a new random variable, and a tolerance interval covers a proportion of the population. Thus, each gives a different inference, with the appropriate one being dictated by the problem at hand. Vardeman (1992) argues that these 'other intervals' provide an inference that is different from that of a confidence interval and are as important as confidence intervals.

5. *Conclusions*

Point estimation is one of the cornerstones of statistical analysis, and the basic element on which many inferences are based. Inferences using point estimators gain statistical validity when they are accompanied by an interval estimate, providing an assessment of the uncertainty. We have mainly discussed parametric point and interval estimation, where we assume that the underlying model is correct. Such an assumption can be questioned, and considerations of nonparametric or robust alternatives can address this (see *Robustness in Statistics*). For more on these subjects see, for example, Hettmansberger and McKean (1998) or Staudte and Sheather (1990). Full treatments of parametric point and interval estimation can be found in Casella and Berger (2001), Stuart et al. (1999), or Schervish (1995).

Ethical Behavior, Evolution of

The distinction between good or bad and what we ought or ought not do constitutes the subject matter of ethics. Early students of the evolution of ethical behavior (EEB) and some sociobiologists attempted to direct the study of EEB into the domain of prescriptive ethics. Twenty-first century sociobiologists are not concerned with the nature of vice, virtue, or the rules of moral behavior, but with the question of the biological origin of ethical behavior. To disregard the distinction between the questions of ethics and the questions of the evolutionary causes and the bases of human ethical behavior is to misunderstand the discipline of EEB, which is not a branch of philosophy or of ethics, but a subdiscipline of sociobiology. No prescriptive code can be derived from the theory of evolution; therefore, the previously used term 'evolutionary ethics' is a misnomer that must be dropped from sociobiological usage. An excellent philosophical examination (Flew 1967) and a superior historical analysis (Richards 1987) on EEB are available.

The ideas on EEB will be exemplified by a review of arguments, first, of the originators of EEB; second, of ecologists, ethologists, geneticists, linguists, neurophysiologists, and cognitive scientists; and third, of sociobiologists and their supporters and opponents.

1. *The Originators of the Idea*

Charles Darwin, in *On the Origin of Species* (1859), established the homology between human and nonhuman primate morphology, but not between human and nonhuman behavior. In his revised edition of *The Descent of Man* (1885), he recognized that the moral sense or conscience differentiates humans from the other animals, and that 'The imperious word *ought* seems merely to imply the consciousness of the existence of a rule of conduct, however it may have originated.' He believed that the understanding of the EEB would be enlarged by studies of nonhuman behavior, and that nonhuman animals possessing parental and filial instinct would exhibit a kind of rudimentary intellectual and moral sense. He supported this by arguing that, first, social instincts lead animals to social groups and to perform 'social services'; second, as the mental faculties develop, images and feelings endure and are subject to recall; third, development of language facilitates communication; and last, acquisition of habits helps to guide the conduct of individuals within the community.

Humans, to Darwin, are social animals who have lost some early instincts but retain the protohuman instinctive love and sympathy for others. Some instincts are subject to group selection; the altruistic social behaviors of early humans were not for the good

of species or individuals, but for the welfare of the group. Humans ought to obey the instincts acquired and prescribed by the rule of conduct within society. These Darwinian views have been accepted, except that a small number of biologists finds the theory of group selection (that is, a natural selection operating on more than one member of a lineage group, in which the selection is beneficial for the group rather than for the individual) inadequate to explain altruism (behavior that increases the fitness of the other at cost to self).

There are three Darwinian contributions to EEB. First, the acceptance of morphology as a product of evolution repudiated creationism and thus, the divine source of morality, and at the same time implied that human behavior is also evolutionarily derived. Second, the rejection by Darwin of what John Dewey called 'the holy arc of permanence' meant that all human behavior, including ethics, evolved, is evolving, and will evolve. Third, EEB is concerned with the origin of ethical behavior, and not with the prescriptions of ethics.

Spencer asserted that ethical behavior began in nonhuman social animals, was developed by—and conforms to—the law of evolution, and reached its full expansion in cultural evolution. He argued that cooperation is beneficial to social units, is a cause of physiological and sociological divisions of labor, and it profits all members in a society, but only when social bargains are respected. Cooperation arose at the dawn of life when altruism was dependent on egoism, and egoism was dependent on altruism. Offspring are preserved and species maintained by altruistic acts. To Spencer, evolution was thus a progressive moral force operating within human society and leading to the ethical improvement of humankind.

Spencer replaced the Darwinian natural selection with the 'survival of the fittest,' and developed his concepts in economic terms that led to Social Darwinism. It is now realized that the nurturing of offspring in human and nonhuman families can only be explained in terms of the Spencerian concept of cooperation, which thus appears to be evolutionary. In social groups there must be selective pressure to encourage altruism and to discourage selfishness. By definition social life is altruistic. Spencer's ideas on cooperation were more fully developed by Kropotkin (1902).

T. H. Huxley (1894, reprinted in Nitecki and Nitecki 1993) supposed that protohuman morphology, human society, intellect, and morality are parts of nature, but that human behavior—unlike behavior in other animals—is not innate; therefore, there is a chasm between humans and other animals. Human character, by which he meant the moral and intellectual essence, is passed from generation to generation. He accepted the pessimistic view of human life as a continuous and uneven struggle against the cosmos, and assumed that competition is the exclusive element of the living world. Perhaps Huxley overstressed competition and selfishness as a natural instinct, and underrated cooperation and altruism as evolutionary factors. His panoramic view of life replaced the old body/soul dichotomy with the nature/culture dichotomy.

Although Huxley objected to Social Darwinism as expressed in the Spencerian 'survival of the fittest,' he nevertheless accepted the seventeenth-century perspective of natural selection as a 'struggle for existence.' It was this eternal struggle between humans and cosmos that colored his view of nature, and blinded him to the role of cooperation in evolution.

2. *The Unintended Developers of the Idea*

The conclusions of early psychological behaviorists were that behavior, with the exception of physiological actions, is purely a cultural phenomenon. Learning was also cultural. However, ecologists (Allee et al. 1949) and ethologists (Tinbergen 1951) established that behavior and learning are processes of the central nervous system, and are products of genetics *and* of social interactions. Thus behavior may be both innate and acquired. Animal social interactions are occasionally in a one-to-one relationship (cause and effect), but transmission from the stimulus to the response is mostly through a complex of neurological channels. Behavior is so complex that it does not allow itself to be controlled by a single gene.

The environment *and* the chemical releasers of animals control and influence behavior by acting upon endocrine glands and upon sense organs. If the cooperative human and nonhuman groups are units of selection, then survival is of *greater* importance to the group as a whole than to the individual.

Ecologists documented that mutualism occurs not only between organelles within cells and among individual organisms, but also in groups and even in kingdoms of organisms: herbivores cooperate with symbiotic algae, bacteria fix nitrogen within leguminous plants, and fungi with algae form lichens. Ecologists postulated that instincts are inborn nervous mechanisms that may be activated, and that instinct contributes to the fitness of both individuals and groups. Animals are social only when acting within the group of the same species.

In the reverse of anthropomorphism, ethologists applied the concepts derived from the studies of nonhuman behavior to humans, and established that both human and nonhuman physiology and behavior are constantly modified, changed, and influenced by the presence of other individuals. Without the presence of another individual, the terms 'good' or 'bad' behavior have no meaning.

Ethologists stressed the role of genes in human behavior, the role of information encoded in the genome, and also the role of development in forming the behavioral patterns. They argued that human nature is neither inherently good or bad, but is both, and therefore 'natural' cannot be equated with 'good' or 'bad.'

The geneticist Muller (1959) reasoned that altruistic acts foster the multiplication of altruistic genes, and that cooperation (or mutual aid) is a genetic factor of great value for the worldwide social organization. He agreed with Darwin that the protohuman group was the primary unit of selection in which altruism developed, but for altruism to become fixed in humans the group must remain isolated. Not only our morphology and our DNA, but also our behavior evolved.

Linguistic studies (Pinker 1997) proved that language capacity is already present in newly born humans. Ecologists had already pointed out that human behavior, including language, requires at least two individuals. Linguists added that this presence is necessary for language to develop. Therefore, the capacity for language is genetic, but it must be socially primed to be activated. Since human infants can do simple additions before they can talk, linguists reasoned that even arithmetic has an evolutionary basis. However, to many researchers the structural features of human language differentiate it from nonhuman communications. Others believed that the difference is of degree only.

Neurophysiological and cognitive studies recognized that all mental activities, including consciousness, are products of the physiological functions of the material brain. Mental activities are programmed by instinct and are controlled in recognized locations in the brain. Consciousness is innate in humans. These investigations shifted the argument from dualism to materialism. It is self-evident that the very long human infancy requires cooperation of parents and society. Infants recognize and learn altruism and love of mother, and how to reciprocate.

It follows, from the ecological to cognitive researches, that nonhuman and much human behavior have evolutionary bases. Biologists now agree that, at least in some nonhuman animals, complex behavior has more than simple genetic components, and that humans are *both* biological and cultural beings. These studies established the positive correlation between brain structure and mental activities, questioned the brain/mind dichotomy, and laid the foundations for the sociobiological analysis of EEB.

3. *Sociobiology*

Sociobiology is the systematic study of the biological basis of *all* social behavior in *all* organisms, including humans (Wilson 1975). Ecologists and neurophysiologists accepted the nonhuman and some human behavior and ability to learn as innate; sociobiologists concluded that altruism is also innate. Sociobiological emphasis on the analysis of altruism reinstated the almost dormant EEB. Originally sociobiologists alleged that, in human choices of ethical behavior, heredity plays a greater role than environment. They hypothesized that since men and women are sexually different, their behavior is also different, and the economic and political ranking of humans is natural.

Since sociobiologists contend that a straight line from nonhuman to human behavior exists, they presumed that the fusion of sociobiology with neurophysiology would explain the rules and properties of ethical behavior. Some sociobiologists proposed that ethics should be biologized and that the range of study of nonhuman behavior should be expanded into the domain of psychology. They assumed that ethical and moral concepts are guided by natural selection and by social forces, and that as long as some philosophers fail to accept the evolutionary bases of social behavior they will continue to reject EEB. Furthermore, the emerging sociobiology threatened the three popular existentialist dogmas: the uniqueness of the individual, the search for the meaning and purpose of human life, and belief in the freedom of choice of action. These assertions raised instant responses.

3.1 *Voices of Dissent*

Anthropologists (Sahlins 1976) immediately objected to the application of sociobiology to human behavior and morality. They claimed that culture cannot be reduced to biology because cultural environment controls the phenotype and behavior, and that human ethical behavior is fundamentally different from nonhuman. In this view sociobiology was mired in a Eurocentric patriarchal worldview.

Leftist and feminist critics (Caplan 1978) saw negative political consequences in genetic determinism and surmised that all social human behavior is exclusively environmental and without biological bases. They accused Wilson of Social Darwinism and sexism, that is, of the puritanical and moralistic defense of the old cultural interpretation of ethics, and of human behavior. They linked sociobiology to Nazism and racism. Those critics claimed not only that the science of sociobiology was wrong, but also that it was morally wrong, and their attack on sociobiology became, and continues to be, an attack on EEB.

The sociobiologists' injection of anthropomorphic terms for descriptions of nonhuman behavior was criticized for confusing homology with analogy and for introducing difficulties in analyzing behavior. Homology, when applied to morphology and behavior, requires common ancestry. Altruistic behavior is a function of the social group, but tendencies of organisms to form social aggregates do not appear homologous. Terms may imply homology, but, if altruism in nonhuman and human animals is not homologous, then the term altruism will incorrectly suggest that ethical principles have biological roots. However, terms usually have more than one meaning that is

decipherable only from the context of the sentence. If anthropomorphic terms are restricted to human actions and new terms are coined for nonhuman behavior, then the concept of EEB can be more clearly defined.

3.2 Soft Answers

The Christian tradition of the Fall, caused by original sin, held that humans are born evil, and Huxley claimed that cosmos is manifestly amoral. The struggle for existence, an intrinsically 'bad' property of all creation, did not need explication, but cooperation and altruism did, and all moral actions were judged in relation to the benefit of the group, however defined. Men sacrificing their lives in war were worshiped as heroes, and those dying for faith were beatified as martyrs. Cooperation and altruism have always been socially rewarded, while selfishness was condemned. It is this emphasis on virtue that the study of sociobiology introduced.

Thus altruism, the contrariant of the cold-hearted selfish power of the cosmos, demanded explanation. Because altruism was difficult to explain by natural selection, which acts only on individuals, Darwin proposed group selection. However, the term 'group selection' is too broadly used and includes population, community, and even species selection. For group selection to operate, all individuals must be related, altruistic, the group must be isolated and the gene flow restricted. Group living may be beneficial when it provides protection from predators (group size decreases predation), but it may also be harmful (it spreads diseases). Therefore, a surrogate model was proposed, that is, kin selection, a form of group selection, which was defined as the natural selection of genes in which the donor benefits its kin and thus favors the survival and reproduction of kin who possess the same genes. Although this process reduces the fitness of the donor, it increases the reproductive fitness of one or more kin and increases the frequency of genes of kin in the future generations.

Three other theories have been offered. First, inclusive fitness (Hamilton 1964) is not only the fitness of an individual and its offspring but also the fitness of *all* kin who share the same genetic constitution. This will insure the reproductive success of an individual, its offspring, and all relatives. Inclusive fitness and kin selection explain the genetic origin of cooperation and altruism.

Second, reciprocal altruism (Trivers 1971) is the genetic behavior causing cooperative behavior in expectation of return of altruistic acts. Reciprocity and most mutual aid are most common among relatives. It was assumed that human disoperation, aggression, reciprocity, kin-selected altruism, and general cooperation are not culturally controlled but are subject to natural selection. Thus, sociobiologists introduced a tit-for-tat concept to explain altruism, and they assumed that tit-for-tat is selected because there must be selection for altruistic acts.

The third theory argued that the unit of selection is a gene, not an individual, and the individual is only a carrier for the gene (Dawkins 1976). Selected genes are selfish and do not act for the survival of species, but only for the survival of the genes themselves. The value element of 'good' and 'bad' was thus replaced with altruism and selfishness as value-free properties. Since sociobiologists strongly adhere to the concept of natural selection, it follows that a struggle for existence, or even an 'arms race' should occur among genes. However, the role of genes in controlling human behavior and the contribution of human embryology to the ontology of behavior are still poorly understood.

Although genes responsible for such human behavior as altruism, homosexuality, and criminality have been claimed by sociobiologists to exist, it is doubtful whether they have been identified. It is also very difficult to differentiate what is genetically or environmentally fixed and what activates behavior, and it is too early to claim a detailed knowledge of the great complexity of behavior or of genes.

3.3 Voices of Assent

Zoology assumes that humans are animals; therefore, after Darwin, it became a proper approach to study the biological aspects of moral behavior, and to accept the comparisons of human with nonhuman social behavior. But, this produces nontrivial consequences. For if humans are animals, the definition 'animal' must include the properties that characterize humans. Thus, human ethical behavior becomes 'natural' and subject to natural selection. Many students of EEB recognize some dependence between evolution and ethics, and accept the role of natural selection in evolution, but are aware of the restrictions placed by natural selection on EEB. Natural selection is only a guiding force, and not the sole source of behavioral (and morphological) changes, and EEB in social groups is only one evolutionary component. The origin of ethical behavior in protohumans and its subsequent development are a subject matter of sociobiology, but the solution of prescriptive ethical problems, of what we ought or ought not do, is a concern of philosophy. While the study of evolution may explain EEB, it does not explain ethical values or goals.

Lumsden and Wilson (1983) emphasized that neither culture nor evolution is autonomous: 'culture is created and shaped by biological processes while the biological processes are simultaneously altered in response to cultural change.' Human ethics works because cultural forces alter the innate bases of

behavior. While genes may control the basic instincts, the behavioral responses to stimuli may be automatic; therefore, the response may not be always driven by natural selection.

The history of the idea of EEB circles around various theories of human nature, the interpretation of which is central to the entire gamut of dichotomies from nature/nurture to brain/mind. The evolutionary psychologist Cyrulnik (1993) called these dichotomies pseudoconcepts, because 'human behavior … is 100 percent innate and 100 percent acquired. Or, what amounts to the same thing, nothing is "innate" and nothing is "acquired." … the acquired can only be acquired by means of the innate, which in turn is always shaped by the acquired. Nature is nurtured!'

What EEB is asking is not prescription, but how we came to think about prescription. Although sociobiologists accept deep evolutionary bases of morality, few of them are comfortable with the concept of 'evolutionary ethics.' The use of this term has begun to disappear, not because all the questions on EEB have been answered, but because the term 'evolutionary ethics' unnecessarily confuses the ethical meanings of 'good' and 'ought' with the biological origin of altruistic behavior.

Ethical Codes, Professional: Business Codes

Business codes are formal or informal standards of behavior that give structure and direction to economic action and behavior. They codify the values of a corporation, an industry, or a whole sector, and thereby create accountability and certainty of expectation. Conceived of as self-binding acts, business codes provide constraints both to collective organizations (e.g., firms) and individual actors (e.g., management) within the economy. In Western economies, as well as in the emergence of a global economy, they play an important role as governance structures because of, and insofar as they make possible, the expansion of economical and societal cooperation.

1. History and Actuality

Voluntary standards of behavior in the economy as a means of self-binding and constraint can be found in early history. Their emergence is connected to the guilds of craftsmen and merchants in the Middle Ages, where they regulated behavior towards the other members of the guilds, customers, co-workers, and employees. In the beginning they were informal and derived from tradition, common rites, and the customs belonging to a trade. With the expansion of long-distance trading these standards were laid down and were adopted by traveling merchants. Thus they became increasingly formal which meant that they became enforceable by third parties. These early business codes served to ensure contracts concerning

future delivery and payment of goods and were enforceable by guild courts and the threat of ostracism (Mitchell 1969).

To the extent that national and international business laws were established and enforceable by government bodies during the nineteenth century, private standards of behavior based on the threat of ostracism and loss of reputation gradually started to lose their importance. But in the 1970s a renaissance of private standards of behavior emerged from two main sources. The first was the internationalization and globalization of markets and production networks, which were and still are unaccompanied by developments of political, juridical, and cultural institutions and their enforceability. Such business codes include maintaining human rights in cooperative relationships, for example with suppliers and partners, and they define common perspectives in areas where different values standards as well as cross-cultural values conflicts hinder the establishment of transcultural teams.

The second source was the organizational decentralization of corporations, which led to an increase in 'gray areas' and decreasing possibilities of utilizing direct monitoring and control mechanisms. Here business codes have to define a common set of values in order to give the company identity and a behavioral orientation. To reach this aim it needs to form vision, mission, and value statements, compliance standards, and rules for dealing with the company's stakeholders (customers, employees, suppliers, environment) (Weaver 1993). Such standards of behavior can be enforced by sanctions and incentives within the company. With regard to customers and suppliers the companies' reputation and brand names are important enforcing mechanisms.

2. *Minimum Standards, Problem Standards, and Corporate Standards*

Business codes are characterized by self-binding, possibilities of private enforcement, and the identity of the actors. Self-binding by voluntary constraints of action, certainty of expectation in contracts by forceability (sanctions, incentives, reputation), and the creation of corporate identity by means of codified and realized values in business routine make standards of behavior a functional equivalent to national regulations and laws. Whenever national or supernational regulations and their enforcement do not exist or are not feasible, regardless of the identity of an actor, private standards of behavior become a dominating issue of economic and societal governance. They are therefore known as 'soft laws' (Fatouros 1994). By creating certainty of expectation for economic action in societies which are characterized by division of labor, business codes directly influence the state of welfare in any given society. With these reliable and trustworthy rules more cooperation and more transactions are made possible than without them.

The distinction between minimum standards, problem standards, and corporate standards enables us to group modern business codes along with the kinds of cooperations and transactions that are steered by them.

2.1 *Minimum Standards*

Minimum standards are instruments serving the governance of global business transactions. There are, for example, 'Guidelines for Multinational Enterprises' and 'Corporate Governance Guidelines' (OECD 1991/1998), a 'Code of Conduct on Transnational Corporations' (UN 1994), and 'Guidelines on the Treatment of Foreign Direct Investment' (World Bank 1992), to name just a few. They define minimum requirements for such areas as working conditions, involvement of unions, safety at work, consumer protection, competition, technology transfer, investment in developing countries, corruption, and human rights.

Minimum standards emerge from bargaining processes between national governments, national and international organizations of employers and unions, and any nongovernmental organizations (NGOs) involved, directed by a recognized international organization (Fatouros 1994). Their status is precarious. These agreements are obligatory for the signing parties although they cannot be enforced by law. Whether it is possible to implement them therefore depends on the voluntary efforts of the contractors as well as on whether or not it is possible to take action against rule breakers or to damage their reputation in a cost-generating way. Their strength lies in the fact that they provide standards which possess some chance of realization while there is no suitable international law available or accessable. Their weak points are the difficulty of implementing and controlling them. Nevertheless, they are a significant component of economic globalization because they are a functional equivalent to the still underdeveloped international business law. Hence, they create a certain formal and political certainty within the world economy which is a crucial demand for worldwide prosperity.

2.2 *Problem Standards*

Problem standards define proposals of behavior that help to solve certain problems, and go far beyond the rules of the game asserted through the minimum standards. One example from the area of ecological sustainability is the 'responsible care' process of the chemical industry's international associations and companies. From the area of social responsibility the

efforts to abolish child labor and forced labor according to the Council on Economic Priorities' standard 'Social Accountability 8000' may be cited. Problem standards are highly ambitious compared to the potentialities and mentality of many companies. Hence they are accepted by only a few companies, mostly by those which have elaborated them, usually in cooperation with NGOs. This may happen in associations or chambers of commerce or in loose assemblies of those companies for whose business actions the problem in question is instantly relevant. Their strength lies in their model character and in the fact that they make practical experiences concerning these standards possible. Their weakness lies in mostly very difficult controlling and in possible competitive disadvantages for those companies that do not succeed in overcoming the costs of implementing and keeping the standards through prices.

2.3 Corporate Standards

Corporate standards codify the constitutive and action-directing values of a corporation. As codes of conduct or codes of ethics they are components of corporate governance, that is, of the leading, steering, and controlling mechanisms of an economic organization. They are also expressions of the distinct philosophy and policy of the corporation. The values of a corporation can be classified as performance values (e.g., profit, quality), cooperative values (e.g., loyalty, team spirit), communication values (e.g., respect, transparency), and moral values (e.g., integrity, fairness) (Wieland 2000). A firm gains identity and distinctiveness as soon as a specific values mix drawn from these four classes of values endows it with a particular profile. Particularity here means that it fits best with the promises of the company, with its tradition and history, and the aspired direction of future developments. As a rule, these business codes provide regulations for coping with suppliers and customers, shareholders and employees, as well as rules of law and of environment protection. They are part of an overall ethics management system by which the business codes are operated and pursued in corporate practice. Normally this is executed by means of internal and external communication, by training, by ethics officers, and by being incorporated in labor contracts, and the system is controlled by monitoring audits (Weaver et al. 1999).

The systems themselves can be divided into law-driven and value-driven ones (Paine 1994). While the first are compliance programs which focus on the observation of the rules of law and are organized by the legal department of a corporation, the latter as value management systems aim at a comprehensive development of the corporate culture specifically concerning relations with the totality of stakeholders. Codes of ethics therefore never make any statements about existing matters of fact, and they never stand in for the moral consensus of all parties that are interested in the company. It is just the other way around. They define the values of an organization against all stakeholders and declare them conditional for further interaction. As conditions of cooperation with and within an organization these values are shaped like commitments of performance. The company commits itself to these values and promises to continually work on the fulfillment of its commitment. This makes it obligatory for all stakeholders also to bind themselves to the values. In the last decade of the twentieth century, about 80 percent of the big US companies had such codes (Center for Business Ethics 1992). In Europe this must be estimated considerably lower, although there are no exact figures available.

Apart from those reasons for the renaissance of business ethics mentioned in the outset another important factor is legal developments. Because of the introduction in the USA of organizational liability in case of deviant behavior of employees, incentive systems have been installed which make it financially worthwhile to document before the court the implementation and communication of a code of ethics, so that in case of an individual breach of law, the organization cannot be held responsible for it (United States Sentencing Commission 1995). Legal developments similar to this can also be observed in Europe. In this context business codes aim to achieve a higher level of transparency and thereby enhance the means of control in the corporation. The strength of standards of behavior in corporations is that they are highly specific and integrate the involved actors in maintaining them by the implementation of incentives. However, they cause problems for any form of control and by the fact that they have to be introduced into the operative actions of the corporation in a relevant way.

3. Functions and Effect

Although all three kinds of business codes refer to different types of cooperation and transactions they are identical in respect of their functions and effectiveness. These can be differentiated as follows:

(a) Business codes are a functional equivalent to national deficits of regulation by way of directing companies to self-binding and self-control.

(b) Business codes determine and define the identity of those corporations that bind themselves to standards of behavior. These corporations are distinguished from other organizations in the public arena of realization and communication.

(c) Business codes are the basis, as well as a criterion of selection, for corporate decisions. Hence, they define the range of liability a company claims beyond existing law.

(d) Business codes internally and externally indicate the behavioral preferences of an organization and at

the same time communicate a challenge to all its stakeholders to bind themselves to them.

(e) Business codes provide certainty of expectation in business relations and make possible the building up of mutual trust by creating a check against informational uncertainty and opportunistic behavior.

(f) Their prevalence on the one hand relies on economic benefits which arise from the acceptance of standards of behavior. On the other hand one runs the risk of losing economic and social reputation in any case of violation of the legal and moral obligations committed to.

(g) The aspects mentioned—self-binding, identity, responsibility, certainty of expectation, building up trust, reputation—constitute a system of mutual effects which lead to an expansion of economic and societal cooperation and to accompanying gains from trade.

(h) These effects can only be reached by actually maintaining the standards of behavior within the business routine of the company. For that purpose they have to be implemented and integrated into the operative processes of the organization and its management. One of the most important instruments in this respect are ethics management systems.

Ethical Codes, Professional: Engineering Codes

Engineering codes of ethics are sets of rules adopted by engineering associations and engineers' professional bodies. They usually include (a) fundamental principles (general guidelines) demarcating the engineering profession; (b) professional rules for engineering practice in dealings with clients, superiors, colleagues (particularly competitors), the profession, and the general public; and (c) procedural rules governing conduct in cases of moral conflict. Codes vary in their degree of legal validity, and range from general guidelines in the form of statements of aims and aspirations, to concrete rules with the status of association bylaws that are binding on all members, on to the vocational regulations of public bodies. Furthermore, many codes do not cover all three elements (a), (b), and (c); as such they are either limited to general principles, restricted to the precepts of professional conduct, or fail to include appropriate procedural rules with a protective function which can be enforced in situations of moral conflict. In particular, many codes fail to clarify the relationship between an orientation to public welfare (a) and the duty to inform the public (b).

1. Tradition

The first codes of ethics for engineers, drawn up in the United States from 1912 onwards, initially consisted only of professional rules of conduct for dealings with clients and competitors (the professional ethos). Although these codes were promptly supplemented by principles stating that public welfare was to be held paramount in the practice of the engineering profession, this step forward was counteracted by the ban on criticism in public of engineering projects and their execution, and by the lack of procedures for the supervision and protection of the engineers affected. Guidelines on environmental sustainability and nature conservation were also lacking in this first phase of development (in 1908, J. Cooke, the president of the US engineering association, foundered both in his goal of combating air pollution by means of binding rules and in his plan to establish judicial proceedings for cases of moral conflict; in 1932, two members of the American Society of Civil Engineers (ASCE) were expelled after they breached the provisions of the ASCE code by disclosing irregularities in dam con-

struction, resulting in the punishment of those responsible; see Layton 1971). While a wealth of different codes were adopted in the United States over the following decades (see Flores 1980, Unger 1982; for an international overview of ethical codes see VDI and Hubig 2000), developments in Europe were rather more restrained. This can be attributed partly to the fact that other organizations were responsible for the control and supervision of technical equipment in Europe (e.g., the technical control board TÜV and its predecessors in Germany) and that the European engineers' associations and the institutes concerned had drawn up legally binding rules for technological design (e.g., DIN, the German Institute for Industrial Standardisation, and VDI, the German Association of Engineers). Furthermore, the more advanced labor and social welfare laws (including protection against dismissal) in force in the European states perform functions that need to be fulfilled by different means in the United States.

In the 1970s, subsequent to a number of prominent scandals in the domain of technical safety (notably the Bay Area Rapid Transit [BART] case, in which engineers who called attention to unsafe aspects of the BART system design lost their jobs despite the fact that their intervention was justified; see Friedlander 1974), it became increasingly clear that codes of ethics needed to include regulations to protect whistleblowers. By the same token, regulations governing conduct in cases of conflict—including the establishment of supportive bodies such as appellate bodies, courts of arbitration, etc.—were needed to prevent engineers being forced into the role of lonely 'heroes' or 'victims' (Alpern 1987, MacCormac 1987, Lenk 1987). The IEEE played a substantial role in these developments. At the beginning of the twenty-first century, codes of ethics are gaining prevalence internationally, but still lag notably behind the much more advanced discussion in the United States: their provisions may be restricted to professional issues, for example, to the domain of general principles (VDI and Hubig 2000).

2. *The Specific Professional Responsibility of the Engineer*

Engineers' codes of ethics have to solve the problem of how the universal moral responsibility which the engineer automatically assumes in his or her capacity as a private citizen can be placed in relation to actual practice in the engineering profession. This first appears to be a problem of application: the engineer is bound to universal moral principles and has to verify whether his or her action is permitted, required, or prohibited by these principles. The engineer's actions may be constrained by the principles themselves. Alternatively, specific internal-technical (instrumental) rules (e.g., functionality and product safety) and (strategic) rules on the maximization of utility and minimization of harm (e.g., use of resources, environmental pollution, long-term societal and environmental impact, etc.) may guide his or her action. Moral conflicts arising here have a similar structure as in other occupational fields.

In addition, some more recent codes take into consideration the specific role responsibility of the engineer. This professional responsibility arises from the engineer's specific knowledge and skills—competencies that cannot be expected of those working in other occupational fields, or of the users of technology, in particular. In addition to bearing the responsibility for the direct consequences of his or her actions in an instrumental-technical or strategic respect, the engineer is obliged to apply his or her specific knowledge and skills to other societal areas by (a) contributing to the early detection of new problematic issues in technological progress and the use of technology, and warning and advising accordingly; (b) calling attention to new alternatives arising in the course of technological development; (c) offering honest criticism of legal provisions with respect to their application and practicability and calling attention to alternatives; (d) using their technical expertise to help draw up standards for technological design and contribute to the discussion of technology-related assessment criteria, and finally (e) preventing foreseeable misuse in the lay public's dealings with technology and limiting the scope for deliberate abuse of technical products and procedures (e.g., by mechanisms to prevent misuse by unauthorised persons—see draft VDI code 2000).

3. *The Values Underlying Engineering Codes of Ethics*

In view of traditional and cultural differences in the basic ethical orientations (value pluralism), most codes of ethics are based on fundamental principles which appear justifiable from various perspectives, and which express a kind of moral common sense. The decisive values and value orientations are thus expressed largely in general and formulaic terms. This may well lead to problems. On the one hand, the potential for conflict which may arise as a result of differing interpretations of the set phrases remains hidden; on the other hand, the fact that the values are immanently contradictory and likely to lead to conflict is often overlooked when general lists of values are drawn up. Rules applying to the narrower domain of professional practice (see point (b) above) focus on the values of loyalty, fairness, solidarity, and contractual fidelity. Here, potential for conflict is most likely to arise as a result of competing commitments to the parties involved: loyalty to clients, superiors, the law,

etc.; solidarity with colleagues, the profession, the users of technology, etc. The fundamental principles of the majority of codes (see point (a) above) refer to public welfare and, more recently, to environmental quality and nature conservation. Reference is also made to individual health, safety and welfare, and universal moral rights (human dignity, human rights). Conflicts between these general value orientations have a similar structure as those in domain (b). Immanent conflicts in matters of public welfare result from the difficulty of identifying collective preferences which are compatible with the conditions of liberalism on the one hand (e.g., Arrow 1963) and from differing interpretations of total utility as either average utility or aggregated utility on the other. Conflicts between the basic values are also apparent in the debate on sustainability in technological design, for example. Further potential for conflict arises when individual and public welfare have to be weighed up against one another in cases of rationalization or rationing, for example, or in the familiar conflicts of interpretation on human rights matters. Unless the resolution of such conflicts is regulated by fixed value hierarchies within the codes (determining, for example, that loyalty to the law takes priority over loyalty to clients), it will only be possible to settle such value conflicts by discursive means. The engineer is not a privileged partner in such discourses, however, and his or her responsibility here lies in the willingness to engage in such discourses (solely the draft VDI code (2000) takes steps in this direction).

4. *Institutionalization of the Engineer's Ethical Responsibility*

In the complex processes of technology generation and use, it is only in the rarest of cases that the engineer as an individual bears sole responsibility for the consequences of his or her direct actions, the role he or she occupies, or way he or she performs this role. The individual engineer possesses only a certain amount of specialist knowledge and has only limited authority to act. However, this does not exonerate the individual from a share of the responsibility for the results of complex actions in which he or she was involved, or from a share of the responsibility for the institutional actions of the organizations (companies, associations) to which he or she belongs, or the decision-making processes in which he or she participates. Individual actions are embedded into the institutional framework in various ways in different codes of ethics. Some codes stipulate institutionalized procedures to relieve, support, and protect the individual engineer in cases of moral conflicts that he or she does not have the power to resolve, and designate appellate and advisory bodies, hotlines, disciplinary procedures, and incentive schemes to which the engineer has recourse in cases of conflict. If no such measures are stipulated, the provisions of the code may be embedded into the institutional framework in the form of a supplementary bylaw. Only then is the association able to implement the code and regulate its members' conduct accordingly (e.g., the IEEE Member Conduct Committee, which interprets the provisions of the code in conjunction with an ethics committee, or incentive systems such as the Carl Barus Award for Outstanding Service in the Public Interest). Provision is also made for training programs and support in legal disputes.

5. *The Legal Status of the Codes*

Codes which take the form of statements of general aspirations and are formulated in terms of fundamental principles are not directly legally binding. Even in this form, however, they have unequivocal legal relevance. First, they provide a point of reference for the filling of unlegislated areas left open by statutory regulations, and thus constitute an important complement to the orientation function of the law. Second—and even more importantly—codes play an important role in the interpretation of gray concepts in labor law, vocational regulations, and the provisions of administrative and civil law when such gray legal concepts as 'public morals,' 'endangering the health of others,' 'significant material assets,' 'state of the art,' 'duty of care for product safety,' etc., need to be more clearly defined in terms of certain standards of responsibility. These standards can be derived from the norms of the engineering profession if these are established in a corresponding code of ethics. Engineers can then refer to the code when making decisions, and the courts can follow the guidelines of the codes when interpreting gray legal concepts.

A code has a greater degree of legal validity if it takes the form of an association bylaw which is binding on the association's members. This makes it possible to protect members from competing demands and expectations and to take disciplinary action in cases of misconduct. Arbitral or association jurisdiction (as is the case in sports clubs, for example) is of course required for a code with the status of an association bylaw to be enforced. A code attains the greatest degree of legal validity as part of the vocational regulations of a professional association which is also a public body (e.g., Federal Chamber of Engineers [*Bundesingenieurkammer*] 1998). All those practicing the profession in question are bound to the code by means of compulsory membership of the association. By giving vocational regulations precedence to all contractual obligations under civil law, but not to labor law, the state surrenders part of its jurisdiction to the profession, thus offsetting the limits of its own powers.

In the United States, in particular, a further link between ethical codification and the law can be observed: under the terms of the Federal Sentencing Guidelines for Organizations (FSGO), the question of whether or not an organization or corporation has subscribed to a code of ethics and corresponding enforcement program ('effective ethics program') in the form of a bylaw is taken into account in sentencing. Under the guiding principle of 'good corporate citizenship,' the state acknowledges that it is not itself in a position to direct corporate action by means of the existing framework regulations, and determines the sanctions to be imposed by considering the corporate will to cooperate in an ethical approach to technology. In Great Britain, the 'Public Interest Disclosure Bill' assures the disclosure of moral conflicts and designates appellate bodies and entities.

Finally, some more recent codes of ethics include an additional guideline which goes some way to determining the engineer's position with regard to legal systems. The 'qualified obedience to the law' required here moderates the effect of external legal regulations. In the problematic case of a formal interpretation of the law (e.g., with respect to new and as yet unforeseen technologies), precedence is given to the intention of the law. Furthermore, problematic legal regulations are to be checked with respect to their compatibility with civil liberties and human rights. In conflicts such as this, the individual engineer is in acute need of the support of an association that has adopted such a code.

Ethical Dilemmas: Research and Treatment Priorities

1. Ethical Dilemmas in Moral Theory

1.1 Causes and Kinds of Dilemmas

Dilemmas appear in situations where (a) moral principles seem difficult to apply to the case at hand, or (b) where various moral principles clash and/or do not guide action.

As to the first case, ethical dilemmas arise due to an epistemic uncertainty like risk assessment or evaluation of the ethical implications of scientific and technological change and/or due to conflicting obligations in light of the new technological advances that support different courses of action. Two kinds of ethical dilemmas can be distinguished: an agent faces conflicting obligations which he cannot both fulfill, and neither obligation is overridden: he ought to do A and he ought to do B, but cannot do both A and B. For example, a father is unable to rescue both of his children from a burning house. He has an obligation to rescue his first child, and he has an obligation to rescue his second child, but neither obligation outweighs the other. Or, moral reasons speak equally for

and against an option with respect to different features of that option: and agent ought to do C and ought not to do C. A doctor, for instance, who has an obligation to provide medical assistance, faces such a dilemma if his help implies a questionable prolongation of a patient's life that might be difficult to assess. No matter how the person in moral dilemmas acts there will be moral losses.

In the second case, an ethical dilemma is due to disagreement about which moral convictions and principles like 'maximize the expected utility' or 'treat a human being as an end in itself' apply to the case. Thus, there is a deeper difficulty about the application of moral principles to practice, if there is disagreement about the principles or if there are several principles that are applicable to the respective case and yield different solutions. There is no standard way of weighing the contending principles in order to decide which predominate in specific cases. Such dilemmas constantly arise in medical practice where it is difficult to assess whether life-saving treatment regards the patient as an end in itself, and should therefore be provided, or whether it disregards patient interests and values.

1.2 Epistemic Dilemmas

Ethical theorists have concentrated on the question about which there is widespread disagreement whether ethical dilemmas can be solved. Some have tried to tackle the problem of moral principles that, if jointly applied, lead to inconsistencies. Two principles are inconsistent, if they cannot be both fulfilled.

Two moral principles in particular are alleged as being unable to guide action in light of seemingly conflicting obligations. (a) The so-called 'agglomeration principle' entails that an agent S is obligated to do A, and is obligated to do B, and therefore is obligated to do both A and B: $[(OA \& OB) \rightarrow O (A \& B)]$. (b) The principle of deontic logic 'ought implies can' infers from the premise that an agent S is obligated to do both A and B that the agent *can* do both A and B: $[(O (A \& B) \rightarrow c (A \& B)]$.

These two principles contradict the standard definition of ethical dilemmas according to which an agent is obligated to do A, and is obligated to do B, but *cannot* do both A and B. Some theorists have tried to differentiate between *prima facie obligations* and *all things considered obligations* in order to show that not every obligation requires to be acted upon. A so-called *deliberative ought* (B. Williams in Gowans 1987) is supposed to help us decide which obligation overrides a seemingly conflicting obligation by referring to stronger reasons (P. Foot in Mason 1996). Dilemmas are thus described to be merely 'epistemic.' Moral principles are shown to be consistent by distinguishing between preliminary and final (R. M. Hare in Gowans 1987) or general and specific (A. Donagan in Gowans 1987) principles. According to R. M. Hare (in Gowans 1987), for example, conflicting prima facie duties are selected on a 'critical level' with the help of actutilitarian considerations. A generally accepted rule might thus be overridden in light of the case at hand. A. Donagan (in Gowans 1987) proposed to specify principles with additional premises in order to provide exceptions to such principles if they seem to be justified. A promise, for example, can be broken if a more urgent and morally defensible action calls for it.

1.3 Are Dilemmas Genuine?

Even though many ethical dilemmas might be solved in such a way, there still remain cases in which no 'deliberative ought' can show which prima facie obligation outweighs the other. Furthermore, it can be maintained that even obligations that are supported by less weighty reasons might still remain in force and do not cease to obligate. There are three arguments that try to support the hypothesis that ethical dilemmas can be insoluble. (a) So-called residual emotions like regret that agents express after a choice between conflicting obligations are purported to show that the obligation not acted upon remains in force like an unfulfilled desire (B. Williams in Gowans 1987). (b) Conflicting oughts are considered to stem from plural sources of value, e.g., obligations, rights, utility, perfectionist ends, and commitments. Hence, if values (and also moral principles) are plural, dilemmas seem to be unavoidable (T. Nagel in Gowans 1987). (c) Feelings of guilt that agents display after a difficult choice are taken to motivate the avoidance of conflicts in the future. They show that dilemmas are real (R. B. Marcus in Gowans 1987; in Mason 1996). As to the solution of dilemmas the considerations of ethical theorists are also constantly challenged in light of the practical problems that technological research, for example, poses.

2. Ethical Dilemmas in Scientific Research

2.1 Risk and Technology Assessment, Professional Responsibility, and Moral Status

Ethical dilemmas arise in many areas of research, particularly where the development and use of new technologies challenges the application of moral concepts, or leads to conflict between moral principles and demand for their extension or further specification. Thus, for two conflicting courses of action different moral arguments, rules or principles can be equally compelling, or their moral costs are difficult to assess. This pertains to problems of risk and technology assessment, the scope of professional responsibility, and to questions of autonomy and the moral status of those affected by these technologies. Ethical dilemmas typically arise in the controversies surrounding life-

saving technologies at the beginning and end of life, life-enhancing technologies to improve the quality of life, the technologies of reproduction, and genetic engineering.

Technological and risk assessment can be dilemmatic in the following way: in the early stage of a technological development, when it is still relatively easy to control its direction, there is an inevitable lack of knowledge to exercise reasonable control; by the time more experience and better understanding of the risks involved is gained, the technology has often developed so much social momentum that it is almost impossible to control it (Collingridge 1980).

The responsibility of scientists can be said to consist of the pursuit of truth in their own area of competence, for wielding social power appropriately, and for making their results generally accessible. Professional responsibilities can lead to moral conflict if, for example, research results and/or the effects of technologies have a potential to endanger others. For example, scientists can have a duty to pursue truth, and they can equally have a duty to avoid harm, and they might not be able to fulfill both. The justification of scientific investigation can only be provided from within scientific research, since expertise is needed to evaluate it. This can undermine social control of research (Erwin et al. 1994).

The application of moral principles to practice also sheds light on the question who or what has autonomous moral status with regard to fetuses, those in permanently vegetative states, members of future generations, animals, and inanimate nature. For example, is research on human embryos permitted in order to foster medical therapy and relieve suffering or do we also have obligations to embryos? Particular moral uncertainty is thus engendered by contexts that demand divided allegiances. For a more detailed treatment of professional responsibility and control, see *Censorship in Research and Scholarship*; *Research Conduct: Ethical Codes*; *Ethical Practices, Institutional Oversight, and Enforcement: United States Perspectives*; *Ethics Committees in Science: European Perspectives*; *Research: Ethnical Aspects of Long-term Responsibilities*; *Objectivity of Research: Ethical Aspects*.

2.2 Ethical Dilemmas in Biotechnology

The far-reaching potential advances in gene therapy and genetic engineering for humans (The Human Genome Project), and the implications for humans of cloning, have given rise to ethical dilemmas scientists have to face. The following examples can illustrate how progress in genetic engineering generates dilemmas between conflicting obligations and/or conflicts due to risk assessment (Chadwick 1992).

The identification of human genes, for example, can lead to the following conflict: on the one hand genetic knowledge enhances therapies for hereditary disease, on the other hand, it poses problems about the potentially exploitative use of resources and genetic information. The attempt to sequence the entire human genome raises ethical questions whether the risks of exploitation outweigh the benefits of knowledge.

Genetic alterations passed on to future generations through so-called germline therapy raise further problems regarding consent while, at the same time, 'improving' human genetic potential for future generations. Do we have an obligation to present generations to relieve suffering by seeking treatments for genetic disease or do future generations have a right to an unmodified genetic inheritance? Equally, the advantages of genetic screening can be outweighed by the costs of stigmatization on the basis of a person's genetic make-up. Such individuals might find themselves unemployable or uninsurable. There also arises the question whether the very existence of genetic screening can exert pressure on individuals with regard to their reproductive decisions, thus impairing their autonomy. How can genetic public health be fostered without practicing eugenics? Arguments about the moral urgency of relieving suffering also conflict with arguments about human dignity that discredit the production of 'designer babies' (Annas and Elias 1992).

The incorporation of foreign genes into the genome of an organism is commonly discussed in connection with animals and plants. One dilemmatic issue concerns the interests of the host organism (particularly in the case of animals), the consequences for human health and for other species, and the risks of releasing genetically engineered organisms into the environment.

A related issue has been the matter of justification of treatment. Animal experimentation poses the question whether animals have moral status to the detriment of life-enhancing research results for humans. As subjects of genetic engineering, for example, farm animals have suffered from unintended deleterious effects, while research animals have suffered the consequences of being intentionally bred for propensity to develop debilitating diseases. A further important issue is related to the question whether an agent who had moral status can cease to have that status. The human cases of the brain dead, anencephalic infants, and those in a permanently vegetative state are cases in point. If so, then the case of xenotransplantation or the transplanting of animal organs into humans is affected. The interlocking questions of moral standing, justification of treatment, and loss of moral considerability can thus cause conflicts as to which consideration should be given more weight. Ethical dilemmas in research are thus a challenge to those within and those outside research, to debate whether research practices and their effects are right and just. For further treatment see *Animal Rights in Research*

and Research Application; *Bioethics: Examples from the Life Sciences*; *Euthanasia*; *Genetic Counseling: Historical, Ethical, and Practical Aspects*; *Reproductive Medicine: Ethical Aspects*; *Research Subjects, Informed and Implied Consent of*.

2.3 Limits to the Application of Moral Principles

Moral rules and principles do not only have to be adapted to the specific circumstances at hand. They also have to be questioned in light of practice. However, in many of the cases that feature in research ethics, often times we do not agree in our moral principles or the moral theories by which they are justified. Even if the application of principles to cases can be specified and thus epistemic dilemmas resolved, there are limits as to what the application of principles can do to resolve dilemmas: the basic problem of dilemmas remains at least in one respect. There is no agreement as to how to balance between various conflicting moral principles in order to decide which predominate in a respective case. Intuitions vary widely, and various normative theories like utilitarianism, Kantianism, contractualism, virtue theory, and feminist ethics usually remain at odds with each other.

It seems desirable to take into account as many considerations as possible on the level of principles themselves in order to highlight the various ethical implications of a case at hand. Not only questions of utility, but also questions of integrity and care can thus be given more weight. Further work, however, needs to be done at the level of ethical theory itself to set out how various principles derived from different normative theories can be balanced.

Ethical Issues in the 'New' Genetics

Genetics, both as a field and as a word, was born in the early twentieth century. The 'new' genetics refers the vast increase in the power of genetics that followed the increased understanding of the biochemical basis for genetics in deoxyribonucleic acid (DNA). That understanding has made it possible to 'read' the sequence of DNA in organisms, including humans; to discover, in some cases, the physiological significance of that sequence; and to contemplate changing the sequence in order to attain desired ends. These heightened powers have both created new concerns and exacerbated older ones.

Concern about implications of the new genetics for human societies grew with scientists' ability to decipher and manipulate DNA. The late 1960s saw discussions of human cloning, followed in the 1970s and early 1980s by safety concerns about recombinant DNA and social concerns about genetic discrimination. When the Human Genome Project was proposed for substantial funding in the United States in the late 1980s, the Project's first director, Dr. James Watson, suggested that 5 percent of the funding be set aside to study the 'ethical, social, and legal implications' of human genetics (Cook-Deegan 1994). The subsequent financial commitment led to the rapid expansion of 'ELSI' studies across many disciplines and the publication of a vast number of articles and books on these topics.

Three general caveats are useful in surveying the resulting discussions. First, although new genetic technologies will sometimes provide great predictive power, oftentimes their predictions will be weak. The percentage of people with a particular set of genetic variations (or 'genotype') who develop a particular 'phenotype' (trait or condition), a percentage known as 'penetrance,' often will be low. Second, although the technologies are quite novel, their implications almost always have parallels in the social effects of other modern technologies. Third, although much of the discussion of the consequences of new genetic technologies has focused on individuals or families, these technologies usually also have implications for broader human groupings. With those caveats in mind, this article will discuss the ethical, social, and legal effects of the new genetics in seven areas: health care, establishing identity, predicting the future, re-

vealing the past, genetic manipulation, ownership and control of genetic material and information, and cultural understandings.

1. Issues Arising from Medical Successes

Writing on social issues of genetics focuses on the dangers of human genetics. It rarely looks at the implications of the hoped-for uses of genetics to prevent and treat disease. The vast sums, private and public, spent on research into genetics are not being committed purely in a search for knowledge, but in the expectation that the research will bring immense medical benefits. The diseases in question may not be limited to 'genetic diseases'; the tools of the new genetics are allowing unprecedented understanding, at the molecular level, of how human cells and human pathogens function. The most powerful lesson of the first 25 years of the biotechnology industry has been that the human body and its functions are more complicated than expected, but those complications are steadily being tackled by the new genetics. A steady stream of new treatments, derived from increased knowledge of genes and their associated proteins, is flowing towards approval.

The results might include a significant extension of average human lifespan; an increase in pharmaceutical costs; and changes, up and down, in the demand for various medical services. The social implications could be substantial on pension plans, voting blocks, and health care systems. Some more focused medical consequences of genetic research such as individualizing patient therapies as a result of genetic tests (called 'pharmacogenomics') or some kinds of proposed gene therapy or tissue replacement will require that treatments be created just for one patient, straining the existing mechanisms for drug development, manufacturing, approval, and financing. Any new treatment will raise questions of availability, both within a country and between countries. The new genetics has created a uniquely high expectation of medical progress; its successes therefore may raise all these issues in dramatic form.

2. Establishing Identity

The new genetics raises three issues centering around identity: forensic identification, personal identity, and ethnic identity.

2.1 Forensic Identification

The new genetics has already led to major changes in forensic identification. Any tissue from a person that contains DNA can be tested for a pattern of identifying markers, sections of the genome that vary from one person to another. Those markers can be compared with markers analyzed from tissue found in connection with a crime (National Research Council 1992). Powerful techniques for analyzing DNA mean only tiny amounts of genetic material are needed, derived from flesh, blood, semen, or even cells found in saliva. A negative test is very powerful. If the markers are significantly different, the tissues cannot be from the same person. Initially, there was concern that a positive match might not be compelling because ethnic groups might share common patterns of markers. These fears have been assuaged through more information on the distribution of the markers. (National Research Council 1996).

Forensic use of DNA is not essentially different from the use of fingerprints, blood groups, or dental records. Like those techniques, it has had to prove itself in judicial cases. Like the earlier techniques, it can never be conclusive. Good defense counsel will always investigate the possibilities of an innocent explanation for the presence of the DNA or for mistakes, contamination, or fraud in the process of collection and analysis.

The real issues about the forensic use of DNA now concern not individual cases, but the collection and retention of DNA or DNA records for identification purposes. Many countries or states are creating DNA repositories with DNA samples from convicted, or even merely accused, criminals. These samples can be used to seek matches in criminal cases or for the identification of human remains. If markers from the samples are analyzed in advance, the results can be put into a database and used to seek 'cold matches' to samples or tissue of unknown origin. These repositories raise two different issues. The first involves their creation. Should people be forced to give samples? If so, who should be required to provide samples—convicted sex offenders, convicted felons, those arrested, or the whole population? A more subtle, but equally important, issue concerns *what* the repository should contain—a DNA sample or only the marker analysis. The markers used for forensic identification are not associated with any traits. If the markers are kept, no information about a person other than identity can be discussed. If samples of whole DNA are kept, however, they could be analyzed for DNA associated with a wide variety of characteristics, raising serious privacy concerns.

2.2 Personal Identity

The furor about the possible use of somatic cell nuclear transfer technology to clone humans involves many issues (National Bioethics Advisory Commission 1997), most of which have already been raised by *in vitro* fertilization. The issue unique to cloning is a

concern about human identity. Would a person with the same genome as another living individual be a copy of the first person?

Monozygotic twins have always shared the same genome. Although their physical similarity is strong, no one doubts that they have individual identities and separate personalities. Cloning by somatic cell nuclear transfer could not produce individuals *more* alike than monozygotic twins. The clone and the source of the clone's DNA would most likely be much less alike. They would develop in the wombs of different women, subject to different environmental influences *in utero*. Once born, they would be subject to different environments, often in different decades. The degree to which identical human genotypes born from different wombs produce similar phenotypes would be an interesting research question, if it could ethically be studied. The popular perception of identity would likely prove grossly exaggerated.

2.3 Ethnic Identity

Ethnic groups often share both a common culture and a substantial degree of common ancestry. This genealogical connection implies a genetic connection; particular variations in DNA sequences, or patterns of those variations, will be more common in some populations than in others. For example, each of the four ABO blood groups, which are genetically determined, are found in all (or almost all) of the world's populations, but in different proportions in different groups. Other variations in DNA sequence may be found at high levels in some groups but rarely in most others (Cavalli-Sforza et al. 1994).

This kind of variation can be used for anthropological research; it could also be used to try to define a person's ethnic identity. Of course, no known DNA variations are found in every member of an ethnic group and never found in nonmembers. Given the human history of frequent intermixing, adoption, and conversion, no such variations are likely. The ethical implications of the naïve use of such inherently inaccurate methods for defining ethnicity will depend on the circumstances, including whether they were adopted by the group itself or imposed on it.

3. Predicting the Future

The most discussed issues arising from the new genetics come from its ability to predict individuals' futures as a result of associations between genetic variations and physical and behavioral traits. The strength of the predictions will vary dramatically. Some conditions, such as Huntington's disease, follow inevitably from possession of a particular genetic variation. For other conditions or traits, a person with a particular genetic variation will have a somewhat increased but still small likelihood of having that condition or trait. The ethical significance of such predictions will vary largely based on who uses what predictions for which ends.

3.1 Prenatal Selection to Avoid Disease

The new genetics brings the ability to test the DNA of the parents and of the embryos and fetuses they create. Where the genotypes are strongly or completely associated with particular phenotypes, whether the children might (when the parents are tested) or would (when the embryos or fetuses were tested) show those traits can be confidently predicted. This kind of prenatal testing has been used for several decades to avoid serious genetic diseases such as sickle cell anemia and Tay–Sachs disease. In some cases prospective parents have been tested to alert to them to whether such a disease is a possibility for their children. This carrier testing is simple and relatively uncontroversial.

Testing of fetuses is possible only with genetic material from the fetus, currently retrieved from the amniotic fluid or from the chorionic villi well into a pregnancy. Both procedures are expensive and somewhat risky. After a direct genetic test of the fetus, the parents could choose to abort or could prepare themselves better for the birth of a child with the particular genetic condition. Testing of fetuses for genetic conditions has been more controversial. Some oppose it because it often leads to abortion, which they condemn as murder. Advocates for the disabled argue that this testing implies that the lives of people with those genetic conditions are not worth living. In the United States, abortion, at least through the second trimester, is legal for any reason, so there has been little discussion of outlawing abortion based on genetic tests; many countries do regulate the reasons for abortion and must face this issue. Even in the United States, a question remains as to whether prenatal genetic testing for such conditions should be encouraged or discouraged.

A recent technical advance may change discussions about prenatal genetic testing. 'Pre-implantation genetic diagnosis' makes it possible to test an embryo before it is implanted. This procedure can only be done with *in vitro* fertilization. One cell is detached from an embryo and the DNA in that cell tested. Based on the results, the parents can decide whether to implant that embryo or not. No fetus would be aborted; instead, some embryos would just not be implanted.

3.2 Prenatal Selection for Genetic 'Enhancement'

Pre-implantation genetic diagnosis increases the possibility of parents selecting children based on genetic traits that would 'enhance' their children. The idea of

using genetic testing to select 'enhanced' genetic traits for offspring has raised many concerns (Parens 1998). Some fear that allowing parents to choose traits for their children would deny those children their right to 'an open future' not of their parents' choosing. Others worry that the rich will be able to buy unfair genetic advantages for their offspring. Still others worry that parental selection will lead to a homogenization of the human gene pool, as parents opt for children with similar traits. Finally, some fear that these parental choices could lead to a self-perpetuating genetic caste system. These results can only follow if genetic variations are identified that strongly predict 'success' and if many parents are willing to undergo pre-implantation genetic diagnosis. Neither is certain.

One might also question whether parents choosing to enhance their children's lives through genetics is fundamentally different from efforts to do the same through environment. Rich parents send their children to 'good' schools. Parents may push their children from an early age to excel in certain activities—Wolfgang Mozart and Tiger Woods are both successful examples. Arguably, a major goal of parenting is to 'deny' one's children certain unhappy or illegal futures. The argument that enhancement through genotype selection is inherently more threatening than other kinds of enhancement is not obvious. (Sex selection is a special case of 'genetic enhancement,' though one that is also done without genetics, by sonography.)

3.3 State-sponsored Prenatal Genetic Selection

The discussion thus far has focused on parental choices about their children's genetic make-up, but those decisions need not be made by parents. Governments have intervened to prevent people with 'inferior' genes from having children; such eugenics laws could come again in more precise forms. 'Eugenics' is discussed in detail in other articles and will not be reviewed here except to note two things. First, state actions to encourage prenatal genetic selection without compulsion can also be 'eugenics.' Second, the ethics of government-sponsored eugenics depends on striking a balance between government public health powers and individual procreative liberty that remains in debate.

3.4 Postnatal Genetic Testing

The possibilities of genetic testing do not end at birth. Genetic tests can help diagnose diseases or predict future disease risks. Like all medical interventions, their value depends on their appropriate use (President's Commission 1983, Institute of Medicine 1993). Postnatal genetic tests provide information that can lead to a medically useful interventions, that can help the patient make life plans, and that might just satisfy a patient's desire to know her future. Genetic testing also has costs. Test results may pose psychological problems for those tested or affect the patient's relationships with family members. They may also have implications for the patient's dealings with the broader society, through employment or insurance discrimination. In the absence of useful interventions, the benefits from genetic testing depend greatly on the circumstances and personality of each individual. Where tests, genetic or otherwise, do not have powerful implications for medical intervention, the strong influence of the individual's personality and circumstances on the value of testing argues for a particularly good process of informed consent, especially when the patient's understanding of the links between genetic variations and disease may be weak. Such testing is particularly suspect for children, if the benefits of such testing could be put off until they reach adulthood and make their own informed decision.

Of course, many nongenetic medical tests predict higher or lower disease risks. The diagnosis of a disease, whether through genetic or nongenetic methods, can trigger many of the same costs as prediction. Genetic diseases do implicate family members to an unusual extent, but shared environments or diets also put family members at shared risk.

3.5 Genetic Discrimination

Great concern has been expressed about the possible uses of genetic tests to discriminate against people based on genetically predicted susceptibilities. Employment, life insurance, and, in the United States, health insurance are the fields where genetic discrimination is most feared. The likelihood of genetic discrimination depends on two different sets of factors: the strength of the prediction possible from genetic information and the social structure governing the relevant fields.

For someone with the allele that leads inevitably to the fatal condition Huntington's disease, genetic prediction is quite powerful. Fortunately, such powerful genetic predictions are rare; it is not clear that employers or insurers would find significant an increased risk of diabetes from 5 percent to 8 percent. Similarly, discrimination in health insurance is mainly a concern in the United States; all other rich countries guarantee all, or almost all, their residents health coverage. Even in the United States, the great majority of Americans with health insurance obtain it through methods that are not susceptible to genetic discrimination. Medicare, Medicaid, and employer-provided health insurance are not medically underwritten—they must accept everyone eligible without using any

medical exclusions. There is little good evidence that genetic discrimination in employment or insurance exists in the United States, although there is clear evidence of public fear of such discrimination.

Whether such discrimination turns out to be common or rare, the question remains what to do about it. Thus far, no general federal law bans genetic discrimination in insurance or in employment (although the opaque Americans with Disabilities Act may prohibit some employment discrimination based on genetic characteristics). Most US states have limited the use of genetic information in health insurance, many have limited their use in employment decisions. No states have forbidden their use in life insurance (Bobinski 2000). The United Kingdom, where the National Health Service makes private health insurance of limited importance, has set up a regulatory authority to pass on whether or not life insurers may require tests for particular genetic conditions, recently allowing the use of Huntington's disease testing. How well statutes limiting genetic discrimination will work remains unclear. If statutes banning genetic discrimination can function with low costs, one might justify them on the ground that they increase the research on and clinical use of human genetics by reducing public fears, whether or not those fears are justified (Greely 2001).

3.6 *Prediction of Behavioral Traits*

The successes of the new genetics have largely been with physical traits or conditions. Public interest in genetics, though, seems to lie disproportionately in behavioral traits. Some human behavioral traits have been linked to genetic variations, including some forms of mental retardation. For the most part, though, efforts to link genetic variations with human behavioral variations have, thus far, had little success. If such predictions were possible, the ethical implications could be substantial (Carson and Rothstein 1999).

Strong links between genetic variations and behavior would undercut notions of personal responsibility for the involved behaviors. At the broadest level, they could affect society's view of the extent of individual free will. More narrowly, they could affect society's view of, for example, 'genetically determined' criminal behavior or sexual orientation, although whether the result would be more or less tolerance for the behavior is not clear. These kinds of genetic predictions could also lead to interventions in individual's lives—people predicted to act violently might be put into custody before they committed any offense. The successful association of behaviors with genetic variations would boost the interest of both parents and governments in prenatal genetic selection.

Societies make predictions about future individual behavior in many ways. Except prenatally, it is not clear that doing a genetic test to determine, for example, musical ability, would offer any advantages over a direct test of such ability. Genetic tests would have an advantage only when the prediction is strong and the behavior is not easily observed directly. At this point, it is not clear to what extent genetic variations will prove able to lead to strong behavioral predictions.

4. *Uncovering the Past*

DNA can reveal aspects of the past as well as the present and future. Sometimes it raises in new contexts issues of the privacy of historical figures in matters such as Thomas Jefferson's relationship with his slave, Sally Hemmings. Other historical uses of DNA raise broader questions.

4.1 *Individual Ancestry*

Genetic variations can be used in a straightforward way to establish close biological relationships. Blood groups or isoforms of particular proteins have long been able to provide such information; direct DNA testing can increase accuracy. The ethical implications of such paternity or maternity testing varies according to its use. If done with consent, it seems unproblematic. If done without consent, it might be justified, as in establishing child support obligations, but would require consideration. One problem occurs where genetic testing, done for some other reason, such as attempting a diagnosis of a child's disease, reveals unsought information about 'false paternity' that be unwelcome or even dangerous.

4.2 *Group Histories*

Analysis of patterns of genetic variation among different human populations can reveal how closely related two populations are. This information then becomes evidence about human history and migrations. It is not conclusive evidence, but joins with linguistic, archaeological, anthropological, historical, and other sources to improve understanding of the human past (Cavalli-Sforza et al. 1994). The evidence may not always be welcome. It may contradict a population's own beliefs about its history and origins. In some situations, that information alone might destabilize or disrupt the entire culture. It could also have modern political implications where ancestral origins, and the length of time in possession of particular territories, could affect land disputes. Whether a historical researcher has ethical obligations to avoid doing research that could provoke such consequences is unclear. Similarly unclear is whether there is an ethical obligation to seek the informed

consent of the entire group to such genetic research that might have consequences for the group (Greely 1997). Such consent has not generally been thought necessary for other historical investigations affecting contemporary peoples; some might argue that 'genetic history' is different, either because of the nature of the materials being used—DNA samples from living and sometimes dead members of the population—or the different degree of certainty perceived for such 'scientific' evidence.

5. *Manipulating Genes*

The new genetics may make it possible not just to read person's genes but to change them. That ability would create additional concerns.

5.1 *Somatic Cell Gene Therapy*

Somatic cell gene therapy involves the placement of a human gene into a living person's somatic cells—cells that do not produce the eggs and sperm that in turn produce the next generation. Somatic cell gene therapy would aim to cure a disease only in the patient, not in the patient's descendants. It was initially conceived as introducing a properly functioning copy of a gene into a person who had a genetic disease as a result of inheriting only improperly functioning copies. Different types of somatic cell gene therapy have since been investigated for the treatment of diseases that are not primarily caused by inherited genes, such as AIDS and cancer. Over 100 clinical trials of somatic cell gene therapy have taken place; very few have, thus far, shown any success.

The genetic aspects of somatic cell gene therapy have been largely uncontroversial. In essence, the gene therapy is merely another drug delivery system, a different way to get a normal human protein to the right place in the body. Somatic cell gene therapy therefore stands in the same position as most experimental therapies. Like such therapies, it has prompted concerns that desperate patients are not truly giving informed consent and that the possible benefits of the treatment are exaggerated. Gene therapy may face the latter problem to a greater extent than most experimental treatments because of the exaggerated public view of the power of anything genetic.

5.2 *Germ Line Gene Therapy*

Germ line gene therapy is much more controversial (Nelson 2000). It would introduce 'normal' human genes into the eggs or sperm of parents, or into the fertilized egg or early embryo of the offspring. The goal would be to change the eventual child's genetic inheritance. This could be done in order to avoid a genetic disease or in order to introduce an 'enhancing' genetic variation. There have been no trials of human germ line gene therapy; indeed, there is an informal moratorium in the scientific community on trying such experiments in humans. Both its feasibility and its value are unclear.

New genes have been successfully introduced into the germ lines of other mammals, but with very low efficiency. At the same time, pre-implantation genetic diagnosis allows parents to choose embryos based on their genetic variations, as long as the parents themselves produced the desired variations. If not, donated eggs or sperm would be a much safer and easier way to introduce the desired genes than somatic cell gene therapy. Germ line gene therapy may turn out to be most important as a barrier to somatic cell gene therapy. If germ line gene therapy were banned, researchers using somatic gene therapy might need to make the difficult showing that the transplanted genes could not 'infect' the patient's germ cells and thus constitute inadvertent germ line gene therapy.

5.3 *Chimeras*

The manipulation of genes permits the creation of 'chimeras,' creatures that are genetically a mix of two species, including organisms that could not possibly mate. In agriculture, this mixing of genes from very different organisms has been perceived by many as unethical and potentially dangerous. Unless one takes a strong view of the sanctity of sharp lines between species, it is hard to make a strong ethical argument against such mixes. On the other hand, one might argue that a gene in the setting of new species might develop different, possibly harmful, functions than in its home species.

Chimeras involving human genes provoke other worries. Intentionally moving nonhuman genes into humans could be seen as lessening the recipient's humanity; moving human genes into nonhumans could be seen as investing nonhumans with some aspects of humanity. The former has not been attempted; the latter is routine. Most of the products of the biotechnology industry are made by creatures that are genetically partially human and partially nonhuman. Human genes are transferred into useful host cells such as yeast that then produce large amounts of the corresponding human protein. Of course, an organism with 6,000 yeast genes and one human gene does not seem very human; concerns about this kind of chimera require a strong belief in the essentially human, or sacred, nature of any human DNA sequence. Moving more human genes or moving human genes into more closely related organisms such as chimpanzees could provoke more serious concern about blurring the definition of humanity.

5.4 Artificial Genes or Genomes

It is possible to create 'new' genes, not found in any existing species, that would create new or modified proteins. One branch of the biotechnology industry specializes in this effort, through what is called 'directed evolution.' The technology takes related genes from different species, recombines them or makes mutations in them, and then examines how well the resulting protein functions. Similarly, scientists could construct, piece by piece, a novel genome. Placed inside a cell, it might be able to generate a new living organism. This issue has been discussed to some extent in the context of the now-abandoned 'minimal genome' project (Cho et al 1999). The safety of making new genes, proteins, or is an obvious concern. A deeper concern would be whether humanity should 'play God' by intentionally creating such new entities. Humans have long created new organisms by cross-breeding between species and by selective breeding within species. New genes are created whenever a gene is mutated. The speculative possibilities outlined here are more significant, and less accidental, interventions. It is not clear whether that makes them ethically different.

6. Ownership and Control

6.1 Research

Rules governing the conduct of human genetics research control the research subject's genetic materials and information. Those rules generally require the informed consent of the subject to the research. Research subjects, however, rarely have any control over the subsequent uses of materials or information derived from them. The California Supreme Court decision in *Moore v. Regents of the University of California* (1990) ruled that the plaintiff could not assert a property interest in a cell line derived from cells taken from his body, although it allowed him to try to prove that the physician-researcher had not gotten his informed consent. Although the *Moore* case is the only decision on this point, current practice generally follows it and gives research subjects no control over who can use their genetic materials and information, for what purposes, or for how long. Current practices also discourage any sharing of financial benefits of the research with the subjects on the theory that the hope of such benefits could be an 'undue inducement' to them to take part in the research.

A new kind of human genetics research raises other issues about the control of research subject information and materials. Associational research seeks to find weaker connections between genetic variations and disease by searching for correlations between the genotypic and phenotypic data of large groups of people. This kind of research requires the creation of a resource made up of health records and DNA samples of hundreds of thousands of people. These resources would be too expensive to create to study just one illness. Instead, the resources would be available to test a wide range of hypotheses. This kind of 'genotype/phenotype resource' is most advanced in Iceland, where the government has given a private firm, deCODE Genetics, the license to create a health records database with clinical medical information on all 275,000 residents of the country.

In the case of Iceland, the legislation also provides that consent is presumed; unless an Icelander opts out of the database, his medical records will be included. The Icelandic plan has raised numerous ethical concerns, including the use of presumed consent, the absence of discussion of the risks and benefits of specific research done on the resource, the degree that privacy would be protected, the access (if any) of other researchers to the company's data, the propriety of having a for profit company control this information, and the financial fairness of the agreements between Iceland and deCODE (Greely 2000). It is not clear on what terms this kind of research will ultimately proceed, in Iceland or elsewhere.

6.2 Patents

When the US Supreme Court, in *Diamond v. Chakrabarty*, approved a patent on a genetically altered bacterium, it started a continuing debate over the patenting and genetics (*Diamond v. Chakrabarty* 1980). To many patent lawyers, DNA is just another organic molecule and patenting of forms or portions of it falls within long-established principles concerning the composition of matter patents on molecules not found in pure or refined form in nature (Eisenberg 1990). Others object to some, or all, genetic patents on a variety of grounds. Those objections can be put into two categories: fundamental and technical.

Some people have fundamental objections to patents on genes, on human genes, or on genetically modified life forms. One set of objections, focusing on genes, contends that they are 'discoveries,' not 'inventions' and so should not be patented. Others point out that genes were made by God, nature, or evolution—in any event, something other than the 'inventors' filing the patent claims—and should not be claimable as someone's intellectual property. Another objection is that human genes are the common heritage of mankind and should be held in common. Still others oppose gene patents as part of broader opposition to biotechnology. Proponents of patents put forward answers to each of these objections; throughout the industrialized world, the proponents have won. Patents on genes, human genes, and to a somewhat

lesser extent genetically modified life forms have been commonly allowed in the United States, Europe, and Japan. It is worth noting, though, that patents usually expire 20 years from the date of application. The first wave of gene patents will soon expire; presumably all patents on human genes will have expired by 2021, 20 years from the publication of 'the human genome.'

Technical arguments continue to rage within the field. The biggest fight has largely been over the patent requirement of 'utility': how much, or little, knowledge about the uses of a genetic sequence is sufficient to convey what kind of patent rights? This controversy became open in the early 1990s when the National Institutes of Health filed patent applications on expressed sequence tags ('ESTs'), small sections of DNA from inside genes of unknown sequence and function. The fight has continued over patent applications on single nucleotide polymorphisms, one base pair differences in the genome. It has also included how much information about a gene and its function is necessary in order to grant a patent.

6.3 Privacy

Protecting the privacy of genetic information is one way to control its use (Annas et al. 1995, Rothstein 1997). But such 'genetic privacy' legislation raises its own set of problems.

The first problem is definitional—what is the 'genetic information'? Information about a person's genetic variations can come from DNA tests, from other biochemical tests, from a naked eye examination, or from family history. A narrow definition, focusing on the results of 'DNA tests,' would miss such powerful information as the 50 percent chance that the child of a Huntington's disease patient carries the Huntington's allele. A broad definition, covering everything from which an inference can be drawn about a person's genotype, would cover almost all medical information. A very high cholesterol level is strong evidence that a person carries two alleles for familial hypercholesteremia. An average or low level is strong evidence that he or she does not.

If almost all medical information leads to inferences about genotypes, it may not make sense to try to protect 'genetic information' separately from medical information. And it may not be possible to 'protect' a person's medical information from the many institutions that have legitimate uses for it, including physicians; hospitals; and those employers, insurers, and governments who pay health care bills. At the same time, the passage of legislation expressly to protect 'genetic' information sends the public the inaccurate message that genetic information is much more powerful and important than other medical information. Legislation to protect genetic privacy has been introduced in the United States Congress but has not yet been passed. Several states have passed such legislation, but it is too early to tell how effective that legislation will prove.

7. Cultural Consequences

The most far-reaching, but hardest to predict, ethical implications of the new genetics may lie in its effects on society's beliefs. Three areas stand out.

First, the new genetics demonstrates graphically that all life is related. Over a third of the genes found in the single-celled brewer's yeast have recognizable relatives in the human genome. Some stretches of DNA appear in close to identical form in humans, mice, and fruit flies. Indeed, there appear to be few, if any, 'human genes'—just human variants of genes shared by all mammals, vertebrates, multicellular creatures, or life forms generally. Darwin's thesis that all earthly life is related by descent from a common ancestor can be seen in these similarities in DNA. It is unclear what cultural significance this will have. It should not promote vegetarianism, because the new genetics shows that carrots and corn, like sheep and cattle, are our relatives. It might, however, promote greater respect for nonhuman life.

Second, the new genetics shows that all humans are closely related. Our DNA differs, on average, at one spot in 1,000. In the regions of the genome that code for protein, the differences are one base pair in 10,000. Humans from opposite ends of the earth are far more similar to each other genetically than chimpanzees from the same band. Genetic theories were used to provide support for a 'scientific' racism in the first part of the twentieth century. The new genetics should provide evidence against such racism.

Third, genetics may shift the balance in the cultural debate between nature and nurture as the source of human characteristics (Degler 1991). Dr. James Watson, co-discoverer of the structure of DNA, was famously quoted as saying 'We used to think that our fate was in the stars. Now we know, in large measure, our fate is in our genes.' DNA may appear to be proof that individuals are powerfully shaped by inherited forces. In fact, the new genetics paints a more complicated picture. Genes play a role in the development of many traits or diseases, but the environment or luck may also be essential. The general population seems to hold a much stronger belief in the power of genes. For that reason, the new genetics could end up promoting a more closed and fatalistic view of human life and abilities than either current society holds or than science would support (Nelkin and Lindée 1995). That reaction may prove to be the most significant ethical challenge of the new genetics.

Ethical Practices, Institutional Oversight, and Enforcement: United States Perspectives

Committees charged with the responsibility for assuring that research involving humans as subjects are called research ethics committees (RECs). Although these committees were designed originally to review biomedical research, their domain has been extended to cover research in the social and behavioral sciences as well.

The Declaration of Helsinki establishes as the international standard for biomedical research involving human subjects the requirement that each research '… protocol should be submitted for consideration, comment, guidance, and where appropriate, approval to a specially appointed ethical review committee …' (World Medical Assoication 2000, Article 13). In most of the world this committee is called the Research Ethics Committee (REC). In the United States, federal law assigns to the committee the name Institutional Review Board (IRB) and the authority and responsibility for approving or disapproving proposals to conduct research involving human subjects (Robertson 1979b). In Canada, the Research Ethics Board (REB) has similar authority to approve or disapprove research proposals, not merely to offer 'consideration, comment and guidance' (Medical Research Council of Canada 1987, p. 48).

1. History

The Nuremberg Code (Superintendent of Documents 1950) and the original Declaration of Helsinki (World Medical Association 1964) made no mention of committee review; these documents placed on the investigator all responsibility for safeguarding the rights and welfare of research subjects. The first mention of committee review in an international document was in the Tokyo revision of the Declaration of Helsinki (World Medical Association 1975).

In the United States, the first federal document requiring committee review was issued on November 17, 1953. Entitled 'Group Consideration for Clinical Research Procedures Deviating from Accepted Medical Practice or Involving Unusual Hazard,' its guidelines applied only to research conducted at the newly opened Clinical Center at the National Institutes of Health (NIH) (Lipsett et al. 1979). We know very little about committee review in other institutions in the 1950s other than that it existed at least in some medical schools. In 1961 and again in 1962, questionnaires were sent to American university departments of medicine. Approximately one-third of those responding reported that they had committees and one-quarter either had or were developing procedural documents (Curran 1970).

On February 8, 1966, the Surgeon General of the United States Public Health Service (USPHS) issued the first federal policy statement requiring research institutions to establish the committees which subsequently became known as RECs (Curran 1970). This policy required recipients of USPHS grants in support of research involving human subjects to specify that 'the grantee institution will provide prior review of the judgment of the principal investigator or program director by a committee of his institutional associates. This review shall assure an independent determination: (a) of the rights and welfare of the … individuals involved, (b) of the appropriateness of the methods used to secure informed consent, and (c) of the risks and potential medical benefits of the investigation.'

The evolution of the federal government's charges to the committee and of its recognition of the need for diversity of its membership was reflected in several revisions of its policy between 1966 and 1969 (Veatch 1975, Levine 1988); these will be discussed further shortly.

2. *Purpose*

The purpose of the REC is to assure that research involving human subjects is designed to conform to relevant ethical and legal standards. Historically, the REC's primary focus was on safeguarding the rights and welfare of individual research subjects, concentrating on the plans for informed consent and the assessment of risks and anticipated benefits. In 1978, the US National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research (National Commission) added a requirement that the REC assure equitableness in the selection of research subjects (Levine 1988, pp. 67ff). The National Commission was concerned primarily with protecting vulnerable subjects from bearing a disproportionately large share of the burdens of research. Subsequently, as participation in some types of research became perceived as a benefit, RECs also assumed responsibility for assuring disadvantaged persons equitable access to such benefits (C. Levine 1988).

A source of continuing controversy is whether the REC has an obligation to approve or disapprove the scientific design of research protocols (Levine 1988, pp. 20–5). Those who argue that they do or should have such an obligation point out that the leading ethical codes establish an ethical requirement for good scientific design. Moreover, they argue, the REC's obligation to determine that risks to subjects are reasonable in relation to anticipated benefits necessarily relies on a prior determination that the scientific design is adequate, for if it is not, there will be no benefits and any risk must be considered unreasonable.

Opponents to assigning such an obligation to the REC, while conceding these two points, argue that the REC is not designed to make expert judgments about the adequacy of scientific design. RECs are generally competent to appraise the value of the science—what the Nuremberg Code calls 'the humanitarian importance of the problem to be solved'—but not the validity of the methods or the results (Freedman 1987, Veatch 1975). In general, responsibility for assessment of scientific validity is and ought to be delegated to committees designed to have such competence—e.g., scientific review committees either within the institution or at funding agencies such as the NIH (Levine 1988, pp. 21–3).

3. *Membership*

The Surgeon General's 1966 memo called for prior review by 'a committee of [the investigator's] associates,' what was commonly called 'peer review.' As of 1968, 73 percent of committees were limited in membership to immediate peer groups; viz., scientists and physicians (Curran 1970, p. 443).

On May 1, 1969, USPHS Guidelines were revised to indicate that a committee constituted exclusively of biomedical scientists would be inadequate to perform the functions now expected of such a committee: 'the membership should possess … competencies necessary in the judgment as to the acceptability of the research in terms of institutional regulations, relevant law, standards of professional practice, and community acceptance.'

Regulations of the US Department of Health and Human Services (DHHS), first promulgated in 1974 and since revised several times, maintain the spirit of the 1969 policy and in addition require gender diversity; at least one nonscientist (e.g., lawyer, ethicist, member of the clergy) and at least one member who is not otherwise affiliated with the institution (commonly and incorrectly called a 'community representative'). Persons having conflicting interests are to be excluded; this concern is also reflected in the Declaration of Helsinki's requirement of a 'committee independent of the investigator and sponsor.'

According to Robert Veatch, the REC is an intermediate case between two models of the review committee (1975): The 'interdisciplinary professional review model,' made up of diverse professionals such as doctors, lawyers, scientists, and clergy, brings professional expertise to the review process, while the 'jury model … reflects the common sense of the reasonable person.' In the jury model 'expertise relevant to the case at hand is not only not necessary, it often disqualifies one from serving on the jury.' Veatch concedes that in order to perform all of its functions the REC requires both professional and jury skills. However, he argues that the presence of professionals makes it more difficult for the REC to be responsive to the informational needs of the reasonable person or to be adept at anticipating community acceptance.

John Robertson (1979a) would correct the 'structural bias' of professional domination by introducing a 'subject surrogate,' an expert advocate for the subjects' interests. DHHS regulations require that a REC which 'regularly reviews research that involves a vulnerable category of subjects, … shall include one or more individuals who are primarily concerned with the welfare of these subjects.' For research involving prisoners, for example, regulations require that at least one member of the REC be either a prisoner or a prisoner representative. There is unresolved controversy over whether persons with AIDS should be appointed to membership on all RECs which review research in the field of HIV infection (C Levine et al. 1991).

4. *Locale*

In the United States the first RECs were established in the institutions in which research was conducted. The 1966 Surgeon General's policy statement required a committee of 'institutional associates.' In 1971 the FDA promulgated regulations which required committee review only when regulated research was conducted in institutions; hence their name, Institutional Review Committee (IRC). Regulations proposed in 1973 by the Department of Health, Education and Welfare, forerunner of DHHS, also reflected a local setting in their term, Organizational Review Board (ORB). In 1974 the National Research Act established a statutory requirement for review by a committee to which it assigned the name, Institutional Review Board (IRB), a compromise between the two names then extant.

RECs are required to comply with federal regulations when reviewing activities involving FDA-regulated 'test articles' such as investigational drugs and devices, and when reviewing research supported by federal funds (Robertson 1979b). Moreover, all institutions that receive federal research grants and contracts are required to file 'statements of assurance' of compliance with federal regulations. In these assurances virtually all institutions voluntarily promise to apply the principles of federal regulations to all research they conduct regardless of the source of funding.

These points notwithstanding, each REC has a decidedly local character. Most have local names such as Human Investigation Committee, or Committee for the Protection of Human Subjects. Each is appointed by its own institution and each lends its own interpretation to the requirements of federal regulations. For example, at one university medical students are forbidden to serve as research subjects while at another, involvement of medical students as research subjects is sometimes required as a condition of approval (Levine 1988, pp. 80–2).

The National Commission recommended that RECs should be 'located in institutions where research … is conducted. Compared to the possible alternatives of a regional or national review … local committees have the advantage of greater familiarity with the actual conditions' (1978, pp. 1–2). The National Commission envisioned the local REC as an ally of the investigator in safeguarding the rights and welfare of research subjects as well as a contributor to the education of both the research community and the public.

FDA's change in regulations in 1981 to require REC review of all regulated research regardless of where it was done created a problem for the many physicians who were conducting investigations in their private offices, many of whom had no ready access to RECs. In response, private corporations developed 'noninstitutional review boards' (NRBs) (Herman 1989). Although there are theoretical reasons to question the validity of NRB review, they appear to be performing satisfactorily (Levine and Lasagna 2000).

In 1986, FDA began to waive the requirement for local REC review for some protocols designed to evaluate, or to make available for therapeutic purposes, investigational new drugs, particularly those intended for the treatment of HIV infection. In such cases RECs were offered the option of accepting review by a national committee as fulfilling the regulatory requirement for REC review. Such practices have caused some commentators to question the strength of the government's commitment to the principle of local review.

Internationally, there is much less commitment to the importance of local review. The International Ethical Guidelines for Biomedical Research Involving Human Subjects, promulgated by the Council for International Organizations of Medical Sciences, require REC approval for all research involving human subjects and recognize the validity of review at a regional or, 'in a highly centralized administration,' a national level (1992). In many European countries, RECs are regional (McNeill 1989).

Several commentators have expressed concern that in the United States the local institution has too much power in the field of protection of human research subjects. Robertson, for example, alerts us to 'the danger … that research institutions will use [RECs] to protect themselves and researchers rather than subjects' (1979a); others point to the close associations between RECs and risk-management offices in many institutions as evidence that RECs are being used in this manner.

5. *Criticisms*

Before 1962, 'a general skepticism toward the development of ethical guidelines, codes, or sets of procedures concerning the conduct of research' pre-

vailed in the medical research community (Curran 1970). In the 1970s several biomedical scientists were harshly critical of the REC system claiming that it tended to stifle creativity and impede progress (Levine 1988, pp. 345–8); survey research, however, showed that only 25 percent of biomedical researchers agreed with the statement that: 'The review … is an unwarranted intrusion on the investigator's autonomy—at least to some extent' (National Commission 1978, p. 75). Behavioral and social scientists were considerably less accepting of review, claiming that their research activities were much less likely than those of the biomedical scientist to harm subjects. Some argued that since all they did is talk with subjects, review was an unconstitutional constraint on their freedom of speech (Levine 1988, p. 359).

According to Peter Williams, RECs do an inadequate job of assuring that risks will be reasonable in relation to anticipated benefits (1984). This is inevitable for three reasons: (a) Federal regulations on this standard are written in vague language in contrast to the more clear direction provided for protecting subjects' rights. Moreover, since the regulations permit consideration of the long-range effects of applying knowledge as benefits but not as risks, they create a bias in favor of approval. (b) The membership of the committee, dominated as it is by professionals, is likely to place a higher value than laypersons would on the benefit of developing new knowledge. (c) Groups confronted with choices involving risks may be either more or less cautious or 'risk aversive' than the average of individuals within the group; this is known as the 'risky shift' or 'group polarization phenomenon.' Williams (1984) and Veatch (1975) believe that in the context of RECs, the groups are likely to be more tolerant of higher levels of risk than they would be as individuals.

Several commentators have proposed that RECs could enhance their effectiveness by sending members to the sites of the actual conduct of research to verify compliance with protocol requirements (Robertson 1979a) or to supervise consent discussions (Robertson 1982). Others respond that while such activities should be done when there are reasons to suspect problems in specific protocols, routine monitoring activities might be detrimental to the successful functioning of the committee by eroding its support within the institution (Levine 1988, pp. 341ff).

6. *Evaluation*

Critics of the REC system claim that there is little or no objective evidence that REC review prevents the conduct of inadequate research. For example, a national survey of RECs revealed that the rate of rejection of protocols is less than one in one thousand (National Commission 1978, pp. 1–216). Supporters of the system respond that the actual rejection rate is much higher if one includes protocols withdrawn because investigators refuse to modify them as required by RECs. Moreover, rejection rates may be a poor indicator of the REC's quality; protocols may be improved in anticipation of the REC's requirements and investigators, fearing rejection, may decide not to submit proposals they think might be rejected by the committee.

It is very difficult to evaluate the REC's performance objectively; satisfactory subjective evaluations can be made only by experienced REC members and administrators (Levine 1988, pp. 358–9). Jerry Mashaw concludes in his excellent theoretical analysis of RECs that: 'If [the REC] is to do its core job well, we must live with its inevitable incompetence at other tasks. Moreover, we must also live with the rather vague regulatory standards and with the continuing inability of the federal funding agencies to know for sure whether [RECs] are functioning effectively. If we would have wise judges and paternalistic [skilled in protecting subjects' rights and welfare interests] professionals, we can neither specifically direct nor objectively evaluate their behavior' (1982, p. 22).

R. J. Levine

Ethics and Psychiatry

Ethics concerns what is right and what is wrong. It is often used synonymously with morality, but sometimes a distinction is made between ethics, the systematic approach to understanding right and wrong, and morality, the forces which govern right conduct. Ethics is central to human experience, and plays a vital role in the profession of psychiatry. In a time of cultural change, the appeal to ethics can help to resolve conflicts of both civic life and self-understanding. Often ethical principles are used in an attempt to find a common ground or a 'higher ground' for resolving disputes or to find a basis for acting in a dilemma.

Ethical codes and traditions are important in defining the norms of professional conduct and even what it means to be a profession. Insofar as ethics deals with intellectual attempts to understand right and wrong (reason) as well as the affective impact of struggling with moral issues (emotion), psychiatric thinking offers an important perspective on ethics. This article deals with both ethics in psychiatry and psychiatry's contributions to ethics.

1. *Types of Ethical Theories*

There is in ethics a constant tension between rule-based (deontological) approaches and approaches which appeal to principle (teleological). Deontological ethical theories maintain that there are rules of action with moral validity independent of the consequences that require adherence, such as keeping a promise, maintaining justice, or following a commandment of God or the state. Teleological ethical theories are based on the principle of utility (utilitarianism) or beneficence, which proposes that the ultimate moral standard is the general happiness of all people concerned, or the greatest net balance of good over evil ('the greatest good for the greatest number'). Situation ethics represents another form of ethical reasoning, called the consequentialist approach, in which an action is judged to be morally right or wrong by assessing the consequences of the action. Much of clinical medicine is consequentialist in that the goodness of actions is judged by their outcomes.

2. *Ethics of Virtue and Character*

Both teleological and deontological approaches to ethics have one serious shortcoming. They depend on the activities of the rational mind of a motivated moral agent to apprehend right and wrong. Moral philosophers and psychiatrists alike appreciate that not everyone is motivated to be moral; that even good people sometimes do bad things; and that people are capable of rationalizing self-interest (Hauerwas 1977, 1981, Pincoffs 1971, 1980).

A delineation of obligations, however essential, is not the whole picture of ethics. Virtue, character and integrity are every bit as important in understanding right conduct. For the professions especially, integrity in concrete situations is the hallmark of virtuous life.

3. *A Brief History of Medical Ethics*

The ethical traditions of the medical profession originate in the fourth century BC with the Oath of Hippocrates. This oath, sworn by healer–craftsmen, has come to symbolize the ethical ideals of the medical profession. In the nineteenth century, first the British Medical Association, and subsequently the American Medical Association (AMA) and professional organizations in other countries began to adopt formal codes of ethics modeled on the principles of the Hippocratic Oath.

By the mid-1960s, the values underlying the doctor–patient relationship began to change. The most notable factor was the emergence of new technologies, which began to change the way we thought about medicine and even what it meant to be human: genetic engineering, organ transplantation, advanced life support, safe abortion and birth control, and medical and surgical treatments based on clinical research. No longer was medical care primarily palliative. No longer could it be assumed that the patient would necessarily want what the doctor might offer (Dyer 1997a, 1997b).

Also in this era, several social movements began to change the way society thought about assumed relationships, with an increased emphasis on the right of the autonomous person to self-determination. Informed consent and autonomy came to be the keys to medical ethics and medical decision-making. Medical ethics in this era became bioethics as it came to be realized that the decisions in medicine were decisions in which society had a stake.

By the 1970s, economics increasingly became a part of thinking about ethics. Allocation of resources became a concern, and the question was often asked, 'Could health costs be contained without rationing care?' The principle of justice eventually superseded beneficence and autonomy in ethical discourse, with an emphasis on fair distribution of medical resources.

3.1 *The Ethics of Advertising*

Most physicians are not inclined to seek patients though advertising. Healthcare organizations, however, may make their appeal through advertising, especially in a market-driven healthcare economy. The 1957 version of the AMA *Principles* prohibited 'solicitation' of patients, by which was meant 'obtaining patients by deception', or making false claims (AMA 1957). After the Supreme Court decision Federal Trade Commission (FTC) vs. AMA (Greenhouse 1982), professional organizations such as the AMA can no longer formally constrain physicians from advertising.

Advertising has two basic goals: (a) dissemination of information and (b) product differentiation. For physicians, providing information about services offered and fees charged is consistent with patient benefit, but attempts to differentiate the product are suspect. Licensing, accrediting and credentialing organizations assume the role of maintaining standards. Beyond the activities of individual practitioners, the larger ethical question for advertising is truthfulness. Notable is the advertising of unhealthy products such as tobacco products and alcohol. Much advertising is antithetical to professional goals of patient benefit (Dyer 1995, 1997a, 1997b).

4. *The Place of Ethics in the Definition of a Profession*

What differentiates a profession from a trade? What makes medicine a profession? The emphasis on the commerce of technology in medicine in recent years may obscure the centrality of an ethical attitude toward the patient, which has traditionally been considered to be the defining feature of a professional life.

A profession may be defined by (a) its knowledge, technology and expertise, or (b) its ethics or values. The habits of modern thought might lead us to believe that this is an either–or choice. Clearly for psychiatry, as for most of medicine, allopathic technologies such as drugs and procedures have become important and perhaps even central in some people's minds. The recent primary care thrust has reopened consideration of a more holistic approach to healing, including talking. Ethics is more fundamental to professional definition than technology. Technology is useful as long as it serves ethical ends but not as an end in itself. Knowledge, technology and expertise are not commodities to be bartered in the marketplace, but skills which may be used to ethical ends under the purview of professional values.

5. *The Hippocratic Oath and the Hippocratic Tradition*

The Hippocratic Oath is a remarkable document, not so much because it answers the ethical questions posed by modern medicine, but because it frames those questions. It articulates principles, notably the principle of patient benefit, which is often helpful to physicians in sorting out where their allegiances lie. Taken together with its corollary, the principle of nonmaleficence (*Primum non nocere*, first do no harm),

the principle of beneficence puts the patient at the center of ethical decision-making. The Hippocratic Oath provides an ethical perspective that calls into questions many of the assumptions of modern culture and transcends the pressures of political expediency.

5.1 The Contemporary Relevance of the Hippocratic Oath

A reading of the Hippocratic Oath reveals many phrases which responsible physicians might not want to follow literally. Medicine was delineated as a higher calling, a covenant with the gods. The Oath provided a relationship with a like-minded family of individuals who shared certain values and self-understanding. It defined the physician's life in a beneficial relationship to those served. Its paternalism was questioned when society emphasized individualistic autonomy, but the Oath's emphasis on justice foreshadowed a larger concern for community interests.

The Hippocratic tradition has at various times and places served as an ethical reference external to immediate expediency, by which physicians may gauge their behavior and to which they can appeal (or by which they may be judged by their colleagues). For example, the World Psychiatric Association censured the practices of psychiatrists in the former Soviet Union and other eastern European countries for the detention of political dissidents. Such mislabeling with psychiatric diagnoses is called the political abuse of psychiatry, for the profession is used for ends other than patient benefit (Bloch 1991, Bloch and Reddaway 1977). Such extreme abuses make a case, which is not always appreciated, for professions being autonomous organizations self-regulated by a code of ethics rather than serving the interests of society which may be politically conflicted. The Hippocratic Oath is an ever-present reminder that acting in the interest of someone other than the patient creates a conflict, a conflict which is often experienced internally by the physician.

5.2 Honor in Medicine

The Hippocratic Oath speaks of honor, holiness and purity. The good name and respect of both the practitioner and the profession are to be earned through consistent application of the ethical principles, and the code provides guidance. Good conduct becomes 'characteristic' of the professional, and a code of conduct organizes one's thinking about good conduct both symbolically and in very practical matters.

5.3 The Fiduciary Principle

The doctor–patient relationship is spoken of sacredly as a fiduciary relationship, a relationship based on trust. That trust must be earned, at the least by the hard work required to acquire the skills necessary to apply the art. But it must also be earned by the consistent application of attentive response to the patient's needs, what we call 'responsibility'. Unlike law or business, where the trustee may act for the client, in medicine the physician must act with the patient and with the patient's consent, implying a partnership. That action may be paternalistic, but if that concern verges on control, the modern patient may well lose trust and confidence.

5.4 Hippocratic Oath for Psychiatrists

Maurice Levine (1972) articulated a Hippocratic Oath for psychiatrists with some unique insights about the values of this profession. His code articulates the importance of self-knowledge or at least self-awareness and constant self-scrutiny. He stresses the need to recognize in ourselves the feelings that patients can stir up, particularly seductive patients, and the importance of getting consultation (or supervision) not just in training but whenever it might be necessary. This is a useful reminder at times when many treatments are briefer and more biological, because many of the complaints of unethical conduct received by the American Psychiatric Association (APA) come from patients whose doctors did not sufficiently deal with their own feelings and acted out in treatment situations. Self-reflection is an important ethical tradition, not only in psychiatric and psychoanalytic circles, but throughout Western culture dating back to the Socratic admonition to 'Know thyself.'

6. Contemporary Codes of Ethics (AMA and APA)

When the AMA was founded in 1847, it adopted a code based largely on the Hippocratic principles of beneficence and honor. This code (*The Principles of Medical Ethics*) has been revised every few decades (most recently in 1957 and 1980). When the APA adopted its first code in 1973, it decided to use the AMA Principles *With Annotations Especially Applicable to Psychiatry*. The principles should be read teleologically, not deontologically as a list of rules. The requirement of honorable behavior of the physician goes to the physician's character and virtue and cannot be reduced to a list of rules. The physician must understand the principles in terms of a higher calling and act in accord with the dictates of conscience.

The APA (1995) may impose four possible sanctions for misconduct by a psychiatrist: admonishment (informal warning); reprimand (formal censure); suspension (not to exceed five years); and expulsion. In this sense, this code is minimalist but essential, serving as a tool for professional discipline. A psychiatrist should know what is specified in the code because he

or she might be subject to sanctions. The modern physician should also understand the principles that underlie the code in order to be able to act in situations which have not been explicitly spelled out. The following discussions illustrate the constant tension between rule and principle and the importance of the physician striving for virtuous action.

6.1 Sexual Misconduct and Boundary Violations

Sexual contact with a patient is unethical. This is one of the least ambiguous sections of the ethical code. It is a tradition that goes back to the Oath of Hippocrates, which speaks of such conduct as 'mischief'. It is important for psychiatrists because the intimacy of the treatment activates strong feelings and fantasies in the doctor–patient relationship, the discussion of which may be essential to healing. In psychiatry especially, the nature of such feelings the patient may have for the doctor (transferences, i.e., derived from significant relationships in the past and activated in the treatment) and feelings the doctor may have for the patient (countertransferences) receive close scrutiny. They are no less important for other physicians, other therapists, or other professionals. It is sometimes argued that the reason sexual contact is proscribed is because of the power differential, an argument which applies equally to employers and employees, supervisors and supervisees, teachers and students. Most basically, the importance of trust in the therapeutic relationship requires forbearance. As a rule, sexual contact with a patient is proscribed.

Those more legalistically inclined might wonder if erotic feelings might be acted on if the professional relationship were terminated. Transferences endure over time, so the interests of the patient–client could never be served by crossing this boundary. The most recent version of the APA *Annotations Applicable to Psychiatry* spells this out: 'Sexual activity with a current or former patient is unethical.' Other examples of boundary violations, which rest on similar considerations, are business relations with a patient, using the professional relationship for other contacts, or profiting from information gained from the therapeutic relationship.

6.2 The Boundary between Ethics and Law

Ethics and the law share a similar concern for right and wrong. But the ethical requirements of professionals do not coincide identically with the requirements of all citizens. The Oath of Hippocrates held physicians to a standard that was not required of all citizens. The AMA *Principles* and APA *Annotations* recognize this tension and expect physicians to 'respect the law' and 'seek changes in those requirements which are contrary to the best interests of the patient.' Civil disobedience against unjust laws is a respected ethical tradition. A physician is a citizen whose professional role requires adherence to principles such as patient-benefit above all.

6.3 Confidentiality

Confidentiality, understood as secrecy, in the doctor–patient relationship is one of the most fundamental principles of professional ethics. Confidentiality has its roots in the confidence or trust that is placed in the physician and on which the treatment depends. It has become increasingly difficult to safeguard confidentiality. Insurance companies, managed care organizations, other providers, courts and sometimes families claim a right to know what is going on in patients' treatments. The possibility of misuse of information from insurance data banks is a large issue. Confidentiality is one of the most fragile tenets in the contemporary era.

At times, principles may conflict. For example, the *Tarasoff* decision obligates a psychotherapist who has knowledge that a patient may intend harm to a third party to notify that third party of the potential risk. Mandatory reporting of suspected child abuse is another example in which the interest of the state in protecting children legally supersedes the physician's duty to maintain secrecy. In a larger context the erosion of confidentiality threatens to undermine the possibility of a kind of therapy that requires developing openness to another person confident that what is disclosed is only for the patient's benefit.

6.4 The 'False Memory' Controversy

Much conflict has developed around the issue of therapists directing therapy to recover memories of childhood sexual abuse, which may not have occurred. In particular, there have been instances reported in which therapists used suggestive methods such as hypnosis in order to recover memories of past sexual abuse that were believed to be repressed. Alleged perpetrators of such abuse have been prosecuted and even jailed. Therapists' zeal about these issues may lead to unethical behavior, even with good intentions, with destructive results for their patients and families (Chodoff 1999).

6.5 The Double Agent Problem

Double agents work both sides. There are situations in which the physician works for someone other than the patient, and there may be a conflict between the patient and the physician's employer resulting in a divided allegiance and compromised confidentiality. The classic case of this is the physician working for the military, trying to get soldiers back into combat. This is ethically analogous to treating the psychotic pris-

oner incompetent to face execution. The student health psychiatrist doing an evaluation for the dean or the psychiatrist doing a pre-arraignment examination have loyalties that go beyond the patient's best interest and which require at the least disclosure of the purpose of the examination and how the information will be used. Increasingly physicians working for corporations, managed care organizations and government hospitals have interests which radically transform the nature of the relationship between doctor and patient.

6.6 *Fees, Billing, and Reimbursement*

The financial arrangements for medical service strike at the heart of the ethical issues in how medicine is valued. Inevitably there must be some sort of exchange for the services rendered, and inescapably there must be some sort of feelings about the monetary transaction. In the dyadic doctor–patient relationship that is a very direct transaction, though it may be buffered by insurance companies, billing and collection processes. Patient benefit and fee-for-service have traditionally gone hand in hand, and the fee (alongside honor and duty, of course) has helped focus the physician's attention on whose benefit should receive attention. One of the general criticisms often leveled against traditional (Hippocratic) medical ethics is that it does not deal with the physician's larger obligations to society and particularly to the distribution of medical services.

One financial arrangement in particular that sometimes questioned is the practice of charging for missed sessions. The APA *Annotations* has specifically addressed this and has said, 'It is ethical for the psychiatrist to make a charge for a missed appointment when this falls within the terms of the specific contractual agreement with the patient' (Sect. 2, paragraph 6). The idea of patients having responsibility for the treatment and ultimately for their health and wellbeing is not something usually considered in medical ethics, but it goes beyond the idea of medicine as technology that the doctor delivers and stresses the patient's investment and commitment to the healing process.

Another financial arrangement that is addressed throughout the AMA *Opinions* and APA *Annotations* is fee-splitting. Physicians should receive remuneration for the work they do, and they should obtain patients by referral based on the quality of their work and the reputation they earn in the eyes of satisfied patients and other physicians. Any incentive such as splitting the fee with a referring physician is considered unethical. It offers a temptation to place monetary gain above the best interest of the patient.

6.7 *Informed Consent*

An issue that has been receiving increasing attention recently is the importance of preserving patient autonomy and control in the context of medical decision-making and participation in research. Recent debate has occurred around the issue of whether patients with psychiatric illnesses are competent to give consent in such situations. The danger in such debate is that psychiatric patients can be further stigmatized with policies that are overprotective and confuse psychopathology with a generalized lack of competence. Efforts to educate patients regarding the nature of medical decisions and research projects should protect their rights by helping them to make decisions for themselves (Appelbaum 1998).

7. *The Ethics of Managed Care*

The current revolution in healthcare financing challenges many traditional assumptions of medical ethics. The most fundamental change is the departure from a dyadic doctor–patient relationship. Doctors in the new environment are being transformed into 'providers,' patients into 'consumers,' and any number of 'third parties' claim an interest in what goes on in that relationship.

In the economic model of marketplace transactions, much more is at stake than how the payment is to be allotted. The metaphor of healthcare as an industry radically transforms the healing process to physiological interventions that take place in a delimited period of time. Physicians become technicians, and patients become recipients of technology, with both likely to be strangers to one another. Medicine is transformed from a human service into a commodity.

In the interest of efficiency or economy these transformations might seem warranted, but the practices we are currently witnessing in the name of managed care must themselves be subjected to ethical scrutiny. Certainly much of what is going on is not ethically justifiable, nor does it serve the ends it was purported to serve. The transformation of medicine from a profession to a trade by the Federal Trade Commission was justified as a cost-saving measure on the grounds that increasing consumer choice (through advertising) would lower costs. The value placed on autonomy set the stage for a transformation in which consumers have very little choice about the healthcare they receive. Healthcare has become an investment opportunity where vast amounts of money have been siphoned away from service delivery into the pockets of executives and shareholders of mega-corporations. The market solution has been a nonsolution to this point in that it has only succeeded in lowering costs without adequately addressing quality of service or the distribution and allocation of services.

The ethical physician is inevitably in tension with a system designed to limit or deny the care given to his or her patients. While recognizing that resources are finite, the ethical physician must struggle to do the best

possible for individual patients without compromising integrity. Many of the practices of managed care are fraudulently unethical, such as gag rules prohibiting physicians from discussing treatment options with their patients. Such policies do not enhance consumer choice, but diminish patient autonomy and oppose informed consent, placing the physician in the position of a double agent without the possibility of disclosure. Many practices of managed care are more subtly unethical, such as misleading advertising or incomplete disclosure. Some practices, such as limiting who may serve on panels, may be in restraint of trade. They are certainly not pro-competitive. Managed care is an ethically unstable response to the healthcare financing dilemma and must be subjected to thoroughgoing ethical evaluation. A just society must demand accountability for its citizens.

8. *Conclusion*

Looking back to the longstanding traditions of medical ethics, we are now in a position to better appreciate the place of the Hippocratic Oath in contemporary medicine. Though it is sometimes criticized for being anachronistic, its true value is apparent. The Hippocratic tradition in medicine provides a perspective of enduring values by which the shortcomings of modern economic expediency may be judged.

Ethics and Values

In the twentieth century, moral philosophy and the theory of value came to be explicitly subdivided into two elements: metatheory, which concerns questions about meaning and justification; and normative theory, which concerns more substantive questions about what is good, right, or valuable. In earlier centuries, these two kinds of question were seldom distinguished. More recently, dissatisfaction with any sharp separation of these areas of inquiry has grown: how are we to judge the adequacy of any account of meaning without asking whether it does some justice to widespread substantive convictions? The distinction nonetheless will make the presentation below more manageable. Its focus will almost exclusively be on so-called 'analytic,' Anglo-American philosophy and its claimed antecedents, although fundamental work on ethics and the theory of value has of course been done in other traditions.

1. Ethics

1.1 Metaethics

There is no agreed-upon distinction between, say, ethics and morality, and the terms are used more or less interchangeably (though Williams 1985 associates 'morality' especially with duty-based systems). Both terms show in their origin a relation to social customs—ethos and mores—and both have a descriptive as well as a normative sense. In the former sense, we can ask 'What was the Greek warrior's ethic?' or 'How has morality evolved in Western Europe over last two hundred years?' In the latter sense, we can ask 'What is the ethical thing to do when one accidentally learns of a deep confidence?' or 'Is it moral for us to carry out animal experimentation?' (see *Conventions and Norms: Philosophical Aspects*).

The descriptive sense seems fairly straightforward, at least once one has noticed that there are wider and narrower uses (see Gibbard 1990). On the wide use, a morality is virtually any code of conduct involving attitudes of approval and disapproval, regardless of its particular content or social standing: a warrior ethic might favor unstinting cruelty toward one's enemies; a personal morality might glorify selfishness or esthetic accomplishment over all else, even if society finds this abhorrent. On the narrow use, morality is taken to involve norms of conduct with a distinctive purport, sometimes characterized in terms of a moral point of view, as contrasted with, say, an esthetic or prudential point of view (see Baier 1958). Morality, narrowlyunderstood, is said to involve some or all of: impartiality, concern for the well-being of others, treating like cases alike, willingness to cooperate, a notion of personal agency and responsibility, associated feelings of impersonal anger, guilt, or deservingness. In the broad sense, we can ask of virtually anyone or any society, 'What is his (or their) morality?'; in the narrow sense, we can ask, 'Does this individual (or this society) have a morality, and, if so, when did it emerge?' Much of the interest of philosophers and social scientists in individual moral development or in the historical development of morality concerns morality in the narrow sense. For example, there is an active debate over whether various ancient civilizations recognized morality, as distinct from enlightened prudence or religious requirement (see Annas 1993).

An important moment came when Prichard (1912) convinced virtually everyone that showing certain principles of conduct to be advantageous would not suffice to show they had distinctively moral standing. Recent interest in the possible evolutionary origins of morality also typically concerns morality in the narrow sense: 'debunking' views tend to emphasize that the gene- and kin-oriented mechanisms of natural selection are not impartial; 'vindicating' views tend to emphasize that these mechanisms could have equipped us with psychological resources—empathy, cooperativeness, concern for fairness—that can be mobilized culturally on behalf of genuinely moral practices (for examples, see Thompson 1995).

Philosophical analysis of moral language in the normative sense also has focused on the narrow use of the term, though this has not eliminated controversy. Central to the disputes has been the question whether moral claims are capable of truth or falsity, the question of 'cognitivism.' Noncognitivists have maintained that the primary semantic function of moral claims is not to state facts, but to express attitudes or commands intended to influence behavior, and so they are incapable of being strictly true or false.'Noncognitivism' is in some ways an unfortunate term, since moral discourse clearly involves a great deal of cognition and conceptual content, even according to those who claim its primary function is to express attitudes (see Stevenson 1944, Hare 1952, Gibbard 1990, Blackburn 1984). For an attitude to count as distinctively moral, it must represent itself as responsive to certain features rather than others (those characterized by a moral point of view), and as regulative for certain emotions (e.g., impersonalanger). Recently so-called 'minimalist' theories of truth have gained currency, according to which the labels 'true' or 'false' can appropriately be applied to sentences of a discourse so long as they enter seamlessly into familiar logical relations, patterns of inference, etc. (Horwich 1990). Since moral statements unquestionably do this—'Stealing is wrong' can be the premise of a normal logical inference, but a command like 'Don't you dare steal!' cannot—there has been a tendency to concede on all sides of the debate that moral statements can be said to be 'truth-apt' or 'propositional' in the minimal sense. This might or might not suffice to earn the label 'realism' about moral properties (see Blackburn 1993).

The burning issue has become: even if propositional, do moral statements have an 'internal' or conceptual connection with motivation, such that making a moral judgment involves an element of endorsement not found in ordinary factual judgments? One can perfectly appropriately assert, for example, 'This rock is granite' without expressing any favorable or unfavorable attitude toward that state of affairs. If one cannot similarly assert 'This situation is immoral' with perfect sincerity and linguistic propriety while having no attitude of disapproval, then there remains a fundamental semantic difference between moral and 'merely descriptive' discourse.

Defenders of 'propositionalism' face a choice: either insist that this expressive function belongs to the pragmatics of moral discourse rather than its semantics, or devise an account of the propositional meaning of moral statements that incorporates motivation 'internally.'

Subjectivists pursue the latter path. A simple subjectivism holds that moral statements are tantamount

to claims about what one, or one's society, approves or disapproves. This view results in a kind of moral relativism: which moral judgments may be applied to an individual or a society depends upon which norms or principles he, she, or they accept. Relativist views have enjoyed a certain popularity, since they seem laudably cosmopolitan, although they typically account poorly for moral disagreement (except as a factual debate over which norms are accepted) and often verge on incoherence, since they may include a nonrelativistic moral recommendation of tolerance in response to moral difference (but see Harman and Thomson 1996 for a sophisticated debate on relativism). Contemporary subjectivists therefore take a more objectivist approach, inspired in part by an analogy between moral qualities and secondary qualities, such as color (McDowell 1985). Color judgments show a high degree of objectivity and intersubjective agreement, so much so that they are often used in scientific observation and social coordination (e.g., 'red' for 'stop'). Yet colors are nonetheless based in part on a subjective response, and those without a certain human-typical perceptual apparatus are incapable of seeing color. Moral judgments might be similar. Those without a certain human-typical motivational apparatus might be incapable of moral experience, but since virtually all of us have (or could develop) these motivations, moral judgments can also be highly objective and intersubjective. So we might think of moral properties neither as independent features of the world, nor as mere projected feelings on our part, but as a pairing of features of situations and characteristic (or ideal-typical) human responses to those features—rather in the way dangerousness might be seen as a pairing or risk and fear—and therefore as response-dependent.

In the moral case, the response—like fear—would have a motivational aspect, perhaps arising from moral training in the virtues rather than sheer human physiology. For someone equipped with moral character, then, moral experience and judgment are necessarily accompanied by a motivating response. Does this sort of subjectivism lead to relativism—different patterns of moral training (say) yield different, yet locally apt, moral judgments? Not quite, since we can take our moral discourse, like our actual color discourse, to be anchored to our actual responses (by a semantic device known as 'rigidification'; see Wiggins 1998). The difficulty now is that those in different moral traditions may simply turn out not to have a common moral vocabulary with us.

Nonsubjectivists typically reject the semantic or 'internal' tie to motivation, and claim that moral judgments can be made without linguistic impropriety even by someone for whom they are normally motivationally inert. Such 'externalist' approaches recognize that in our ordinary life we presuppose certain typical motivations—so that it will be somewhat misleading to utter 'This situation is immoral' if one does not intend thereby to indicate or express any negative attitude toward it. But similarly, if, in normal circumstances, one utters 'I believe that she's coming at noon,' one's listeners can suppose that one thereby endorses their believing likewise, though one does not *contradict* oneself in saying, 'I believe that she's coming at noon, but don't take my word for it.' Expressions of belief, and of moral evaluation, play certain roles in our social lives owing to various prevailing or presupposed background conditions, but these do not all become part of the very meaning of these words—or perhaps, the distinction between what 'belongs to meaning' and what 'belongs to pragmatics' is so soft that we should not allow ourselves to be driven to surprising conclusions like relativism or rigidification by the so-called 'motivation problem.' Externalists are divided into naturalists, who think the properties attributed in moral discourse are within the ambit of ordinary empirical knowledge, and non-naturalists, who think of moral properties as in some sense *sui generis*.

The first need to explain how morality can be so controversial, if moral questions are in principle resolvable by matters of natural fact; the second need to explain how moral properties can be known or referred to, if they are not causally related to our experience. Some naturalists outright identify moral concepts with certain natural concepts; others give a broadly functional characterization of the role or meaning or moral terms—the truisms about morality and its social role—and leave conceptually 'open' the question which particular acts, practices, etc. play the relevant role (for some varieties, see Brandt 1979, Railton 1986, Boyd 1987, Brink 1989, Lewis 1989, Jackson and Pettit 1996). Of course, one possibility is that nothing can be found that will play all or most of the role ascribed to moral properties, resulting in an error theory of moral discourse rather like atheism about religion (Mackie 1977). Non-naturalists argue that morality is not alone in showing the need to give an account of how we are able to talk about or have knowledge of 'nonempirical' phenomena—mathematics poses similar problems (see Ross 1930, Wiggins 1988).

G. E. Moore, a non-naturalist externalist, famously diagnosed a 'naturalistic fallacy' in moral philosophy, but the import of this claim has been widely misunderstood (Moore 1903). He did not doubt, and few in the twentieth century have doubted, that moral evaluation supervenes on nonmoral, natural properties—roughly, those properties accessible to empirical experience and investigation. It is, according to this view, a mistaken picture of value to think that two situations could be identical in all empirical features yet one correctly judged good and the other bad. In this sense, then, 'naturalism' is not at issue in these metaethical debates, and a kind of transition from 'is' to 'ought' is possible: we are able to learn whether acts are good or bad, once we have mastered moral

concepts, by learning of their empirical features. Moore's point is that moral concepts are conceptually distinct from the natural concepts or criteria we might use to apply them—we do not *contradict* ourselves by asking whether happiness is good in itself, even if, as a matter of fact, it is (Frankena 1939). This is perhaps to be contrasted with supernaturalist thinking about ethics, according to which some supernatural feature— such as autonomous approval by a deity—is necessary for moral standing. Most contemporary moral philosophy would not sustain the conclusion that 'If God is dead, everything is permitted.'

Oscar Wilde has Mrs. Cheveley say, after being reprimanded by Gertrude Chiltern, 'Do you know, Gertrude, I don't mind your talking morality a bit. Morality is simply the attitude we adopt towards people whom we personally dislike' (*An Ideal Husband*, Act II). Such a 'debunking' depends on a contrast between the normative purport of morality and the normative status it actually possesses or deserves. If 'x is wrong' simply meant 'I personally don't like x', there would be no presumption that it would be bothersome to be told that what one is doing is wrong. Morality might simply dress up personal dislikes in judgmental clothing. But giving an account of the meaning of moral terms—a metatheory—involves saying just what this dressing-up consists of. (A collection of related essays and a more extensive survey is to be found in Darwall et al. 1996.)

1.2 Normative Ethics

It is difficult to imagine that moral properties have nothing to do with likes and dislikes, or broadly, with what matters to people or to sentient beings generally. Thus there does appear to be something profoundly subjective about it. Yet it strives to develop objective forms of evaluation on this subjective base. We can see normative moral theories as seeking to develop a synthesis of subjective and objective elements that: (a) presents a credible account of moral rightness and value, one which fits reasonably well with our firmest moral judgments on reflection; (b) is psychologically and socially realistic ('ought implies can'; a condition that is growing in importance in philosophy as we learn more about cognitive and motivational psychology and social dynamics); (c) involves no suspect metaphysical or epistemological assumptions (see *Parfit* 1984, Sinnott-Armstrong and Timmons 1996); and (d) enables us to locate a compelling basis for moral evaluation that would explain how those judgments could credibly be justified, criticized, and improved—since we are all aware of moral judgments that seemed obviously right or self-evident (such as the permissibility of slavery or the moral irrelevance of animals), that we have subsequently come to reject. A normative moral theory should illuminate the deeper springs of moral concern (if such can be found), even if it calls for some normative rethinking on our part. This set of concerns is sometimes called seeking wide reflective equilibrium (Rawls 1971; see *Reflective Equilibrium*).

We find three major living traditions in normative moral theory, one claiming as its spiritual ancestor Aristotle, the second David Hume, and the third Immanuel Kant.

On Aristotelian accounts, the fundamental question of ethics is 'What is the good life?,' and the answer is thought to take the form: the virtuous life (for some Aristotelian approaches, see Aristotle 1989, McDowell 1985, Williams 1985, MacIntyre 1981). Virtues are robust traits of character, drawing on normal human faculties and motivations but shaped by proper moral training, that enable an individual to see what is best or required, and act appropriately, in a wide range of circumstances. Virtue thus involves cognitive, affective, and conative elements. Moreover, virtues are thought to be mutually-reinforcing ('the unity of the virtues'), and to yield a life that is itself good for the virtuous person to lead. Typically, one cannot formulate strict principles of action that govern the virtuous agent: moral conduct essentially involves the exercise of judgment (shaped by the 'moral experience' of the virtuous agent), yet this need not preclude fairly objective recommendations about specific situations—much as we think that persons of sensitivity, discernment, and knowledge tend to converge in esthetic judgment even if esthetic evaluation cannot be captured in terms of strict rules. Although virtue theories take agents and their motives as the primary locus of moral evaluation, the view need not simply be individualistic. Aristotle, for example, thought the virtuous life to be possible only in the right sort of social and political setting, and only if one plays one's appropriate role in that setting (see *Virtue Ethics*).

Humean accounts, though they may make room for virtue, typically do not assign it so fundamental a role. They seek to understand morality as a scheme of social cooperation and regulation that enables individuals and groups to achieve sought-after ends that they could not attain individually, or on the strength of native instinct. In Hume's own view (see Hume 1888, a related view is found in Adam Smith 1976), we are natively equipped with many of the sentiments necessary for such cooperation and regulation—empathy (what Hume called 'sympathy'), an intrinsic concern for kith and kin, a willingness to defer to custom, etc.—but others within this tradition (e.g., Bentham) suppose humans to be egoistic hedonists. Each strand solves the 'motivational problem' for morality in a distinctive way—Hume by the reshaping of native sentiment toward greater impartiality and willingness to cooperate through social conventions and 'artificial' in addition to 'natural' virtues, Bentham by the use of socially backed 'sanctions' for changing the incentives individuals face. Both of these strands recognize the need for a common, objective standard for moral

assessment: 'the general interest.' An influential form of this general approach is utilitarianism, which has taken a vast number of particular forms. Essential to it are two features: (a) a notion of a person's good or well-being that can be assessed prior to judging moral worthiness—a theory of intrinsic nonmoral value (which need not be hedonistic, but could be perfectionist or involve the satisfaction of informed desires, personal or impersonal); (b) a way of evaluating acts or practices across individual lives and over time by comparing tendencies to promote intrinsic nonmoral value, impartially assessed (which characteristically is thought of as maximizing, but need not be).

Such value-based theories, often called consequentialist or teleological (end-oriented), hold that the good is prior to the right (see *Consequentialism Including Utilitarianism*). Morality partakes of the subjective because intrinsic goodness is grounded in what does, or could, matter to people (or to sentient beings generally) for its own sake. Yet morality is objective, because it seeks to ground distinctively moral judgments on an unbiased and impartial assessment of how that act or practice affects the long-term realization of intrinsic value in our lives.

On Kantian accounts, there is an attempt to locate a ground of rightness that is not in this way wholly dependent on such tendencies to promote nonmoral good. In some sense, the end does not entirely justify the means, and certain constraints on right action, or prerogatives for individual choice, exist that are not functions solely of actual or typical consequences. Indeed, there is on Kantian views some resistance to the idea that we can characterize 'intrinsic nonmoral good': happiness derived from using another inappropriately as a means, e.g., torturing an innocent, is not, they claim, a good at all. Normative theories that thus claim that the right is prior to the good are sometimes called deontological (duty-based). Although Kant's own view is a bit hard to categorize at its foundation, views of Kantian inspiration have become the dominant and best developed form of philosophical deontology. (Other forms include: Lockean natural rights theories, e.g., Nozick 1974, see *Libertarianism*; and rational intuitionism, e.g., Ross 1930. For a discussion, see Scheffler 1982.) Humean moral theorists are able to give a rationale for encouraging nonconsequentialist moral norms or motivations by a 'second-order' consequentialist argument: this is necessary to avoid individually or collectively self-defeating behavior (see Parfit 1984). But how are we to give a rational justification of moral actions and duties, or constraints and prerogatives, if we are willing to fly directly in the face of consequences for what we most value? The Kantian approaches this question from the standpoint of a responsible agent asking 'What have I reason to do?' (see *Practical Reasoning: Philosophical Aspects*). From this standpoint, we recognize that desires and goals do not automatically give reasons to act, since they are themselves up for scrutiny—and not merely because some are stronger or more basic than others.

A desire for revenge, however powerful or however much a part of human nature, ought to be fought, rather weighed in an individual or social 'utility function.' We know from experience that we are free enough from the control even of 'natural' desires and interests to do this. If one claims that one's act is rationally permitted, one in effect licenses the maxim on which it is based as legitimate for anyone in similar circumstances. Like ideal legislators, we thus authorize ourselves to act by 'making law,' aware of the condition that we ought to be—even when we would prefer otherwise—subject to the very same law (the imperative is categorical). This universalizability condition on our wills brings an element of objectivity and generality to our decisions, based not on actual or probable consequences, but on a notion of ourselves as autonomous (literally, 'self-law-giving'; see *Autonomy, Philosophy of*), seeking the moral law (see Kant 1964; also see *Kantian Ethics and Politics*). Some contemporary Kantians prefer to understand this in terms of a hypothetical social contract: we show that our action is permitted or required by rules that we would all agree to (or find reasonable) in a situation of initial freedom and equality. Some acts or practices that would have good consequences—promoting social peace by treating individuals paternalistically in a secretive way, or permitting inequalities that raise total utility but do not tend to benefit all members of society—might thereby be ruled out (Rawls 1971, Scanlon 1998; for a related view, expressed in terms of the conditions for nondistorted social communication, see Habermas 1990; also see *Contractarianism*). Other contemporaries inspired by the notion of autonomy have seen in this doctrine a radical affirmation of individual human freedom. Jean-Paul Sartre, for example, gave a distinctively existentialist account of 'choosing for all mankind,' holding that we can lapse into bad faith if we attempt to escape this absolute responsibility for our acts by pointing to things 'beyond our control,' such as 'regrettable circumstances,' 'natural urges,' or even 'moral principle' itself (Sartre 1946).

One might see these three traditions as each emphasizing a different, yet important root of morality: the notion of the moral life as the best or fittest sort of life for humans (Aristotle); the notion of the moral life as one of benevolence and freedom from prejudice (Hume); and the notion of the moral life as one of respect for one's own freedom and rationality as well as that of others (Kant). Can all these elements be combined into one normative theory? No overarching synthesis has been found, and any view that seeks to be at all systematic cannot, so to speak, guarantee that it is optimal in three dimensions at once. Kant, aware there could be no guarantee, nonetheless took it to be an essential condition of the rationality of moral conduct that autonomous self-legislation would in the

end yield both good consequences overall and a good life for humans—happiness and virtue would be united as the 'highest good,' if not in this life, then in the afterlife—but later Kantians have largely given up this doctrine of 'rational faith' and argued that Kant's account can stand even without postulating that these conditions are met.

An alternative response to this sense of multiple roots of morality is to claim that no systematic account of normative ethics should be attempted. Different circumstances, roles, personal histories, and so on make different sorts of moral consideration more or less appropriate, and this is an ineluctable fact of moral life. A relation with one's spouse or child is seldom best regulated by 'the general interest' or 'universalizable maxims,' a legislator cannot generally rely on personal virtue to tell her how to shape a complex piece of environmental law, and in our relations with animals we cannot regulate our conduct as if we were operating in a reciprocal realm of rationality. Experience and wisdom, and caring, not theory, enable us to act and deliberate well in a complex moral world (see Larmore 1987). This view was given some impetus by, and finds continuing support in, a growing literature on moral development, where individuals who score highly on traditional tests of moral-theoretical sophistication may do poorly in practice in comparison with those capable of greater personal caring, empathy, and adaptiveness (see Gilligan 1982, Damasio 1994). Defenders of normative theory insist that systematic ambition is an essential antidote to arbitrariness or narrow-mindedness, even though it must of course be combined with suitable motivation and sensitivity. Moral particularists (Dancy 1993) and some feminists (see Card 1991) counter that the systematizing impulse can itself become a form of moral insensitivity and arbitrariness.

This is probably a healthy dialectic in normative ethics. It is important to emphasize, however, that resistance to normative moral theorizing need not be combined with a resistance to metaethical theorizing: moral particularism is often defended on the ground of an account of the meaning of moral concepts or the ground of moral justification. Thus, on one influential view (Ross 1930), morality consists of many mutually independent *prima facie* duties and permissions, the bearing of which on particular situations is not governed by general rules. Ross grounded his view in a non-naturalist intuitionism in metaethics, and numerous contemporary defenses of Ross-like normative theories or other forms of particularism draw upon the idea that moral concepts are response-dependent (see Dancy 1993) or that fundamental values are plural and incommensurable (see Stocker 1990).

2. *Theory of Value*

In the first half of the twentieth century, theory of value (axiology) was a flourishing, central area of philosophy, represented by such major figures as G. E. Moore (1903), John Dewey (1929), C. I. Lewis (1962), and Ralph Barton Perry (1954). It has since gone so thoroughly out of style that it is difficult for a contemporary philosopher to recognize the themes or structure of a book like Perry's *Realms of Value*, with its chapters on *Motor-Affective Psychology, Gradation, Integration, and Mutation, The Science of Science*, and *The History of History*. This may partly be the result of a familiar tendency within disciplines to subdivide into specialities: ethics, esthetics, rational choice, law, epistemology—all of these are domains of evaluation, yet they seldom are united together under a common rubric. Yet, like specialization generally, it involves some loss of perspective. The value-theoretic aspects of some subdisciplines within philosophy became, at least until fairly recently, relatively invisible (epistemology, for example) or radically de-emphasized ('philosophical esthetics'). This has also given the mistaken impression that the so-called 'fact/value' distinction is disciplinary—ethics on one side, science on the other. But value theorists would be quick to point out that values (but not simply moral values) as well as facts are fundamentally involved in all areas of human practice and inquiry.

There are excellent reasons for focusing on value as such. There is independent interest in investigating the nature and structure of value. Some questions about objectivity, cognitivism, and realism are familiar from metaethics, but others, such as the distinctions among intrinsic, extrinsic, inherent, and instrumental value, or the holistic vs. atomistic character of value, or the possibility of commensurability or interpersonal comparison, merit sustained scrutiny (see also *Value Pluralism*).

Moreover, that moral philosophy in the twentieth century has been overwhelming preoccupied with questions of rightness and obligation (deontic or directive categories), rather than questions of value (axiological or evaluative categories), has given us a lopsided picture of morality and of the 'motivation problem' for ethics. Perhaps an ought judgment expresses some motivation on the speaker's part, but a judgment that a way of life would be valuable seems to be more dependent on the actual or potential motivation of those to whom it is applied. Further, evaluative judgments in general seem more directly responsive to facts of psychology, sociology, and history than directive judgments (see Wiggins 1998, Williams 1985). The emphasis on deontic judgment has also tended to divorce philosophical ethics from value-involving subjects where duty plays a less conspicuous role. Kant and Hume, for example, saw quasiesthetic evaluative judgment as at the foundation of morality.

Finally, a certain lost opportunity for philosophy for mutual enlightenment between 'analytic' and 'continental' philosophy occurred during the twentieth century. Moore (1903) observed that the philosopher

whose outlook seemed closest to his own was Brentano (1902). Theorists within the phenomenological tradition in philosophy and psychology, such as Kohler (1938) and Heidegger (1962), explored our experience of value in life in ways quite comprehensible from the standpoint of, say, Dewey (see *Phenomenology: Philosophical Aspects*). Frankfurt School (see Habermas 1990) criticisms of an overly narrow construal of value can be read alongside a growing body of Anglo-American literature critical of current notions of value in philosophy and economics, especially in rational choice theory and cost-benefit analysis (see Maclean 1986, Anderson 1993; also see *Economics and Ethics*).

Ethics Committees in Science: European Perspectives

Research in medicine, including methods and results of other disciplines like biology or psychology, is for a major part, undertaken with the aim to improve the understanding of normal and abnormal structures, functions, and regulations of man. The results may contribute to a higher effectiveness of diagnosis and treatment of disease. Research on man may include the use of personal data, of cells or tissues of human origin, and interactions with, or interventions on, a person. It is obvious that research, understood in such a broad sense, can interfere with the autonomy, the dignity, and the fundamental rights of a person participating in a scientific project. In order to protect these fundamental rights the Declaration of Helsinki of the World Medical Association (1996) recommends, that an 'experimental protocol' should be 'transmitted for consideration, comment, and guidance to a specially appointed committee.' These committees are usually known under the term 'ethics committee,' a term covering a lot of very different bodies based on a variety of regulations, from formal laws to codes of deontology of doctors. These regulations vary from country to country. An older publication 'Ethics Bodies' (1992) gives an overview on the situation in 28 states of the USA. A recent publication (Deutsch and Taupitz 2000) reflects the approach in several states from various continents and different systems of regulations. It will be the basis for the following considerations.

It is generally accepted that the above mentioned Declaration of Helsinki had a most important influence on constitution and function of ethics committees, although it has nowhere reached the degree of a formal law. Nevertheless, it has been introduced in a very different way into the system of regulations of the states. In contrast to this, the declaration is obviously not observed in the USA.

Promoted by the declaration, ethics committees have been established by a broad variety of organizations, for example, university hospitals, general hospitals, medical associations, or pharmaceutical companies. This development very often preceded activities of parliaments or administrations. Introducing legal regulations, parliaments, and administrations, for their part, tried to respect and to overtake, as far as possible, with respect to constitution and internal right, the experience achieved by the already existing committees.

The first legal basis for ethics committees, in most cases, have been the drug laws. These specialized prescriptions have been expanded in an analogous way on all the other kinds of medical research on man, including medicinal products. Consequently, in some countries, the parliament has covered the whole of research on man by laws, decrees, or similar kinds of legitimation.

The protection of persons participating in biomedical research is generally considered being the principal obligation of ethics committees. The term 'protection' is understood as a prevention of physical damage as well as the protection of fundamental rights of the person concerned. The main point under this view of protection is to assure that the person participating in a research project gives his or her free, informed consent. This consent has to be given for a special project and has to be documented. Other points of consideration are data-protection and an adequate assurance of persons undergoing the research. In several countries the committees also have the duty to prevent the researcher himself or herself to be too audacious in undertaking a scientific project. Ethics committees have to prove the scientific quality and the ethic acceptance of research projects. There are a lot of points for such an examination, namely, minimization of risk by using methods with known risks whenever possible; acceptable relation between risk and potential direct benefit for the person concerned; and for the improvement of knowledge with the leading idea 'the lower the expected direct potential benefit, the lower the acceptable risk and burden,' a careful recruitment of participating persons with respect to the special problems of vulnerable persons. So far persons who are not able to consent, shall be included in the project, the informed consent has to be given by the legal representative in accordance with the national legislation. This representative has to receive all the information that is given to a person able to consent. Other points of examination are documentation of the results; use of collected data following the research protocol with guarantee for the privacy of the person; and protection of all persons (especially vulnerable persons) against force or undue influence on this decision.

In some countries the ethics committees have to prove the quality of the responsible researcher, the adequate equipment of the research institution, the foreseen benefit for the person concerned, as well as for the society and any kind of remuneration for researchers and persons participating in a project. In a number of countries, and this will be one of the most important tasks for the future, ethics committees have to monitor the research and to receive periodical reports of the ongoing project. Upcoming results or serious adverse events my lead an ethics committee to change its former vote.

The committees should intensify the discourse on ethical questions including statements of so-called national ethics committees. The unreflected acceptance of ethical guidelines, promoted by national ethic bodies, is neither wanted nor expected.

In decision-making the ethics committee has to respect national or federal laws regulating drugs, medicinal products, or the system of assurances. If there are special laws regulating medical research, like the '*Loi Huriet*' in France, the Medical Research Council Act in the Republic of South Africa, or the Federal Common Rule in the USA, these regulations have to be observed as well. Administration, legislation or 'guidelines for ethics committees' formulated by a competent body, may oblige ethics committees to fulfil the requirements of The Declaration of Helsinki.

In the Republic of South Africa, the ethics committee of the Medical Research Council instituted by law, is responsible for regulating and the control of research, as far as it is undertaken for, or with support of, the Medical Research Council. This council has the right to publish guidelines for the function of ethics committees. In the case of a conflict between these guidelines and the regulation of a local ethic committee the prescriptions of the Medical Research Council have priority. In New Zealand, the ethics committee, instituted by the Health Research Council, itself founded by law in 1990, has the right to elaborate ethical guidelines for the Research Council itself and to elaborate standards for other ethics committees. The principal task of this ethics committee is the examination and admission of local ethics committees, which have to be accredited in a formal way and must follow the so-called national standard.

Membership and composition of ethics committees vary in such a wide range, that a special consideration is not given with one exception: the composition has to be 'multi-disciplinary,' laymen should be included, both sexes have to be represented in an adequate manner.

Ethics committees need some kind of administration and financing. This is done by preference, for the national ethics bodies by Ministers of Social Affairs, of Health, or of Research. Local ethics committees are mostly supported by the instituting organization, for example, university hospitals. In some countries, for example, the Federal Republic of Germany, the states' laws prescribe that ethics committees have to be instituted by the medical associations and by faculties of medicine.

Generally, ethics committees are responsible for all research undertaken in the institution, by which they have been instituted. There may be some exceptions. In the Republic of South Africa only research projects that are supported by the Medical Research Council, have to be presented to such a committee. In Israel, the Director General of the Minister of Health has the right to reserve examination and approval of special kinds of research to the national ethics committee. In these cases, the decision of this committee is binding for local ethics committees. In some countries, the institution of ethics committees is restricted to states or community hospitals. Private hospitals are independent in their decision to introduce, or not introduce, such bodies.

The duty to seek the decision or the advice of an ethics committee is regulated in a different, but simple and understandable way. There are legal prescriptions, there is the legally based code of deontology, like in the Federal Rebublic of Germany or, in most cases, it is the administration, which requires such a step. In this field, considerations like approval by the responsible administration or financing play a major role. The conclusion is justified that the award of a grant depends on a favorable vote of an ethics committee.

In contrast, it is very difficult to define the legal or binding character of such a vote. Votes are considered as expertise, as anticipating expertise, as advice, as help and orientation, or as an approval. The character of advising is reflected by the official name of the national French ethics committee as '*Comité consultatif*.' Positive or favorable votes are considered in all countries as a basic condition for undertaking a research project. Also, in the case of a negative vote the researcher, at least theoretically, has the right to decide on the undertaking of his project. This situation is, again in theory, given, for example, in the Federal Republic of Germany. In reality, it is the ethics committee that decides by its vote whether a research project is done or not. During a research project, in some countries ethics committees have the right to intervene. They can, with respect to, for example, serious adverse events, change their decision or, in the worst case, withdraw a positive vote.

There is a growing interest on whether there is some kind of hierarchy of the ethics committee within a country. As already mentioned, some national ethics committees, for example, in Israel, in New Zealand, or in the Republic of South Africa, have the right to prescribe guidelines for local ethics committees, or to accept general points of view for special fields of research to be followed by local ethics committees.

In some countries, higher authorities may intervene or correct the decision of local ethics committees. A researcher who does not agree with the decision of the local ethics committee can call the national ethics committee in Denmark. The national Committee may come to another decision that will be binding. In France, a negative vote has to be presented to the Minister of Health, who has the right to suspend it. The Minister of Health in Spain has independent of the vote of the relevant ethics committee, the possibility to stop a research project or to introduce a change with respect to national laws.

There is only little knowledge on formation or continued education of members of ethics committees or of methods of control of an ethics committee as a

decision-making body. As an implemented system there is only the monitoring of IRBs by the 'Department of Health and Human Services' or by the 'Center for Drug Evaluation and Research' of the Food and Drug Administration in the USA.

Since 1997 the World Medical Association has tried to introduce a fundamental revision of its 'Declaration of Helsinki.' The 52 general assembly of the WMA adopted a revised version in October 2000. It is an open question whether this new version will gain the same outstanding importance as the former one. Beside this, there is a growing tendency in many states to introduce legal regulations of all kind of research by so-called 'research laws.' Such a law, based on a national legislation or on international conventions, for example, guidelines of the European Union or the 'Convention on Human Rights and Biomedicine' of The Council of Europe would bind all researchers, whereas the Declaration of Helsinki and prescriptions linked to it, are only compulsory for medical doctors. Ethics committees may exist in other fields of science other than medicine. Published details of such bodies are not known.

Ethics for Biomedical Research Involving Humans: International Codes

There are three leading international codes of ethics for biomedical research involving human subjects: the Nuremberg Code (reprinted in Levine 1988), the World Medical Association's (WMA) Declaration of Helsinki (2000) and the International Ethical Guidelines for Biomedical Research Involving Human Subjects developed by the Council for International Organizations of Medical Sciences (CIOMS) in collaboration with the World Health Organization (WHO) (1993); these will be referred to respectively as 'Nuremberg,' 'Helsinki' and 'CIOMS Guidelines.'

At the close of World War II, in Nuremberg, Germany, certain leaders of the Nazi regime were put on trial for having committed 'crimes against humanity.' During the course of one of these trials, the so-called doctors' trial, the first international code of research ethics, the Nuremberg Code, was written. Subsequent international codes were designed to improve on or to interpret the efforts of their predecessors. WMA began its project in 1953 because it recognized '… a need for professional guidelines designed by physicians for physicians (as opposed to the Nuremberg Code, which was formed by jurists for use in a legal trial).' The result of this project was its code of research ethics which was adopted at the World Medical Assembly in Helsinki, Finland in 1964. CIOMS introduced its Guidelines in 1982 by stating that they were designed to provide guidance for the correct application of the principles of Helsinki, particularly when the research is initiated by researchers and sponsors in technologically developed countries and carried out in developing countries. However, in the revised Guidelines, published in 1993, there are several substantial departures from Helsinki's requirements. At the time of this writing, CIOMS Guidelines are once again being revised. (For further discussion of the subject matter of this paragraph, see Levine 1996.)

1. *Ethical Universalism or Pluralism?*

Discussions of international codes of ethics generally reflect a tension between ethical universalism and cultural pluralism. Universalists hold that ethical principles are identical in all human societies and in all historical periods. It is as if ethical principles exist in nature and are waiting to be discovered. The reason that they appear to change from time to time is that our ability to discern and understand them changes (one hopes for the better). The pluralistic position, by contrast, is that ethics are invented (not discovered) in the course of conversations conducted within particular societies; the results will necessarily reflect the histories and traditions of the cultures in which the conversations are conducted (Levine 1996).

The writers of Nuremberg and Helsinki each attempted to create universal documents. By contrast, the CIOMS Guidelines, which although they recognize some ethical principles as 'transcendent,' also acknowledge the validity of some degree of cultural pluralism. The writers of the CIOMS Guidelines aspire to 'global applicability,' a document that provides adequate ethical guidance for all known contemporary

societies with the understanding that revisions will be required from time to time as ethics change in response to changing circumstances and understandings (Levine 1996).

International codes of research ethics have no legal authority except to the extent that parts or all of them are incorporated in the laws of nations or other political entities having the authority to enact and enforce laws. This point notwithstanding, these documents have important moral status in that those who wish to criticize the ethics of various research activities generally rely on one or more of these documents to ground their judgments.

2. *The Content of the Ethical Codes*

Three ethical principles generally are recognized as 'basic' or 'fundamental' in the ethics of biomedical research and practice. These principles, which were first articulated in their most widely used form by the US National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research (National Commission), are 'respect for persons,' 'beneficence,' and 'justice.' The first—and to this date, only—explicit reference to these principles in the international codes is in the 1993 revision of the CIOMS Guidelines. However, the National Commission found in Nuremberg and Helsinki implicit statements of respect for persons and beneficence (National Commission 1978, Levine 1988); concern for justice is also implied in the introduction to Nuremberg. Whether or not these principles are universally valid is the topic of a controversy beyond the scope of this article (Levine 1996, Macklin 1992).

The purpose of the ethical codes is to provide guidance on how research involving human subjects should be carried out so that it is responsive to the requirements of the basic ethical principles. Because they are considered relevant to virtually all fields of human behavior, the principles themselves are stated at such a level of abstraction that they do not provide clear direction on what behaviors are required or forbidden. Ethical norms (or rules) are incorporated in ethical codes to clarify what behaviors are prescribed or proscribed by the document. Ethical norms are either substantive or procedural. A substantive norm specifies behaviors that are required (or forbidden) because they are morally right (or wrong). Some procedural norms specify procedures that should be performed to determine the most appropriate behavior when the behavior has not been specified by a substantive norm. Other procedural norms are designed to provide documentary evidence that research has been conducted in accord with the relevant substantive norms (Levine 1988).

An illustration. The principle of respect for persons requires that human persons must never be treated only as means to the ends of others. The substantive norm that requires informed consent is a specification of one way in which this principle is to be made operational in the conduct of research involving human subjects. The procedural norm that requires review and approval by an institutional review board affords a method for determining what specific bits of information must be divulged to prospective subjects in a particular research protocol. Another procedural norm that requires the signing of a consent form provides documentary evidence that the behavior required by the substantive norm has been accomplished.

Ethical codes written by ethical universalists tend to have a high proportion of substantive norms. Those that espouse cultural pluralism tend to have a larger proportion of procedural norms. Substantive norms predominate in Nuremberg and Helsinki while the CIOMS Guidelines contain a relatively large number of procedural norms along with abundant commentary on how the norms should be interpreted in various specific circumstances.

All of the substantive norms articulated in the leading international codes of ethics are variations on and elaborations of seven general normative statements (Levine 1988). The first three of these are most closely related to the principle of beneficence which requires that those who perform research should maximize possible benefits and minimize possible harms and, further, that they should not deliberately injure any human being.

(a) There should be good research design. This norm is linked inextricably to the purpose of doing research—to contribute to the development of generalizeable new knowledge. If the research is not designed adequately, there is little or no chance that it will make the desired contribution to the development of knowledge. As stated in the CIOMS Guidelines (1993, p. 38), '… scientifically unsound research is *ipso facto* unethical in that it may expose subjects to risk or inconvenience to no purpose.'

(b) There should be competent investigators. One purpose of this norm is identical to that of the first; competent investigators are much more likely than incompetents to succeed in producing beneficial new knowledge. In addition, there must be at least one member of the team of researchers who has the clinical competence to monitor the health of the subjects with a view toward prompt intervention as indicated to preserve the health of the subject by (e.g.) ending the individual's participation in the research or by administration of an antidote to some toxic substance. As stated in Helsinki (Article 15): 'Medical research involving human subjects should be conducted only by scientifically qualified persons and under the supervision of a clinically competent medical person. The responsibility for the human subject must always rest with a medically qualified person …'

(c) There should be a favorable (or reasonable) balance of risks and benefits. This is a judgment that

must be made by the investigator and affirmed by the research ethics committee before the prospective subject is presented with an invitation to participate. The risks of interventions and procedures that hold out the prospect of direct benefit to the subject are justified much the same as they are in the conduct of medical practice—in terms of the anticipated benefit to the subject. The risks and benefits of interventions and procedures that do not hold out the prospect of direct benefit for the individual subject (nonbeneficial procedures) must be justified in terms of the anticipated benefit to society. Nuremberg (Principle 6) requires that: 'The degree of risk to be taken should never exceed that determined by the humanitarian importance of the problem to be solved.' Plans to employ nonbeneficial procedures that present more than minimal risk in vulnerable populations require special justification. If in the course of conducting the research, the balance of risks and benefits ceases to be favorable, the investigator is required to intervene appropriately. Nuremberg requires: 'During the course of the experiment the scientist … must be prepared to terminate the experiment … if he has probable cause to believe … that a continuation … is likely to result in injury, disability or death … .' (Principle 10) Helsinki does not call for separate analysis of the risks and benefits of individual components of research as described above. Rather, it calls for the evaluation of entire research protocol as either beneficial or nonbeneficial. 'The physician may combine medical research with medical care, only to the extent that the research is justified by its potential prophylactic, diagnostic or therapeutic value.' (Article 28) This is a remnant of Helsinki's historical distinction between therapeutic and nontherapeutic research; reliance on that distinction undermines the validity of the entire document (for further discussion of the problems created by this illogical distinction, see Levine 1999).

The next two of the general substantive norms are most related to the principle of respect for persons:

(d) There should be informed consent. The first principle of Nuremberg set forth the definition of informed consent that, with minor variations, has been incorporated in all subsequent codes and regulations.

> The voluntary consent of the human subject is absolutely essential. This means that the person involved should have legal capacity to give consent; should be so situated as to be able to exercise free power of choice, without the intervention of any element of force, fraud, deceit, duress, overreaching, or other ulterior form of constraint or coercion; and should have sufficient knowledge and comprehension of the elements of the subject matter involved as to enable him to make an understanding and enlightened decision. This latter element requires that before the acceptance of an affirmative decision by the experimental subject there should be made known to him the nature, duration, and purpose of the experiment; the method and means by which it is to be conducted; all inconveniences and hazards reasonably to be expected; and the effects upon his health or person which may possibly come from his participation in the experiment.

(Principle 1) In this way, the prospective subject is invited to accept the researcher's goals as if they were his or her own at least for the duration of his or her participation. The result is that the subject is not treated as *merely* a means to the researcher's goals.

(e) There should be respect for privacy and maintenance of confidentiality. 'Privacy' and 'confidentiality' are often incorrectly used as synonyms. 'Privacy' refers to the 'freedom of the individual to pick and choose for himself the time and circumstances under which, and most importantly, the extent to which his attitudes, beliefs, behavior and opinions are to be shared with or withheld from others' (Kelman 1977). 'Confidentiality' refers to a mode of management of private information; if a subject shares private information with (confides in) an investigator, the investigator is expected to refrain from sharing this information with others without the subject's authorization or some other justification. CIOMS Guidelines require:

> 'The investigator must establish secure safeguards of the confidentiality of research data. Subjects should be told of the limits to the investigators' ability to safeguard confidentiality and of the anticipated consequences of breaches of confidentiality' (Guideline #12).

The final two general substantive norms are most closely related to the principle of justice which requires fairness in the distribution of both the burdens and benefits of research.

(f) Selection of subjects should be equitable. From the 1940s through the mid-1980s, the prevailing attitude among commentators on and policy makers in the field of research ethics was that participation in research was dangerous to the subjects and that researchers were likely to exploit the socially and economically less powerful individuals who were most likely to serve as research subjects. For this reason, the ethical codes and regulations of that time focused on the protection of the prospective subject from bearing an unfair share of the burdens of research. The criterion for determining whether an individual (or a class of individuals) was in need of 'special protections' was 'vulnerability.' In the 1970s, vulnerability tended to be equated with 'limited capacity to give informed consent' and special procedural and substantive norms were developed to protect the rights and welfare of children, prisoners, the institutionalized mentally infirm, and fetuses (Levine 1998). The category 'vulnerable' has been expanded subsequently to include others including 'subordinate members of hierarchical groups, persons with limited financial

resources and persons living in developing countries or communities' (CIOMS 1993, p. 30). Since the mid-1980s, research participation increasingly has been recognized as beneficial to both individuals and the class of persons they represented. This change began as a response to the AIDS activists who in 1986 pointed out that participation in a placebo-controlled clinical trial of AZT was not to be considered burdensome; it was, they argued, beneficial in that it was the only way people could have access to the only drug that anyone believed might be directed at the cause of their disease. Since then, ethical codes and regulations have begun to interpret the requirement for equitable selection of subjects as requiring also that vulnerable persons be assured of receiving a fair share of the benefits of participation in research.

(g) There should be compensation for research-induced injury. CIOMS Guidelines require: 'Research subjects who suffer physical injury as a result of their participation are entitled to such financial or other assistance as would compensate them equitably for any temporary or permanent impairment or disability.' They note, however, that 'In some societies the right to compensation is not acknowledged' (CIOMS 1993, pp. 35–6). One such society is the United States.

3. *Exploitation of Subjects in Developing Countries*

In the past, industrial sponsors and investigators from technologically developed countries occasionally conducted research designed to evaluate their therapeutic innovations in developing countries. This was done to lower the costs of the research and to take advantage of the less complex and sophisticated regulatory systems typical of developing countries. This was unfair in that these innovations, once proved safe and effective, were generally not available to the residents of developing countries owing to economic factors.

With the aim of preventing such exploitation CIOMS Guidelines require special justification for conducting research in developing countries (e.g., the research must be responsive to the health needs and priorities of the 'host' country) and special obligations for the sponsors (e.g., they must engage in capacity-building in the host country to enable it to conduct independent ethical and scientific review). The 1993 version of the CIOMS Guidelines requires that any product demonstrated safe and effective in such research should be made 'reasonably available' to the residents of the country at the conclusion of the research.

Helsinki requires that a new therapy it must be '… tested against those of the best current prophylactic, diagnostic, and therapeutic methods' (Article 29). This standard, which is designed to prevent exploitation of all patients including those residing in developing countries, may also have the undesired effect of obstructing the development for use in developing countries inexpensive alternatives to expensive therapies employed in developed countries. The latter are generally the 'best current … therapeutic methods.' An alternative standard which would not have this disadvantage currently is being considered by CIOMS: 'the highest attainable and sustainable' standard (Levine 1999, 2000). 'Highest attainable' means that one should provide the best one can offer under the circumstances of the research rather than settle for the standard prevailing in the host country (often no therapy at all). The upper limit of what should be provided is defined by 'sustainability.' It would be unethical to develop a therapy that could not be made available to residents of the host country (sustained) after the research has been completed. Such research would not have been responsive to the health needs and priorities of the host country.

Ethics in Organizations, Psychology of

The concern over questions of ethics in organizations represents a new area of research. Its focus is the ethically justifiable moral responsibility for the structures and processes in organizations. This article will first attempt to elucidate what is meant by the concepts of organization, morality, and ethics in order to arrive at a definition of ethics in organizations. Contractual theory forms the link between ethics and organizations. It, however, requires an underpinning in fundamental ethical theories. Then there will be a brief discussion of exemplary instances concerning ethics in organizations. Finally, a description of the different forms taken by the enforcement and implementation of ethical standards in organizations will be given.

1. *The Concept of the Organization*

Organizations can be understood as legal entities for which, on the basis of a contract, people work (Coleman 1990, see *Organization: Overview*). Organizations act as legal entities through the actions of their employees. For this reason, organizations can also be characterized as secondary agents. In addition to having voluntary members who work for it, an organization may also have compulsory members. Such compulsory membership may be based upon national laws and regulations, as in the case, of students in compulsory schools, prison inmates, military inductees, forced laborers, or the inmates of psychiatric institutions. The discretion of members of an organization as representatives of the organization (i.e., those in a superior position, such as management or professional staff) over other members of the organization (i.e., subordinates) are created on the basis of contractual and legal relationships. The relationship between a person and an organization has three aspects: (a) people act towards the organization as a legal entity, for example, when a person enters into a contract of employment with the organization; (b) by virtue of this contract, people take on a specific role in the organization and then act for the organization, for example, as a 'superior'; and (c) in the context of the organization people also act for themselves, for example, when they try to prevent the promotion of a colleague in order to be promoted themselves.

2. *Morality and Ethics in Organizations*

Moral judgments and actions (see *Religion: Morality and Social Control*) are permanent components of the activities of individuals in organizations. One's own actions and the actions of others are judged as good and bad, just and unjust, fair and unfair. This can be accompanied by specific emotions such as outrage, embarrassment, or regret. In addition, people discuss what would have been a morally appropriate action in a given situation. While doing so, they attempt to give grounds for their conclusions (Gethmann 1989). At times, however, moral utterances are used as weapons in order, for example, to give others a bad conscience, to exclude others from access to particular resources, or to mobilize others to support one's own cause. Thus, whereas morality is part of our everyday practice, ethics is concerned with the conceptual analysis of moral linguistic expressions (meta-ethics) as well as with the rational justification of norms on the basis of ethical theories (normative ethics). Ethics is thus a considered reflection on morality. Rationally justified moral demands and norms can be characterized as moral and ethical demands.

One important meta-ethical question for ethics in organizations is the problem as to whether it would make sense to ascribe to organizations not only a juridical, but also a moral and ethical responsibility (Curtler 1986). Speaking in favor of a morally and ethically justifiable responsibility of organizations is the fact that organizations can be understood as agents, and that the ends of these agents are not in every case reducible to the ends of the members of the organization. The question, however, is whether one should start from the assumption that organizations are to be understood as ends in themselves rather than as the means to the ends pursued by individual people. However, speaking against the view that organizations have an ethically justifiable moral responsibility is the fact that organizations have neither feelings of pain, nor a sensitivity for the suffering of others, empathy, or a conscience. Lenk and Maring (1992) come to the conclusion that people cannot exculpate themselves morally and ethically simply by pointing to the responsibility of the organization. Alternatively, the proof of the morally and ethically unacceptable actions of individual people does not automatically mean an exculpation of the organization.

The problems of normative ethics in organizations are the following: What objectives may organizations

legitimately pursue vis-à-vis the members of the organization? What objectives may people in the organizations pursue? What conditions must organizational rules satisfy to be ethically acceptable? What should the interactions between people in organizations and between people and the organization be for them not to violate any ethical rules? Ethical problems such as these can occur in both profit and nonprofit organizations.

3. *Normative Ethical Theories*

Organizations are based on contracts. These contracts are morally and ethically permissible as long as they satisfy the following conditions (Garrett and Klonoski 1986, pp. 88–91): (a) the contract does not come about as the result of coercion, but rather is based upon the voluntary consent of all contracting parties; (b) the contracting parties know the terms of the contract; (c) no side may make intentionally false statements vis-à-vis the other parties about the underlying circumstances of the contract or consciously fail to disclose relevant facts to them; and (d) the contract cannot obligate the contracting parties to carry out morally and ethically unacceptable actions. From an ethical perspective, people should not enter into any contracts with organizations which could obligate them to carry out morally and ethically unacceptable actions. Since organizations can act only through the actions of people, it should also be possible in this way to rule out morally and ethically unacceptable actions by organizations. In practice, one of the difficult problems is the question of determining how dissimilar negotiating positions should be viewed; the side with the weaker negotiating position may face coercion to enter into the contract on the conditions of the stronger side.

However, theoretical contractual considerations are not fundamental from an ethical point of view, for they presuppose that there are criteria available by means of which one can distinguish between morally and ethically unacceptable actions and morally and ethically neutral actions. In addition, the justification for complying with contracts can also not be based solely on a contract; for, if the foundation of contracts were only personal interests, there would be no reason not to breach a contract at precisely the moment when one's personal interests could be better served by breaching the contract.

The focus of utilitarianism (see Glover 1990, see *Utilitarianism: Contemporary Applications*) is on general good. Utilitarianism postulates that in a choice from among various possible courses of action, the moral and ethical courses of action are those whose empirical consequences result in the greatest good of all parties involved. Accordingly, it does, in general, make good sense to comply with contracts. If, however, in a particular situation it would be better for the overall good of all of the parties involved not to comply with a contract, one has, in the view of utilitarianism, an ethical duty to breach the contract. Thus, utilitarianism cannot underpin ethically contractual demands in organizations. Nevertheless, for behavior that is not covered by contracts, utilitarianism can tell people how they should conduct themselves toward others in organizations.

The respecting of basic rights (see *Human Rights, History of*) as an unconditional moral and ethical duty is the object of the so-called categorical imperative of Immanuel Kant (1964, p. 96), who demanded that one never treat oneself and others only as a means, but always also as an end in itself. This is expressed in the demand for the respect of a person's dignity, freedom, and right to life. The other basic rights, such as, for example, the right to privacy, property, freedom of conscience, or the right to freedom of expression can be derived from these fundamental human rights. One criticism expressed about Kant is that he merely postulates the categorical imperative as a 'fact of reason' without providing any further grounds for it.

Discourse ethics (Habermas 1990, Apel 1999) takes as its point of departure the assumption that only a rational clarification of conflicts of interests can be an ethical clarification of conflicts of interests. According to discourse ethics, a rational clarification occurs whenever, through the exchange of sound arguments, an agreement is reached which can be consented to by all affected parties without coercion. Thus it is important to create conditions which enable the people involved to enter into a debate concerning the norms in dispute. Since conflicts can only be clarified rationally through debate between the affected parties, the preconditions for debate also constitute the basis of ethics. An important ethically relevant precondition for debating is that those debating may not exclude other people able to act and speak on their own account from debating with them, for consent to a debate is rational when it is based solely upon the recognition of the argument's better grounds. And it is from these preconditions that the so-called principle of universalization of discourse ethics follows. It states that a norm is only just if and when all affected parties are able to accept the consequences and side effects expected to arise from the universal compliance with the norm for the satisfaction of the interests of each individual. Any skeptic wishing to give reasons for the ethical thesis that there are no universally binding rational norms would have to begin to argue. In doing so the skeptic has in fact already become involved in a rational argument. If, however, he or she has become involved in a rational argument, the skeptic has thus already accepted the preconditions of argument and the principle of universalization it implies.

Thus, discourse ethics is, in contrast to utilitarianism or Kant's categorical imperative, rationally grounded. If one follows discourse ethics, a person is ethically bound by contracts only as long as, and to the

extent that, it can be assumed that all contracting parties fulfill their commitments. If a party does not fulfill its commitments and if the compliance with the contract is thus attended with unreasonable disadvantages for the other parties, then the ethical duty to adhere to the contract is also suspended.

4. Exemplary Instances

In this section a rough outline will be given of some exemplary instances concerning ethics in organizations.

To regulate admittance, an organization frequently applies a procedure for the selection of personnel. These procedures must not violate the applicants's right to rational self-determination and freedom from emotional and social harm. To ensure transparency, before the selection procedure is carried out, applicants should be informed of its objectives, the approach, and the possible consequences. The selection process is to be conducted tactfully and respectfully. The diagnostician is obligated not to disclose certain facts to third parties. This is to protect applicants from potential social stigmatization. The question of the justice of selection strategies is posed by the problem of whether people are hired merely as the result of how well they do in a diagnostic procedure. Should other criteria be decisive factors, the consequence would be a deviation from the allocation of the most qualified applicants to positions. Such a strategy could in the long run, however, have a detrimental effect on the common weal.

Within the organization employees are subordinated to the instructions of a manager on the basis of the employment agreement. They thus give up a part of their autonomy, trusting that the superior will neither misuse it for the benefit of the organization nor for his or her own personal benefit. From this there ensues an ethical and moral responsibility of the superior for the care and welfare of his or her employees. In the view of discourse ethics, the superior must implement this duty so that it becomes progressively unnecessary. This means that he should transparently organize the conditions within his or her area of responsibility and should manage the employees in such a way, that in the framework of their actions in the organization, they can win back, piece by piece, their self-responsibility.

Putting pressure on someone to act against conscience reduces a person to the status of a pure means for the predetermined ends of others and in so doing violates the basic moral and ethical right to rational self-determination. If the superior becomes convinced that a member of the organization has, on the basis of honorable motives, refused an activity for reasons of conscience and has seriously examined his or her matter of concern, the manager should make every effort to entrust that member of the organization with another activity.

Micropolitics is understood as the secret machinations by which individual members of organizations, or special groups in organizations, act for the attainment of private advantages (Velasquez et al. 1983). From the viewpoint of moral and ethical basic rights, the use of micropolitical tactics are to be rejected because the possibilities of another person achieving rational self-determination are restricted by means of tricks and deceit. A consequence of the discourse ethics view is the demand that people in organizations should collaborate on creating and preserving structures which make possible the open resolution of conflicts.

The following criteria have been postulated for the creation of quality working conditions in organizations (Levine et al. 1984, Luczak et al. 1989, p. 58): (a) at work people should find working conditions that are feasible, tolerable, unrestricted, and not dangerous; (b) in terms of job content, the work assignment, working environment, and pay should meet standards of social adequacy; (c) in addition to this, work should be accompanied by a certain amount of latitude in terms of activities and scope of operations; (d) the work should provide an opportunity to acquire skills; (e) it should give the worker satisfaction and preserve and further develop their personality, i.e., their self-confidence and willingness to take on responsibility; (f) the workers should, in addition, have the possibility of participating in the organization of their working conditions; and (g) finally, the effects of the working conditions should be socially compatible (e.g. pro-family). Apart from this, demands are made for environmentally friendly working conditions.

As many case studies prove, safety insufficiencies and risks are frequently well-known in factories, planning offices, and laboratories long before there are deaths and disasters. Often the members of the organization are aware of such insufficiencies. If they do not get any response to their warnings in the organization, some contribute to the protection of the public by making these risks public (James 1989).

The due-process doctrine (Carroll 1992, pp. 421–8) concerning the termination of employment, demands that discharges ought to take place in accordance with codified regulations. Thus, notice of termination should not be given arbitrarily, but only when certain facts can be shown to be the case. The affected parties are to be informed of the grounds for the termination. They should have the opportunity to comment on these grounds and thus effect, if appropriate, the rescinding of the termination.

5. Forms of Enforcement and Implementation

There are starting points available for rendering morally and ethically acceptable conduct practically possible by and in organizations at the macro, intermediate, and micro levels.

At the macro level of many national constitutions, government agencies are committed to the protection of fundamental human rights or to compliance with the principle of equal treatment. It is, however, disputed in many countries whether, for the guaranteeing of these principles, the state or the administration of justice ought also to intervene or be permitted to intervene legally in the relationship of private organizations and members of organizations. In addition, a problem of substantive law is the extent to which it is not just promulgated, but actually applied as well.

At the intermediate level, independent unions and a right to strike guaranteed by the government have played an important role. Unions, however, frequently do not only pursue moral and ethical objectives, but above all the particular interests of their members. Professional associations with a high public reputation, such as the professional associations of scientists, engineers, physicians, architects, or psychologists (Lindsay 1996), can also influence practices at the intermediate level by means of moral and ethical conduct guidelines for their members in organizations (see *Ethical Codes, Professional: Business Codes*). Associations in which organizations have joined together can likewise introduce moral and ethical standards on the basis of a voluntary self-commitment on the part of the organizations. The motivation behind the introduction of standards, however, is frequently not only the facilitation of morally and ethically acceptable conduct in organizations, but also the improvement of reputation in the public eye as well as the avoidance of statutory regulations. Although such self-interested motives are legitimate, they must not result in a biasing of the standards.

On the micro level, the public denunciation of organizations on the basis of unethical practices can be an effective means of enforcing moral and ethical standards in organizations. If individuals with a high degree of moral sensitivity have a very strong position in an organization, as is sometimes the case for private entrepreneurs, the result can be that they try to make their moral views binding for the objectives, rules, and processes in the entire organization. Even individual members of an organization without any special position in the organization can trigger changes as conscientious objectors or 'whistle-blowers.'

Regarding the implementation within the organization of external legal and ethical standards, two ideal-typical strategies are currently being discussed, namely the so-called compliance approach and the integrity approach (Paine 1994). In the compliance approach externally predetermined standards are translated into internal active and restrictive regulations, compliance with which is enforced within the organization by means of controls and sanctions. In the integrity approach an effort is made through an organizational development process at all levels of the organization to activate the moral sensitivity of the members of the organization. The danger in the compliance approach is that, due to the strong outside control, members of the organization become morally desensitized and develop a mentality of getting around the guidelines. In the integrity approach, members of an organization cannot invoke written rules to defend themselves against morally and ethically inadmissible expectations. What is important is a sensible combination of the compliance and the integrity approaches.

6. *Summary*

Organizations can be understood as legal entities for which, on the basis of a contract, persons work. Moral judgments and actions are permanent components of the activities of individuals in organizations. Ethics is a considered reflection on morality. Ethics in organizations deals with the ethically justifiable moral responsibility for the structures and processes in organizations. People cannot exculpate themselves morally and ethically simply by pointing to the responsibility of the organization. However, the proof of the morally and ethically unacceptable actions of individual people does not automatically mean an exculpation of the organization. Discourse ethics can underpin the ethical commitment to transparent contracts entered into voluntarily. In addition, the basic-rights approach provides concrete examples and discourse ethics provides formal rules for the determination of ethically unacceptable obligations to which one should not commit oneself in a contract. Exemplary instances were discussed, namely ethical guidelines for personnel selection, ethical problems in the superior–subordinate relationship, the freedom of conscience in organizations, the ethical problematic of micropolitics in organizations, the right to make public abuses in organizations (whistle blowing), as well as ethical rules for dismissal from organizations. Different forms taken by the enforcement of ethical standards in organizations at the macro, intermediate, and micro levels were presented. Finally, a sensible combination of the compliance and the integrity approaches regarding the implementation of moral and ethical standards in organizations was proposed.

Ethnic and Racial Social Movements

Ethnic and racial social movements (hereafter E/R social movements) are goal-directed actions sustained by groups whose identity is recognized by the presence of racial or ethnic markers. These markers typically include skin pigmentation, ancestry, language, and history of discrimination, conquest, or other shared experience. For simplicity (and to avoid invoking unscientific assumptions about race), many researchers prefer the label *ethnic mobilization*. Ethnic mobilization includes activities that range from small-scale, sporadic events to well-developed campaigns and/or civil war.

Several conceptual distinctions have facilitated the understanding of the emergence, growth, and decay of E/R social movements. Some (but not all) scholars distinguish *ethnic mobilization* from *ethnic solidarity*. Solidarity is characterized as the conscious identification (and loyalty) with a particular race or ethnic population, measured by attitudes or organizational involvement. This distinction has allowed Minkoff (1995) to analyze the effects of the growth of racial solidarity organizations on the rate of racial protest activity and vice versa.

Social movement theories distinguish various forms of movements by their duration, target, tactics, violence, and audience. These distinctions yield three broad categories of E/R movements: (a) territorial sovereignty movements that demand regional autonomy, separatism, diaspora settlements, and/or secession; (b) protests that demand expansion of a group's civil and economic rights or demand an end to discrimination; (c) collective attacks ranging from genocide, ethnic cleansing, and mob violence, to symbolic threats. Studies of E/R movements traditionally analyze these forms separately (Horowitz 1975, Banton 1983). For example, race riots are distinguished from other types of ethnic conflict by expressions of violence that might involve hundreds or thousands of persons in activity that lasts several hours or more (Spilerman 1970, Myers 1997). Protests for civil rights typically include marches, demonstrations, sit-ins, and other similar tactical forms (McAdam 1982). To the extent that E/R social movements seek to eradicate and replace existing geographical and administrative state boundaries, they provoke violence on the part of insurgents and state authorities. This is particularly true for separatist or secession movements demanding formal withdrawal from a central political authority (or, in the case of irredentist/diaspora movements, claiming territorial sovereignty for formerly dispersed populations) (Hechter 1992).

Most studies focus on one of these forms of E/R social movement within a single country. Other researchers have used comparative research designs to test the emergence of various forms in different settings (Gurr 1993). These designs allow researchers to pursue questions about the diffusion of E/R social movements across national boundaries.

Two key questions drive research efforts in this area. First, how does ethnic identity become transformed into social movements? Second, what explains the emergence and persistence of E/R movements?

1. *The Transformation of Group Identity into Social Movements*

To transform subjective group identity into goal-directed ethnic mobilization, a group must overcome the seemingly natural resistance of individuals to sustain collective action. By invoking norms of group loyalty, social sanctions sometimes transform inert groups into meaningful and purposive social action. Consequently, members are continuously constructing group boundaries (Barth 1969, Hechter 1987a). Social

movements tend to develop when these boundaries are challenged and group identities are defended.

When does sporadic ethnic activity become a social movement? Answering this question is difficult because no thresholds have been established in the empirical literature. In contrast to isolated ethnic events, these social movements involve sustained efforts to evoke major changes in political goals, such as policies regarding subordinate groups, redefinition of citizenship boundaries or rights, and/or efforts to exclude, subjugate, or control a population or region. Thus, social movements tend to be more enduring and continuous than are other forms of ethnic mobilization.

Historical evidence suggests that nation-building activities have often provoked enduring E/R social movements. For example, Smith (1979, p. 34) identifies a sequence of events that encourage separatism, beginning with initial state-building processes including creation of a centralized bureaucracy and diffusion of national educational institutions. A related line of research has emphasized the role of elite mobility into leading institutions also shaping E/R movements. If ethnic elites find their mobility blocked, ethnic mobilization around claims of minority discrimination will arise (Williams 1994).

An extreme form of violent social movements against a target population is genocide or ethnic cleansing. Historical examples often include claims of ethnic or racial purity that required exclusion or extermination of some other group. Most recently, this form of violence has arisen as former states (or modern empires) fragment or dissolve entirely and attempt to forge new and ethnically homogeneous identities (Jalali and Lipset 1992). The consequence is often a combination of pogroms, terrorist movements, disenfranchisement, and other methods of physical attack such as lynchings, rape, or civil war.

2. *The Dynamics of Movements: Emergence, Growth, and Decay*

Several prominent theoretical traditions have been offered to explain the emergence, growth, and decay of E/R social movements. Each is distinguished by an emphasis on one or more processes of changing economic, political, and/or ideological environments as key features shaping the trajectory of these movements.

2.1 Economic Factors

2.1.1 Internal colonialism theory. Internal colonialism theory suggests that a combination of uneven industrialization and cultural differences among regions in core nations cause ethnic grievances to become the basis of enduring political contention. In this view, the sources of ethnic solidarity include uneven regional development that reinforces or creates inequality, dependence on external or international investment, and an occupational structure that is highly segregated along ethnic lines. Furthermore, according to this argument, a high level of ethnic solidarity and a division of labor segmented along ethnic lines provokes ethnic conflict in developed regions, rather than in impoverished areas (Hechter 1975).

2.1.2 Competition theory. Some counterevidence suggests that states experiencing a decline in ethnic inequality experience movements expressing claims for autonomy and political rights for minorities, while patterns of ethnic violence occurs in states that exclude ethnic minorities from the political process (Smith 1979, p. 35). Competition theories of race and ethnic relations offer an explanation for these findings. According to competition theory, declining inequality among regions (or groups) promotes competitive conflict among race and ethnic groups (Olzak and Nagel 1986). This is because declining inequality and intergroup contact release forces of competitive exclusion and conflict (Barth 1969). In this view, E/R social movements result from conditions of niche overlap (rather than from niche segregation). For example, competition theorists argue that ethnic conflict arises when ethnic groups within nations come to compete in the same labor markets and increase their access to similar sets of political, economic, and social resources (Nielsen 1985, Olzak 1992). Split labor market theories further suggest that ethnic conflict intensifies when groups command different levels of wages and conflict becomes divided along both economic and ethnic lines (Bonacich 1972). Mobilization based upon race or ethnic identity occurs as dominant groups attempt to reassert their dominance over newly competing groups, or as formerly disadvantaged ethnic groups challenge the existing power structure.

2.1.3 Rational choice theory. This perspective emphasizes shifts in the calculus of the costs and benefits attached to ethnic mobilization. According to this view modern ethnic movements occur with regularity because they have unique properties that allow them to overcome the free rider problem that encourages nonparticipation. According to this view, because ethnic groups are able to form dense social networks, group solidarity is high, minimizing costs of mobilization. Simultaneously, ethnic groups can efficiently

apply systems of monitoring behavior, insuring loyalty, and sanctioning members (Hechter 1987a). Building on rational choice models, Fearon and Laitin (1996) and Weingast (1998) have linked the strategic aspects of ethnic identity to violence, as elites build on existing ethnic loyalties. Additionally, Bhavhani and Backer (2000) argue that the presence of genocidal norms (that sanction in-group members who decline participation in ethnic mayhem) tends to increase the scale of ethnic violence. One testament to the power of these norms is that the intensity of ethnic killing can remain high, despite a history of intergroup cooperation and trust among groups.

2.2 Political Factors

These perspectives emphasize the role of shifts in political constraints and opportunity structures that influence the trajectory of E/R social movements. Horowitz (1975) examines the centrifugal force of ethnic political parties, which maintain ethnic loyalties through institutional arrangements and patronage based on ethnic loyalties. Some social scientists argue that the decline of authoritarian regimes coincides with the resurgence of ethnic or nationalist movements because the retreat of strong, repressive authorities leaves a power vacuum (Gurr 1993). As the former military and administrative structures recede, local level elites mobilize ethnic loyalties and take advantage of this vacuum. Along similar lines, McAdam (1982) provides evidence from the USA that suggests that shifts in political opportunities (either positive or negative) drove the rates of protest activity during peak periods of civil rights insurgency. State repression may subdue such movements, but this effect is often temporary.

2.3 Cultural/Ideological Factors

2.3.1 Nationalism. All forms of E/R movements articulate demands that invoke one or more cultural themes of nationalism, rights of self-determination, expansion of human rights, and basic rights of sovereignty (Smith 1979, Hechter 1987b). Sovereignty claims usually refer to shared experiences of 'a people,' which can be real or imagined (Anderson 1991). Moreover, the acceptance of the legitimacy of nationalism has parallels in the diffusion of a worldwide human rights movement, which acts as an orienting frame for states and E/R social movements.

2.3.2 Diffusion. Social movement tactics, organizations, and claims have diffused across national borders, creating an international network of E/R social movements that share common themes. Self-and-other definitions based on racial markers, linguistic, or historic patterns of subordination justify and legitimate these claims in virtually all of the world's states. For instance, Olzak and Tsutsui (1999) find that although integration into a world system of power and domination facilitates E/R movements, these effects vary considerably across countries. In addition, processes of diffusion have intensified the international scope of these movements, transforming them into highly contentious international issues.

Ethnic Cleansing, History of

'Ethnic cleansing' is a term that has come into common usage only with the recent war in former Yugoslavia. It describes the process of the forced deportation of peoples or nations from their homes and homelands. Even though violence and murder often take place in the course of ethnic cleansing, it is not the same historical phenomenon as genocide, which involves the intent to kill off part or all of a people. For a variety of reasons, some scholars find the term problematic. Nevertheless, it is useful not only for describing the attacks on national groups in former Yugoslavia, but for understanding similar instances of the violent expulsion of nations from their homelands throughout the twentieth century.

1. *The Term 'Ethnic Cleansing'*

The war of Yugoslav succession gave the term 'ethnic cleansing' its currency in the popular press and its meaning for political leaders, academic commentators, and the International Tribunal in the Hague. The term burst into public consciousness in the West in May 1992, and was used with increasing frequency during the following summer to describe Serbian attacks against Bosnian Muslims in Bosnia–Herzegovina (Gutman 1993). In this context, the use of the term 'ethnic cleansing' indicated that Serbs and Bosnian Serbs assaulted the Muslims with the intention of driving them out of targeted territories that the Serbs wanted to make ethnically Serbian. Subsequently, the term was also applied to Serbian attacks on Croats during the 1991–1992 Serbian–Croatian war, Croat attacks against Bosnian Muslims in 1992–1993, and Croat attacks against Serbs in the Krajina during the summer of 1995. All of these attacks were motivated by the desire to seize and secure these territories for their own national groups.

Most recently, the term 'ethnic cleansing' has been applied to the crisis in Kosovo, both in connection with the Serbian offensive against the Kosovar Albanians in the winter and spring of 1998–1999, which saw nearly a million Kosovars driven from their homes, and as a way to describe the Kosovar Albanian attacks on the Serbs since the conclusion of NATO bombing in May 1999. The origins of the term also are related to Serbian–Albanian relations in Kosovo. The term 'ethnic cleansing' was first used by Serbs in the mid-1980s to describe what they claimed were Kosovar Albanian attempts to drive the remaining Serbs of Kosovo from the province by means of economic pressure and physical threats (Vujacic 1993).

From the beginning of its use in the west to describe the events in Yugoslavia, the term was criticized on a number of grounds. Some commentators thought it was little more than a euphemism for genocide (see *Symbolism in Anthropology*). Others were critical of the way genocide and ethnic cleansing were used interchangeably (Hayden 1996). In fact, distinctions between ethnic cleansing and genocide have been usefully drawn to understand the differences between the character of the Serbian attacks on the Bosnian Muslims, in particular, and genocides carried out earlier in the century. The intention to murder all or part of a nation, ethnic, or religious group, is critical to the definition of genocide developed by Rafael Lemkin during World War II and made part of international law in Article II of the United Nations Convention on the Prevention and Punishment of the Crime of Genocide, December 9, 1948 (Melson 1992). The intent of ethnic cleansing is to drive a nation, ethnic, or religious group out of a designated piece of territory, not necessarily to murder them.

The problem remains that ethnic cleansing is not free of genocidal implications. The Serbian massacre of some 7,300 Muslim men in Srebrenica should be characterized as genocide, even if the ultimate goal was to drive the Muslims from the territory. In this connection, the Croatian massacres of Bosnian Muslims in the Lasva Valley in the spring of 1993 were classified by the International Tribunal in the Hague as 'ethnic cleansing,' rather than 'genocide.' Critical was the intent to drive the Muslims from the region rather than the intention of mass murder.

Some scholars identify the mass rape associated with ethnic cleansing in Bosnia as an attack on the reproductive potentialities of the Bosnian Muslim nation and therefore a form of genocide (Allen 1996, Stiglmayer 1994). It should in no way diminish the horrific quality of the crime to suggest that its purpose was fundamentally to drive Muslims from towns and villages seized and claimed by Serbs. It was therefore a part of the ethnic cleansing of the region rather than genocide. The mass rape in Bosnia led the Inter-

national Tribunal in 1998 to classify it, for the first time in its long history, as a 'crime against humanity.'

The word 'cleansing' is sometimes criticized by scholars because it ostensibly sanitizes a process that is otherwise brutal and murderous. But in the Slavic form of the word, for example *ciscenje* (Serbo–Croatian), *oczyszczanie* (Polish), or *chistki* (Russian), cleansing can refer to violent purges and is often used in a political context. The German word for cleansing and purges, *Saeuberung*, was used in pre-Nazi and Nazi eugenics and racial theorizing to indicate the need for 'purifying' the German race. In both Slavic and German, cleansing has a double meaning: the individual has been dirtied by alien elements and must be cleansed as a result, and the nation has been infiltrated by ethnic 'others,' who must be excised from the social body. Violence is implied in both. The definition of who belongs to an ethnic group is clearly determined by subjective criteria (see *Ethnic Groups/ Ethnicity: Historical Aspects*). The existence of the group itself often is a creation of the persecutor.

2. *Ethnic Cleansing and Modernity*

As quickly as 'ethnic cleansing' was accepted in public discourse as an appropriate description for the attacks in former Yugoslavia, scholars began applying the term to similar episodes in the past and present. Some analysts looked at ethnic cleansing as a phenomenon deeply rooted in human society going back to the beginning of history (Bell-Fialkoff 1996). The Assyrians, the Babylonians, and the Greeks are claimed to be the first ethnic cleansers. From this point of view, the causes of ethnic cleansing in Bosnia more often than not are traced to supposed 'ancient hatreds' between the peoples of the region.

A second approach looks at ethnic cleansing, like genocide, as a fundamentally modern phenomenon, one associated with the development of the modern state (see *State, History of*) and the goals of its political leaders (Ahmed 1995, Baumann 1989). Especially the 'high modernist' aspirations of the late nineteenth and twentieth-century state, which seeks to control, homogenize, and manipulate its population, lead to episodes of ethnic cleansing (Scott 1998). The political ideology of the Serbian leadership and its relationship to the control of state power are at the core of the problem in the Balkans, not 'ancient hatreds.' The political manipulation of recent conflicts, like those during World War II in Yugoslavia, set the stage for ethnic cleansing in the 1990s.

The modern state also commands the means to engage in ethnic cleansing. Not only can it register and identify the ethnic other, it uses modern means of communications to initiate and justify its ethnic cleansing campaigns. Propaganda and the mass media are critical to creating the appropriate images of enemies within and justifying forceably deporting the other. If earlier in the century newsreels and radio conveyed the messages of hatred and prejudice, television became critical to the late twentieth-century catastrophes in Yugoslavia and Rwanda. The state also uses modern means of warfare and transport to move populations from their homelands. Machine guns make it easy for small contingents of troops to guard (and sometimes to murder) large numbers of ethnic others. The sealed railway freight car might well serve as a symbol for ethnic cleansing, especially in Europe. Tens of millions of people were forced from their homes in hellish rail deportations; hundreds of thousands died from hunger, thirst, exposure, or disease in the process of transportation alone.

The major episodes of ethnic cleansing in the twentieth-century world reinforce these ideas. As a crucible for 'industrial killing,' World War I set the tone for the rest of the century (Bartov 1996). Yet even during the Balkan Wars of 1912–1913, some half a million people were driven from their homes or fled their persecutors. The Young Turk triumvirate that led the Ottoman Empire during World War I was responsible for the ethnic cleansing and genocide of the Armenians in 1915. Approximately, 750,000 to 1,200,000 Armenians died as a result. The modernizing Turkish leader, Mustapha Kemal, drove the Greeks from Anatolia in 1922–1923, in a clear case of ethnic cleansing. Hundreds of thousands of Greeks died in the process, many in refugee camps in Greece and the islands from hunger and disease. Hitler and the Nazis engaged in a form of ethnic cleansing that quickly degenerated into genocide and the Holocaust (see *Holocaust, The*). The Third Reich arrogated to itself a huge territorial realm (*Lebensraum*) where it would bring in German settlers and forceably expel the allegedly inferior local ethnic inhabitants. The case is complicated by the fact that Nazi rhetoric was consistently eliminationist, while the government's policies until World War II were oriented towards forced deportation and population transfer. Gypsies, Poles, and Russians were involved in Nazi plans of racial destruction, as were the Jews, their primary target.

Stalin and the Soviet leadership engaged in a particularly Bolshevik form of ethnic cleansing (Martin 1998). During World War II alone, nearly a million people from the Northern Caucasus and Crimea—Chechens, Ingush, Karachaevtsy, Balkars, and Crimean Tatars, among others—were driven out their home territories to Central Asia. These 'punished peoples' were slated for elimination as nations, if not necessarily as individuals. Still, so many of them died in the process that their survivors speak of genocide. During and after the war, some 11.5 million Germans were ethnically cleansed from their previous homes in Eastern and East Central Europe, primarily Poland, Czechoslovakia, and Hungary. Roughly two million died or were killed in the process. Poles were ethnically cleansed from Ukraine and Ukrainians from Poland (Ther 1998). During the separation of India and

Pakistan, in 1947, some 10 million people, Hindus, Sikhs, and Muslims, were driven from their homes or fled persecution. The list goes on: Rwanda, Yugoslavia, Nagorno-Karabakh, and East Timor, among others.

3. *A Taxonomy of Ethnic Cleansing*

In these cases and others, the impulse of political leaders is to employ modern integral nationalism (see *Nationalism: General*) to achieve, maintain, and/or build political power. Nationalism claims superiority for the genetic material of the dominant nation, and it counters alienation and anomie by trumpeting a sense of collective belonging. It promotes the perception of shared national values, culture, and experiences. However, modern nationalism also fosters unity and common purpose among the dominant nation by denigrating the qualities of the subordinate ones. Part of nationalist rhetoric is the identification and stereotyping of the 'other,' an ethnic, religious, and/or national minority. The other cannot be tolerated because of their inherent inferiority and treacherousness. These minority groups are targeted for persecution and forced deportation, which almost always takes place in the context of violence.

Those who are left behind become even more dangerous than those who are forced out: thus the impetus in ethnic cleansing is to drive out every member of the minority, leaving no exceptions. There is a totalistic impetus to ethnic cleansing as a result. Sometimes, in the case of the Armenians, the Jews, and the Tutsi, ethnic cleansing turns into genocide or overlaps with genocide. But almost everywhere, the 'unmixing of peoples' (Brubaker 1996) involves the application of extreme violence. Even in those cases where population exchange is mandated by international treaties—Lausanne in 1923, Potsdam in 1945, and Dayton in 1995 are the most famous examples—they usually follow upon, rather than prevent or ameliorate, ethnic cleansing.

Ethnic cleansing almost always takes place under the cover of war) or in a period of transition from war to peace. The force of international opinion or journalistic inquiry is easily neutralized. Paramilitaries are involved in ethnic cleansing even more than regular army units. Strategic objectives for displacing a people are used as a way to justify the actions. Sometimes, the territory inhabited by the targeted minority is designated as strategically located. Sometimes, the argument is that the nations themselves are allied with foreign enemies. During war, normal civil laws are often suspended; men are accustomed to bloodletting; refugees and the dead and wounded are a normal part of the landscape. Soldiers follow orders, and few are punished for attacking the 'other.'

Yet the violence of ethnic cleansing has a different character from that of war. In war, men in military formations are aligned against one another and fight with guns and machines in a more or less reciprocal exchange. In ethnic cleansing, it is usually an armed perpetrator who attacks an unarmed civilian. Those who are conducting the 'cleansing' have complete power over the other, producing a variety of brutal and sadistic practices that have little relationship to the normal rules of military engagement. They burn down homes, rape women and girls, beat helpless victims, and rob indiscriminately. In the process of dislodging peoples from their homes and their homelands, every cruelty—maiming, branding, torture—has been used.

The violence of ethnic cleansing is therefore directed almost exclusively against civilians. This usually means women, children, and the elderly. The gendered quality of ethnic cleansing is notable. Unarmed women and girls are attacked and brutalized in almost every case. The history of rape, mass rape, and rape murder in Bosnia–Herzegovina, where some 50,000 rapes are said to have taken place, was not unique to ethnic cleansing, as it has occurred throughout the world. Females are targeted both as the biological source of the future of ethnic groups, and as the bearers and teachers of national cultural values. They are often the primary victims of ethnic cleansing, as men are the major victims of war.

It is never sufficient in ethnic cleansing simply to expel a people from the designated territory. Their physical and cultural monuments and artifacts are targeted for destruction, as well. Serbs routinely blew up mosques and desecrated Muslim graveyards; Turks tried to destroy the remnants of Armenian and Greek civilizations in Anatolia; Jewish gravestones were used to pave roadways or factory floors, as were the gravestones of the Chechens and Ingush. The names of the peoples, of their towns, and of their regions, were routinely changed, removed completely from sight, chipped away from stone engravings, and even banned from speech. There should be no physical traces left of their previous existence. They are written out of history, or histories are rewritten to denigrate their roles in the region they formally inhabited.

4. *The Future of Ethnic Cleansing*

There is every reason to believe that ethnic cleansing will continue to take a fearsome toll on innocent human beings in the twenty-first century. Part of the problem is that international institutions have a very difficult time intervening in sovereign countries for humanitarian reasons alone. Most of the great catastrophes of ethnic cleansing and genocide in the twentieth century—the Armenian genocide, the Holocaust, Rwanda—were well known to the world community. Yet little if anything was done to stop them.

The recent NATO actions in Bosnia and Kosovo

demonstrate just how difficult it is to gain international consensus for intervention. The Russian involvement in Chechnya might well end in ethnic cleansing; only the most tepid of protests are registered on behalf of the hundreds of thousands of innocent refugees from the conflict. Even when intervention takes place, it is very difficult to separate nations peaceably who have experienced the ravages of ethnic cleansing. One of the fallacies of those who justify ethnic cleansing is that peace is advanced by forceably creating homogeneous nation-states. Instead, long-term animosities and national traumas are engendered that can explode into violence and war.

Especially in the former communist world, there are numerous countries with weak state structures, underdeveloped civil societies, and struggling economies. Where political elites are willing to play the 'nationalist card' in order to mobilize populations on behalf of the modernizing nation-state, ethnic cleansing might well occur. Under similar circumstances, countries like Turkey, Afghanistan, Pakistan, and Indonesia could also be vulnerable to attacks on minority nations.

Ethnic Conflict, Geography of

Ethnic conflict is a worldwide phenomenon. Much of it is territorially based, entailing disputes over the control of space. It occurs over a wide range of spatial scales, from the interstate level to the urban neighborhood. Violence takes place at the extreme, though a significant amount of ethnic conflict is characterized by nonviolent behavior. Causal factors can range from material welfare concerns to identity issues. A range of territorially based solutions or at least attempts at conflict regulation have been put forward.

1. Spatial Scales

It is possible, from a geographical perspective, to classify ethnic conflicts into three categories—the interstate, the intrastate and the micro-scale or intra-urban. However it must be stressed that there are powerful linkages between the various scales. Events at the interstate scale can reverberate down into the individual states and may even have consequences at the level of urban neighborhoods. Likewise, conflicts at the urban micro-scale can impact at the larger spatial scales, even as far as triggering ill-feeling or worse, in the 'international' arena.

1.1 Ethnic Conflict at the Interstate Scale

The geographical distributions of many ethnic groups do not conform neatly to existing state boundaries (the

Basques and the Kurds provide clear examples of this). The misfit between state and ethnic group boundaries may generate claims. As Donald Horowitz (1985) has put it 'if irredentism is conceived as a movement to retrieve ethnic kinsmen and their territory across borders, the common disjunction of group boundaries and territorial boundaries offers scope for irredentas aplenty.' Horowitz further notes that a decision to attempt to forcibly retrieve ethnic group members across a border is, in the main, a government decision. This contrasts with secession, which is an ethnic group decision to break away from the state that the group currently finds itself penned into. Secession may involve an attempt to form a separate state, or it may mean breaking away from one state and joining another.

Stanley Lieberson (1972) has stressed that an ethnic group has the possibility of reducing or eliminating any disadvantage it may suffer, by opting for political separation. As he points, out such a strategy is not available to other disadvantaged groups in a stratified society (for instance those disadvantaged on grounds of gender, age or economic position). Thus, as Lieberson outlines it, the most fundamental difference between ethnic and other forms of stratification lies in the fact that the former is nearly always the basis for the internal disintegration of the existing boundaries of the state. Since the objective is most likely to be the formation of a new state, the best way to describe such secessionist groups is to refer to them as 'ethnonationalists.' Such attempts at the disruption of existing states will not be greeted favorably by existing governments. Thus secession is likely to be pursued and to be resisted by the use of violence.

Interstate ethnic conflict also manifests itself through the roles of 'external national homelands' (Brubacker 1996) and ethnic diasporas. With the former a state may feel an obligation towards its fellow ethnics in one or more other states. This obligation may translate into attempts to influence those other states' policies towards the homeland state's co-ethnics, or to the offering of immigration and citizenship privileges for returning members of the ethnic diaspora. Involvement, however, may extend to irredentist claims. Ethnic diasporas, on the other hand, may express concerns about circumstances in their original (real or mythical) home countries. In this case elements in the diaspora communities will press their 'own' government to adopt policies that are perceived to be advantageous to fellow ethnics in the 'old country' or ethnic homeland. Irish Americans vis-à-vis Ireland, Jewish Americans vis-à-vis Israel and Arab Americans vis-à-vis Palestine are clear instances of this. Indeed some of these groups may well adopt stances that are more extreme that those taken by their fellow ethnics 'back home,' or as Samuel P. Huntington has put it, they may be 'more Catholic than the Pope' (Huntington 1997). He also observes that diaspora communities become particularly active in the age of electronic communication: 'the commitments of diasporas are reinvigorated and sometimes polarized by constant contact with their former homes.'

Ethnic conflict at the interstate level is also evident in what Samuel Huntington labels 'fault line wars.' While these wars erupt at the interfaces between 'civilizations' (labeled by Huntington 'Western,' Islamic,' African' etc.), they frequently involve localized ethnic groups, acting, as it were, as the standard bearers of their respective global-scale groupings. Of course, some of these fault-line wars occur at the intrastate level. In either case they are struggles for control of people and of territory.

Population transfers play a significant role in many interstate ethnic conflicts. If borders cannot be adjusted, peoples may be 'adjusted' instead. Sometimes the ethnic territories are 'purified' by agreement, as with the transfer of Greeks and Turks in the early 1920s. Frequently, however, transfers are achieved by expulsion or—the ultimate savagery—by genocide. Finally, it can be noted that some transfers are associated with what John McGarry (1998) calls 'demographic engineering' on the part of states. Here 'agents' may be moved in, being populations allotted special roles on behalf of the state concerned; on the other hand some groups perceived as 'enemies' may be moved out, enemies being defined as groups whose present locations pose problems for the authorities and an obstacle to their goals (these goals generally being ones of territorial control). As with all types of population transfer, these movements can occur both within and between states.

1.2 Ethnic Conflict at the Intrastate Scale

Gurr and Harff (1994), in their book on ethnic conflict in world politics place ethnic groups into four categories—ethnonationalists, indigenous peoples, communal contenders and ethnoclasses. Ethnonationalists are relatively large and regionally concentrated ethnic groups, which live within the boundaries of a single state or straddle several adjacent ones. They are likely to be seeking a greater degree of autonomy or even independent statehood. Indigenous peoples may also be seeking some degree of autonomy, but are particularly concerned about the discrimination and exploitation experienced at the hands of the more technologically advanced peoples who, by and large, control them. Communal contenders, unlike ethnonationalists, do not seek separation or secession, rather, they seek to share power in the governance of the state they reside in.

As with communal contenders, ethnoclasses seek equality. Unlike them, however, they are usually spatially dispersed, rarely having a well-defined territorial base (for example, where ethnic entrepreneurs operate in specialized, spatially dispersed economic niches). Consequently, in their case, strategies aimed

at secession from the existing state or at seeking some degree of autonomy within it are not relevant.

Thus, while some ethnic group conflicts impinge at the inter-state level, many are contained within the one state and do not spill over 'international' boundaries. The roles played by dominant groups in these situations are crucial—they set the context for the other ethnic groups present. What Hennayake (1992) calls majority ethnonationalism can generate a reaction in a situation he refers to as interactive ethnonationalism. In a similar vein Brubacker (1996) writes of 'nationalizing states' where dominant elites promote the language, culture, demographic position, economic flourishing or political hegemony of their own group, creating an environment disadvantageous to the cultural aspirations and material interests of the other ethnic groups present within the state. Indeed here issues of inclusion and exclusion are met, seen at their most general in the distinction between 'civic' and 'ethnic' nationalism. With the former, the nation is ethnically inclusive of all those who subscribe to the nation's political creed. With the latter the claim is made that an individual's deepest attachments are inherited, not chosen (Ignatieff 1993). National identity is defined by ethnic identity—*ein Volk*: *ein Staat*.

The maintenance of political and social cohesion in multi-ethnic states will be possible under three contrasting circumstances: first, where we find civic nationalism to be dominant, second, where one ethnic group is dominant and third, where an external power exerts hegemony. This latter situation has been particularly prevalent where imperial powers have operated—from the British, French, German, Austro-Hungarian and the Russian empires of the nineteenth and early twentieth centuries to what Michael Ignatieff (1993) refers to as the Soviet and American joint imperium after World War II. However with the collapse of all but one of these, the lid of the pressure cooker has been lifted and apparently solid states have fragmented (the Soviet Union and Yugoslavia being the most notable instances). This has led to the (re-) emergence of previously suppressed or slumbering ethnic groups. Such a reawakening has threatened the fabrics of many states, generating movements that call for varying degrees of separation (from secession to regional autonomy).

Ethnic struggles at the intrastate level, from time to time, have been characterized both by what may be called 'census wars' and by 'symbolic strife.' With reference to the former Donald Horowitz (1985) has coined the phrase 'winning the census'—here there are concerns about existing (ethnic) demographic balances and future trends. As he puts it 'numbers are an indicator of whose country it is.' Census watching becomes an obsession; arguments occur regarding the accuracy of census enumerations, and in some cases ethnic numeral balances are so sensitive that the census is abandoned (as happened, for instance, in Lebanon).

Matters of symbolism also take on a huge importance in states with internal ethnic conflict. Raymond Breton (1984) argues that the symbolic order is a key component in constructing and maintaining a collective entity. A dominant ethnic group will attempt to impose its symbolic order on the state—flags, official language, anthems, etc. Other ethnic groups may resist this process, with the consequence that many symbols become contested and contribute to disunity. Ethnonationally contested spaces, in particular, are notable for their symbolic discensus. Of course symbols may well help create unity within a particular ethnic group, but in terms of inter-ethnic relations they divide.

Within-state ethnic conflict may arise between indigenous or well-rooted populations, on the one hand, and recent, less well-rooted immigrants on the other. If the immigrant flow is overwhelming (numerically or technologically) the indigenous ethnic group(s) will find themselves marginalized (as was the case in North America). However many immigrant flows have to accommodate themselves to the pre-existing social and political environment. In this case, conflict will be over equality of treatment—the immigrant will not expect (or presumably wish) to take over the state that receives them.

1.3 Ethnic Conflict at the Micro-scale

Ethnic conflict gains its greatest intensity at the small scale—here individuals and small groups interface with each other as part of the daily round. Rural, relatively low population density environments can experience intense conflict (as well as day-to-day coexistence), but it is usually in the urban, big city environments that ethnic antagonisms can achieve a peculiarly focused, 'molecular' nastiness.

In the urban context, foreign origin migrants attempt to establish themselves as do those from within the state, some of which may also have their origins in ethnically differentiated regions. While conflict is not necessarily an inevitable outcome, it is of frequent occurrence, as the migrants compete with each other and with the receiving society for scarce resources of housing, employment, educational opportunities and so on. In these circumstances many ethnic newcomers experience a degree of residential segregation, part based on the wishes of the immigrant and migrant ethnics themselves, part based on the somewhat hostile response of those who see themselves as the 'hosts.'

From a bottom-up perspective, ethnic groups may be seen to cluster together residentially for reasons of physical defense, from a wish to distance themselves from the embarrassment of contact with ethnocentric others, and, indeed from a wish to have a base for organizing politically and thereby gaining a say in the decision making in the wider society through judicious use of the electoral system. In the more extreme

conflict environments, the segregated residential cluster can provide a base for organizing physical attack against a wider society that is seen to be oppressive. This is where the urban guerrilla is most likely to thrive. Finally segregation can provide a context for cultural preservation, one where the ethnic culture can be tended and, indeed, transmitted to future generations. Some of this clustering is for very positive reasons, but conflict can also be a key generating factor (Boal 1987).

From the viewpoint of the encompassing society, segregation also has its merits—it provides a means of containing 'alien' populations, it insulates host culture from what may be perceived as undesirable influences, it provides a means of manipulating and minimizing the electoral impact of the immigrant ethnics and, at the extreme, it sets up the ethnic clusters as readily definable targets for attack. Beyond the urban scale, Nurit Kliot (1986) refers to intermingled ethnic clusters in Lebanon as 'hostage situations.' The same situation can apply at the urban scale.

Much ethnic conflict at the urban scale is relatively low key, entailing competition for access to the resources of everyday life and frictions over cultural matters. However, some cities become cockpits of ethnonational strife. In this situation, local conflicts and competition become embroiled in issues of sovereignty, and are thereby greatly intensified. Meron Benvenisti (see Bollens 2000) has labeled such cities 'polarized,' while Joël Kotek (1999) has applied the term 'frontier'. According to him, frontier cities are above all disputed places because they are subject to contradictory and opposing sovereignty claims. For Kotek, a frontier city is 'a territory for two dreams.'

The urban encapsulation of ethnonational conflict may be seen as the city merely mirroring wider conflicts over sovereignty, secession, irredentist claims and desires for regional autonomy. More accurately, cities displaying ethnonational encapsulation are, in reality, actually key players in the conflicts in their own right. Examples, such as Jerusalem, Belfast, Brussels, Montreal, Nicosia and Sarajevo make the point. Indeed some of these cities are the epicenters of the wider conflict and are the focus of particularly intense ethnonational disputation. Jerusalem stands out in this regard.

2. *Conflict Regulation and Resolution*

Solutions to ethnic conflicts can take a number of forms—territorial approaches, dominance approaches and mutuality approaches. Territorial solutions entail actions that increase the ethnic homogeneity of specified territorial spaces. The most extreme approaches involve the removal—by genocide or by forced population transfer—of one or more ethnic groups, producing what might be called 'purified' spaces. More acceptably, territorial approaches can involve the creation of separate states for each ethnonational group (partition or secession), or for cantonal or federal arrangements within the one state. Of course processes of integration/assimilation can also remove difference within a given state. If these occur by consent, then inter-ethnic relations are likely to be positive; if they occur in a coercive manner the consequences will be alienation and the consequent storing up of future conflict.

Dominance is where hegemonic control is exerted by the most powerful group present in a multi-ethnic environment. It is unlikely to provide a long term solution to inter-ethnic conflict—rather it suppresses it, leading to a situation where one is likely to find reluctantly acquiescent ethnic minorities at best, considerable alienation at worst.

Mutuality is where ethnic groups in conflict reach a point where they are prepared to enter into a process of mutual recognition and acceptance. Consociational/power sharing arrangements within the state will be the outcome. In this situation we would find what has earlier been referred to as civic nationalism. Space is shared in a process of mutual accommodation (see discussions in O'Leary and McGarry 1995 and in Boal 1999).

Ethnic Conflicts

1. What is Ethnic?

Ethnicity is ancient and ubiquitous, and commentaries on ethnic differences have been highly variable over time and place. The term has been used variously to signify 'nation,' 'race,' 'religion,' or 'people,' but the central generic meaning is that of collective cultural distinctiveness. For the present we shall avoid the popular but awkward and potentially misleading 'ethnic group' in favor of the more convenient term ethny. An ethny here is a culturally distinctive collectivity, larger than a kinship unit, whose members claim a common origin or descent. The prototype is a local endogamous population sharing cultural traits that differentiate it from other collectivities. From such groupings, more extended ethnies develop by nepotism, extended endogamy, fictive kinship, descent myths, political enclosures, economic linkages, and territorial expansion. For modern large-scale ethnies the 'symbolic' boundaries can be quite vague and elastic but the essential retained qualities are ascribed membership (by birth) and cultural identity (cf. Williams 1994, pp. 52–3, 57–8).

An elementary but critical distinction, often ignored in scholarly discussions, is that ethnicity can refer either to boundary-markers—an ethny's distinctive culture or lines of social closure—or to the content of the issues (or 'stakes') in ethnic confrontations. Thus, an 'ethnic conflict' can mean that two or more distinctive ethnies are fighting to control scarce resources (oil, gold, timber, diamonds, water, land, fishing grounds). The contenders are ethnic but the stakes are not. But in other cases, the objects of rivalry or violent conflict are themselves ethnic: language use, religious practices, marriage customs, domestic law, ceremonies and holidays, and so on. Especially likely to lead to severe conflict are situations in which rigidly-bound ethnies are rivals for political control of centralized states. Many so-called ethnic conflicts are struggles over non-ethnic goods, but genuine 'conflicts of identity' are those in which boundaries are rigid and salient and the objects of contention are cultural.

Much scholarly disputation has centered upon whether ethnicity is primordial or instrumental. Primordial ethnicity is seen as closely tied to kinship and descent, rigidly bound, enduring, emotionally charged. Instrumental (situational) ethnicity is thought to be ambiguous, changeable, driven by considerations of advantage or disadvantage in the pursuit of immediate interests. Indeed, it has long been recognized that ethnic boundaries are often permeable and changeable—because of territorial intermingling, continuous variations in cultural traits, interethnic interactions, intraethnic diversity, and state interventions (Levine and Campbell 1972, Chap. 7). But the inclusive reality is that ethnies are both primordial and circumstantial—some are fluid, others rigid; some endure over centuries, others are short-lived. Over the long run, much change can be observed. But in the short run, of one lifetime or a few generations, strong ethnic boundaries are often associated with great inequalities of social, economic, and political status, with strongly felt grievances, and with passionate commitments, solidarities, and conflicts. Today's world of vast migrations and rapid economic and political changes often results in change and merging of ethnies, and individuals frequently have multiple ethnic identities. Nevertheless, there is no prospect that ethnicity will disappear: it might be said, to paraphrase V. Pareto that those who seek to totally abolish ethnicity are engaged in cutting holes in the water. Because membership is an ascribed status, intra-ethnic relations tend to be diffuse and particularistic; for the same reason ethnic politics tends to be exclusivistic. While ethnies thus look backward into origins and history, they also look sidewise to persons who share in communal distinctiveness, and forward into a future of shared fate.

Struggles over definitions in this field have a long and complex history. Because the objects of interest are inherently complex, the search for the One True Definition will obviously fail.

This consideration also applies to definitions of our other key term, conflict, which is loosely used in ordinary discourse. In the present review conflict refers to social behavior, not to psychological processes or cultural contradictions; it consists of a struggle in which an opponent seeks to neutralize, defeat, injure, or eliminate another. It is not synonymous with competition, regulated contestation or rivalry. In particular, the distinctive character of violent conflict

must be recognized. Violence is a qualitatively distinct form of conflict (Williams 1994, p. 54, Brubaker and Laitin 1998, p. 426).

2. Recent Changes in Research and Theories

In the first decades after World War II, as overly simple theories of innate racial differences were discredited, the dominant explanations of ethnic conflict focused upon prejudice and discrimination—first in terms of individual personality and then as features of social location and of institutional norms and practices. Later research emphasized macrosocial factors and conditions, including state structures and policies as well as interstate relations.

For understandable reasons, much research on ethnicity until recently focused upon domestic (national) populations and truly comparative studies were few. Accordingly, many theories have been concerned with intra-societal processes such as economic competition, internal colonialism, labor markets, assimilation, and prejudice and discrimination. Overlapping in time, however, and increasingly prominent have been historical and comparative studies: of ethnic nationalism and conflict, of multiethnic societies, of international linkages and interventions, and of democide and genocide.

As attention has been drawn increasingly to worldwide perspectives, earlier preoccupations with psychological factors and anthropological case studies have receded in favor of systematic comparison and statistical analyses of large data-sets. Frequent and severe ethnic warfare and large-scale immigration and flows of refugees from political repression and civil wars have stimulated both types of research. Since the 1960s, the increasing use of multivariate statistical modeling of large data-sets has produced many substantial empirical generalizations. The worldwide compilation of data by Gurr (1993) indicates that contention among ethnies for control of central states is the most deadly form of communal conflict—even more so than ethnonationalist movements or the struggles of indigenous peoples. Analysis of many protests and violent mass actions in the former Soviet Union during 1965–89, showed that nonviolent protests tended to come from mobilization of well-educated urban populations having substantial organizational resources (Beissinger 1992). Protracted ethnic civil wars cluster in weak but repressive states in the Third World and in the peripheries of industrialized countries. Numerous comparative studies show that ethnic conflicts are more severe in autocratic than democratic states; democracies have more numerous but less deadly protests. An exhaustive compilation and analysis of available records show that genocides and democides are greatest in non-democratic polities (Rummel 1994, see Horowitz 1997, Johassohn and Bjorson 1998).

The most recent research has recognized the severe limitations of case studies and of static correlational analyses, as well as the hazards of simplified 'one-factor' theorizing. There is increased emphasis on multivariate studies and upon the timing and sequence of relevant events and conditions. Correspondingly, more studies are using the techniques of event history analysis, qualitative comparative analysis, and ingenious combinations of narrative accounting together with newer statistical techniques. Comparisons are increasingly regarded as essential to reliable generalizations across time and societal contexts. There is renewed emphasis upon the need for disaggregation of data along with the equally urgent specification of concepts to identify the different types of states, of kinds of ethnicity, of opposition and competition and rivalry, of grievances, of the diverse types of conflict and of violence, of processes of mobilization and de-mobilization. Particular attention is now directed to the ways in which ethnic relations are affected by new transnational processes.

3. Characteristics of Violent Ethnic Conflict

Just as ethnies are diverse, so are the forms of ethnic conflict. The main types are: turmoil, internal war, democide and genocide. Turmoil includes strikes, demonstrations, mutinies, sabotage, rioting, and terrorism. Internal war involves armed collective violence as in *coups d'etat*, separatist rebellions, civil or guerrilla wars, and revolutions. Democides are state-organized or incited mass killings of political opponents and dissidents; genocides are organized efforts to destroy a whole cultural, religious, or racial population (Rummel 1994). These types represent different combinations of: (a) the extent of mass mobilization; (b) the degree of centralized organization and control; and (c) the amounts and kinds of violence. Usually turmoil is low on all three conditions; revolutions involve maximal levels of all; democides and genocides maximize the slaughter of unarmed civilians. Although ethnic wars may not be more difficult to terminate than other civil wars (Licklider 1993), the ethnic factor tends to create perceptions of total and irreversible threat and thus to encourage extraordinary ferocity and brutality, as attested by the frequent observation of torture and mutilation of victims (Liberia, Sierra Leone, Rwanda, Kosovo, Sri Lanka). In any case, once violent conflicts are under way, they develop their own dynamics—attracting opportunists, creating desires for revenge, shifting alliances and balances of forces, transforming issues. Initial conditions may not predict outcomes, and limited conflicts that are easy to start can escalate into protracted warfare.

Complexity and fragmentation frequently characterize ethnic and regional partisans. A clear example is presented by Basque nationalist movements, which were criss-crossed by class, rural-urban, linguistic,

religious, and ideological cleavages so that they were both 'complex and paradoxical' (Shafir 1995, p. 102); even the small militant underground organization, ETA, itself experienced repeated schisms. In Sri Lanka, the Tamil resistance to the central state repeatedly divided into opposing factions (Tambiah 1986). In the southern rebellion against the Sudanese government, tribal and local allegiances as well as ideological differences have plagued the movement and its armed forces. In Liberia, state collapse resulted from factional civil warfare, and in Somalia a central state splintered into clan fighting.

In the scholarly literature, there is a growing emphasis on the distinctive characteristics of violence over nonviolent forms of opposition and protest (Williams 1994, p. 62, Tambiah 1996, p. 292, Brubaker and Laitin 1998, pp. 426–7). Indeed Brubaker and Laitin contend that the study of violence should be treated as an autonomous phenomenon in its own right (1998, p. 426). Nevertheless, a rich store of case studies provide instructive data, as in the growing literature on Rwanda and Burundi.

4. *Sources of Ethnic Conflict*

Around the world at the close of the twentieth century ethnic-related conflicts were frequent and deadly; nearly all wars in the 1990s were intra-state and most of these involved ethnic cleavages. How are these remarkable facts to be explained?

Some popular interpretations are not convincing. Collective ethnic violence is not primarily due to 'modernization' (urbanization, commercialization, industrialization): some of the most lethal ethnic-related conflicts have been in less modernized countries such as Rwanda, Burundi, Sudan, and Zaire. Nor is the partial end of the Cold War, allegedly 'unleashing' suppressed ethnic antagonisms, a satisfactory account; the superpowers actually exacerbated many ethnic confrontations and the upsurge in ethnic conflicts began in the 1950s and 1960s, long before the diminution in superpower rivalries. Furthermore, scepticism is warranted of the notion that the rise of ethnic warfare results from the release of so-called ancient hatreds. Long-ago, wrongs are effective instigators of today's conflicts only when reactivated and politicized, often as the product of elites' manipulation (Gagnon 1994, 1995). Of course, the deadly effects would not occur unless there were some ethnic identities and allegiances to which political appeals could be made. But peaceable neighbors do not suddenly attack one another merely because their ancestors once fought. Such 'general laws' as that people tend to more often favor others when the others are fellow ethnies than when they are not, tells us little about specific cases in which a wide variety of other conditions may be involved. So generalized propositions about how initial conditions of disadvantage and discrimination can lead to group-level grievances still leave us searching for additional and/or intervening conditions that convert discomfort into collective grievances. Undoubtedly sociobiological characteristics (including propensities for group formation and conformity) constitute a fundamental substratum for ethnic solidarities and conflicts (van den Berghe 1981). Likewise, resource scarcity with the frequent accompaniment of incompatible claims (to water, land, any other resources) must always be taken into account.

But more specific and more proximate conditions and dynamic processes provide the more convincing explanations for the numerous violent ethnic confrontations we now observe. For example, a theoretically significant observation is that severe ethnic conflicts are most common in recently independent states that were formerly colonies of major powers or are successor states resulting from the disintegration of multiethnic polities. These countries typically are multiethnic, relatively poor, with weak but repressive states. Under these conditions, the state is a main source of wealth and prestige and rivalry for political control is likely to be intense while ethnic membership frequently is crucial in political contention. Economic scarcity and social pluralism thus combine with state centrality to encourage communal politics. Because the stakes are high and the outcomes are seen as irreversible, resorting to violence is tempting. In the great majority of such severe conflicts, lack of a common civic culture and of positive inter-ethnic interdependence, combined with struggles for control of the state, create intense threats and countermobilizations. Ethnicity is rendered highly salient and provides an attractive base for political entrepreneurs. A common result is that ethnic rivals come to see each other as rigid groupings and membership as crucial to all life-chances. Every move in that direction escalates and polarizes. Not surprisingly, then, conflicts among communal contenders for power are much more deadly than conflicts involving ethnonationalists or indigenous peoples (Gurr 1993, pp. 98–9). State expansion and impositions upon ethnies are likely in rentier states in which governing elites have sources of income independent of the potential electorate, as in Nigeria and the former Zaire. In collapsed states—as in Lebanon, Somalia, or Liberia—central authorities lose control over contenders for power and multiple-armed struggles result. Partisan external support to states and rebels often has prolonged and intensified ongoing ethnic-related violent conflicts.

In Gurr's formulation (1993), the main factors favoring conflict include strong identity, inequalities and grievances, political opportunity structures allowing mobilization, provocative state policies, and international contagion and diffusion. Many of the ethnic conflicts reviewed by Esman (1994), Gurr (1993), and Horowitz (1985) develop into protracted warfare because one party believes that another seeks total and irreversible domination: 'they will enslave

our children and our children's children,' 'they intend to kill us all.' Diverse case studies, from Northern Ireland, to Sri Lanka, to Lebanon, to Rwanda, and others have emphasized that fear of extinction is far more common in protracted ethnic conflicts than previously recognized. In a drastic oversimplification, it can be said that the most dangerous situations cluster in multiethnic societies governed by centralized but weak and repressive states that fail to provide voice or autonomy to aggrieved ethnic and regional dissidents. Thus, strongly-bound and relatively large ethnies seek control in political systems that do not favor compromise and power-sharing. Particularly explosive are: (a) situations of lost autonomy in unstable polities; (b) abrupt impositions of cultural and economic deprivations by a dominant ethnic state, (c) intrastate conflicts attracting partisan external interventions.

5. *Why is There Not More Ethnic Conflict?*

At any given time only a small percentage of ethnies are politically mobilized. (cf. Levinson 1991–96, Gurr 1993). Of all ethnic disputes, only a small percentage result in collective violence and even fewer in civil war. Most of the world's ethnies are not fighting each other or other states within which they reside. Of the some 1600 major cultural groupings, less than 300 have recently mobilized in politicized protest or rebellion and only some 30–40 wars are ongoing in a particular year. To explain the impressive record of peaceful coexistence, of mutual accommodation, and even of active cooperation must be the task of future research and theory-building. Nevertheless some general observations even now seem justified. First, the reverse of the factors here adduced to help account for conflict can aid our understanding of ethnic peace. For example, we should look for relatively 'open' political systems with non-ethnic parties, lack of imposed segregation and discrimination, relatively equitable distribution of opportunities and rewards, and the presence of an array of conflict-resolution devices and arrangements.

The most obvious circumstance accounting for the failure of ethnies to mobilize for conflict is their members' relative satisfaction with or accommodation to the status quo. If ethnic identity carries with it no acute grievances or severe threats, there is little incentive to disturb existing relationships. This is an important but banal and intellectually uninteresting case. A second case is more provocative: ethnies that have deep grievances but do not rise up in conflict. Often their conflict potential is negated by weakness: lack of resources, internal dissension and social fragmentation, lack of a committed elite, small size, and geographic dispersion. (It must be noted, however, that weakness is a relative matter and some apparently weak ethnies do attack much stronger opponents.) A third factor may be labeled simply as fear—fear of the consequences of protest or rebellion. The apprehension may be that other ethnies will respond in oppositional and hostile ways, or that a repressive and ruthless state with abundant resources will severely punish a rebellious ethny. External aid, so often important, may be lacking or perceived as dangerously unreliable. For these and other reasons, even highly aggrieved ethnies may avoid the more violent forms of protest. To more fully understand the necessary and sufficient conditions for ethnic peace and cooperation clearly requires additional fine-grained analyses of the many specific cases that now exist. Meanwhile the evidence and analyses that are rapidly accumulating provide favorable prospects for advances in knowledge in this crucial field of deep human concerns.

Ethnic Conflicts and Ancient Hatreds: Cultural Concerns

The view that ethnic conflicts today can be traced back to ancient group hatreds is known as essentialism, sometimes also called 'primordialism.' It is very popular in nonscholarly circles, but has very few proponents in the scholarly world.

Essentialism relies on two interconnected arguments, sometimes made together. It refers to 'primordial' or 'ancient animosities' as a cause of contemporary conflict. The animosities are said to be based on inherent differences of race, religion, or culture, going back into ancient times; and it is further contended that individuals acquire the characteristics of their races, religions, or cultures. A second essentialist argument is that ethnicity inheres in human beings, meaning that all of us inevitably search for, or can easily be made to care for, our ancestry and blood. Either way, conflict results, for a rational calculus is superseded by the emotional ties of blood, or by ancient hatreds. Human beings live out not only the positive attributes of the collectivity to which they belong, but also its prejudices with respect to other groups. Again and again in history, intrinsic group differences activate prejudices and trigger violence.

More than any other view discussed below, this perspective dominates the portrayals of ethnic conflict in newspapers and magazines. Almost any popular account of conflict between Hindus and Muslims, Serbs and Croats, Arabs and Jews, Whites and Blacks, Catholics and Protestants, Hutu and Tutsi is marked by phrases such as 'old animosities,' 'tribalism,' and 'ties of blood' (Kaplan 1993). In the academic world, too, this view has had its exponents. Clifford Geertz (1973) was among the first scholars after the Second World War to popularize the term 'primordialism.' More than Geertz, however, Walker Connor has been a leading and consistent advocate of the essentialist view. Man, argues Connor, is a 'national, not rational animal' (Connor 1994). So powerful is the search for origins in human beings that both Hitler and John Jay, says Connor, were driven to emphasize common ancestry to build their nations. 'Blood binds more firmly than business,' argued Adolph Hitler; and the Americans, contended John Jay, are 'a people descended from the same ancestors,' 'despite,' adds Connor, 'the presence of settlers of Dutch, French, German,.... Scottish and Irish extraction' on American soil in the eighteenth century.

Few academic scholars subscribe to the essentialist view today. On the whole, essentialism tends *not* to make a distinction between ethnic (or national) identity on the one hand and ethnic (or national) conflict on the other. Though it is a problem not confined to essentialism alone, as explained below, essentialists do tend to conflate the two. It may well be that for building community feelings, leaders tend to, or have to, emphasize ancestry. Conflict, however, does not necessarily follow. It is one thing to call up an imagined common ancestry *across* ethnic groups, in which case the attempt would be to build bridges. John Jay's example above would illustrate a bridge-building invocation of an assumed ancestral commonality. It is, however, something quite different to summon the common ties of blood explicitly against an ethnically distinguishable group, in which case the result could well be ethnic hatred and violence. Hitler's attempt would clearly belong to the latter category, not the former.

That both John Jay and Hitler had to invoke common ancestry implies neither that man is a national animal, nor that he is a rational agent—he could be both. Nor do such attempts inevitably reignite ancient animosities. Ethnic, or national, identity can well be a source of meaning and security, without implying hatred for another ethnic or national group. These two aspects of ethnic or national identity—positive and negative—are by now well understood and clearly distinguished (Taylor 1997).

Those who came to be known as 'instrumentalists' launched the first systematic attack on the essentialist view. Indeed, going back to the late 1960s and 1970s, 'essentialism vs. instrumentalism' was the first big theoretical axis around which scholars sought to formulate their views and understand the virulence of ethnic animosities and violence (Young 1995). The key proposition of instrumentalism rests on the purely instrumental use of ethnic identity for political or economic purposes by the elite, regardless of whether the elite themselves believe in ethnicity (Hardin

1995).The two views are presented as being fundamentally at odds; one focuses on the intrinsic power of ethnic differences, the other concentrates on their instrumental value, political or economic.

The emphasis of on how leaders strategically manipulate ethnicity for the sake of power has an intuitive appeal because the behavior of many, if not all, political leaders can be cited in support. But this view also runs up against a fundamental difficulty. The elite may indeed gain power by mobilizing ethnic identity, without actually believing in it, and may therefore behave instrumentally. But if the masses were only instrumental about ethnic identity, why would ethnicity be the basis for mobilization at all? Why do the leaders decide to mobilize ethnic passions in the first place? Why do they think that ethnicity is the route to power, not the economic interests of the people? And if economic interests coincide with ethnicity, why choose ethnicity as opposed to economic interests as a central symbol for mobilization?

In principle, an instrumental resolution of these problems exists. Ethnicity can serve as a 'focal point,' which is defined as set of symbols so obvious, unique and easily comprehensible by the members of a group that it can facilitate convergence of individual expectations, and hence be useful as a mobilization strategy. The idea of 'focal points' comes from Schelling's seminal treatment of the coordination problem in bargaining. In the famous Schelling example:

> When a man loses his wife in a department store without any prior understanding on where to meet if they get separated, the chances are good that they will find each other. It is likely that each will think of some obvious place to meet, so obvious that each will be sure that the other is sure that it is obvious to both of them (Schelling 1963).

Ethnicity, in other words, can be viewed as one such focal point for mobilization; it is not valued for its own sake. Its potential for mobilization may be deployed to extract goods and services from the modern sector, or to establish power, by some leaders (Bates 1974).

However, the idea of a 'focal point' is also not sufficient to explain ethnic mobilization, for it does not distinguish between different kinds of collective action and what their respective costs might be. Ethnic *mobilization* for political action is not the same as ethnic *coordination* for economic and social activities. By providing a social occasion, festivals may indeed bring people together even if not every one appreciates the ritual meaning of celebration or mourning; and by forming mutually converging trust, geographically spread ethnic kinsmen are also known to have supplied credit in long-distance trade without a prior explicit contract between trading partners.

But the analogy of a focal point cannot be extended to group action when the costs of participation for the masses are very high. By its very nature, ethnic mobilization in politics is group action not only in favor of one's group *but also often against some other group*. An increase in the rights and power for one group often means a diminution in the ability of some other group(s) to dictate terms, or a sharing of power and status between groups, where no such sharing earlier existed. Ethnicity in intragroup, social or economic transactions is thus very different from ethnicity in intergroup political conflicts. The former illustrates the value of ethnicity as a focal point; the latter presents problems of a different order. When an individual provides credit to ethnic brethren without an explicit contract, incarceration, injury, or even death is not the likely cost he bears in mind. Such costs are not unlikely in ethnic or national conflicts. For something to be manipulated by a leader when death, injury, or incarceration is a clear possibility, it must be valued as a good by a critical mass of people, if not by all (Horowitz 1985). A purely instrumental conception of ethnicity cannot explain why ethnic identities are mobilized by leaders at all (Elster 1988).

Does this mean that essentialism is right after all about the primordial character of hatreds. Do such hatreds indeed play an important role in contemporary ethnic conflicts? Are there any other approaches to answering this question beyond essentialism and instrumentalism?

Since the mid-1980s to early 1990s, the study of ethnicity has been profoundly influenced by constructivism (Varshney 1997). Part of the constructivist inspiration has come from postmodernism, but postmodernists are not the only constructivists. At varying levels, scholars as diverse and 'unpostmodern' as Eric Hobsbawm and Ranger (1983), Linda Colley (1992), and Benedict Anderson (1983) have shared the constructivist view, and demonstrated how so many identities that we take for granted today were quite recently constructed in history.

The central claim of constructivism is that the formation of ethnic or national identities is a modern phenomenon. Does this claim by any chance imply that there were no Hindus, Muslims, Jews, Christians, Tibetans, and Han Chinese in premodern times?

Such a claim would obviously be quite absurd, and that is not the constructivist contention either. The claim simply is that identities in premodern times tended on the whole to be face-to-face and operated on a small scale. Ordinary people rarely interacted beyond their local environments. Conflict, when it emerged, was managed locally and identities were considerably flexible. Extralocal communities did not include 'the people'; such larger communities consisted primarily of the ecclesiastical elite and the court-based aristocracy and nobility.

Modernity changed the meaning of identities by bringing the masses into a larger, extralocal, framework of consciousness. It made identities and communities wider and more institutionalized. In what has become a classic constructivist argument, Colley shows how shared Protestantism, opposition to

France, and the benefits of empire managed to dissolve the bitter historical disputes between the Scots and the English, and led to the construction of a British identity in the eighteenth and nineteenth centuries. In Benedict Anderson's *Imagined Communities*, one of the most influential texts in the field today, the emphasis is on how modern technology and a modern economic system—the printing press and capitalism, to be more precise—made it possible to have imaginations about large, popular, and secular communities based on language, which overtook the premodern, extralocal, religious communities of the clergymen on the one hand and the aristocratic dynasties on the other.

The constructivist emphasis is on the construction of group categories by the knowledge-elite, its promotion by centers of power, and its effects on 'the people.' For example, the Census, a modern instrument of categorization, would typically ask the masses whether they were (a) Hindu, (b) Muslim, or (c) Christian, even if in their self-image the masses felt their culture borrowed from all three and their identities were an intersection of (a), (b), and (c). Fuzzy identities, even when real, were not registered as such and were instead split into lucid, modernist boundaries. Furthermore, if public policy, based on such census categorizations, allocated patronage, public office, or state grants, then the very act of census categorization would begin to create larger identities.

Such categorization, according to constructivists, was not innocent or scientific. The power elite created some categories, not others. The selectivity was based on their preconceptions of what the building blocks of a society were, or on a calculation of what divisions would maintain their power. Thus, only those narratives acquire staying power that get promoted by the elite.

On postcolonial societies, the principal constructivist claim is that the major contemporary ethnic cleavages were a creation of the colonial power and, given the immense power of colonial masters, such divisions have endured, and will last for a long time. Of course, the power of the colonial masters was not unlimited. They did require local alliances and the new categories were established with co-optation of the indigenous elite in the colonial framework of power. In a sense, thus, the argument is about the nature of the colonial *system*, not about the evil intentions of the colonial masters. 'Modern colonialism,' writes one of the best practitioners of the constructivist genre, 'instituted enduring hierarchies of subjects and knowledges—the colonizer and the colonized, the Occidental and the Oriental, the civilized and the primitive, the scientific and the superstitious, the developed and the underdeveloped. …(T)he colonial rulers enacted their authority by constituting the "native" as their inverse image…not because of the colonizer's bad faith but due to the functioning of colonial power…' (Prakash 1994).

Let us take a concrete example of this abstract claim. On India's Hindu–Muslim conflict, constructivists argue, there is no universally acceptable theory about the origins, rise, and spread of Hindu–Muslim antagonisms; rather, there have only been 'discourses' or 'narratives.' In the hands of the British, a primordial antagonism between Hindus and Muslims dating back centuries became the 'master narrative,' even though there was enough evidence of Hindu–Muslim coexistence. Primordial antagonism was not the 'truth' about Hindus and Muslims. It was constructed and promoted as such by the British, partly because it suited them to split India into its two largest religious groups, and partly because the 'natives,' argued the British, could not constitute a 'modern' nation—they could think only in terms of premodern religious communities. Hindus and Muslims may have existed before the British came to India, but being a Hindu or Muslim did not refer to large, political identities. It only signified small, personal, and village-based cultural identities.

In what ways are these arguments a challenge to essentialism? Do they advance our understanding of ethnicity or ethnic conflict? What might their pitfalls be?

To explain the contemporary power of ethnic cleavages, essentialism either referred to old animosities or to the pull of ancestry. It was unable to see how the episodes suggesting old animosities might have been selectively retrieved by the knowledge elite, ignoring the many instances of cooperation and coexistence. The argument, one might parenthetically note, is also different from instrumentalism. For instrumentalists, ethnicity is basically a mask for a core of interests, and as interests change, the masks also do. Constructivists show why some identities, striking roots in popular consciousness, endure and do not easily change. To call such identities a mask is to undervalue their endurance and not understand their historical roots. The fact that they are constructed does not mean that they are not *deeply* constructed. Identities do not often, or automatically, change as interests do.

Has constructivism won the battle of arguments, defeating essentialism (and instrumentalism)? There are significant unresolved problems in the constructivist claim as well. After all, the basic constructivist argument for ethnic conflict in developing countries is that the colonially created master narratives, emphasizing cleavages between communities, led to conflict. The explanation provided for the formation of ethnic *identity* is thus also extended to ethnic *conflict*. Whatever one may say about the constructivist explanation for modern identity-formation, its extension to conflict does not make sense.

To illustrate this point, let us return to the example of Hindu–Muslim conflict. Is Hindu–Muslim conflict ubiquitous in India, or is it concentrated in some pockets? One could also ask the question more

generally: does ethnic conflict tend to get evenly spread through the length and breadth of a country, or does it develop local or regional concentrations? If it is true that ethnic violence tends to be unevenly distributed and pockets of violence coexist with vast stretches of peace, then invoking the ubiquitous power of a system-wide, nationwide, master narrative as an explanatory device will not do. Either there are several master narratives in a country, one hegemonic in some regions, others powerful elsewhere; or some other, locally based, factors intervene between the potential power of narratives to cleave society and generate violence, and the actually observed patterns of violence. To the detriment of constructivism, it turns out that ethnic conflict indeed tends to be locally concentrated, not evenly geographically spread, even though ethnic identities may be ubiquitous. This is as true of India, as of the US, and Northern Ireland, countries with such remarkable divergences otherwise.

Essentialism thus may have lost out to other ways of looking at ethnic conflicts, especially its claim that contemporary ethnic conflict is based on ancient hatreds which the scholars of ethnicity simply don't find acceptable any more. But we should note that other alternatives are also riddled with some serious problems of evidence and explanation. It may be that as knowledge of ethnic consciousness evolves further, a new approach that somehow combines the strength of each approach and seeks to eliminate the weaknesses of each will come about. It is hard to tell what this syncretistic approach would look like.

Ethnic Groups/Ethnicity: Historical Aspects

1. Is 'Ethnicity' Ancient or Modern?

From one point of view, ethnic groups, and the conflicts between them, are as old as humankind. The ethnopsychiatrist Devereux (1975) therefore used examples from Homer, Herodotus, Sophocles, Plutarch, and Xenophon to the Bible to develop his conceptual approach to *Ethnic Identity: Its Logical Foundations and Its Dysfunctions*. Among a total of 56 groups on whose basis Devereux develops his theories are ancient Hebrews, Spartans, Sedang, Arunta, Mohave, Hipa, Yuma, and numerous examples from modern Europe, especially from the time of fascism.

From another vantage point, ethnic identity is a feature of modernization. The sociologist Glazer (1975), for example, noted in his essay on the *Universalization of Ethnicity* that while processes of modernization could be expected to weaken primordial ethnic identities, in fact, mass societies had created a new need for 'some kind of identity—smaller than the State, larger than the family, something akin to a 'familistic allegiance.' Hence the production of ethnic difference could be expected to intensify and increase under modern conditions.

What speaks for the first assumption is the impressive array of social conflicts involving differences in the sense of belonging and of group membership. There is also the history of the word 'ethnos' which goes back to antiquity and contains an interesting doubleness of standing for people in general as well as for people who are different from the speaker (the Greek *ethnikos* was a translation of Hebrew *goy*), making 'ethnos' available as a term of in-group self-description and of out-group ascription.

What speaks for the second assumption is the fact that in the modern period, with its intensified migration and urbanization processes, ethnic identifications could free themselves from all other moorings in the modern period, that ethnic identification has proliferated steadily and that, at the end of the twentieth century, it seems to have engulfed the whole globe. While the ancient Greek word 'ethnos' has remained the root of many related words (including 'ethnic'), the modern period has contributed a whole vocabulary for the perception and discussion of ethnic matters. The words include 'race' (which emerged in the context of the Spanish Inquisition) and the twentieth-century neologisms 'racism,' 'genocide,' 'ethnicity,' and 'identity.'

2. *Brief History of the Vocabulary of Ethnicity*

The word race, derived from Italian *razza*, Spanish and Castilian *raza*, and Portuguese *raca*, became widespread in the fifteenth and sixteenth centuries. An English example from 1570, referring to the 'race & stocke of Abraham,' supports Leo Spitzer's theory that the obscure ultimate roots of race may lie in the word 'generation.' Verena Stolcke has shown that the word 'race' could mean 'the succession of generations (*de raza en raza*) as well as all the members of a given generation.' In addition to the word's relation of 'generation,' in fifteenth century Spain *race* connoted 'quality' and 'nobility of blood' (an aristocratic sense) as well as 'taint' and 'contamination' (a meaning opposite to that of 'nobility'). Race in its negative sense appeared in the doctrine of purity of blood (*limpieza de sangre*), 'understood as the quality of having no admixture of the races of Moors, Jews, heretics, or *penitenciados* (those condemned by the Inquisition).' The more modern word race thus shared the ambiguity inherent in the ancient *ethnos*.

Twentieth-century fascists used the word racism (coined in analogy to other modern '-isms' such as communism) as a positive term to describe the importance they assigned to race. The term racism came into general use only in the 1930s, and it acquired its pejorative sense when it became associated with intellectual critiques of fascism. Hirschfeld's (1938) remarkable antifascist book *Racism* marked the turning point.

Another neologism to emerge in the period of the struggle against National Socialism was genocide, introduced by Lemkin (1944) in the book *Axis Rule in Occupied Europe*. Lemkin studied the new, eliminationist Nazi occupation policies (most especially toward Jews, but also toward other nationality groups in occupied countries) and found that these measures intended to destroy 'the essential foundations of the life of national groups, with the aim of annihilating the groups themselves.' The attacks on political and social institutions, on 'culture, language, national feelings, religion, and the economic existence of national groups' were steps toward the 'destruction of their personal security, liberty, health, dignity, and even the lives of the individuals belonging to such groups.' As examples of 'genocide legislation,' Lemkin reproduced the texts of numerous laws, including those that established German as the official language in Luxembourg, banned the Cyrillic alphabet in Croatia, and placed Kosovo under Albanian rule. Lemkin's coinage 'genocide' was disseminated widely when the United Nations adopted it in 1945 in an indictment of Nazi leaders for having 'conducted deliberate and systematic genocide—namely, the extermination of racial and national groups.'

The English word ethnicity was once recorded in 1772, in an obsolete instance where it denotes 'heathenish superstition.' In the sense in which we now use it, the word was revived only during World War II, at a time that race had become compromised by racism. Warner reintroduced 'ethnicity' as social category, parallel to sex, age, and religion, by which human beings can be differentiated from each other. In *The Social Life of a Modern Community*, co-authors Warner and Lunt (1941) argued that an 'individual was classified as belonging to a specific ethnic group if (a) he considered himself or was considered by the…community as a member of the group, and (b) if he participated in the activities of the group.' Warner and Lunt introduced the noun when they stressed that 'the concept of ethnicity is not based simply on place of birth.' Just like 'ethnos' and 'race,' 'ethnicity' was an ambiguous term. On the one hand, Warner's 'ethnicity' was an inclusive category, by which every inhabitant of a community could be classified. On the other hand, it could be a term that excluded dominant groups and refer to all inhabitants of the New England community he studied except 'the natives, or Yankees.' Warner used the word 'ethnicity' again in later publications; and Riesman (1953) employed it in an essay. However, the term became more popular only in the 1970s, especially when it was used in the titles of Glazer and Moynihan's (1975) collection *Ethnicity: Theory and Experience* and of Greeley's (1974) study *Ethnicity in the United States*.

The word 'ethnic' has been in circulation for a somewhat longer time. Going back to the noun ethnos, the word was used to refer not just to people in general, but to 'others.' In English usage, the meaning shifted from 'non-Israelite, Gentile' to 'non-Christian.' Thus, the word retained a quality of defining another people, and often negatively, as 'heathens.' Only in the mid-nineteenth century did the more familiar meaning of 'ethnic' as referring to a secular group of people emerge. However, the English language has retained the pagan memory of 'ethnic' in the sense of ethnic as 'other,' as 'nonstandard.' The *Oxford English Dictionary*, thus, traces three strands of meaning that coalesced in the modern sense of 'ethnic' (as in 'ethnic

group'): (a) 'pertaining to nations not Christian or Jewish; Gentile, heathen, pagan' (the oldest sense of the word, documented since the fifteenth century); (b) 'peculiar to a race or nation' (going back to mid-nineteenth-century uses in the sense of 'racial'); and (c) 'ethnic minority (group), a group of people differentiated from the rest of the community by racial origins or cultural background' (popular since World War II).

3. *Approaches to Ethnic Groups, Ethnic Identity, and Ethnicity: A Sampling*

The ethnic group became the subject of scholarly discussion with Weber's (1978) foundational definition in *Economy and Society* written before World War I and first published posthumously in 1922. Weber saw ethnic groups as 'those human groups that entertain a subjective belief in their common descent because of similarities of physical type or of customs or both, or because of memories of colonization and migration; this belief must be important for the propagation of group formation; conversely, it does not matter whether or not an objective blood relationship exists.' He emphasized the sense of commonality (*Gemeinsamkeit*, 'ethnic membership' in English translation) that does not in itself constitute a group but that 'facilitates group formation.' Weber offered a broad international perspective and discussed such ethnic groups as American Negroes, Serbs and Croats, German-speaking Alsatians, Poles in Prussian Upper Silesia, Baltic Germans, and French Canadians. Weber used 'racial' and 'ethnic' interchangeably and wrote that the 'question of whether conspicuous 'racial' differences are based on biological heredity or on tradition is usually of no importance as far as their effect on mutual attraction or repulsion is concerned. Weber also discussed ethnic groups under the term 'nationalities,' the word dominant in the period of World War I and the Versailles treaty.

In his focus on the 'subjective belief,' Weber's concept of the ethnic group implies a psychological component. When Sigmund Freud reflected on the subjective sense of belonging, he arrived at a formulation that was to lead to the coinage of another key term. In a 1926 B'nai Brith address, Freud wondered about his subjective sense of Jewishness—which was independent of religious faith or ethnic pride—and saw it as the result of what he called 'the secret familiarity of identical psychological construction' (*Heimlichkeit der gleichen inneren Konstruktion*). When Erikson (1950) attempted to translate Freud's phrase in *Childhood and Society*, he offered the term identity as an English equivalent for Freud's notion. As Gleason has shown, it was a word that took: for instance, Seligman and Johnson's (1930–1935) *Encyclopedia of the Social Sciences* still had no entry for identity and discussed fingerprinting techniques under 'identification,' whereas Sills's (1968) *International Encyclopedia of the Social Sciences* carried a substantial essay.

Simmel (1908) described an individual as defined by an always varying web of only partly overlapping, multiple group affiliations. He also focused on the figure of the 'stranger' who is 'near and far at the same time.' Simmel's stranger is 'the person who comes today and stays tomorrow' without ever becoming completely part of the group within which he lives. Simmel viewed the European Jew as the exemplary 'stranger.' Simmel's attention to multiple group memberships and to the special role of an outsider who is also an insider gave rise to a focus on marginality in the study of social structures and to the question how 'ethnicity' relates to other, simultaneously existing group affiliations?

In his essay '*Human Migration and the Marginal Man*,' Park (1928) applied Simmel to issues of migration. Park viewed marginality and the race-mixing as the rule and not the exception in human history, and saw the 'marginal man' as the ideal figure for the study of 'the processes of civilization and of progress.' The marginal man thus became a key figure for an understanding of modernity, urbanism, and cosmopolitanism; and marginality and assimilation became central terms for the study of ethnicity.

In his often-cited book *Assimilation in American Life: The Role of Race, Religion, and National Origin*, Gordon (1964) outlined such pluralist and assimilationist concepts of ethnic integration as 'melting pot' (the term derived from Israel Zangwill's play of 1908), 'Anglo-conformity,' and 'pluralism' (the term the philosopher Horace M. Kallen adopted from William James and ethnicized). Others have added such terms as 'ethnogenesis' or 'ethnic differentiation' to Gordon's helpful array of terms.

Devereux (1975) took as his point of departure the question how ethnic identity can be related to other forms of identity. He emphasized what he called the 'dissociative' nature of ethnic behavior that was not actually prompted by past tradition but was informed by a contrastive and presentist strategy of opposition of one ethnic group against another. Ethnicity, seen this way, 'is logically and historically the product of the assertion that 'A is an X because he is not a Y'—a proposition which made it remarkably easy to identify and homogenize Xness, exaggerating the differences between the Xs and Ys. 'X does not equal Y' was thus the fundamental ethnic formula.

Writing after World War II, Devereux located the fascist potential of ethnic movements in this reduction of complex authentic identity to contrastive one-dimensionality in the name of ethnicity. 'Ethnicity' could demand that it overrule all other group affiliations with which it might be in conflict. Devereux saw the danger of ethnicity as an 'all-or-nothing proposition,' for in the complex ensemble that constituted

individual identity, ethnicity could turn out to be one feature that is superimposed—Devereux calls it 'hypercathected'—over all other features of a personality, including the important characteristic of shared membership in the human race. This was a strange logical operation that could produce catastrophic and disastrous actions—including ethnic cleansing and genocide.

In his important essay on *Symbolic Ethnicity: The Future of Ethnic Groups and Cultures in America*, Gans (1979) called attention to the ways in which modern ethnic identification may work by external symbols rather than by continuous activities that make demands upon people who define themselves as 'ethnic' so that a gentle ethnic diversification could take place in an assimilative framework.

These observations were important for approaches that looked at ethnic processes and conflicts not only as residues of primordial differences, but as new constructions and inventions. Three widely received books supported this direction of inquiry, Berger and Luckmann's (1966) general *The Social Construction of Reality: A Treatise in the Sociology of Knowledge*, Hobsbawm and Ranger's (1983) *Invention of Tradition*, focusing especially on Europe and Africa, and South Asia specialist Anderson's (1983) *Imagined Communities: Reflections on the Origins and Spread of Nationalism*. The constructivist turn opened up the whole interrelationship of ethnicity and culture to new inquiries, as the focus shifted from the issue of how ethnic culture was preserved or succumbed to assimilation to the question of how ethnic groups emerged and how ethnicity was constantly reimagined and reinvented.

In his landmark introduction to *Ethnic Groups and Boundaries*, Barth (1969) drew comparatively on wide-ranging field work on such groups as the Pathans in Swat, the Yao in China, or the Lapps in Norway in order to develop an influential approach to ethnicity. He suggested that we 'ask ourselves what is needed to make ethnic distinctions emerge in an area.' Barth argued:

> When one traces the history of an ethnic group through time, one is not simultaneously, in the same sense, tracing the history of "a culture": the elements of the present culture of that ethnic group have not sprung from the particular set that constituted the group's culture at a previous time, whereas the group has a continual organizational existence with boundaries (criteria of membership) that despite modifications have marked off a continuing unit.

Barth saw the essence of ethnicity in mental, cultural social and not necessarily territorial boundary-constructing processes which functioned as cultural markers between groups. For Barth it was 'the ethnic *boundary* that defines the group, not the cultural stuff that it encloses.' Barth directed attention to processes of boundary maintenance and argued that 'members of all ethnic groups in a poly-ethnic society' could 'act to maintain dichotomies and differences.'

In *Urban Ethnicity*, Cohen (1974) investigated the emergence of ethnic distinctions against the background of power relations and insisted on ethnicity as a category that may apply to dominant elites as well as marginal groups, with examples ranging from Sierra Leone to the city men of London.

The conceptual richness of the pioneering scholarship and of provocative work from the 1960s to the early 1980s supported a growing body of empirical work on ethnic groups around the globe. Questions of ethnic persistence and emergence, of power relations and agency, of assimilation and pluralism, of marginality, ethnic invention, symbolic ethnicity, and boundary construction, permeated scholarship in many disciplines at a time in which intellectual attention as riveted by issues of ethnicity, class, and gender. The proliferation of scholarly work reached such proportions that by 2000, there were hundreds of books whose titles contained the relatively new word 'ethnicity.'

4. *Exemplary Scholarly Engagements with Ethnicity*

Starting in the 1970s, studies in many disciplines placed a new emphasis on ethnicity. Emigration and immigration, slavery and freedom, and ethnic mergers and conflicts had been the subjects of many earlier historical and sociological works. But such topics now assumed a new position of centrality in the various disciplines. In the US, for example, the pioneering work by Marcus Lee Hansen, Oscar Handlin, or John Higham inspired many historians—among them Rudolph Vecoli, John E. Bodnar, Kathleen Conzen, and Matthew Jacobson, to turn to topics of immigration or related to the ethnic heterogeneity of the US. Of all American ethnic groups, African Americans have particularly been the subject of historical research, ranging from the early work by Carter G. Woodson, W. E. B. Du Bois, and John Hope Franklin to scholarship by Nathan I. Huggins, Leon Litwack, or David Levering Lewis.

The *Journal of American Ethnic History* is one of many specialized journals that have accompanied the establishment of black and ethnic studies departments in the US. Thernstrom and Orlov's (1980) *The Harvard Encyclopedia of American Ethnic Groups* gives a sense of the whole field, both in its thematic entries and in its accounts of 107 American ethnic groups. In Germany, a handbook such as *Ethnische Minderheiten in der Bundesrepublik Deutschland: Ein Lexikon*, (Schmalz-Jacobsen and Hansen 1995) offered an overview of German ethnic groups and issues, with a certain focus on such linguistic minorities as Danes and Sorbs. Noiriel, *Le creuset français: Histoire de l'immigration,*

XIXe–XXe siècles (1988) offered an account of emigration and immigration in France. In *Ethnic Groups in Conflict*, Horowitz (1985) analyzed explosive ethnic fault lines around the globe.

5. Conclusion

While ethnic identification seems fluid and ready to emerge unpredictably in new circumstances, it is also remarkable how many areas of the world have been enmeshed in intermittent ethnic conflicts for a very long time. As long as the sense of belonging—be it ancient or modern in origin—persists among members of groups and as long as conflicts arise between different groups, there will be ample material for ethnic scholarship.

Ethnic Identity/Ethnicity and Archaeology

Many would think that the study of ethnicity is a recent topic in archaeology but this is only partially true. Archaeology has always been involved in the identification of ethnic groups in the past, but it has done this using different terms. In the early years of archaeology ethnic groups were called 'peoples' and 'nations.' These terms were later substituted for that of 'archaeological cultures' from the start of the twentieth century (Díaz-Andreu 1996). It is only since the 1980s that the growing influence of anthropology upon archaeology has persuaded the latter to begin to talk about ethnicity and ethnic groups.

Ethnicity will be defined here as that aspect of a person's self-conceptualization and his or her conceptualization by other individuals that results from identification with one or more broader groups in opposition to others, on the basis of perceived cultural differentiation or common descent (Jones 1997). Not all archaeologists, however, would agree with this definition. It does not focus on the ethnic group in itself as something objective and describable, as many archaeologists would like. Far from it, the definition provided here stresses perception and, although it does not intend to deny commonalities among the members of the same group, it does not consider them essential for the characterization of an ethnic group.

The definition above considers ethnic identity as multidimensional, for it argues that individuals can identify with one or more broader groups. It proposes, therefore, that multiple ethnic affiliations may coexist and overlap in the same subjects. Each person is (or is potentially) associated with various groups that would enter into the definition of ethnicity. A Mancunian, for example, can feel him/herself as Mancunian, as a person from Lancashire, as English, British, European or a world citizen. However, because of our political education, if asked which ethnic identity they have, individuals will provide a political answer, for only one ethnic identity will be given, usually the one that coincides with their national identification. This reaction has been expected from each citizen since the end of the eighteenth century. However, this might not necessarily be what people feel and what people felt in the past.

Two more aspects may be added to the proposed definition of ethnicity. The first is that ethnic identity can be described as situational. Each of these complementary and enriching ethnic identities, can individually come into play in various situations, depending on where people are, what the situation is and what political ideology they hold. Each individual is active regarding his/her ethnic identities and the daily negotiations will entail that one or several of them are made manifest. Secondly, ethnic affiliations are fluid. They are and have been in a continuous process of flux, as is reflected by the appearance and disappearance of group names throughout the several centuries referred to in written sources.

Of the two theoretical approaches currently predominant in the study of ethnicity, the primordialist and the instrumentalist, the conceptualization of ethnicity provided above fits with the latter. The primordialist perspective considers ethnicity as something inherent, acquired by birth. Thus, the instinctive attachment of the individual to his or her territory and culture is emphasized and the ethnic group is regarded as the natural universal unit of human organization. The instrumentalist perspective, however, views ethnicity as a fluid and situational group identity. It is through practice that individuals perceive and negotiate their ethnic allegiances. This perspective stresses the social aspect of ethnicity as a regulatory device for social behavior and social organization within each ethnic group and between different ethnic groups. Archaeology has traditionally perceived ethnic identity from a primordialist stance and it is only in the last two decades that the instrumentalist viewpoint has made its appearance.

Archaeological discussions of ethnicity have a long history. Throughout much of archaeology's history, material culture has been understood in a very straightforward manner as a basis for inferring ethnicity. The presence of specific types of material culture and the absence of others have been considered as diagnostics to define groups. For example, the characteristic prehistoric incised beaker pot was seen to indicate the presence of the Beaker culture in an area and, similarly, the presence of Samian pottery attested to the presence of Romans. This way of looking at ethnicity has been dominant from the early days of archaeology, although it was only clarified theoretically at the turn of the nineteenth century and early twentieth century with the culture historical approach. Culture history first appeared in Austro-German anthropology (Zwernemann 1983). It was adopted in archaeology a decade later, mainly through the work of the German archaeologist Gustaf Kossinna (Trigger 1980, p. 44). The pre-eminence of German archaeology at this time favored the spread of the theory elsewhere. However, whereas anthropology dropped the term 'culture' in the 1920s, and instead began to use 'tribe,' finally substituting it by 'ethnic group' (Jenkins 1997), archaeology has only very recently been rethinking its use of 'culture' and beginning to explicitly discuss, problematize, and theorize ethnicity.

Within the culture historical perspective ethnic groups were called cultures (or civilizations, in the case of nonprimitive societies). The first definition of culture was proposed by Childe. As he put it, 'we find certain types of remains—pots, implements, ornaments, burial rites, house forms—constantly recurring together. Such a complex of regularly associated traits we shall term a 'cultural group' or just a 'culture' (Childe 1929, p. v–vi) (see *Classification and Typology (Archaeological Systematics)*). In the views on culture/ethnicity of Childe and other culture historians there was no place for fluidity and negotiation, neither was there a place for perception. One could say that, in practice, archaeologists considered peoples almost as a byproduct of objects. For example, changes in material culture were often interpreted as the result of invasions, i.e., as the substitution of one ethnic group by another. The following statement is typical of the archaeology of the period:

> These two groups of hoards [in the British Late Bronze Age] may be taken to indicate first, definite invaders … and second, their fusion with the inhabitants and the absorption, modification, or discarding of their exotic types (Kendrick & Hawkes 1932, p. 135).

Despite the emphasis on invasions and migrations, individuals (who were presumably involved) were perceived as passive spectators of the more important process. Hence, Childe, when discussing the archaeology along the river Danube could say: 'whether these Moravian peasants actually came themselves up the Danube is immaterial; their culture did' (Childe 1927, p. 85).

Culture history archaeologists viewed cultures or ethnic groups as organic beings, as living personalities. Their features were conceptualized like those of an individual. A culture was born, developed, and eventually declined, before moving on to another cycle of emergence, rise, and decay. The impact of these ideas are evident in the quasi-obsession with origins at this time, exemplified by such titles as *The Dawn of European Civilization* (Childe 1925) and *The Beginnings of Egyptian Civilization* (Brunton 1929).

In many ways processual archaeology or New Archaeology continued some of the trends seen in culture history into the 1960s and 1970s (Jones 1997, pp. 107–9; see *Theory in Archaeology*). The aim of processual archaeology was to develop methods to understand the formation of the archaeological record and to refine approaches to inferring past behavior from observations of that record. This led to a growing interest in, for example, site formation processes (see *Geoarchaeology*), ethnoarchaeology (see *Ethnoarchaeology*) and the use of analogy. There was thus an emphasis on the use of a rigorous hypothetico-deductive method (involving the testing of models and the use of inferential generalizations about the past). Within this perspective, culture was seen as a system of interrelated components (Binford 1968, pp. 16–23). It was, however, later to be criticized, in the same way that functionalist anthropology was, for its rather fixed views of human behavior.

As distinct from archaeology, the subjectivist or emic perspective for the study of ethnicity was increasingly being accepted in anthropology, at least beginning in the 1970s (Jones 1997). The general recognition of the role of perception in the definition of identity, and in particular of ethnicity, is partly a consequence of the influential work of Fredrik Barth. Barth (1969) radically changed the study of ethnicity with his proposal that ethnicity was something that could not be objectified, but was defined by diagnostic socially relevant factors for membership and the (successful) ascription of the members to their ethnic group. Although he pointed out that all ethnic groups have their own overt signals (diacritical features that people look for and exhibit to show identity), together with basic value orientations (the standards of morality and excellence by which performance is judged), he considered that the critical features that defined ethnicity were self-ascription and ascription by others, and that there was 'no simple one-to-one relationship between ethnic units and cultural similarities and differences. The features that are taken into account are not the sum of "objective" differences, but only those which the actors themselves regard as significant' (Barth 1969, pp. 13–14). Barth's proposal ruled out the possibility of there being an objective and objectified way to designate ethnicity, and to use material culture as a critical factor in the study of ethnicity, and instead perception took on an essential role. Barth's ideas were later refined by other authors. Among them the work by Ronald Cohen should be emphasized. Cohen (1978) went even further than Barth when he stressed the situational and fluid character of ethnicity, whose influence was only possible as far as it was a meaningful element in social interaction. Although neither Barth nor Cohen, nor any of the other authors arrived at the contention expressed above—that ethnic identity is multidimensional, and it is likely that multiple ethnic identifications coexist in the same person—Cohen (1978) almost reached this conclusion. Some of his examples clearly pointed in that direction. He even stated that 'the same person can be categorized according to different criteria of relevance in different situations' (Cohen 1978, p. 388), but instead of conceding that more than one of these characterizations could be ethnic, he continued to consider ethnicity as monolithic.

Barth and Cohen were not dealing with prehistoric peoples, and never considered the issue of whether ethnicity was an appropriate concept to be applied to the past. There have been some claims that the concept is not applicable to precapitalist societies. Eriksen (1993, p. 80), for example, argued that outside Europe ethnicity appeared only after peoples' contact with capitalism. There is some truth in Eriksen's view, as some new ethnic groups were indeed created by colonizers (Cohen 1978, p. 383, Gulliver 1969, p. 15), or even by anthropologists (Cohen 1978, pp. 380–3). However, colonizers seem to have created these new ethnic groups on the basis of pre-existent ones, either amalgamating, separating or reorganizing them.

Colonizers may not have been successful in all their new creations, but in some they undoubtedly were. In the case of anthropologists, Cohen acknowledges that some of them had to provide a name for a 'tribe' (a concept which Cohen sees as equivalent to ethnic unit) 'even when the group faded imperceptibly into other named groups more or less similar and was broken up into named subgroupings that had strong we/they feelings dividing them.' (Cohen 1978, pp. 38–1.) Following the definition of ethnicity provided above, one should interpret these anthropological categorizations, on the one hand, as reflecting the multiple levels of ethnic affiliations among these groups. On the other, they should be understood as an example of how anthropologists themselves used their own sense of a 'we/they' division in order to classify 'the other' in their own (nationalistic) language. Their nationalistic perspective would lead them to deny all groupings as ethnic and hence to the need to decide which of them was the only one—the proto-ethno-nation—that

should be considered as their object of study. As was indicated above, nationalism has left a definite mark on the way that ethnicity has been understood, mainly with respect to its one-dimensional characterization.

In archaeology the first major break with the processual paradigm occurred only in the early 1980s, much later than in anthropology, to which it was clearly related. The seminal book in this process was Ian Hodder's *Symbols in Action* (Hodder 1982b), which was, not coincidentally, an ethnoarchaeological study (see *Ethnoarchaeology*). Hodder depicted the manipulation of material culture by several groups in East Africa as active in creating social relationships, and stressed the need to find ways of interpreting the meaning(s) of material culture. Wider discussions of this topic were, however, well underway by then, as shown by many of the contributions to *Symbolic and Structural Archaeology* (Hodder 1982a). The major aim of this body of research was the study of living cultures 'in order to shed some light on the analysis and interpretation of cultures in prehistoric archaeology'(Hodder 1982a, p. 1). Interestingly, Hodder's ethnoarchaeological work originated from an overtly processual hypothesis, which was to test the relationship between resources, interaction and cultural similarity (1982a, p. 8), and it was assumed that cultural similarity would 'reflect' degrees of interaction (Hodder 1982a, p. 9). However, observations made during Hodder's ethnographic fieldwork, however, showed that while the use and distribution of certain items such as drinking cups, wooden eating bowls and stools followed the expected patterns, those of other items, such as spears and calabashes, did not. Hodder concluded that 'the extent to which cultural similarity relates, for example, to interaction, depends on the strategies and intentions of the interacting groups and how they use, manipulate and negotiate material symbols as part of those strategies' (Hodder 1982a, p. 185). These interacting groups were ethnic (tribal), but other subgroups within those societies, such as younger men and women, were also seen to follow their own strategies in their relations with the dominant older men.

Despite Hodder's important contribution on ethnicity, archaeology remained reluctant to analyse this issue of ethnic identity for several years. In 1989 Shennan published a much-cited article in this area but in it he referred mainly to culture instead of ethnicity (Shennan 1989). This was not the case in the Polish journal, *Archaeologia Polona*, which, in 1991, dedicated an entire issue to ethnicity and archaeology. The articles published here, together with others that have subsequently appeared (e.g., Dìaz-Andreu 1998, Dietler 1994, Funari 1999), show that the debate was becoming more intense. This process was further fostered by the 1997 publication of Jones's book, *The Archaeology of Ethnicity*, which provides archaeologists with an excellent overview of the state of the art.

Ethnic Identity, Psychology of

Ethnic identity is a dynamic, multidimensional construct that refers to one's identity, or sense of self, as a member of an ethnic group. An ethnic group can be thought of as a subgroup within a larger context that claims a common ancestry and shares one or more of the following elements: culture, race, religion, language, kinship, and place of origin. Ethnic identity is a central defining characteristic of many individuals, particularly those who are members of minority or lower status groups (Liebkind 1992, Phinney 1990).

Ethnic identity has traditionally been most salient in immigrant-receiving countries like the USA and Australia, but it has become an increasingly important issue throughout the world, as social and political changes have increased the amount of contact among people from different ethnic groups and, in some cases, have led to ethnic conflict. Social scientists have attempted to understand ethnic identity from a variety of perspectives. This article examines the development of ethnic identity and the ways in which ethnic identity changes over time and contexts. It concludes with a discussion of the implications of ethnic identity.

1. *The Formation of Ethnic Identity*

1.1 *The Beginnings of Ethnic Identity*

An ethnic identity is developed and modified as individuals become aware of other groups and of the ethnic differences between themselves and others, and attempt to understand the meaning of their ethnicity within the larger setting. Ethnic identity may have its origins in the infant's attachment to caregivers and the fear of strangers that is experienced early in life. The family provides the initial bases for feelings about what is normal and comfortable, and these feelings are generally supported in the immediate community. In homogeneous settings, familiar practices are not recognized as ethnic.

Once children encounter others who are different in appearance, language, behaviors, or attitudes, they begin to categorize themselves and others. Frances Aboud (1987) has shown that children learn their ethnic self-label between the ages of four and seven years, although the age varies with the group and the amount of contact with other groups. By eight or ten years of age, children develop an understanding of ethnic constancy (the fact that their ethnicity does not change over time or superficial changes). Cognitive developmental level influences the way in which children understand ethnicity. Young children understand ethnicity in literal and concrete terms, defined by food, customs, and language. With increasing cognitive competence, children begin to develop a group consciousness and to understand ethnicity in terms of norms and values (Quintana 1998).

Socialization plays an important role in the content and meaning children attach to their own ethnicity. Children acquire knowledge about their ethnic culture through the process of enculturation (Bernal and Knight 1993). Children's feelings about their ethnicity are influenced from an early age by the family and community. When families provide strong positive images of their ethnicity, children's early feelings about their ethnic group are likely to be positive. A vital ethnic community also provides a context in which children can form a positive sense of their group.

Children are influenced as well by messages from other groups and the larger society. When a group is held in lower esteem or is disparaged by others, these negative messages may become internalized. Children may then hold conflicting or negative feelings about their ethnicity and express the desire to belong to another group. However, in childhood ethnic identity remains largely unexamined; that is, children have not thought through for themselves the meaning of their ethnic group membership (Phinney 1989).

1.2 *The Search for a Meaningful Ethnic Identity*

Beyond childhood, the process of ethnic identity development becomes more complex. During adolescence, identity formation is a critical developmental task, particularly in complex modern societies. Like ego identity, the process of ethnic identity has been conceptualized in terms of stages, with an individual moving from the unexamined attitudes of childhood, through a moratorium or period of exploration, to a secure achieved ethnic identity at the end of adolescence (Phinney 1989). The moratorium period begins for adolescents as a result of their increasing cognitive ability, their growing understanding of social and historical processes, and in some cases, personal experiences of discrimination. As ethnic identity becomes a salient issue, many youths, especially those from ethnic groups with lower status or power, question the meaning of their ethnicity and its place in the larger context (Phinney 1989).

This search for a meaningful ethnic identity can lead to a wide range of emotional reactions, both positive and negative. Individuals may become deeply involved in learning about their ethnicity. This process may lead to exaggerated claims about their group. It may

result in constructive and creative actions aimed at affirming the value and legitimacy of one's group and establishing a positive basis for a group identity (Tajfel and Turner 1986).

Conversely, the process of examining and dealing with the social implications of one's ethnicity may lead to feelings of insecurity, confusion, or anger. Individuals who are confused or ambivalent about their ethnic identity are likely to react more strongly to perceived threats to their ethnicity (Worchel 1999). They may experience strong negative feelings toward other groups, particularly in cases where a group has been the victim of negative or exploitative intergroup behaviors or where group members feel that their needs and aspirations are being thwarted. Such attitudes can lead to violence when legitimate means of ethnic affirmation are seen as ineffective. Much interethnic violence results from feelings of threat to one's ethnic identity. This process is assumed to be relevant primarily to disadvantaged minority groups, but it can apply as well to members of a dominant group who feel threatened by changing demographics, for example as a result of large-scale immigration.

1.3 The Achievement and Internalization of Ethnic Identity

The optimal outcome of the ethnic identity formation process is the achievement of a secure and confident sense of one's ethnicity. This mature sense of self as an ethnic group member is assumed to include positive feelings about one's group and to be a source of personal strength and positive self-evaluation (Phinney 1989, Tajfel and Turner 1986). Feeling secure about one's own ethnic identity is also assumed to be associated with more positive attitudes toward other groups. An achieved ethnic identity may be related to the ability to assume the perspective of other groups, to adopt a multicultural perspective, and to see the place of one's own group in a larger perspective.

2. Ethnic Identity Across Time and Contexts

Although developmental processes underlie the formation of ethnic identity, ethnic identity may be renegotiated throughout life in response to individual, contextual, and historical changes. Ethnic identity varies in the short term over differing contexts, with strong ethnic feelings emerging in settings where ethnicity is highly salient, such as traditional ethnic celebrations, and receding in settings which de-emphasize ethnicity. Many bicultural individuals experience variation in the strength of their group identities as they move between ethnic and nonethnic contexts, such as home, school, and workplace, and change their language and behaviors to suit the context.

2.1 Ethnic Identity and Immigration

Group identity issues are raised most dramatically when individuals and groups move across national and cultural borders, or when political borders change around stable groups. As migrants, refugees, guest workers, and other travelers come in contact with other cultures, questions of identity are raised both for the mobile groups and for the societies where they settle. These processes are highly dependent on the environmental context, including the size and structure of ethnic communities, the history and current status of ethnic groups in the larger society, and attitudes of other members of the society toward diversity.

For immigrants, changes in ethnic identity over time depend on a number of influences, including age at time of immigration and generation of immigration (that is, whether one is an immigrant, child of immigrants, grandchild of immigrants, etc.). Adult immigrants typically retain a strong identity with their culture of origin without identifying strongly as members of the larger society. Children who migrate at a young age adapt more quickly than their parents to a new setting and are likely to become bicultural, identifying with both the ethnic group and the larger society.

2.2 Retention of Ethnic Identity

For later generations of immigrants, that is, the children and grandchildren of immigrants, and for stable ethnic groups within larger societies, the retention of ethnic identity depends both on factors within the ethnic group and on the broader societal or historical context. Ethnic group members differ in the extent to which they desire to retain their culture and the degree to which they wish to become part of the larger society. Societies differ widely in their relations with minority groups, their policies toward ethnic groups, and the attitudes of members of society toward immigrants and minorities.

As a result of these varied influences, ethnic groups and their individual members may adopt different group identity modes, similar to modes of acculturation (Berry 1990). When individuals or groups wish to retain their ethnic identity and maintain their ethnic language and customs, and when ethnic institutions support such activities, ethnic identity can remain strong over long periods. If they also develop a sense of belonging to the larger society, they become bicultural or integrated. If they retain a strong ethnic identity and do not become part of the larger society, either by choice or because of nonacceptance, they may be described as separated. On the other hand, individuals and groups who give up their ethnic identity and become identified with the larger society are assimilated. Finally, those who give up their ethnic

identity but do not become part of the larger society are seen as marginalized.

The ways in which these patterns play out over time is highly variable. Ethnic communities may be maintained over many generations and can be revitalized when circumstances permit. Groups that are culturally or phenotypically different from the larger society, or that experience prejudice and discrimination, may remain separated over many generations, as in the case of gypsies in Europe or African Americans in the USA. For these groups, ethnic identity typically remains strong and salient over time. In contrast, when distinctive cultural or phenotypic markers are absent and when there is little desire to maintain one's ethnic culture, assimilation is likely in the third and later generations, as has been the case for most European Americans in the USA (Waters 1990).

3. *Implications of Ethnic Identity*

Because of the centrality of ethnic identity for group members, together with social and political processes that support or threaten such an identity, ethnic identity can have positive or negative implications for the individual and for the larger society.

Most psychological research has shown that ethnic identity is positively associated with psychological well-being, but the relationship is complex, and the impact is likely to depend on the particular aspect of ethnic identity being considered. A widely used measure of ethnic identity (Roberts et al. 1998) suggest two distinct components of ethnic identity: an affective component, comprising a sense of belonging and positive feelings about one's group; and a developmental component, involving the extent to which one has explored and resolved ethnic identity issues (Phinney 1990). The affective component shows a consistent though modest correlation with self-esteem; those who feel more positive about their own ethnicity have higher self-esteem and lower levels of depression. Conversely, internalized negative feelings about one's own group are related to negative feelings about oneself. The developmental component has a weaker relationship with psychological well-being, perhaps because of the variability of attitudes that occur during development. Nevertheless, the attainment of a secure and confident identity appears to be the basis of positive feelings about oneself and others.

Feelings of belonging to the larger society also contribute to well-being. Research with immigrants has shown a bicultural identity to be the most adaptive, and a marginal identity to be the least adaptive (Berry 1990). When individuals and groups have the freedom to express their values and practice their ethnic customs, ethnic identity can be the basis of powerful positive feelings. Societies that thwart the desire of ethnic group members to affirm and express their group identity may experience turmoil and violence (Worchel 1999).

The study of ethnic identity is relatively recent in psychology. The knowledge that we have is based on a limited amount of research, and there are many areas in need of study. Longitudinal studies are needed to provide deeper insight into the processes by which ethnic identity changes over time. Links to other aspects of identity need to be explored, to determine the extent to which ethnic identity is similar to or different from national, racial, cultural, or other group identities. Research has focused on relatively few groups and situations; future research should extend the range of groups studied and the national and regional settings that provide contexts for ethnic identity development and expression. Increased collaboration among researchers from different countries would be valuable in exploring whether the current findings apply to the wide diversity of ethnic groups in the world. Finally, because the study of ethnic identity remains fragmented, there is need for conceptual models that can integrate research across different settings. Because of the growing importance of ethnicity throughout the world, it is imperative for the behavioral sciences to gain a better understanding of ethnic identity and its implications for society.

Ethnicity: Anthropological Aspects

The concept of 'ethnicity' derives from the ancient Greek *ethnos*, referring to human collectivities living and acting together. It is typically translated today as 'people' or 'nation.' Since the 1900s, the linked concepts of ethnicity and ethnic group have passed into everyday discourse. They have become central to the politics of group differentiation and advantage in the culturally diverse social democracies of Europe and North America. With notions of 'race' in disrepute since 1945, ethnicity has become a rallying cry in the bloody re-ordering of the post-Cold War world: 'ethnic cleansing' stands shoulder to shoulder with earlier euphemisms such as 'racial hygiene' and 'the final solution.' In the markets of the affluent west and north, to call a commodity 'ethnic' is to imply the value of 'authenticity.' In the social sciences, ethnicity—including related topics such as 'race,' 'nationalism,' and 'difference'—has become a rapidly expanding specialism.

1. Corporate Groups and Cultural Differences

One of anthropology's earliest ambitions as a comparative scientific enterprise was to explain and understand human diversity. This aspiration has remained central to the social and cultural anthropological imagination—and to the limited, but significant, unity of purpose that divergent national and intellectual anthropological traditions have succeeded in maintaining—ever since. The different approaches to this quest which have characterized the discipline's twentieth-century history have, for most of that period, been rooted in two interrelated anthropological axioms. On the one hand, there is an understanding of human social life as based in membership in definite, bounded corporate groups. On the other, the basic unity of humankind is understood as crisscrossed by patterns of cultural differentiation.

These fundamental concepts emphasize similarity (corporate groups) and difference (cultural differentiation), the two basic dimensions of all processes of social identification. In groups, we are both together (as us) and apart (from them). Although the two notions, and their implication in each other, remain constant, how they are defined, and the relationship between them, has changed since the nineteenth century. This process can be understood as a gradual shift from documenting the social structure and customs of 'tribes,' to attempting to understand the complex dynamics of 'ethnic groups.'

During the colonial and immediately postcolonial eras, anthropology's theoretical preoccupation with corporate groups was manifest in the assumption that 'primitive peoples' were characteristically organized into tribal groups. In one move, the concept of 'the tribe' distanced tribal society from civilized society, in both common-sensical and analytical discourse, and provided the anthropologist with a theoretical model of the nature of 'noncivilized' social organization which could organise ethnographic data and function as a framework for cross-cultural comparison. At the same time as the difference between 'them' and 'us' was established, the basic similarity between different sorts of 'them' was proclaimed. This 'tribe-group' model was not, however, an explicit analytical framework; it was, rather, implicit in most ethnographic studies, neither examined nor questioned.

2. The Anthropology of Ethnicity

One of the earliest anthropologists to doubt the usefulness of the notion of the tribe was Leach (1954), who argued, in his study of highland Burma, that tribes, as discrete bounded entities, were essentially models developed by outsiders, for their own purposes, not locally meaningful principles of everyday social organization. Locals might talk about themselves as if there were clear-cut collective identities and entities, but everyday interaction and organization revealed a more complex pattern of overlap, variation, and fluidity.

By the 1960s, the notion of 'the tribe' was gradually being replaced in British social anthropology by the, perhaps less colonial-sounding, 'ethnic group.' However, the underlying assumptions about corporate groups and cultural difference had probably not changed much. Within American anthropology, the increasing use of an ethnicity model, over the same period, can also be understood as part of a long-term, incremental shift in the discipline's axiomatic metatheoretical model of difference: from 'race,' to 'culture,' to 'ethnicity' (Wolf 1994).

2.1 Ethnic Groups and Boundaries

The paradigm shift towards a social constructionist model of ethnic groups followed the publication of the Norwegian symposium edited by Barth (1969). The subtitle of this collection of essays—*The Social Organization of Culture Difference*—tells us a great deal

about both anthropological understandings of ethnicity (cultural differentiation), and Barth's take on it (as social organization). In the 'Introduction,' he argued against the presumption that the social world was made up of 'distinct named groups.' Ethnicity, the boundaries of ethnic groups, and indeed their ontological status as collectivities, could not be accepted uncritically as fixed aspects of the social reality in question. Instead, Barth insisted that ethnic identity—and its production and reproduction in routine social interaction—must be treated as essentially problematic features of social life, as emergent properties of everyday interaction. The ethnographer must examine the practices and processes whereby ethnicity and ethnic boundaries are constructed socially.

Barth and his colleagues shifted the anthropological emphasis from the static evocation of tribal identity as a feature of social structure, to a recognition of ethnic identity as a dynamic aspect of social organization: ethnic identification is something that people can and do manipulate, depending on the needs and possibilities of the context. People are not 'at the mercy' of their ethnicity, nor do they do things simply because they are ethnically 'X' or 'Y.' Ethnicity is not an imperative. In acknowledging this, *Ethnic Groups and Boundaries* marked a shift from an interest in the uncivilised peoples of the colonies and ex-colonies, to a more equitable concern with the complex heterogeneity of all societies.

Barth's emergent alternative framework had several key features. First, the analysis of ethnicity starts from the definition of the situation held by social actors. Second, the focus of attention then becomes how ethnic boundaries are maintained or changed in the structured interaction between 'us' and 'them' which takes place across boundaries. Third, the ethnicity of actors is not necessarily fixed; it is defined situationally. Fourth, ethnic identity depends on ascription, by members of the ethnic group in question and by outsiders with whom they interact. Fifth, ethnicity is not a matter of 'real' cultural differentiation; differences are in the eye of the beholder, the 'cultural stuff' which had been hitherto believed to determine group identification is somewhat irrelevant. Finally, ecological issues are influential in producing and reproducing ethnic identity: economic competition for scarce resources plays an important role in the generation of ethnicity.

2.2 Ethnicity as Socially Constructed

This social constructivist model of ethnicity can be traced back to the ideas of sociologists such as Max Weber, Everett Hughes, and Erving Goffman. Although *Ethnic Groups and Boundaries* was the model's most systematic, extended, and influential statement, similar arguments can also be found in the work of contemporary North American anthropologists such as Moerman (1965) and Cohen (1969). It has dominated discussions of ethnicity within European and North American anthropology since.

This basic paradigm was developed by Handelman (1977). Acknowledging the importance of boundaries, and the situational negotiability of ethnic membership, he argued that Barth overemphasised the centrality of social interaction in establishing boundaries, at the expense of acknowledging the role of culture. For Handelman, the cultural content of ethnicity is an important aspect of its social organization. A dichotomy between the cultural and the social is misleading. He argues further that ethnicity is incorporated—made socially significant—in differing degrees of intensity and territoriality, on which depends its salience in individual experience. Moving from 'the casual to the corporate,' Handelman distinguished the ethnic set, the ethnic category, the ethnic network, the ethnic association and the ethnic community. Ethnicity can, for example, organize everyday life without ethnic groups featuring locally as meaningful social forms.

What we can call 'the basic anthropological model of ethnicity'—it has become a 'normal science paradigm' of sorts—has many virtues. In stressing social process and the practices of actors, it encouraged a move away from the various strands of determinism of the 1970s and early 1980s. The emphasis upon social construction discourages the intrusion of biological conceptions of ethnicity or 'race' into social analysis. Finally, the importance that is attached to the views and self-perceptions of social actors themselves undermines the taken-for-granted ethnocentrism of much social science. These are important gains, and in all of these respects the approach may be said to have anticipated some of the most valuable aspects of postmodernism and poststructuralism.

However, the approach has suffered at the hands of some of those who have most wholeheartedly embraced it. In stressing concepts such as 'group,' 'category,' and 'boundary,' and processes of 'maintenance,' Barth—despite his intentions to the contrary—contributed to the further reification of the ethnic group as a perduring corporate entity. In particular, the spatial and physical overtones of the notion of the 'boundary' allow the superficial or the careless to celebrate the situational flexibility of ethnicity without taking on board the more difficult questions about the nature of collective social forms in which Barth is interested. In their enthusiasm for processes of boundary maintenance—negotiation and strategizing—many of those whose analyses owe much, if not everything, to Barth have taken for granted what he did not, i.e., the 'group' that is the object of the research.

Three other, related, criticisms are worth mentioning. First, although the locations where Leach, Barth, and others did their fieldwork—South-East Asia and the Middle East, for example—do allow for flexibility

and a degree of choice with respect to identification, the same is not true everywhere. In many other contexts—such as Northern Ireland or Kosovo—there may be much less room for maneuver. Second (although this is changing), many anthropologists, in their celebration of the positivities of everyday life, still appear reluctant to recognize power imbalances. The third criticism concerns the relative lack of theoretical attention which has been given to the relationships between ethnicity, on the one hand, and other principles of social identification, particularly class and stratification, on the other.

None of these problems, however, are inescapable theoretical weaknesses of the general anthropological approach. Recently, a solution to some of them has been put forward in the application to the study of interethnic relations of the distinction between groups and categories (Jenkins 1997). It is important to distinguish between two analytically distinct processes of ascription: group identification and social categorization. The first occurs inside the ethnic boundary (group members identify themselves), the second outside and across it (a collectivity and its members are categorized by nonmembers). Social categorization, in particular, is intimately bound up with power relations. It reflects the capacity of one group successfully to impose its categories of ascription upon another set of people, and the resources which the categorized collectivity can draw upon to resist that imposition. Acknowledging the significance of this distinction places relationships of domination and subordination on the theoretical center-stage.

2.3 Ethnicity as Personally Meaningful

If ethnic identity is a flexible matter, dependent on situation, it is legitimate to ask what it really means to the individuals concerned. This question has generated discussion about the nature of ethnic identity and is a perennial topic in the textbooks. Is ethnicity a fundamental, primordial aspect of human existence and self-consciousness, essentially unchanging and unchangeable in the demands it makes upon individuals and the bonds which it creates between the individual and the group? In other words, is ethnicity an aspect of 'human nature'? Or is it, to whatever extent, defined situationally, strategically or tactically manipulable, and capable of change at both the individual and collective levels? Is it, indeed, wholly socially constructed, as the post-Barth conventional wisdom might suggest?

This debate takes its place alongside a range of essentially philosophical controversies about human nature, the human condition, and the capacity of humans to intervene in their own lives, to determine or to be determined. But the 'primordial model' also has other historical roots, in the Romantic reaction to Enlightenment rationalism. Finding some of its more respectable voices in Herder and Hegel, this is much more than an academic point of view. Tragically, it has provided the intellectual charter for terrible—to the point of murderous—ethnic chauvinism, nationalism, and genocide. The ideology of primordialism naturalizes ethnic groups and justifies chauvinistic ethnic sentiments. Academically speaking, it can, for example, be identified at play in the ongoing debate about the modernity and nature of nationalism (e.g., Smith 1994).

Within anthropology, the name that is most often identified with a primordial model of ethnicity is Geertz (1973). Writing originally in 1963, Geertz was concerned to understand the obstacle that 'primordial attachments'—known variously as tribalism, parochialism, or communalism, and encompassing more than ethnicity—posed to the development of the modern political sentiment of citizenship in emergent post–colonial 'new states.' This was an important recognition—if one was needed—that whatever else it is about, ethnicity is also about affect and the sometime power of culture to move people.

So on the one hand we have negotiable identities, while on the other there are primordial attachments. The apparent conflict between the 'primordialist' and 'situationalist' perspectives is, however, not as clear-cut as it seems. It is hard to resist the conclusion that the debate has generated more heat than light. Both positions arguably have at least as much in common as not, and the protagonists are certainly usually misrepresented, sometimes to a remarkable degree.

To look, for example, at what Geertz actually said, he recognized explicitly the role of culture in defining the primordial 'givens,' and that primordial attachments are historically and situationally variable in their power to move people. He is also clear that what matters is that ties of blood, language, and culture are seen by actors to be ineffable and obligatory; that they are seen as natural. He is concerned with the terms in which attachments are understood and mobilized locally; with what people believe. Finally, Geertz further argues that these putative 'primordial attachments,' far from being necessarily ancient, may actually be stimulated and quickened by the political modernization of nation-building.

Barth, for his part, has never neglected the power and stability of ethnic identifications. As much concerned with the persistence of ethnic boundaries as with their flux, what he said was that under certain, not uncommon, circumstances ethnic change can happen, not that it must. Furthermore, his point of view is often presented fossilized in its 1969 incarnation. Since then he has explored the importance of ongoing, and historically relatively stable, 'streams of tradition' or 'universes of discourse,' within the constraints of which ethnic identities are produced and reproduced in practice. Most recently, he has acknowledged the need to add micro- and macrolevels of analysis to the intermediate level upon which his

original arguments concentrated. This means looking at what ethnicity means for individuals.

There are other reasons for becoming impatient with this debate. In the evocative words of one teaching text, it offers a contrast between 'ethnicity in the heart' and 'ethnicity in the head' (Banks 1996). This alerts us to the need to acknowledge affect and emotion in our considerations of ethnicity. But there is no necessary contradiction between instrumental manipulation, on the one hand, and sentiment, on the other. They may, in fact, go hand in hand. They may also, of course, conflict. But so may different sentiments or opposing instrumental goals.

There is, however, good reason to reject totally any strongly primordialist view. Too much ethnographic evidence exists of the fluidity and flux of ethnic identification and of the differing degrees to which ethnicity organizes social life in different settings, for any other position to be sensible. However, nor, on the other hand, can we deny the longevity and stubbornness, under particular circumstances, of ethnic attachments. But to acknowledge this point does not necessitate either embracing a primordial model, or abandoning the idea of social construction. It is not stretching the point to regard ethnic differentiation—the social construction of 'us' and 'them,' marked in cultural terms—as a ubiquitous feature of human sociability, and hence of all human societies. Arguments about whether or not ethnicity is 'situational' or 'primordial' confuse the ubiquity of a social phenomenon such as ethnicity with 'naturalness' (implying determinism and presocial powers of causation). To suggest that ethnicity is ever present, as one of the 'givens' of human social life, is not to endorse the primordialist point of view.

Within anthropology, the primordial intellectual position is unconvincing largely because it is something of a straw man. The scholarly debate about 'instrumentalism' and 'primordialism' exaggerates the differences between, for example, Geertz and Barth, and it does neither justice. More widely, it is tempting to suggest that the notion of the 'primordial' should be banished from the social-science lexicon altogether. On the other hand, however, it would be irresponsible to forget the debate altogether. Crude primordialism is essentially a common-sense view, with enormous power in the world. In sheep's clothing it occasionally makes an academic showing, indirectly, in the guise of sociobiology and discussions about territoriality. These views cannot be simply ignored, and an anthropological perspective—rooted in social constructionist assumptions—has much to offer as a critique of the naturalization of chauvinism and ethnic conflict.

2.4 *A Basic Anthropological Model of Ethnicity*

Despite the criticisms and debates summarized here—and in unacknowledged harmony with post-1980s discourses about 'difference,' globalization, transnationality, and so on—the 'basic anthropological model of ethnicity' remains in place as disciplinary conventional wisdom. In its foundational emphasis upon social construction, its recognition of the fluidity as well as the solidity of identity, and its refusal to biologize or naturalize what are sociocultural phenomena, it remains the cornerstone of any anthropological approach to the topic. It can be summarised thus:

(a) ethnicity is about cultural differentiation (bearing in mind that similarity and difference are inextricably connected),

(b) although ethnicity is centrally concerned with culture—shared universes of meaning—it is also rooted in, and to a considerable extent the outcome of, social interaction,

(c) ethnicity is no more fixed or unchanging than the culture of which it is a component or the social situations in which it is produced and reproduced, and

(d) ethnicity as a social identity is collective and individual, externalized in social interaction and internalized in personal self-identification.

However, that there is a relatively consensual model, combined with the anthropological enthusiasm for detailed ethnography rather than systematic theory, may lead to some things being taken for granted. In particular, there is a perpetual need to struggle against the tendency to reify culture and ethnicity. Although we talk about them in these terms, neither culture nor ethnicity is 'something' that people 'have' or to which they 'belong.' They are, rather, complex repertoires which people experience, use, learn and 'do' in their daily lives, within which they construct an ongoing sense of themselves and an understanding of their fellows.

The reification of ethnicity may also lead to its being seen as typically—or even only—an attribute of the Other. We need to remind ourselves all the time that each of us participates in an ethnicity—perhaps more than one—just like them, just like the Other or 'the ethnic minorities.' National identity may, however, be easier to recognize in ourselves than ethnicity. Nationalism and the construction of national identity are explicit projects of the state (and, if nothing else, we have passports). In the 'modern world,' the contours and contents of national identity, and the contexts of its uses and justifications, may be more visible than ethnicity. It is, therefore, no surprise that the anthropology of nationalism is a recent growth area (Eriksen 1993).

Although anthropologists may not have to remind themselves that national identity—as a variation on the theme of ethnicity—is socially constructed, there is a need to keep this idea firmly in the public eye. The timeliness of Wolf's warning (1994) that 'race,' 'culture,' and 'people' are 'perilous ideas,' makes the social constructionist, anthropological model of ethnicity as relevant at the turn of the twenty-first century

as it was in the 1960s. Anthropology's comparative global reach and local-level research focus, its emphasis upon culture and social construction, and its capacity to see individual trees as well as the collective wood, relativizes notions about ethnicity and undermines the naturalization of ethnic or national identity. That remains an important contribution to our understanding of the modern social world.

Ethnicity, Crime, and Immigration

Ethnicity is often conflated with race, from which it must be distinguished. Being an immigrant is a legal status conferred upon persons who come as permanent residents to a country other than their native land. Crime is deviant behavior that is in breach of the law. In all Western-style democracies, racial, ethnic, and immigrant minorities are an object of penal repression which is disproportionate vis-à-vis their percentage of the total population. This article reviews the explanations proposed to account for this fact. For detailed treatment of their various elements and for further reference, see *Discrimination: Racial*; *Ethnic Conflicts*; *Ethnicity, Sociology of*; *Integration: Social*; *Underclass*; *Migration: Sociological Aspects*; *Minorities*; *Ethnic and Racial Social Movements*; *Multiculturalism: Sociological Aspects*; *Racial Relations*; *Racism, Sociology of*; *Conflict Sociology*; *Race Identity*.

1. Identifying and Measuring the Problem

All Western democracies collect data on immigrants and more generally on noncitizens living within their respective boundaries, although these data cannot record the significant number of illegal immigrants. It is thus possible for these countries to collect justice statistics on the very general basis of who is a national citizen and who is not when having a brush with the penal system. However, these statistics are not further broken down according to racial and ethnic origin. Even if state immigration departments keep tabs on where immigrants are coming from, this kind of information is not recorded by other departments. Consequently, justice statistics are generally not discriminant with respect to ethnicity and race. In continental Europe, such discriminant statistics would seem a throwback to pre-Second World War racism and bring back the yellow stars nightmare. In other countries such as Canada, ethno-racially discriminant statistics are believed to violate basic civil rights, with the exception of data on Aboriginal people, which have traditionally been collected because First Nations are endowed with a special legal status. However, there are two countries where justice statistics sensitive to race and ethnicity are collected. The first is the US, where such data have been collected for a long period of time, and the other is the UK, where a 1995 Home Office letter to Chief Constables required them to introduce a system of ethnic monitoring of suspects and offenders. The UK also conducts victimization surveys that discriminate between ethno-racial groups either as victims or offenders.

It is then crucial to stress that despite its intensity, the debate on crime, race, ethnicity, and immigration does not in most countries rely on facts, but on spotty data generated by academic research and biased media impressions. In continental Europe or Canada this situation is not about to change.

2. Basic Distinctions: Race, Ethnicity, and Related Categories

Several distinctions must be made in order to discuss the issues properly. First, ethnicity must be distinguished from race. *Race* refers to outward physical attributes such as the color of the skin, whereas

ethnicity is comprised of cultural traits, and is a factor of *identity* for those who share these traits. Second, the status of being an *immigrant* is a legal construct and differs in this regard from race and ethnicity which are cultural constructs. The fact that being an immigrant is primarily a legal status in Western societies implies that there are forms of immigration which are illegal. In contradiction, asking whether one belongs legally or not to a racial or an ethnic group is generally a spurious question. However, race and ethnicity can be construed as a legal status, as it was in Nazi Germany, in South Africa during the period of Apartheid, and in Rwanda, where one's identification papers indicate whether one is a Hutu or a Tutsi. As is shown by these examples, attempts to enshrine in law differences with regard to race or ethnicity have often resulted in human tragedies. One exception to this assertion is granting a specific legal status to *Aboriginal peoples* in countries such as Australia, Canada, New Zealand, the US, and in South America. The purpose of this measure—which was very imperfectly achieved—was to recognize that the Aboriginal peoples were the first nations that populated these countries and that they were entitled as such to certain privileges.

The importance of making the preceding distinctions is embodied in one cardinal rule for addressing the issues raised in this article: the wider are the categories used—e.g., being white or black-skinned—and the lesser the probability to shed light on an issue (Georges-Abeyie 1989).

3. *Further Basic Distinctions: Disparity and Discrimination*

There is one last distinction that does not refer to groups of persons but that defines the most important issue discussed in relation to these groups. Disparity should not be confused with discrimination. *Disparity* is a descriptive notion and refers to a difference, which reveals itself through disproportion or over-representation. For instance, it is well known that African Americans are disproportionately represented in the US prison population with regard to their number in the total population. *Discrimination* refers to the differential treatment of groups without respect to the behavior or qualifications of individuals belonging to such groups (Walker et al. 1996, p. 16). Discrimination can be used to explain disparity. It varies in scope from cases of *individual* prejudice to differential treatment which is applied *systematically* at all thresholds within a system. *Systemic*, as opposed to *systematical* discrimination, occurs when disparity is unintendedly generated by features integrated within a system of rules. For instance, very few Asian immigrants were hired in Western police forces because of obsolete height requirements that they could not meet.

4. *The Main Issues*

Until the 1990s, the issues most debated concerned racial and ethnic minorities in their relation to crime. In recent years, immigration also became an issue through the problem of illegal immigrants. Because the US and the UK are the only countries collecting data that are sensitive to ethnic and racial differences, this article will focus mostly on US and UK data.

4.1 *Disparity or Discrimination*?

The evidence of disparity is overwhelming, particularly with respect to the most repressive component of the penal system, that is, incarceration.

(a) Although African Americans comprise 12 percent of the US population, they account for 31 percent of the federal and for 51 percent of the state prison population (Walker et al. 1996, p. 205).

(b) In 1992, Black people constituted 5 percent of the population of the UK but made up 18 percent of the prison population (Dhokalia and Sumner 1993, p. 28).

(c) In 1988, nearly one in three inmates in the Canadian western provinces were of Aboriginal ancestry. Aboriginal people make up almost 10 percent of the federal inmate population, although they make up less than 2 percent of the Canadian population (Law Reform Commission of Canada 1991, p. 67, note 166).

These figures on the over-representation of racial or ethnic minorities are the same with respect to the operation of other components of the criminal justice system, most noticeably the police. In a 1975 experiment conducted in two precincts of San Diego, nearly half of all people stopped and questioned by police were African Americans, even if they respectively represented only 17.5 percent and 4.8 percent of the population of the two precincts in the study (Walker et al. 1996, p. 101). The evidence is similar for the UK (W. Skogan 1990, *The Police and Public in England and Wales: A British Crime Survey Report*. Home Office Research Study No. 117, HMSO, London). Racial profiling still is a persistent feature of policing.

Such being the evidence for disparity, what of its explanation by ethnic or racial discrimination? Two quotes from the work of Robert Reiner epitomize the present predicament of research in this respect. Reiner wrote in 1989 that despite methodological caveats, 'the quantity and quality of (the) evidence is such as to render any doubts about discrimination fanciful' (Reiner 1989, p. 8). He also wrote in 1992 that it was 'inconceivable that the (statistical) approach could ever conclusively establish racial discrimination' (R. Reiner, quoted in D. Cook and B. Hudson (eds.), *Racism and Criminology*, Sage, London, 1993, p. 8). Therein lies the paradox. On the one hand, the evidence of disparity is so overwhelming that it

seemingly does not allow for explanations other than intended discrimination. On the other hand, most statistical attempts to demonstrate the presence of discrimination are inconclusive, when all variables are duly controlled. For instance, African Americans and Hispanics were respectively found to be six and four times more likely to be shot by police in Chicago between 1974 and 1978. However, when the research controlled for the risk status, defined in terms of arrests in the context of the perpetration of a serious violent crime, the racial disparity vanished, and it was white perpetrators that were more likely—but not by much—to be shot by police (A. Geller and K. J. Karales 1981 *Split Second Decisions: Shootings of and by Chicago Police*. Chicago Law Enforcement Study Group, Chicago, p. 119). Such erosion of the discrimination factor in controlled statistical research occurs most of the time (Hagan 1988).

What then is the explanation of racial and ethnic disparity in criminal justice?

(a) There is no question that discrimination plays a role. However, it is difficult to assess its extent, which is revealed only by complex statistical analysis highly dependent on data quality (Blumstein et al. 1983, Hood 1992).

(b) Factors which are in themselves racially and ethnically neutral also account for disparity. Judges tend to incarcerate youths when their family cannot provide any support for their rehabilitation. The number of broken African American homes being high, more young African Americans are consequently put in jail. There are many of these neutral factors, ranging from the way in which an immigrant community tries to integrate (Smith 1997, p. 759), to special forms of drug addiction (crack vs. powder cocaine) that are repressed with disproportionate severity (Tonry 1995, p. 188).

(c) Nevertheless, the most thorough and methodological research generally concludes that it is the differential involvement of minorities in the perpetration of crime that mainly explains disparity (Smith 1997). This conclusion is frustrating because it only pushes the problem one step further: why are some ethnic and racial minorities more involved in crime?

4.2 *Intra- or Intervictimization*

Another volatile issue is whether perpetrators victimize members of their own racial or ethnic community or whether they cross the ethno-racial divide. The answer to this question varies from one country to the other.

(a) In the US, white offenders victimize the white community in more than 90 percent of cases. However, the percentage of white victims from African American offenders ranges between 40 percent for all violent crime and 60 percent for robbery (Walker et al. 1996, p. 49).

(b) In the UK, white offenders cross the ethno-racial divide much more frequently, 68 percent of Asian and 50 percent of Afro-Caribbean victims having identified their aggressor as white in recent British crime surveys (1988 and 1992; Smith 1997, p. 715). Afro-Caribbeans also cross this divide, 23 percent of Asian victims having identified their aggressor as Afro-Caribbean.

The difference between the US and the UK in terms of the tendency of whites to attack other communities may in part be explained by the fact that the Afro-Caribbean community is less than 1 percent of the total UK population, whereas African Americans account for 12 percent of the US population.

4.3 *Issues Related to Illegal Immigration*

Although illegal immigration is an old phenomenon, the issues that it raises have taken a particular urgency after 1990 but they have not been thoroughly researched yet. Three issues can be singled out. First, the criminal networks involved in smuggling illegal immigrants have grown immeasurably since the end of the Cold War and the explosion of civil strife in former Eastern bloc countries. Second, although it is directly related to the previous one, the issue of the transnational exploitation of prostitutes, often recruited in refugee camps, is a pressing one, for which the police have no immediate answer. There is finally the question of how to react to illegal immigrants who have settled for a number of years in their adopted country, where they have begun to be socially integrated, but where they have failed to meet the legal requirements to obtain legal citizenship.

5. *Conclusion*

This article has focused mainly on the overpunishment of racial and ethnic minorities and on its possible explanations. There is a concomitant phenomenon which falls outside the scope of this article, but that deserves to be mentioned: it is the underpunishment of members of the white majority when they victimize minorities (Radelet 1989). Finally, it ought to be stressed that in the present context of globalization, the migratory fluxes will increase, thus sharpening the edge of the issues that we have been discussing. As long as most Western countries will resist collecting data sensitive to race and ethnicity, their policies on integration will be developed in a blind vacuum.

Ethnicity, Race, and Health

This article provides an overview of the role of race and ethnicity in health. Racial and ethnic statuses are primarily social categories that can reflect differential exposure to health-related risks or resources. Accordingly, across a broad range of societies, disadvantaged racial and ethnic populations have elevated rates of disease and death. Racial disparities in health are persistent over time. Data suggest that racial differences in health largely reflect racial variations in socioeconomic circumstances, but individual and institutional discrimination often play an incremental role. Understanding racial and ethnic variations in health requires greater attention to data quality issues and to assessment of both the resources and vulnerabilities to which population groups are exposed.

1. *What is Race and Ethnic Status?*

Historically, race has been viewed as capturing biological variation within human populations. However, the concept of race never rested on a firm, scientific foundation. Racial taxonomies pre-dated modern scientific theories of genetics and carefully executed genetic studies. Thus, race emerged as a sociopolitical construct, useful not only to classify phenotypic variation but also to justify the exploitation of groups defined as inferior. Historically, the conceptualization of race has been influenced by cultural and political considerations, and race has served important ideological functions in society (Duster 1984). For example, medical research in the nineteenth century attempted to document that blacks were biologically inferior to whites and therefore more susceptible to a broad range of diseases (Krieger 1987). Importantly, such data provided a scientific justification for slavery and economic exploitation.

Understanding and addressing the role of race and ethnicity in health requires a clear understanding of what race is, and the identification of the specific risk factors and resources linked to racial and ethnic status that may be responsible for variations in health. A growing body of evidence indicates that the traditional conceptualization of race is flawed. Scientific data reveal that 95 percent of human genetic variation exists within racial groups (Lewontin 1982). That is, there is more genetic variation *within* races than between them and, although there are patterns to the distribution of genetic characteristics, our racial categories do not capture biological distinctiveness. Our current racial categories are more alike than different in terms of biological characteristics and genetics, and there are no specific, scientific criteria to classify the human population unambiguously into discrete biological categories with rigid boundaries (Lewontin 1982). Racial taxonomies are arbitrary, and race is more of a social category than a biological one.

Although ethnic groups can share a range of phenotypic characteristics due to their shared ancestry, the term 'ethnicity' is typically used to highlight cultural and social characteristics instead of biological ones. Ethnic groups share some combination of common geographic origins, family patterns, language, common values, cultural norms, religious traditions, literature, music, dietary preferences, and

employment patterns. Thus, the current 'racial' categories really capture ethnic variation; that is, they reflect common ancestry, history, or culture. Some have suggested that the term ethnicity should replace 'race' in health research, and the term race should be abandoned (Cooper 1994). However, although not useful as a biological category, race is an important social category. It is what sociologists call a master status—a central determinant of social identity and obligations, as well as of access to societal rewards and resources. Given that racial categories have reflected racism and its consequences (oppression, exploitation, and inequality) historically, collecting the appropriate data on race can facilitate ongoing monitoring of the magnitude of differentials and enhance understanding of their causes and the development of effective interventions to address them.

Relatedly, although variations in health are evident for many ethnic groups, much of the marked variation is evident for minority racial and ethnic groups. The term minority is used, not to represent the numerical size of a population, but rather to reflect the stratification and access to power and resources of that group. The current minority groups in the United States, for example, reflect the intersection of racial and ethnic status combined with economic disadvantage. Only those population groups that experienced prejudice and discrimination historically and have been unsuccessful in assimilating are minority groups.

2. *Racial and Ethnic Variations in Health*

Across a broad range of societies, racial and ethnic statuses predict variation in health. The United States has routinely reported health statistics by race, and the role of race and ethnic status is readily evident in US data. National mortality data reveal that African Americans (or blacks) have death rates that are higher than whites for 13 of the 15 leading causes of death in the United States (NCHS 1991). The differences in death rates are small for some conditions, such as atherosclerosis, but at least twice as high for deaths from diabetes, kidney disease, homicide, septicemia, prenatal conditions, and HIV/AIDS. These pervasive disparities across such a broad range of health conditions are striking. In US data, Hispanics and American Indians have lower mortality rates than whites for cardiovascular disease and cancer, but higher rates for some causes of death, such as diabetes and cirrhosis of the liver. In contrast, the Asian American population has mortality rates that are lower than those of whites.

Until recently, the United Kingdom did not focus on racial/ethnic variations in health. However, analyses of death rates by country of birth suggest that there may be important racial/ethnic variations in health status in England (Balarajan and Raleigh 1995). These patterns are complex and vary by both the specific ethnic group and health outcome under consideration. For example, death rates from coronary heart disease and stroke are higher than the national average for persons from the Indian subcontinent and the African commonwealth. In contrast, Caribbean immigrants have mortality rates lower than the national average for coronary heart disease but higher for hypertension and stroke. Similarly, persons from the Indian subcontinent and the Caribbean have higher-than-average mortality for cancers of the liver, gall bladder, and cervix. Death rates from breast and lung cancer are lower in these three major immigrant groups, but Asians have high rates for oral cancer, and Caribbeans have high mortality rates from prostate cancer.

The experience of the United States and England is not unique. In a comprehensive review of racial and ethnic differences in disease internationally, Polednak (1989) reveals that racial and ethnic status predicts variations in health across a broad range of societies. Disadvantaged racial/ethnic groups, such as the Maori in New Zealand, blacks in South Africa, and Aboriginal populations in Australia, have higher rates of disease than the more advantaged groups within their societies. For example, for the 1991–6 period in South Africa, compared to the survival experience of white infants, the infant mortality rate was 5.2 times higher for blacks, 4.2 times higher for Coloureds and 1.3 times higher for Asians (Sidiropoulos et al. 1997). Recent Australian data reveal that the rate of low birthweight infants for indigenous mothers is twice that of their nonindigenous peers, and the neonatal mortality rate (deaths of liveborn infants within 28 days of birth) is 2.6 times higher for babies born to Aboriginal mothers compared to the rest of the population (McLennan and Madden 1999). These elevated mortality rates persist throughout the life course, with Aboriginal males and females having a mortality rate between ages 35 and 44 that is at least seven times higher than that of the nonindigenous population. Moreover, there is considerable variation by ethnic status in multiple societies, with some ethnic groups having higher frequencies of some disease conditions but lower frequencies of others (Polednak 1989). For example, among European groups, the French tend to have low rates of heart disease, the Poles low rates of stroke, and the Finns low rates of breast and colorectal cancer.

2.1 *Persisting Racial Disparities in Health*

One important feature of racial differences in health is the persistence of the racial gap in health status over time. For example, despite declining death rates from stroke in England between 1970 and 1983, there was the persistence of elevated rates of stroke deaths for persons from the Caribbean and Africa (Balarajan and Raleigh 1995). Table 1 shows that, in 1950, blacks

Table 1
Mortality rates by race 1950—97

	All-cause mortality Deaths per 100,000 population			Infant mortality Deaths per 1,000 live births		
Year	White (W)	Black (B)	B/W Ratio	White (W)	Black (B)	B/W Ratio
1950	800.4	1,236.7	1.5	26.8	43.9	1.6
1960	727.0	1,073.3	1.5	22.9	44.6	2.0
1970	679.5	1,044.0	1.5	17.8	32.6	1.8
1980	559.4	841.5	1.5	10.9	22.2	2.0
1990	492.8	789.2	1.6	7.6	18.0	2.4
1997	456.5	705.3	1.5	6.0	14.2	2.4

Source: NCHS, 1999

in the United States had an overall death rate that was 1.6 times higher than that of whites. Mortality rates have declined for both racial groups over time, but in the late 1990s, blacks had a death rate that was still 1.6 times that of whites (NCHS 1999). For several causes of death (heart disease, cancer, cirrhosis of the liver, and diabetes), the black/white ratio was wider in the late 1990s than in 1950. There were multiple paths to this pattern of persistent racial differentials (Williams 1999). For some outcomes, such as heart disease, declining rates are evident for both racial groups, but the black/white difference widened due to more rapid improvements in the health of the white population than of the black population. For cancer and diabetes, there were stable or declining rates for whites, but increasing rates for blacks. For other outcomes, such as stroke and unintentional injury, the black/white gap was virtually identical in the late 1990s to what it was in 1950. However, influenza and pneumonia stand out as the only causes of death where the black/white difference in mortality has narrowed over time due to more rapid improvements in the health of the black compared to the white population. We need an enhanced understanding of the reasons for this success so that we could develop interventions to replicate it.

Infant mortality data tell a similar story. The right panel of Table 1 indicates that, compared to the 1950 infant death rate, the 1997 infant mortality rate was three times lower for blacks and more than four times lower for whites (NCHS 1999). However, the relative difference in rates between the two racial groups was larger in 1997 than in 1950. A black infant was 1.6 times more likely than a white infant to die before his or her first birthday in 1950. This ratio increased to 2.4 in 1997.

3. *Economic Status: A Central Determinant of Health*

Although racial and ethnic status do not tell us much about underlying biological risks for disease, they do reflect an important part of the economic inequality and historic injustice that has existed in particular societies. Racial differences in economic circumstances are central to understanding health status variations.

3.1 *Racial Differences in Socioeconomic Status*

There are important differences in power and socioeconomic status (SES) across major racial and ethnic groups. Table 2 presents levels of per capita income and poverty rates by race in South Africa from a World Bank-funded national survey on Living Standards and Development conducted in 1993. Racial disparities in economic circumstances are striking. Whites in South Africa have a per capita income (R 32,076) that is almost 12 times that of blacks, five times that of Coloureds, and two and a half times that of Asians (Whiteford et al. 1995). In a similar vein, compared to the poverty rate of whites of 2 percent, the rate of poverty is 29 times higher for blacks, 10 times higher for Coloureds, and more than three times higher for Asians. For all racial groups, the poverty rate is higher for children than for the total population.

In the United States, blacks, Hispanics, and American Indians have lower rates of income, education, and occupational status than whites. The Asian population in the United States is overrepresented at both ends of the SES distribution. Compared to whites, Asians have higher levels of median income, but some subgroups of the Asian population, such as the Hmong, Laotians, and Cambodians, have lower levels of income and higher rates of poverty than the black or the American Indian population. This highlights the heterogeneity that exists within many of the major racial and ethnic categories, and the importance of attending to the variation within these subgroups. For multiple health outcomes and multiple racial/ethnic groups, an overall statistic masks the variation that exists for subgroups within that population.

Data for the US also reveal that racial differences in income understate the true magnitude of racial differences in economic circumstances. Income captures the flow of economic resources into the household. Wealth

Table 2
Selected socioeconomic characteristics and race, South Africa 1993

SES Indicator	African	Colored	Asian	White
1. Per capita income (Rand)	2,717	6,278	12,963	32,076
2. Poverty				
Percent poor, all	57.2	19.8	6.8	2.0
Percent poor, children	63.9	23.1	9.6	2.1

Table 3
United States life expectancy, at age 45, by family income (1980 dollars)

	Females			Males		
Family income	White	Black	Difference	White	Black	Difference
All	*36.3*	32.6	*3.7*	*31.1*	*26.2*	*4.9*
1. Less than $10,000	35.8	32.7	3.1	27.3	25.2	2.1
2. $10,000–14,999	37.4	33.5	3.9	30.3	28.1	2.2
3. $15,000–24,999	37.8	36.3	1.5	32.4	31.3	1.1
4. $25,000 or more	38.5	36.5	2.0	33.9	32.6	1.3

NCHS 1998; NCHS 1997.

reflects the accumulated economic reserves that can cushion a decline in income and facilitate long-term planning. Racial differences in wealth are considerably larger than those for income. For example, in the United States, the median net worth of whites ($44, 408) is almost ten times larger than that of blacks, and eight times larger than that of Hispanics. Moreover, measures of wealth make an incremental contribution in predicting variations in health over and above measures of education and income (Williams and Collins 1995).

3.2 Race, SES, and Health

Research reveals that SES differences between the races account for much of the racial/ethnic differences in health. For example, adjusting black/white disparities in health in the USA for SES sometimes eliminates, but always substantially reduces, these differences. Table 3 illustrates these patterns. It presents US life expectancy at age 45 by family income for black and white males and females. At age 45, white males have a life expectancy that is almost five years longer than their black counterparts; and white females outlive their black counterparts by 3.7 years. Several important trends are noteworthy. First, for both racial groups, income is strongly linked to life expectancy. Consistently, persons of lower levels of income have lower life expectancy than their more economically favored peers. Second, the effect of SES on health is not confined to the low end of the income distribution. Persons of each higher level of income experience better health than those at the level immediately preceding theirs, at least up to the highest category used here (which is about the median).

Third, the difference in health status by SES for both black and white men is larger than the overall racial difference. African American men in the highest income group live 7.4 years longer than those in the lowest income group; the comparable number for whites is 6.6 years. The overall racial difference for men was 4.9 years. Although SES predicts variation in health for both black and white women, for women, the overall racial difference is somewhat larger than the differences between SES groups. The life expectancy data also reveal an independent effect of race, even when blacks and whites are comparable in income. At every level of income for both men and women, African Americans have lower levels of life expectancy than their white peers. This pattern has been observed across multiple health outcomes, and for some indicators of health, such as infant mortality, the racial gap becomes larger as SES increases.

3.3 Racism: An Added Burden for Non-dominant Populations

There are several factors linked to historical or contemporary racism that can account for these differences. Racism refers to organized institutional structures and policies, built on an ideology of superiority that allocates systematically fewer societal resources to groups regarded as inferior. Racial residential segregation in the United States and South Africa has been a prime example of a societal structure that importantly restricted socioeconomic opportunity and mobility for groups regarded as inferior (Cell 1982, Jaynes and Williams 1989). Residential segregation determined housing conditions, education and employment opportunities, and thus truncated

economic mobility. Because of conditions created by residential segregation, SES indicators are not equivalent across race. There are racial differences in educational quality in elementary and high schools. Similarly, the income return for a given level of education varies by race. For example, data from the United States reveal that, at every level of education, blacks and Hispanics, working full time in the labor force, have lower levels of income than whites (Williams and Collins 1995).

We noted earlier that there were large racial differences in wealth. These racial differences in wealth are evident at all levels of income, and are largest at the lowest income level (Williams and Collins 1995). For example, persons in the lowest quintile of income in the United States, the net worth of whites is $10,257 compared to $1 for blacks and $645 for Hispanics. For most US households, housing equity is a major source of wealth. Thus, contemporary racial differences in wealth reflect the institutional discrimination that was embodied in government housing policy and the practices of banks and the real estate industry a generation ago (Jaynes and Williams 1989). There are also large differences in purchasing power across race. For example, on average, African Americans pay higher prices for a broad range of goods and services (such as groceries, housing, and insurance) because of the higher costs in the residential contexts in which they reside. Residential segregation has also led to the concentration of poverty and the non-equivalence of neighborhood environments across race. Compared to whites of equivalent income, blacks in the USA live in communities lower in SES and resources, such that, in the 171 largest cities in the USA, the worst urban residential context for whites is better than the average context of black communities (Sampson and Wilson 1995).

Second, the health status of adults is influenced not only by current SES but also by exposure to adverse economic conditions over the life course. Non-dominant racial groups are more likely than their economically favored counterparts to have experienced economic deprivation, elevated rates of illness, and deficits in medical care during infancy and childhood. Some research suggests that the health status of adults may be affected adversely due to childhood diseases and living conditions, as well as to nutritional deprivation in the intrauterine environment or during infancy and childhood (Elo and Preston 1992). Thus, the persistence of racial differences in adult health, even in the face of adjustment for SES, could reflect, at least in part, racial differences in early-life economic and health adversity.

Third, racial discrimination and prejudice may constitute added risk factors that adversely affect health. There is evidence of systematic discrimination in the quantity and quality of services across racial groups, including medical care (Williams 1999). Studies in the United States reveal that, even after adjustment for SES, health insurance, and clinical status, whites are more likely than blacks to receive a broad range of specific medical procedures. These disparities exist even in contexts where differences in economic status and insurance coverage are minimized, such as the Veteran's Administration Health System and the Medicare program.

Research also suggests that subjective experiences of unfair treatment may be an important type of stress that can affect health adversely. Several studies reveal that experiences of discrimination are related adversely to physical and mental health (Krieger 1999, Williams and Williams-Morris 2000). Some recent data suggest that exposure to experiences of discrimination makes an incremental contribution to explain racial differences in self-reported measures of health over and above SES (Williams 1999). Other data indicate that a widely held societal stigma of inferiority can create specific anxieties, expectations, and reactions that can adversely impact socioeconomic performance as well as mental health status (Williams and Williams-Morris 2000, Steele 1997). First, across multiple societies, groups viewed as inferior have lower educational performance. Second, members of negatively stereotyped groups may internalize societal stereotypes such that the stereotype becomes a self-fulfilling prophecy leading to poor performance. Alternatively, the threat of poor performance can lead to anxieties that affect academic performance adversely. Third, some limited research suggests that African Americans who endorse negative cultural images of their group tend to have higher levels of depressive symptoms and substance use.

3.4 Changes in Racial Inequalities in Health

Data from the United States suggest that patterns of racial inequality change over time in response to larger socioeconomic changes. For example, although it was noted earlier that the black/white gap in overall mortality was identical in the late 1990s to what it was in 1950, over this time period there were times of both widening and reduced racial differentials in health. For example, the Civil Rights Movement improved the economic circumstances of blacks and narrowed the black/white gap in income during the 1960s and early 1970s. Correspondingly, mortality rates for blacks declined, both on a percentage and an absolute basis, more rapidly than those of whites between 1968 and 1978 (Williams and Collins 1995). Similarly, during this time period, the life expectancy increases for black males and females were larger on both a relative and an absolute basis than those for whites. However, the economic status of blacks relative to whites stagnated in the mid-1970s and worsened during the 1980s. Similarly, the black/white gap in health worsened for multiple indicators of health status during this decade. The black/white gap in life expectancy, infant mortality, and excess deaths in-

creased between 1980 and 1991 (Williams and Collins 1995). For example, for five consecutive years after 1984, the life expectancy at birth for blacks progressively declined from 1984 levels, while that of whites continued to increase progressively. These data are consistent with research, which shows that the health of populations is affected by a broad range of economic factors, including growth, stability, and inequality (Brenner 1995). For example, mortality from all causes tends to increase about two to three years after the low point of a recession. These data highlight that both race and SES have powerful influences on health because, as master statuses, they shape the experience of and exposure to almost all psychosocial and environmental risk factors for health.

4. Data Quality

Race is routinely used in both the health policy and the research literature in a routine, atheoretical, and uncritical manner, with little attention given to the measurement difficulties that are attendant on the assessment of racial categories. However, there is growing attention to reliability and validity problems linked to the assessment of race that have implications for the quality of available data on racial differences in health (Hahn 1992, Williams and Collins 1995).

4.1 Problems with the Numerator

In the United States, it is well documented that the numerators for officially reported death rates and some other health events are underreported due to the discrepancy between interviewer-observed race and respondent-reported race. This problem is minimal for data on blacks and whites, but substantial for American Indians, Asians, and Hispanics. Persons who self-identify with these groups are often misreported as white on death certificates and in other health statistics contexts. This numerator problem leads to an underestimation of health events for these racial/ethnic groups.

4.2 Problems with the Denominator

Another problem affecting the quality of racial data is the accuracy of the denominators used in calculating rates of health events. In many countries, data collected by the official census are used as the basis for denominators. In the United States, Census Bureau evaluations of the extent of the undercount based on administrative data and demographic trends reveal that, while the overall undercount for the United States population is small, it is considerably larger for blacks than for whites, and is especially large for middle-aged black males. Importantly, the use of a denominator that is undercounted inflates the obtained rate in exact proportion to the undercount in the denominator. Thus, most officially reported mortality and morbidity rates for middle-aged black males are about 15 percent too high. Currently, demographic analysis estimates of Census undercount are available only at the national level, and it is likely that the omission of black males from households (the major cause of the undercount of blacks) varies by geographic area and could thus be considerably larger for some states or municipalities.

4.3 The Challenge of Defining Race and Ethnicity

Data from the US also suggest that there is considerable inconsistency in reporting racial, and especially ethnic, status over time. Given that many persons are multiracial or multiethnic in ancestry, self-identity appears to be importantly linked to the particular context of measurement. Relatedly, there is considerable debate over the optimal terminology to be used for particular racial groups, the number of racial groups for which data should be collected, the boundaries between racial and ethnic status, and whether new categories should be developed for persons who are of mixed ancestry. For a growing number of persons in society, racial and ethnic status is not singular and static, but multiple and dynamic (Evinger 1995).

Complicating the definitional problems linked to race is the fact that categories of race and ethnicity are often assessed differently across societies, over time within particular societies, and by different agencies and institutions even within the same society. In the USA, for example, the standard birth and death certificates were revised in 1989 to include identifiers for Hispanic status. But the wording of the question assessing Hispanic status varies from state to state, and the data on Hispanic ethnicity is not completely reported in all states. Similarly, many health surveys and federal data-collection systems in the USA use one question to assess race and a separate one to assess Hispanic origin, while other agencies use one combined question to assess both racial and ethnic status. Importantly, differing wording of racial and ethnic questions will provide varying estimates of the size of racial/ethnic populations.

5. Resources and Acculturation

Health-enhancing resources exist even in the most disadvantaged racial and ethnic populations. Much research on the health of the disadvantaged has focused historically on pathology and vulnerability. However, the available health data clearly suggest that health-enhancing factors are also resident within contexts of economic deprivation. For example, despite high rates of poverty and low rates of health insurance coverage, Mexican immigrants still have a

relatively good health profile. Similarly, although African Americans are disadvantaged on almost every indicator of physical health status compared to whites, they have surprisingly good levels of mental health (Williams and Williams-Morris 2000). Rates of suicide are markedly lower for blacks than whites, and blacks tend to have equivalent or lower rates of psychiatric illness compared to whites. These data suggest the need to identify cultural strengths and health enhancing resources that exist within disadvantaged communities, and that may shield these populations from at least some of the negative exposures in their social context. Research has nominated the quality of family and extended kin relationships, as well as the role of religious institutions and participation, as key health-enhancing resources that may reduce some of the negative effects of stress on the health of disadvantaged populations. More research is needed on the mechanisms and processes by which these factors operate, and the ways in which they combine with existing risk factors to affect health.

In many societies, many minority racial and ethnic groups are immigrant populations. The health profiles of these groups may reflect their immigrant status importantly and may change with increasing length of stay in the host society. In the United States, immigrants of all the major racial/ethnic groups have lower rates of infant and adult mortality than their native-born counterparts (Williams 1999). Importantly, these patterns persist even when immigrant groups, such as Mexicans in the United States, are lower in SES and have limited access to medical care. At the same time, other data suggest that, across a broad range of health status indicators such as infant mortality, low birth rate, cancer, high blood pressure, adolescent pregnancy, and psychiatric disorders, the health status of immigrants worsen with length of stay in the USA (Williams and Collins 1995). The mechanisms and processes responsible for these negative effects of acculturation are not fully understood. Several behaviors that adversely affect health status appear to increase with length of stay. It has also been suggested that there may be health-protective aspects of indigenous cultures and belief systems that are lost with increasing time in a new society.

Culture is a construct that is widely invoked in discussions of racial and ethnic variations in health. However, it is often treated as a residual explanation for unexplained differences in health. There is a critical need for the theoretical identification and the empirical assessment of the specific cultural beliefs and behaviors that are presumed to affect health. Moreover, researchers must avoid labeling as cultural what are more structural differences in the social position of different groups. Culture is dynamic and its development and persistence must be understood within the context of powerful reciprocal influences that are operative as social groups interact with the constraints and opportunities of their specific environment.

6. *Concluding Recommendations*

Future research on racial/ethnic variations in health must assess comprehensively racial and ethnic status. This should include the assessment of the considerable ethnic heterogeneity that exists within all of the widely used racial categories. Second, researchers must recognize that there is no generic health model that applies equally to all racial or ethnic minority populations. Research and health policy regarding race should be attentive to the distinctiveness of each racial group, including using the terms that are broadly recognized and preferred by a substantial proportion of respondents of particular racial groups. The fluidity of racial and ethnic categories requires periodic monitoring and updating measures of racial and ethnic status. Importantly, whenever racial and ethnic data are reported, more attention must be given to the interpretation of these data. For example, it is always necessary to indicate why race or ethnicity is being utilized, the limitations of racial and ethnic data, and how the findings should be interpreted. Given the strong association between racial/ethnic status and SES, the presentation of data on racial differences should routinely stratify them for SES within racial groups. Failure to attend to these issues of presentation and interpretation may misspecify complex health risks and even perpetuate negative racial stereotypes. Finally, future research must conceptualize and operationalize increasingly the specific factors linked to race that might affect health.

D. R. Williams

Ethnicity, Sociology of

Ethnicity was conspicuous in Athens, Rome, and Alexandria, and it was also a factor in the Indian caste system, the millet of Muslim societies, and in other instances of segregated groups. In these premodern cases, ethnic relations were taken for granted, and imposed, by superior authorities, traditions, abrupt power relations, or the individuals involved themselves. It is principally in modern settings that processes like the emergence of the nation-state—as the primary focus of identification—and the growth of a meritocratic–individualistic civilization have seemed to leave no room for continuous ethnic allegiances. It is also then that the persistence and increasing saliency of ethnicity have led scholars to delve into the phenomenon as a sociological issue. Max Weber (1978) spoke of ethnicity to designate collectives characterized by religious, historical, linguistic, or racial traits. Since the 1960s, following the political awakening of Blacks and other groups in the USA, 'ethnic group' became popular among sociologists while some of them proposed 'imagined communities' (Anderson 1983). Such groups respond to a variety of syndromes, and may also be factors of political change—especially in democratic settings—when they contribute to the assertion of multiculturalism and eventually evolve, in this era of globalization, into 'transnational diasporas.'

1. *A Kind of Collective Identity*

Above all, ethnicity consists of a reference to a collective identity, i.e., how and how far individuals: (a) feel committed to people whom they see as fellow-members of their group, (b) perceive that group as conveying singular, 'original' and 'unique' values, norms, or symbols, and (c) accordingly, distinguish themselves from nonmembers (see also Eriksen 1993). This notion describes an essentially subjective phenomenon and, beyond the structures and interests wherein it may concretize 'objectively,' it involves dilemmas more often than unambiguous assertions. Hence, the same identity may be phrased in different (possibly antagonistic) terms, over time (i.e., diachronically) or among different circles in the group (i.e., synchronically). A classic example is the Jewish identity. Traditional Jewishness has for long been the dominant trend among Jews, up to the advent of modernity, and it still defines Judaism by (a) its commitment to Jews' welfare anywhere, (b) its insistence on the religious faith and its constraints, and (c) its messianic aspiration to a repositioning vis-a-vis the non-Jew through Redemption. Many non-Orthodox and free-thinkers are, in contrast, (a) committed to a community which they perceive as (b) carrying universalistic values under the cover of

parochial customs, while at the same time, (c) also seeing themselves an integral, though distinct, segment of non-Jewish societies. The nationalists, as for them, speak of (a) patriotic commitment to (b) a notion of a Jewish nation that is, (c) 'territorialized' in the 'ancestral land,' as the basis of the 'normalization' of the Jewish condition among nations. These different versions pertain to a same identity only because they answer the same questions: the commitment to Jews, the perception of their singularity, and an understanding of the relation to non-Jews (Ben-Rafael 1998) (see also *Identity: Social*; *Race Identity*; *Identity Movements*). Such different versions of the same identity articulate distinct symbols or attach contrasted meanings to the same symbols. In both cases, they broadly, though not exclusively, draw these symbols, which are theirs, from the same 'store'—myths of descendancy, time-honored customs, and sanctified objects or places. As a rule, these symbols also include language, even though its relation to ethnicity is unpredictable in modern settings where political and cultural imperatives impose the public use of official languages and downgrade ethnic codes to the role of secondary vernaculars. It remains that linguistic elements—a regular register, a restricted vocabulary, typical expressions or a characteristic accent—tend to signal social intercourse involving an ethnic dimension and mark, under its different versions, a group's contrastive identity (Fishman 1989).

The different markers attached to the various versions of a same collective identity represent diverse manners of stating the group's 'uniqueness.' The comparison of these versions should reveal a common denominator that could be viewed as their deep structures. This denominator should make explicit the nature of the collective claims of the members of the group from society—whether or not these claims are consensual among them. The pertinence of this methodology is less obvious, however, when it comes to the more arduous comparative discussion of different identities, that is, of independent formulations of 'uniqueness.' In this respect, the analysis is to widen its scope to the social and cultural context, and its search for a common criterion of evaluation is to switch its focus from 'identity' to 'identification.'

2. *The Parameters of Identification*

More than the markers themselves, it is indeed their saliency in the social practice that indicates how far individuals refer to ethnicity in their daily life. This aspect points to the vitality of ethnicity, that is, the degree that ethnics identify with their particular identity through their participation in a wider society. Ethnic identification stands thus at the opposite of assimilation which depicts the abandonment by individuals of their original features and their increasing likening to people who embody, in their behavior and attitudes, the culture prevailing in society. Unlike acculturation, assimilation also includes collective identities, and researchers who have studied these processes show the role played here by three factors, namely, inequality, the dominant culture, and ethnics' own aspirations.

2.1 *Social Inequality*

The Chicago school has initiated a tradition in ethnic research which focuses on inequality in metropolitan areas; Robert Park, William Thomas, Florian Znaniecki, or Louis Wirth, for instance, emphasized race relations and immigrant groups. Later on, Leo Kuper explained ethnicity on the basis of domination relations, while Edna Bonacich investigated labor market participation. They and others also focused on ethnics' unequal access to social and educational opportunities, self-actualization, and empowerment (Giddens 1991). All in all, they show that ethnic groups tend to concentrate, and remain, in inferior strata as the outcome of two categories of factors: discrimination and weak human capital. By discrimination one means normally-'irrelevant' pressures of exclusion exerted against a group from outside. It is rationalized, especially where ethnicity is associated with race (Banton 1988), by ethnocentric and racist perceptions among the stronger group. While these attitudes may be diffused by people who feel threatened themselves, they sustain practices of inferiorization and instill deprivation that is found in ethnic identification, a manner for retaining self-dignity (see *Prejudice in Society*; *Egalitarianism, Sociology of*; *Race Relations in the United States, Politics of*). On the other hand, human capital refers to formal education, cultural predisposition, or models of behavior that account for individuals' capability to seize social opportunities. It is when members of a group exhibit weak human-capital assets that they are particularly vulnerable to discrimination. The confinement to lower status signifies that the group is of little attractiveness to other people, and this relative isolation accounts for restricted exposure to the prevailing culture (see *Inequality*). Hence, the group may be left to its parochial symbols and styles in the margins of society. By the same token, the contrary is true of mobility. Whether it concerns a small or large cohort of the group, mobility implies acculturation and lower saliency of ethnicity as a result of education, personal relations with 'others,' and participation in middle-class frameworks (see *Mobility: Social*). The extent, however, that acculturation leads to assimilation still depends on other factors.

2.2 *The Dominant Culture*

The culture which is predominant in society is another pertinent factor. The 'void of community,' it is often

contended, created by modernity induces individuals—mobile and nonmobile alike—to value the retention of community. Instrumental thinking which pervades all areas of life brings ethnics to aspire to self-expression and to assert their particular identities (Taylor 1994). More specifically, it is also contended that the 'dominant culture' is a contingency that may display diverse perspectives toward ethnicity and influence it in different manners. By this notion, one means the beliefs, values, and symbols that identify the society, according to those—the elite or larger social segments—which constitute its leading political forces. These forces give expression to the dominant culture by defining the legal frame of the social insertion of ethnics and weighing on the public opinion through media and policies. Hence, in Germany, the notion of *Volk* has for a long time stated the supremacy of the nation over the individual, and its anchorage in a given history and culture (Brubacker 1992). As a consequence, naturalization laws obstructed the acquisition of German nationality for non-Germans who reside in the country, even for decades. In the USA where an assimilationist notion of 'melting-pot' has been gradually substituted by a pluralistic concept of 'salad-bowl,' groups are entitled to retain their particularism while becoming Americans and adjusting to its culture. In France, the 'republican nation' is understood as a homogeneous whole—a 'community of citizens'—which expects new groups to integrate society on these terms (see also *Nation: Sociological Aspects*). Hence, these dominant cultures display distinct perspectives vis-a-vis ethnics' social evolution, i.e., assimilation, pluralism, or segregation.

2.3 The Group's Aspirations

The ethnics also play a part here, and it is at this point that identity is introduced as a factor of identification. In the same material and cultural circumstances, indeed, it is according to the contents of their identity that members of some groups may tend to be 'assimilationist' where others are 'retentionist' (Glazer and Moynihan 1963). Kinship ties, a common country of origin, or a collective religion are often depicted as 'primordial' bonds carrying special strength (Geertz 1963). More specifically, religion has often shown its power to retain the dedication of believers, and sustain the cohesion of communities, in front of assimilatory forces (Smith 1992). Even when challenged by modernity and secularism, it might be rephrased so as to retain relevance. At the limit, fundamentalism, which is one such rephrasing, acknowledges the predominant role of politics in modern societies to formulate the essentials of the faith in terms of a 'total' political project. Acting then as a quasi-Jacobinian force, fundamentalism, which itself stands out on behalf of a religious-ethnic collective, leaves little room in its utopia for any form of particularism (Eisenstadt 1997). It remains that as a case of ethnic community, and all other factors being equal, a religious group generally exemplifies the extreme end of 'retentionism,' the opposite of those who view assimilation as the realization of their aspiration.

3. The Diversity of Profiles

All three factors thus say 'something' of their own about ethnic identification/assimilation: (a) the concentration of a group in a lower class distances members from the surrounding culture, at the benefit of retentionism, while, in contrast, social mobility sustains acculturation; (b) a dominant culture encourages retentionism when it is segregative or pluralistic, and assimilationism when it requests cultural uniformization; (c) according to their own original perspectives, the orientations prevailing in the group influence its members whether to evince or to underrate their collective identity. Viewed together, these independent expectations widely account for the various profiles and extents that groups constitute 'contrastive entities' in society. This question puts in perspective material conditions and interests, cultural contexts and identity, and thus accounts for the maintenance, erasing, or reshaping of ethnic boundaries, e.g., what Stuart Hall calls ethnic 'cut-and-mix.' Empirical cases illustrate the syndromes yielded by this comparative methodology. American-Indian communities are an example of (a) an underprivileged category that suffered from discrimination and carried little human capital; (b) a case where the dominant culture was segregationist; and (c) a group whose basic orientations sustained the retention of its legacy and identity. The small number of acculturated but rarely assimilating mobile elements remains a part of their community best depicted as *enclave*. A low-class group such as *Afro-Americans* (until the mid-twentieth century) may, however, aspire to assimilation. Its weak collective identification leaves its few mobile elements free to aspire to assimilation. This, however, is *usurpation* for a segregationist dominant culture, which pushes them to form a 'black bourgeoisie' midway their original community and the dominant group. The *Quebecois*, a widely low-class population for decades, most often aspired to remain distinct from the assimilationist English-Canadian culture. Many stood for *autonomy*, even independence, while mobile elements split into supporters of assimilation, offered by the dominant culture and the retentionism of identity favored by the group's basic aspirations. Regarding *Brazil's Blacks*, again a disadvantaged group, no taboo, either from the dominant culture or the group, prevents assimilation. This is of little significance for the majority as only a few mobile individuals may contemplate integrating the pre-

dominantly white middle-class, leaving thereby their fellow-ethnics in *crypto-segregation*. In a context where mobility is more general in the group, *South African Indians* experienced *middle-class closure* under Apartheid, as a result of both the dominant culture's segregationism and their own reluctance to give up their particularism altogether. Ethnic markers and the concomitant adoption of traits indicating acculturation thus circumscribed the boundaries of quite a cohesive group. A model that may be labeled *margins to the center* concerns the mobile assimilationist Australian-Asian groups who are maintained at a distance by a pluralistic dominant culture. They are similar to the former case but emphasize less their own legacy, and more the markers of acculturation. Still different, the mobile *French Jews* confront a determinedly assmilationist dominant culture. Many effectively assimilate but others still share the group's original retentionism by maintaining homogeneous *networks*. The voluntary character of their allegiance accounts for the variety of their versions of collective identity. Where mobility has erased inequality and deepened acculturation, and the dominant culture and the ethnic group are both open to each other, one may finally speak of genuine *assimilation*, as illustrated by numberless groups ranging from Italians in France to Norwegians in the US.

4. *Multiculturalism, Globalization, and Transnational Diasporas*

In summary, the phrasing of their collective identity defines ethnics' self-perceived 'uniqueness' as a group; their identification/assimilation draws out their social boundaries. The identity explains the nature and consequent rationality of ethnics' claims and interests in terms of public goods, illustrating what Boudon (1993) calls 'normative rationality.' Identification accounts for the ethnics' determination to pursue these goods, as it fluctuates in the context of material and cultural conditions as well as according to the contents of their collective identity, which is a reminder of what Boudon calls 'subjective rationality' (see *Rationality in Society*). It is in this latter dynamic respect that beyond 'how society influences ethnic groups?' arises 'how ethnicity influences society?' This issue is mainly pertinent in a modern democracy, where nearly any group able to 'mobilize' its members has access to political opportunities, even when disapproved by the elite or public opinion. Parties or pressure groups presenting themselves on behalf of ethnics may gain influence, even recognition, if powerful enough to impose their participation and shrewd enough to exploit the rivalries characteristic of the political scene. Moreover, a successful group brings to ethnic politics other dormant allegiances (see also *Ethnic Conflicts*; *Ethnic and Racial Social Movements*). The risks implied by ethnic politics for the groups involved are indeed limited by the unconditional welfare rights that are anyone's in democracy, and which warrant ethnics a 'costless' liberty of political action. In turn, legitimate ethnic politics increases the systemic incoherence and fragmentation of the setting, substantiating the notion of multiculturalism (Rex 1996) by challenging the dominant culture, where it is assimilationist in its very ideological premises (see *Multiculturalism: Sociological Aspects*). Such developments are still amplified by 'globalization' processes which include new means of communication, an expansion of worldwide mass media, and improved air transport. By drastically reducing the significance of geographic distances, these circumstances stimulate new flows of emigration from all parts of the world toward wealthy countries. They also signify that integrating a new society does not necessarily imply for immigrants, emotional, cultural, and even social detachment from their countries of origin. From the onset, immigrants may institute direct contact with their families in the homeland as well as with friends and relatives living in other places. They are able to create a space of communication, including regular visits to and from the homeland and elsewhere, where the retention of languages and symbols of origin remain pertinent. On the other hand, in the context of rising multiculturalism in many of these societies which also often happens to be welfare states, such new groups also rapidly acquire the skills necessary for participation in open ethnic politics. Hence, while this global era is marked by a cultural uniformization forwarded by the influence of the West (Bauman 1998), one of the distinctive features that Western societies now share in common is their internal diversity. All these, however, do not exclude that these immigrants are not moved, as well, by the aspiration to integrate their 'choice society' by acquiring its legitimate language and culture. What these conditions indicate is the emergence of 'transnational groups' (Soysal 1994) attempting to illustrate additive bilingualism, dual culture, and at the limit, 'dual home.' While by the sequels of their original culture, they add to the diversity of their actual society (see *Migration: Sociological Aspects*), by the imprints of their experience in new cultural and social landscapes they produce the heterogeneity of their Diasporas. It is this duality that makes transnational diasporas a kind of bridge between choice societies and homelands that not only connect states but also populations.

Ethnoarchaeology

Ethnoarchaeology is the study of variability in material culture and its relation to human behavior and organization among living peoples in order to strengthen archaeological inference. The term first entered the literature in 1900 when the US anthropological archaeologist, Jesse Walter Fewkes, referred to himself as an 'ethno-archaeologist.' Since then, there have been a number of synonyms coined including 'action archaeology,' 'living archaeology,' and 'archaeological ethnography.' Most archaeologists prefer the term 'ethnoarchaeology' for this form of research.

1. History of Ethnoarchaeology

Its beginning is closely tied to the onset of anthropological archaeology in the USA around 1880. Most of the archaeological work was coordinated by the Bureau of Ethnology (later, the Bureau of American Ethnology) and was carried out in the American Southwest. Stimulated by the general theory developed by Lewis Henry Morgan (1877), archaeology was seen as the extension of ethnology into the past. Early workers include Fewkes, who worked with the Hopi Puebloan people (1900) and Frank Hamilton Cushing, who worked with the Zuni Puebloan people (1886). The concerns were upon the development of 'Puebloan society' through a study of its antecedents using archaeology aided by ethnology of the living Puebloan peoples.

With the publication of Morgan's final contribution in 1881, the Bureau hired an architect to document ruins and contemporary communities (Longacre 1999a). Victor Mindeleff and his younger brother spent more than a decade doing fieldwork in the US Southwest and used the data they collected among Puebloan peoples as an aid to interpreting archaeological sites (e.g., Mindeleff 1900). Both Cushing and Fewkes used design symbolism on pottery as an aid to archaeological inference.

Although from a contemporary perspective these early attempts at exploring behavior and organizational aspects of past societies seem simplistic, the questions they were concerned with have a modern tone. They did pioneer the methods of ethnoarchaeology, and they did use the results to strengthen their conclusions. At about the same time, in other parts of the world similar approaches begin to appear (e.g., Mitchell 1881).

A new general theory became dominant in US anthropology after 1910, and this had a profound effect on the nature of archaeology in the USA. It is most closely associated with Franz Boas and is often referred to as '*historical particularism*' (Darnell 1969). The emphasis on reconstructing culture history through a focus on culture 'traits' resulted in defining prehistoric cultures and placing them in time and space. The basic outline of prehistoric cultural development in the USA began to emerge as a result, but without the social or behavioral concerns of the previous era.

For nearly 50 years, anthropological archaeology continued to be dominated by this theoretical ap-

proach. As a result, archaeology became increasingly out of step with general anthropology, leading to great tensions within the field. The Kluckhohn–Taylor attack on the lack of modern directions in archaeology (Kluckhohn 1973, Taylor 1948) resulted in rapid changes in the field. By the early 1950s, explicit concern with social institutions in the past were returning to archaeology through settlement pattern studies pioneered by Gordon R. Willey (1953, 1956). The first attempt to reconstruct prehistoric social organization appeared at this time (Martin and Rinaldo 1950). Not surprisingly, a return to ethnoarchaeology appears then as well, after a hiatus of 50 years.

One of the first calls for such a return was made by the English archaeologist O. G. S. Crawford (1953), who based it upon his work in East Africa. He felt that a study of modern pottery and other materials among the living societies in the area could enrich archaeological interpretation. In 1956, Kleindienst and Watson (1956) called for 'action archaeology,' and, encouraged by Robert Braidwood, who was working in Iraq and believed that a study of modern villages, agriculture, and tools would help with an interpretation of the region's prehistory, Patty Jo Watson undertook ethnoarchaeological fieldwork in Iran (1979). The first ethnoarchaeological monograph of this new era was Raymond H. Thompson's *Modern Yucatan Maya Pottery Making* (1958).

The pace of ethnoarchaeology quickened after 1960, in response to the rise of the New Archaeology. Lewis Binford launched his fieldwork among the Nunamiut Eskimo in the 1970s (Binford 1978a). At the same time, Margaret Hardin began her lifelong interest in ceramic ethnoarchaeology through fieldwork among Tarascan Indians in Mexico (Hardin 1970) and, more recently, among Zuni potters in New Mexico (1989). Warren DeBoer and Donald Lathrap began their studies among the Conibo-Shipibo in South America (DeBoer and Lathrap 1979), as did Ian Hodder in East Africa (Hodder 1977) and Dean Arnold in Mexico and Peru (Arnold 1975, 1983, 1989). Kramer followed her earlier village ethnoarchaeology in Iran with a major project in India, where she focused on urban pottery production and distribution (Kramer 1982, 1997). Longacre began his field project among the Kalinga people of northern Luzon, Philippines in 1973, work that continues today. Brian Hayden launched the Coxoh Ethnoarchaeological Project in 1977, fieldwork that focused upon both stone tools and ceramics in the Maya Highlands (Hayden and Cannon 1984, Hayden 1987).

There are very few peoples left in the world who still make and use stone tools, especially chipped stone implements. Not surprisingly, there are relatively few ethnoarchaeological studies of such peoples. Hayden's work mentioned above as well as Richard Gould's project in Australia (1968) and recent studies by Stephen Brandt in Ethiopia on stone scrapers made and used in the processing of cow hides (personal communication) are examples. World globalization is reducing the availability of traditional crafts such as pottery making or stone tool production for ethnoarchaeological research.

Although chipped stone tools are extremely rare among modern hunter-foragers, we do have examples of ethnoarchaeological studies of bow and arrow hunters who use arrow points of metal or wood. One excellent example is the work of Griffin (1997), who has done fieldwork among Agta peoples of northeastern Luzon, in the Philippines. Most of the hunting is done by males among the Agta, but some hunting with the bow and arrow is done by skilled females as well.

Binford's ethnoarchaeological fieldwork among the Nunamiut has provided important contributions to our understanding of site formation processes (1978a, 1978b, 1979, 1980). His detailing of accumulations of faunal remains presents information that is useful in interpreting animal bone assemblages in prehistoric sites. Another important ethnoarchaeological example is continuing work among the Hadza peoples of east Africa by Bunn and O'Connell and their colleagues, focused on the implications of animal bone distributions in Hadza camps (O'Connell 1990, Bunn et al. 1991, Bunn 1993).

2. *Contemporary Approaches in Ethnoarchaeology*

Contemporary ethnoarchaeology is stimulated by several robust theories, including behavioral archaeology (Schiffer 1976) and the postmodernist inspired 'interpretive' anthropology (Hodder 1987). One area of great contribution by ethnoarchaeology lies in formation process research. Basic data, such as records of pottery use lives in ongoing societies, collected by multiple projects, have provided the basis for what has come to be called 'accumulations research' (Varien and Mills 1997). An understanding of subtle surface alterations reflecting use of pots has resulted in many insights to help archaeologists interpret prehistoric data.

One example of this is the pioneering work by Skibo (1992), which explores residue analyses with pottery collected among the Kalinga. Another area of important contribution to archaeological inference from ethnoarchaeology centers on the relationship between degree of standardization of particular products and the degree of specialization of the producers. If there is indeed a relationship, then prehistorians could look for the beginnings of standardized pottery, for example, as a correlate of the presence of craft specialists. Thus, early processes of state formation might be explored through ceramic standardization analyses. But is there really a link between standardization and specialization?

Ethnoarchaeological research would seem to be the ideal approach to explore the degree of linkage. One might begin with a field investigation among people where each household made its own pots. The Kalinga are a good example of this mode of production, and in many villages each household has at least one potter at work. Examining the degree of standardization, in this case metrical standardization, with a large sample of cooking pots reveals variation at about 12 percent. That is, in any dimension or in any ratio (height to aperture, etc.), Kalinga pottery varies about 12 percent. This provides a baseline to compare the pottery produced on a household basis with pottery made by more specialized producers, such as a group of craft specialists making pottery for market.

Several other field sites in the Philippines have now been used to provide the degree of metrical variation in pottery produced by specialized producers. The neighborhood of Paridijon, in the small city of Gubat in Sorsogon Province in southeastern Luzon, has around 70 potters working full-time (as weather and parenting duties permit) to produce thousands of kitchen pots, flower pots, and stoves per week. Measuring thousands of cooking pots from Paridijon reveals metrical variation hovering around 6 percent, roughly half that of Kalinga pottery. Using these data, a study was conducted using prehistoric cooking pots from Grasshopper Pueblo, a prehistoric community in Arizona to assess the mode of production. The Grasshopper pottery varied at 12 percent metrically, suggesting that the household mode of production was in place in this fourteenth-century community (Longacre et al. 1988).

Additional field sites have been explored that suggest that the link between specialization and standardization is not simply the unintended by-product of rote production as has been suggested, but rather is a deliberate attempt by specialized producers to make standardized products for their consumers. As a corollary of this, the older, more skilled potters make pots that are far more standardized than those made by beginner potters, even reaching an astounding 3 percent metrical range of variation (Longacre 1999b).

Identifying general principles such as these, which link variation in material culture to specific aspects of human behavior and organization, result in strengthening the power of archaeological interpretation. Ethnoarchaeology is one source for the identification of such regularities; experimental archaeology is another. A combination of the two would seem to hold special promise as a source of such principles.

Exploring performance characteristics (Schiffer and Skibo 1998) provides one example. The cooking pots produced by the craft specialists in a neighborhood of San Nicolas, a small city in Ilocos Norte Province in northwestern Luzon, are shiny and black in color. The potters explain that the black color makes their pots stand out and thus easily found by customers in the markets. This is an example of a visual performance characteristic. Consumers identify the pots from these potters as more durable than those from competing potters.

After the pots are formed and dried, the surface is covered with a red slip with a high iron content. The pots are then polished and then fired in a 'bonfire' at about 750 degrees centigrade. When they are fired, they are removed from the fire and immersed in a pile of rice chaff, and this produces a very smoky reducing atmosphere that turns the pots black. To test whether or not such treatments affect the performance characteristics of the pots, a collection of pots was commissioned for a series of experiments in the lab. Pots that had no slip or blackening were collected, as were pots that had only the red slip exterior. Pots that were blackened but that had no slip, as well as pots that were produced as the potters normally do were also collected.

Experiments were conducted on the collection at the University of Arizona in the Laboratory of Traditional Technology. Strength was measured using the three ball on one tester (Neupert 1993). Heating effectiveness was also measured by recording the length of time it took to bring an amount of distilled water to 90 degrees centigrade. These were critical performance characteristics in assessing the durability and cooking effectiveness of the pots in the sample.

The results indicate that the traditional blackened pots with red slip are not much stronger than any other variant, but that their heating effectiveness is much higher than the others. So in addition to the visual performance characteristics of the black pots, they cook more efficiently than pots with alternative surface treatments.

This approach, combining ethnoarchaeology and experimental studies, holds great promise for improving our understanding of decisions made by potters in the prehistoric past. It is a direction of study that can profitably be applied to other forms of material culture as well. This would seem especially true for the study of stone tools. As noted above, there are few people left in the world who still make and use stone tools. But there are a number of expert flint knappers today who can make replicas of stone tools that can be used in experiments under controlled laboratory conditions. Expert knappers who pioneered such an approach include Don Crabtree and François Bordes. At the turn of the twenty-first century, whole laboratories devoted to experimental archaeology are appearing, such as the Laboratory of Traditional Technology founded by Michael Brian Schiffer at the University of Arizona and the Center for Research into the Anthropological Foundations of Technology established at Indiana University by Nicolas Toth.

Traditional ethnoarchaeology continues to be carried out all over the world, leading to new insights about the relationships between variability in material

culture and the behaviors of the people responsible. Such work continues to be useful to archaeologists who employ such findings in their own research. Scott Van Keuren (1999) has drawn on Margaret Hardin's earlier (1977) work among Trascan Indian potters to infer the work of individual potters in a collection of prehistoric Puebloan pottery from Arizona. This, in turn, has led Van Keuren to explore aspects of prehistoric social organization in the area, an ultimate outgrowth from ethnoarchaeology.

New ethnoarchaeology is being carried out worldwide and promises important contributions. Mark Neupert (1999) has just completed a study of elite factionalism in a small city in the Philippines and the attempts on the part of the elites to capture the allegiance of craft specialists. The subsequent split of the potters is reflected in the different clay sources utilized by each faction. Another excellent example of contemporary ethnoarchaeology is the Phuket Project, a long-term research endeavor by Pamela Rogers and Richard Engelhardt in southwest Thailand. They have been working in the Phuket Islands with the Chaw Lay people, a group of maritime foragers producing shell middens that have been extensively studied and documented. They have developed a model of maritime adaptation of coastal peoples, and are testing the model with archaeological data from the islands of Hong Kong (Rogers 1999). Although opportunities for traditional ethnoarchaeology are diminishing, work continues, and we can expect new insights into artifact variability and site formation processes to result.

Ethnobiology

1. What is Ethnobiology?

Traditional societies, often referred to as indigenous or tribal people, usually accumulate significant environmental knowledge through their everyday experience with nature and natural resources. The intimate relationship between their livelihood and nature commonly gives rise to an ecocentric perspective, reflected in attitudes towards plants, animals, water, and soil, in which nature and society are viewed as an indivisible whole. Such perspectives are concretized in iconography and imagery of the sculptural forms, and the associated ethics are transmitted through tales and legends (Vatsayan 1993).

One of the concerns of ethnobiologists and related researchers is to document and assess the value of ethnobiological information, especially in regard to rapidly depleting biodiversity and other forms of ecosystem degradation. Unlike modern human societies whose impact upon ecosystems may be seen as exogenous transformations, traditional societies tend to influence the functioning of ecosystem from within (Ramakrishnan et al. 1998) in order to derive a variety of benefits. These benefits are of three kinds: (a) economic—traditional crop varieties and lesser known plants and animals of food value, medicinal plants, and so forth harvested from the wild (Ramakrishnan 1992); (b) ecological/social—manipulation of biodiversity for coping with uncertainties in the environment and global change, for controlling soil water regimes and hydrology, soil fertility management through soil biological processes, and for efficient organic residue management; and (c) ethical—cultural, spiritual, and religious belief systems centered around the concept of the sacred species, sacred groves, and the sacred landscapes.

2. The Context

Ethnobiology started off as an appendage to classical taxonomy and systematic biology, essentially listing species collected from the wild and used by traditional societies. Whilst there is much accumulated literature of a descriptive nature on the food and medicinal species used by traditional societies from different parts of the world, which in itself is important (National Academy of Sciences 1975, Jain 1991, Berlin 1992, Hladik et al. 1993), it is only recently that ethnobiology has begun to look at the dynamics of the relationships existing between individual species and populations, and between ecosystems and landscapes.

A pioneer of ethnobiology, Conklin (1954) distinguished two distinct shifting agricultural (swidden) systems among the Hanunoo forest farmers in the Philippines: (a) the 'partial' performed by migrants from outside and using swidden as a simple means of producing a crop and (b) the 'integral' reflecting the traditional, year-round, community-wide, largely self-contained and ritually sanctioned way of life. Subsequently, a plethora ethnobiological research has followed, exemplified by the work of Kunstadter and Chapman (1978) which classifies swidden systems in Thailand on the basis of the use of resources and the relationships between cultivation and fallow periods in these agroecosystem types. Ramakrishnan (1992) has further elaborated this typology for north-east India, taking into consideration ecological, socio-economic, and cultural considerations. 'Traditional Ecological Knowledge' (TEK) emerges from such work and constitutes a rapidly evolving area of research (Johannes 1989), with serious implications for our understanding of the human dimensions of ecology. That TEK is often embedded in local belief

systems blurs the heretofore boundaries between ethnobiology and ethnology (Ramakrishnan et al. 1998).

There is an increasing realization that traditionally valued species could play a more important resource role for society at large, including food and medicinal resources (National Academy of Sciences 1975). More recently, however, interest in TEK has moved in the direction of understanding the interconnections that exist between ecological and social processes, determining the functional attributes of ecosystems/landscapes (Ramakrishnan 1992), and exposing the long-term interactions between nature and society that give rise to ecosystems that might otherwise be seen as 'natural' (Alcorn 1984). The way in which traditional societies perceive and manipulate biodiversity in the landscape, both in space and time, to ensure ecosystem stability and resilience, and have evolved ecologically sound biotechnologies of land management, such as those geared for soil fertility and soil water enhancement, to cite two examples, are now deemed important for environment and development and, increasingly, for global change science (Ramakrishnan et al. 1996). At the rate at which global change is occurring, a major proportion of all species on earth will be lost over the next century, and yet it is those species that we need to build a secure future (Raven 1998). TEK offers improved understanding of ecosystem maintenance and, hence, species preservation as well as holistic and cost-effective approaches to sustainable development.

3. *Economic Benefits*

There have been various attempts to evaluate the economic value of tropical forest biodiversity used by traditional societies, apart from the fact that these species provide basic subsistence. Such evaluations are partial, largely concerned only with the direct uses, and rely upon various assumptions about and mechanisms for attributing market values. Examples include an annual value of US$16–22 per ha for the forests near Iquitos, Peru, in Amazonia (Padoch and de Jong 1989), and US$117–244 per ha for non-timber forest products used by forest dwellers from different parts of India (Chopra 1993).

3.1 *Medicinal Plants and Alternate Medical Systems*

The ethnobiology of medicinal plants from the tropics has been rediscovered, complete with an understanding of how traditional uses reflect alternative medical systems. The traditional system of medicine in India, *Ayurveda*, provides many medicines from the Neem tree, *Azadirachta indica*. The recent commercial patenting of the active principle Margosan-O derived from this tree, which has been extracted successfully, chemically stabilized, and patented by Western industry for its pesticidal properties, is an elegant example of commercial exploitation of traditional knowledge. The term exploitation is appropriate, given that this species has been part of the Indian traditional systems of medicine since antiquity, and yet the economic rewards of the patent do not return to the people on whose knowledge the patent is partially based.

Alternate medical systems currently form the basis of primary healthcare for a very large number of the world's population. The role of these indigenous practices in addressing the healthcare needs of developing countries, integration of these alternate systems into the national planning process, and investments for capacity building to preserve and perpetuate this traditional knowledge and for renewed research to build upon this knowledge base, increasingly is recognized (Bodeker 1994). In spite of a variety of myths that marginalized traditional healthcare in the past (Fig. 1), some developing countries, such as India and others from Asia, have taken steps to strengthen research on these remedies and to integrate the holistic practices into the national healthcare. These events challenge the belief that Western medicine is the only effective way of dealing with health problems and seek to provide complementary therapy.

TEK health systems have served some 2,800 culturally distinct communities living in India composed of over 50 million 'tribals' belong to over 600 ethnic communities (Dube 1998). About 76 species of animals—16 invertebrates and about 60 vertebrates—are known to be part of the tribal medicine in India alone. Over 9,500 wild plants are recognized to be of ethnobotanical value of which over 7,500 as medicines, 3,900 as edibles, 500 for fibre, 400 as fodder, 300 as pesticides; many of them have the potential for commercial exploitation (Ministry of Environment & Forests 1994). The Ayurveda system, noted above, can be traced to *Vedic* (Hindu religious texts of antiquity) times (circa 1500 BC). With vegetable products dominating this ancient medical system, diet, and drugs derived from plants were considered to be part of a holistic approach to treatment of diseases. Reserpine yielding *Rauwolfia serpentina* for hypertension and a gum that is hyoplipidemic drug yielding, *Commiphora wightii*, are just two examples of the untapped wealth of resources available in this system. Apart from this, there are a variety of traditional medical practices, including the *Unani* system largely restricted to the northern part of India and the *Siddha* system in the southern region. With such a rich tradition in India alone and equally diverse systems elsewhere in the tropical world, the opportunities to develop refined drugs to feed the global market are vast. These cheap herbal remedies are part of a thriving alternate system of medicine, with minimal side effects in clinical experience (Valiathan 1998).

(a) Facilitation procedures: induction of early fruiting in Durian (*Durio zibethinus*) through grafting techniques; facilitating fruit production and their collection at lower levels of the tree such as Citrus and the Asiatic jackfruit as in Asian and Central American tropics; or even deflecting them away from the trunk, but at a lower level through a bamboo blade wedge inserted into the fruit producing stem of tall growing banana in Thailand; shaping square-section bamboos that are easier to handle for scaffolding, by placing mould of four wooden plates around supple new shoots, as practiced in the Philippines

(b) Increasing production: surrounding the tuber of yam with hollow banana stem, before planting, to encourage tuber growth through a humid environment around it, as done in Madagascar; girdling the stem of Cassava plant about 10 cm above the soil or grafting done between two species of Cassava done by Indonesian farmers to promote root growth and thus increase tuber production; fusion of seedlings of many fruit trees such as citrus, durian, mango, jackfruit, and starfruit done in Thailand and Indonesia to stimulate tree growth and production; watering the fruit directly through capillary action of a wick, as done in arid regions of Sri Lanka for enlarging the size of the gourds; using whole trees as physical barriers to harvest water from mists, using the Garoe tree (*Ocotea foetens*) or *Agave fourcroydes*, as done in Canary Islands or using Olive trees as in Oman; tying stones by many in the Asian tropics, at the tip of the developing snake gourd, to produce straight large fruits; pantropical technique of rapid multiplication of many tree species through pole cuttings; placing clumps of soil between leaves of young trees of sugar palms in Bangladesh to increase plant growth and sap production

Figure 1
Traditional manipulation techniques used by rural communities (Halle 1996)

3.2 Lesser Known Plants of Food Value

Humans have used a few thousand plant species and a large number of animals as a source of food collected from the wild. Of these, only a small fraction has been domesticated, and still fewer numbers are used extensively. Today, about 20 plant species largely sustain the entire world population with food. Alarms have been raised, however, that this reliance may be imprudent and concern mounts to consider an increase in the use of lesser known plants to meet food demands of a growing world population, especially those with less access to the dominant crops, to cover the possible risk involved in our dependence on those species, and to explore pathways for agriculture less dependent on high energy input, modern agriculture alone. Many of the lesser crop species are cultivated by traditional societies as part of multispecies complex agroecosystems, others are collected from the wild (Swift et al. 1996). These considerations prompted a panel of experts of the US National Academy of Sciences (1975) to evaluate a range of under-exploited tropical plants of promising economic value, and select list of a few dozen species that, in their opinion, hold promise for development. Similarly, another set of promising leguminous species were identified for their value as food, fodder, timber, gum, green manure, and soil reclamation (National Academy of Sciences 1979).

3.3 Traditional Tropical Phytopractices

Moving from individual to collective species, Halle (1996) identifies a variety of manipulation techniques and practices applied to individual or groups of plants in order to improve the quality and quantity of products obtained from them (Fig. 2). He concludes that these traditional technologies from diverse geographical regions share some common features based on an intimate knowledge of plant growth that offer possibilities for transfer to other systems of plant management.

4. Ecological/Social Implications

4.1 Interconnections between Ecological and Social Processes

Historically, scientific research on biodiversity in ecosystem functioning omit humans in the definition of the ecosystem boundary, although the synergism between human activity, such as burning, and the resulting landscape have long been known. Traditional societies, intimately linked to the environment for their livelihoods, afford the opportunity to examine

Traditional medicines are of value only when their active ingredients are known, and they are purified (*isolated?*) for mass production

Based on screening done by various drug development programmes, minimal therapeutic benefit is to be found in traditional medicines

Traditional health systems may have some value for treating chronic, low-level conditions but are of no value to treat acute or emergency care

Little scientific knowledge is available on the safety and efficacy of traditional medicines, and research efforts should be directed to toxicity and efficacy research

The global value of traditional medical knowledge is limited to providing leads for developing Western medicines and for tropical biodiversity conservation

Figure 2
Myths contributing to the marginalization of traditional healthcare (Bodeker 1994)

their part in the functioning of the ecosystem, especially in the tropics. In such contexts, the role of biodiversity in ecosystem functioning portends to change substantially as the social, economic, and cultural dimensions determining ecosystem properties are revealed. Such a shift in understanding the interconnections between ecological and social processes has implications for sustainable management of natural resources in developing countries in which local communities have a participatory role.

In this new approach, the village is seen as an ecosystem, with all its ramifications for agriculture, animal husbandry, and the domestic sector embedded with the forest and forest-related activities, such as hunting and gathering of food, fodder, fuel wood and medicinal plants collection, and forest-linked traditional farming practices, such as shifting agriculture (Ramakrishnan 1992, Swift et al. 1996). This approach integrates humans within the ecosystem. It implies that much ecosystem structure and function must be understood as an integrative process and that conserving biodiversity is crucial for the immediate survival of people and ecosystems.

4.1.1 Traditional agroecosystems. Traditional societies maintain a variety of complex, multispecies agroecosystems, operated under varied levels of production intensity. These range from casually managed shifting agricultural systems through an array of rotational fallows, agroforestry systems, compound farms, traditional cash cropping systems, and crop rotation systems at the middle intensity levels, to modern high input agriculture. The ecological complexity of these agroecosystems are due to biodiversity (subspecific and species level—crop and associated biodiversity) both in space and time.

4.1.2 The concept of home garden. Of all the traditional agroforestry systems, the 'home garden' of the tropics, variously called kitchen, house, or forest garden, deserves special attention. They display much variation in their structural and functional attributes, depending on the ecological and social settings in which they occur. Imitating a natural forest with a highly stratified and compacted set of economically important trees, shrubs, and herbs in small plots of 0.5 to 2 ha, these gardens can have over a hundred species (Millat-e-Mustafa 1998). The household is able to obtain many of its requirements from this system year round, such as food products, firewood, spices, ornamentals, and medicinal plants. Detailed economic and energy output/input analysis done on the north-east Indian systems (Ramakrishnan 1992) suggest that, generally speaking, these systems are highly efficient.

Contrary to suggestions that home gardens are confined only to more fertile soils, studies in Cherrapunji in north-east India indicate that they can also be a TEK response to declining soil fertility and site degradation from shifting agriculture (Ramakrishnan 1992, Millat-e-Mustafa 1998). In this case, more fertile conditions are humanly induced. Indeed, TEK-based changes in garden diversity, structure, and management have been reported from the upland central region of Mexico as a response to industrialization and population increase (Gliessman 1990). Such adaptations are a response to labor constraints, available off-farm employment opportunities, and insurance against possible loss of outside income.

Much more needs to be known about the organization and functioning of these unique human-managed ecosystems. A redeveloped system built upon TEK is critical to meet with sustainable livelihood concerns and provide cash income to traditional societies in the biodiversity-rich regions

of the world, especially in the context of global environmental change.

4.1.3 Agroecosystem biodiversity manipulations. It is not only the mere presence of biodiversity and the functional role it has for traditional societies that is significant, but the manner in which these societies manipulate this biodiversity for ecosystem functional attributes and landscape integrity. In the shifting agriculture of the hills of north-eastern India, for example, the number of species in a mixed cropping system declines drastically with shortening of the agricultural cycle (Ramakrishnan 1992). The farmer also shifts emphasis from cereals under a long 30-year agriculture cycle, to tuber and vegetable crops under a shorter 5-year cycle, which are more nutrient-use efficient species. Even on the same slope, such crops are emphasized on the top of the slope and the less efficient ones are largely placed towards the base, reinforcing the diversity of species while improving production and risk aversion. Through mixed cropping involving a large number of species in space and time, and traditional weed management strategies, shifting agricultural farmers in north-east India, as elsewhere, ensure effective checks on nutrient loss during the cropping phase. The traditional weed management practice, where about 20 percent of the weed biomass is left undisturbed in the plot by the shifting agriculture farmer is also a practice common to the Mayan agriculture in Mexico, with implications for agroecosystem sustainability (Altieri and Liebman 1988).

Traditional societies also ensure the integrity of the systems at the level of the landscape. The Apatani tribe in north-east India have evolved elaborate wet rice cultivation systems that are adapted to gradients in soil fertility and water availability, linked with traditional management options possible within the landscape (Ramakrishnan 1992). Widening plots by digging adjacent higher ground down to an irrigable level seems to be successful responses to population increase and new market opportunities, as also demonstrated for Tara'n Dayaks of West Kalimantan in Indonesia (Brookfield and Padoch 1994).

The lessons learnt from such manipulations of biodiversity done both in space and time as adaptation to a variety of environmental changes involving population pressure, land degradation, biological invasion, and climatic uncertainties, are important for biodiversity management in resource-rich regions of the tropics (Ramakrishnan et al. 1996). These are being used to design strategies for agroecosystem redevelopment (Swift et al. 1996).

4.1.4 Pathways for agroecosystem redevelopment. TEK is embedded in the complex, multispecies agroecosystems maintained by their various custodians and offers a basis for more environmentally sustainable systems of resource production. The objective of TEK-based redevelopment efforts is to maximize production focused on *in situ* conservation of agro-biodiversity (Swift et al. 1996) and on strengthening internal processes for relative stability and resilience within the system (Altieri and Liebman 1988, Gliessman 1990, Ramakrishnan 1992, Woomer and Swift 1994). To achieve these goals, TEK focuses on cropping patterns based with such attributes, among others, as (a) optimization of production along a nutrient gradient where it occurs, (b) synchrony in nutrient release from the soil and uptake by the crop, (c) efficient recycling of biomass residues, and (d) weed management rather than weed control.

This approach to developing agroecosystems stands in contrast to the 'green revolution pathway' based on high intensity management predicated on external energy subsidies. To reach it often requires an 'incremental pathway' (Swift et al. 1996) which builds upon traditional systems in a step by step manner sensitive to ecological, social, and cultural constraints under which traditional societies function. This pathway builds towards a 'contour' one in which the full range of agroecosystem principles are employed to reach ecologically attuned but high levels of production.

4.1.5 Manipulating natural/crop biodiversity through keystone species. The role of socially selected, ecological keystone species in conserving and enhancing biodiversity and manipulating functions in forest ecosystems has not been explored adequately. Keystone species provide critical ecosystem functions that help to preserve biodiversity. Often they are also socially or culturally valued as well. Therefore, they can be used not only to manage pristine ecosystems (Ramakrishnan 1992), but also to build biodiversity in degraded natural and human-managed ecosystems through appropriate rehabilitation strategies (Wali 1992, Lamb and Tomlinson 1994) that ensure people's participation (Ramakrishnan et al. 1994). For example, in areas of north-east India where the shifting agricultural cycle is less than 5 years and the landscape is highly degraded, a legume of lesser known food value, *Flemingia vestita*, is socially valued and used to support a 1–2 year fallow and even non-fallow system of cultivation. By fixing 250 kg of nitrogen per hectare per year, this keystone species ensures sustainability of these low-input agroecosystems, under conditions of extreme pressure on the land and low soil fertility (Ramakrishnan 1992). The adjacent successional forests are also enhanced by a socially selected keystone species. Nepalese alder (*Alnus nepalensis*), a nitrogen-fixing species, and many bamboo species (*Dendrocalamus hamiltoni*, *Bambusa tulda*, and *B. khasiana*) with ability to conserve nitrogen, phosphorus, and potassium play a key role.

The interphase between ecological and social processes, exemplified in socially selected keystone species, is critical for biodiversity management in the context of rapid change, but has only just started to receive research attention. Such keystone species may also be found within the sacred groves of traditional societies, as in the case of *Englehardtia spicata*, *Echinocarpus dasycarpus*, *Sysygium cuminii*, and *Drimycarpus racemosus* which conserve high levels of nitrogen, phosphorus, and potassium in otherwise highly infertile soils in north-east India. They are also found at the landscape level within indigenous 'forest reserves' set aside within the forest-agriculture landscape as found among the Tara'n Dayaks of West Kalimantan, Indonesia (Padoch 1993) and elsewhere (Alcorn 1984, Ramakrishnan et al. 1994). The species within these reserves are protected by strictly enforced, community rules of use, with implications for sustainability.

5. *Ethical Considerations. Conserving the Sacred*

In some cases, refugia in a given region are given the status of 'sacred groves,' complete with cultural beliefs, institutions, and practices that create 'social fencing' for relict ecosystems. Often these groves occur within derelict landscape, otherwise heavily affected by humans. To this concept can be added those of the 'sacred species' and 'sacred landscape.' The former are keystone or resource critical species as described above (e.g., sacred Basil, *Ocimum sanctum*, and Neem, *Azadirachta indica*). Sacred landscapes scale up from species and groves to large areas intermeshed natural and human-made ecosystems. The Ganga watershed of the Central Himalayan Garhwal region in India, for example, consists of a variety of landscapes sacred to Buddhists (Ramakrishnan et al. 1998), while sacred mountains exist elsewhere, such as the holy hills of the Dai of Xishuangbann in Yunnan province in China (Messerli and Ives 1997). Such landscapes and related uses are ancient in time and worldwide in distribution (Monasterio 1994).

The state-of-art ecological knowledge on conserving this sacred cultural heritage is now synthesized (Ramakrishnan et al. 1998) with a view towards biodiversity conservation and seeking new paradigms for sustainable management of natural resources. Ethnobiology has, thus, evolved through TEK towards a holistic view in which ecology, economics, and ethics combine. A major aim is to recast the circular connections among them, now broken (Bormann and Kellert 1991), in order to provide alternative understanding and means of addressing questions of environment and development.

6. *Conclusions*

Ethnobiology has moved from an important descriptive stage of study to an even more important understanding of the linkages between ecological and social processes as they affect biodiversity and ecosystem functioning. This understanding, in turn, is being used to address biodiversity conservation and sustainable land-use management. Ethnobiology also lends itself to system-level assessments, linking its process studies to traditional agroecological management strategies, such as water harvesting systems, which can be used to produce for human consumption while triggering ecological rehabilitation. It is heartening to witness the growing recognition of the historic and existing interaction of various cultures with their surrounding ecosystems and landscapes and the extent to which these interactions have shaped them. Thus, ethnobiology increasingly promotes synergism between science and world views arguing against the segregation of the biosphere into the 'natural' and the 'people,' and for holistic concepts, such as the 'biocultural region' (e.g., Walton and Bridgewater 1996). Based on this movement, ethnobiology is becoming increasingly relevant in the area of sustainable management of natural resources, with concerns for livelihood and development of traditional societies based on a value system that they understand, appreciate, and therefore engage.

Ethnocentrism

Ethnocentrism is a term that passed from the social sciences into broader English discourse during the twentieth century. In current usage, it means culturally biased judgment, i.e., applying the frame of reference provided by one's culture to an object, action, person, or group of a different culture. The term as introduced by William Graham Sumner in his seminal treatise *Folkways* (Sumner 1906) was explicitly sociological and included biased judgment as one of several features in a theory linking group solidarity with intergroup antagonism as a universal characteristic of human societies. Sumner's theory influenced research on ethnic relations and nationalism during the first half of the twentieth century. Later, the critique of Sumner by Merton and Rossi (1957) gave attention to the concept of ethnocentrism as problematic in social research, and LeVine and Campbell (1972) used the term as a rubric under which to review theories of intergroup relations and attitudes and to construct a framework for comparative research on the subject. By the end of the century, however, interest in ethnocentrism as a sociological concept had waned, even as the adjective 'ethnocentric' was commonly used as a descriptor or epithet in discussions of intercultural attitudes.

Sumner's brief but dense and multifaceted discussion of ethnocentrism in *Folkways* remains a primary source of theory on this subject. Although Sumner acknowledged previous work by the Austrian sociologist Ludwig Gumplowicz, and Coser (1956) has cited Marx and other earlier theorists for certain aspects of ethnocentrism, Sumner himself may have coined the term ethnocentrism (as well as 'ingroup' and 'outgroup') and was responsible for endowing it with wide-ranging theoretical implications for the social sciences:

> The conception of 'primitive society' which we ought to form is that of small groups scattered over a territory. … A group of groups may have some relation to each other … which draws them together and differentiates them from others.

> Thus a differentiation arises between ourselves, the we-group, or in-group, and everybody else, or the others-group, out-groups. The insiders in a we-group are in a relation of peace, order, law, government and industry, to each other. Their relation to all outsiders, or others-groups, is one of war and plunder, except so far as agreements have modified it … .
> … *Sentiments in the in-group and towards the out-group*. The relation of comradeship and peace in the we-group and that of hostility and war towards others-groups are correlative to each other. The exigencies of war with outsiders are what makes peace inside, lest internal discord should weaken the we-group for war. These exigencies also make government and law in the in-group, in order to prevent quarrels and enforce discipline. Thus war and peace have reacted on each other and developed each other, one within the group, the other in the intergroup relation. … Sentiments are produced to correspond. Loyalty to the group, sacrifice for it, hatred and contempt for outsiders, brotherhood within, warlikeness without—all group together, common products of the same situation. These relations and sentiments constitute a social philosophy. It is sanctified by connection with religion. … Virtue consists in killing, plundering, and enslaving outsiders.
> … *Ethnocentrism* is the technical name for this view of things in which one's own group is the center of everything, and all others are scaled and rated with reference to it. Folkways correspond to it to cover both the inner and the outer relation. Each group nourishes its own pride and vanity, boasts itself superior, exalts its own divinities, and look with contempt on outsiders. Each group thinks its own folkways the only right ones, and if it observes that other groups have other folkways, these excite its scorn. Opprobrious epithets are derived from these differences. 'Pig-eater', 'cow-eater', 'uncircumcised', 'jabberers', are epithets of contempt and abomination. The Tupis called the Portuguese by a derisive epithet descriptive of birds which have feathers around their feet, on account of trousers. … For our present purpose the most important fact is that ethnocentrism leads a people to exaggerate and intensify everything in their own folkways which is peculiar and which differentiates them from others. It therefore strengthens the folkways (Sumner 1906, pp. 12–13).

This passage shows both the scope of Sumner's discussion—covering attitudes and stereotypes as well as social relationships, organizational features and warfare—and his commitment to the theory that ingroup–outgroup dynamics generate internal solidarity and cultural coherence as well as hostility and warfare. Sumner claimed these dynamics and the concomitant attitudes to be universal in human societies, although he was aware that not all peoples were warlike. Social scientists before and after Sumner discovered many of the same phenomena in their own research, but his influential passage became a point of reference for subsequent social theory and research on war and peace, ethnic relationships, and intergroup conflicts and attitudes.

Ethnocentrism as a process simultaneously promoting ingroup solidarity and outgroup hostility has been described at different levels, in many places and historical periods, not only by sociologists and anthropologists but also by political scientists, historians, and journalists. It is as familiar now, particularly in ethnic politics, as it was in Sumner's time. But Sumner's theoretical claims have been criticized and largely rejected by sociologists and anthropologists. Merton and Rossi (1957), in formulating the sociological theory of reference groups, pointed out that individuals often belong to, or wish to belong to, more than one group, making the ingroup–outgroup boundary ambiguous and the outgroup often an object of admiration rather than contempt. They argued that the ethnocentrism syndrome as Sumner formulated it should be seen as a special case of human intergroup relations rather than universal, as he claimed.

Anthropologists have been similarly critical. Describing many parts of the world where ethnic groups do not have bounded territories and individuals and groups change ethnic affiliation, anthropologists cast serious doubt on generalizations presuming that human groups have clear boundaries and stable membership (Leach 1954, Barth 1956, 1969, Goody 1956, Moerman 1965, LeVine and Campbell 1972, pp. 81–113). Furthermore, the threat-dependent ethnic and national identities that Sumner assumed were products of a natural human tendency have increasingly been seen by anthropologists as deliberately constructed by leaders to gain adherents and seize power. Finally, it now seems likely that the intense nationalism and threatening military competition of the Western world in 1906 predisposed Sumner and his readers to accept ethnocentrism as a universal fact of human social life in advance of the comparative evidence. With better evidence and a different experience of international relations, we are less inclined to accept his theory.

Thus the sociology of Sumner's ethnocentrism syndrome, viewed in the light of recent evidence and newer perspectives, seems a dated fallacy of early twentieth century social science. The central problem has been that without clear and stable boundaries between ingroup and outgroup, the question of whether ingroup solidarity and outgroup hostility are consistently interdependent cannot be unequivocally answered. Group boundaries, if they ever were clear, have become more and more blurred as international migration and communication have intensified. Sumner's concept, as he generalized it, is not an accurate guide to the real world, but the question arises, if Sumner's formulation of the ethnocentrism syndrome has no merit as social theory, why does it seem so familiar as ethnographic description? How it is that, despite globalization, the contemporary world produces so many examples of conflict between ethnic groups differing in language, religion, and other customary practices, with mutual disparagement and threat-dependent solidarity escalating to intergroup violence? Answering this question through social research requires the investigation of the ethnocentrism syndrome as a contingent historical phenomenon, examining in detail how the ideological and organizational patterns to which Sumner called at-

tention have emerged in particular cases and how long they have lasted.

The term ethnocentrism remains in use to refer to culturally biased judgment, the act of applying the frame of reference from one's own culture to someone or something belonging to another culture. The *Dictionary of Anthropology* (Barfield 1997, p. 55) defines ethnocentrism as 'the belief that one's own culture is superior to others, which is often accompanied by a tendency to make invidious comparisons. In a weaker form, ethnocentrism is the tendency to look at other cultures through the filter of one's own cultural presuppositions.' As in Sumner's examples in the passage quoted, ethnocentric judgments are usually derisive epithets, in which outgroup practices that deviate from ingroup norms form the basis for an insulting characterization: 'pig-eaters,' 'uncircumcised,' 'jabberers.' This can reflect a naïve form of ethnocentrism, called phenomenal absolutism by Segall et al. (1966), in which a person unreflectively takes his own culture's values as objective reality and automatically uses them as the context in which he judges less familiar objects and events. Alternatively, it can reflect a judgment made with full knowledge of cultural variability, but with an equally or even more scornful attitude. An ethnocentric judgment can be treated as a cognitive phenomenon, but it has emotional component as well. In its cultural form it is usually called an ethnic stereotype. Such stereotypes were intensively studied in American social psychology before and after World War II, up to the mid-1950s (Allport 1954). Since then, there has been relatively little research on ethnic stereotypes, but the concepts of ethnocentrism and stereotypes are still widely used in the mass media, in programs of training in intercultural communication, and in public discussions of racial prejudice and ethnic relations. The teaching of anthropology, through publications as well as in the classroom, is often justified by its role in reducing the ethnocentric attitudes of Western populations.

Ethnogenesis in Anthropology

Ethnogenesis is a process by which a distinct ethnic group emerges with a common sociocultural consciousness of belonging. In the 1960s Singer (1962) analyzed the process among African-Americans and Sturtevant (1971) subsequently introduced this term into the anthropological study of native Americans. Since then it has been widely utilized for examining the consciousness of belonging among various populations.

Although Sturtevant did no more than point out how ethnogenesis could be used to analyze the historical establishment of group distinctiveness, the concept has been regenerated during the 1990s with new implications. It is used to focus on the interaction between global and local histories, especially on local initiatives to deal with the impact of globalization. Ethnogenesis therefore refers to cultural and political struggles by indigenous and enslaved populations to create enduring identities at times of often violently imposed radical change resulting from European domination—such as demographic collapse, forced relocation, or enslavement. The idea of ethnogenesis refutes the established view of societies in the Third World as isolated, static, and ahistorical. Instead it pays attention to their creativity and ways of making history.

1. Theoretical Background

Currently the focus on issues of ethnicity has shifted from study of particular ethnic groups to looking at the dynamic process of ethnogenesis. This was made possible by the continued development of new theoretical understandings of ethnicity. Following Barth's contribution (1969), the subjective and interactive

aspects of ethnicity began to gain attention. Despite the pre-eminence accorded the objective and primordial aspects of ethnicity by earlier perspectives, Barth did not regard ethnic identity as constituting an *a priori* reality, but as being an interactive process of self-definition and classification by others.

Actors categorize themselves and others in relation to how they interact with one another. It is when they use an ethnic identity to categorize themselves that Barth sees an ethnic group emerging. He rejected the prevailing idea that geographical and cultural isolation or separation is essential to the preservation of ethnic groups and the maintenance of cultural diversity. Instead he insisted that ethnic differentiation forms an overall social system; what is to be studied, consequently, is not the internal relations of the individual ethnic group, but the way the different ethnic groups establish boundaries. This perspective led to the view that ethnicity involved a formative process.

Another shift in the 1980s was the emergence of new perspectives that sought to deconstruct ethnicity as an essential entity. Deconstructionism in the social sciences exercised its influence to show how seemingly essential categories such as sex, generation, and race are far from being natural and *a priori*, but are an invention of modern society. Hobsbawm and Ranger showed that what had been taken to be traditional elements in symbols, customs, myths, and identity were actually invented as part of a dynamic process in the course of modern nation-building. According to this view, ethnic identity is also a modern invention that has been shaped in a political and historical way within the frame of the nation-state. This deconstructionist perspective, together with a subjective active view of ethnicity, provided a basis for the social sciences to theorize the phenomenon of ethnogenesis.

2. *Ethnogenesis and Ethnocide*

The concept of ethnogenesis has developed from studies of societies in the New World. Here the indigenous population was conquered and oppressed in the centuries after 1492. In addition, an enormous number of people with different cultural-linguistic backgrounds were transported from Africa and set to work as slaves. This is a process of ethnocide.

Ethnocide means the extermination of a culture. It involves the systematic destruction of cultural identities, ecosystems, political authorities, and religious rituals and belief systems. Common forms of ethnocide included the forced conversion to the religion of the colonizers, the banning of the use of native languages and cultural practices, and the forced relocation from the homeland to reservations.

Although it differs from genocide, which means the physical destruction of a whole people, the distinction is not always clear, and the two phenomena may occur together. Following the arrival of Columbus in the New World in 1492, the Arawak and Carib peoples he encountered, whose population is estimated to have numbered around 10 million, were almost entirely wiped out within 100 years. Virtually no indigenous people now remain in the Caribbean, although some were able to flee to the American continent where they merged with other survivors to generate new cultures.

In the century after the discovery, the indigenous population of South America, estimated to have been around 40 million, declined to about 440,000. In Australia in the nineteenth century the situation was much the same, although there were not as many people to be killed. The people of Tasmania, with an estimated population of 23,000 in 1803, were exterminated before the end of the century. Other people, on the verge of cultural extinction, have attempted to establish distinct cultural identities in order to reorganize their societies and secure their existence. This is a process of ethnogenesis. There is therefore a direct relationship between ethnocide and ethnogenesis. Where ethnocide takes place, one will usually also find ethnogenesis.

In the present day, peoples who were enslaved or marginalized under colonial domination are able to revive their cultural identities and reclaim their right to existence. This has gained momentum with the setting-up of statutory and voluntary organisations in the international context.

3. *Mechanisms of Ethnogenesis*

Minority populations which were marginalized in the world politico-economic system needed a shared consciousness of belonging. This required definitions of group boundaries, and processes of cultural creation, revitalization, and appropriation.

The creation of a religious ideology and practice was one means of integrating different groups into one unit. The enslaved African populations of the Caribbean, for instance, had originally come from a variety of sociocultural backgrounds with different languages, religions, value systems, and social structures. Despite these differences, they invented rituals, oaths, and a common set of religious values. This bricolage of different African elements became marked with the emergence of a Maroon identity in Jamaica in the middle of the seventeenth century.

In 1655, Britain took Jamaica from Spain by force. African slaves took advantage of the resulting turmoil to escape from the plantations into the forests and mountains. These deserters comprised a medley of ethnic origins, from Senegambia and the Gold Coast to the Congo and Angola, and even to the east coast of Africa. They were able to establish their own political authority and military alliances in the seventeenth and eighteenth centuries. Such polities created and mobilized common religious ideologies and practices

based on rituals of spirit possession, which produced a shared consciousness and generated a common identity.

Ethnic identity may also be developed through a revitalization of precolonial symbols and ritual practices, as was the case with the Seminoles of Northern Florida. In the eighteenth century, when British, French, and Spanish forces were competing in the region, a distinct Seminole ethnicity emerged from the variety of Muskogean and other peoples with different cultural-linguistic backgrounds, who had colonized this region. They established new chiefdoms which closely followed the traditional Muskogee patterns. Among Muskogean peoples, who had previously been only loosely related with each other, there was the powerful division of Kawita, which overpowered the others and standardized and transformed a variety of politico-religious cultures under its hegemony. The early Seminole settlements still acknowledged Kawita's suzerainty. This meant giving a central role to rituals of the mythical creation of sacred fire, originally controlled by Kawita's traditional chiefs whose authority was thereby revitalized in the newly created Seminole societies.

Ethnogenesis may also take place through appropriation. From the late fifteenth century, indigenous peoples in the Third World were in most cases conquered by overwhelmingly superior European powers and forced to accept the religion, language, and way of living of the colonizers. In doing so, however, they often created a new ethnic identity by the way they transformed and adapted the ritual symbols of the Europeans. For instance, the Kapon and Makushi of Venezuela and Guyana emerged when the Christian saints and deities brought by the European colonizers were reinterpreted according to the traditional cosmology of indigenous peoples who used these ritual symbols to forge new cultural identities.

4. *Ethnogenesis in the Twentieth Century*

Although the process of ethnogenesis can be clearly seen in small-scale societies in the Third World following colonization, it has also developed in the process of modern nation-building. The ideology of the nation-state expressly aims to transform different ethnies into one nation with a single national culture. The principle is often different from the practice. The ruling group, in most cases the majority group but sometimes a numerical minority having dominant power, has generally monopolized the political-economic interests and imposed its culture on the others in the name of the national culture. In response, marginalized peoples have attempted to generate a new ethnic identity in order to claim their sociocultural and politico-economic rights within the frame of the nation-state. Modern ethnogenesis may be classified in three main ways.

The first type is integration. Those peoples who originally had formed separate and independent polities without any consciousness of belonging together were given the same name and treated as one group by European explorers, missionaries, anthropologists, and administrators. They accepted this name and formed a new identity in accordance with the imposed boundary, in order to resist or negotiate with the colonial regime, especially in modern nationalist movements that sought political independence. In the process, a new ethnicity emerged. This type of ethnogenesis can be seen among the Aborigines in Australia, the Inuit in the Arctic regions and the San in the Kalahari, where the central government has adopted policies of multiculturalism to secure minority group rights—the government needs fixed sociocultural units in order to assist political autonomy and cultural preservation.

The second type is amalgamation, which occurred frequently in African societies at the time of independence. In Kenya after World War II, for example, an active African nationalism was organized by two major ethnic groups, the Kikuyu and the Luo. Political elites from smaller ethnic groups united under the hegemony of these two groups and gradually formed new cultural identities. Thus the Luyia emerged in the 1940s to bring together 17 Bantu-speaking peoples, among them the Maragoli, Bukusu, and the Wanga, who lived in what was then the North Kavirondo district of western Kenya. The word Luyia, meaning the communal space in which people sit around the fire, was appropriated for the the idea of mobilizing a consciousness of brotherhood among those from western Kenya who studied at Makerere University in Kampala.

The same sort of amalgamation took place among the 10 or so Eastern Cushitic-speaking ethnic groups in the Rift Valley. This ethnogenesis was promoted by those who studied at the prestigious Alliance high school in Nairobi in the 1940s. They invented the name of a new ethnic group, the Kalenjin—literal meaning 'I'm telling you' (in the plural sense)—and it started to spread among influential members of the home communities in the 1950s. Aidan Southall has termed this type of ethnogenesis 'supertribalization.'

The third type is separation. During the period of colonial domination, some small indigenous ethnic groups were subsumed into bigger neighboring groups or were put together in one large unit, either voluntarily or forcibly. Later they have attempted to revive their former cultural identity and secede from the constituted group, to create an independent ethnic group for themselves. The Suba, mainly living in the small islands of Lake Victoria, had been Luo-ized for a century, and their language was beginning to become extinct. But after the multiparty system was reintroduced into the Kenyan political scene in 1991, which caused the nation-state to become more ethnicized, the Suba political elite began to dif-

ferentiate Suba from Luo and promoted the Suba culture and language. In so doing they are again forming themselves into a distinct ethnic group.

In the contemporary world system indigenous peoples and ethnic minorities who were once colonized and marginalized have begun to assert their socio-cultural and politico-economic rights. Because re-fashioned ethnic identities play a large part in such assertions, ethnogenesis is becoming a key concept in understanding society in the twenty-first century.

Ethnography

1. Introduction

'Ethnography' has turned into a complicated concept. To understand why, it is useful to go back to a time when it was thought to be simpler. Traditionally, the term was used to label what anthropologists did when they did their research.

By 'anthropologist' is meant here those anthropologists—sometimes called 'ethnologists'—who work with living peoples to explore and document their culture. Their research involved long-term involvement in a community called 'participant observation,' discussions of topics of interest with community members called 'informal interviews,' and a record of the experience called 'field notes.' Ethnography also labeled the book-length report that an anthropologist wrote, using intuitive methods of analysis called 'immersion in the data.' The ethnography, the book, was also called a description of the *culture* of the community, although the culture focus was more characteristic of work in the USA than in Europe.

This straightforward definition of ethnography must be understood in its historical context. Anthropological research, as practiced in the early to middle twentieth century, usually involved an Anglo-American or European working in a small isolated community in a remote area of the world, with a group of people who often lived without modern amenities, had little or no formal education, and existed at a modest if not impoverished economic level. The anthropologist took up residence in the community, and set out to learn who the people in the community were and how they lived. Depending on their interests, anthropologists investigated topics as diverse as economic and household tasks, social organization and religious beliefs, family life and local markets—virtually anything that made up daily life. Since they also lived in the community, anthropologists visited with people, attended communal events, and worked together with community members on common projects, including the ethnography itself.

As one learned the community's way of living, one said one was 'doing ethnography.' Ethnography, then, named the process of learning what for the anthropologist was a new and different way of talking, thinking, and acting.

When the work was done, a monograph was usually written—a report of this exploration into the community's way of life. One could point to that book and say it was an 'ethnography' as well. Further, one could also say that the book was a description of the group's culture.

Traditionally, then, ethnography named both a research process characteristic of anthropology and a research product, often a book-length description, but at any rate a representation of the culture of the community in which the research had been done. (Agar 1996 introduces this traditional view and contextualizes it in light of more recent discussions.)

Because anthropologists set out to learn ways of thinking, talking, and acting whose nature they could not specify before they started their research, ethnography did not look much like traditional science. In fact, the scientific status of ethnography has been an issue since its beginning.

Traditional science sought universal laws; ethnography went after local particulars. Traditional science emphasized control of the research process; ethnography featured adaptability as the nature of community emerged. Traditional science evaluated a sample by size and strategy; ethnography, by competence, social position, and relationship to subject. Traditional science preserved initial concepts through the course of the research; ethnography developed new ones. Traditional science rested on linear models; ethnography, on models more systemic and processual. Tra-

ditional science represented data with numbers; ethnography more often used words.

Over the last twenty years it has become clear that ethnography cannot be adequately modeled or evaluated by traditional science. Some still argue that it should be. Some argue that it is a different kind of science. Some argue that it should be classed with the humanities. The issue is treated in Sect. 2 of this article.

A second problem arose with the nature of ethnography as a product, a description of a culture that resulted from the research. Anthropologists assumed that small communities represented a single culture, one that was internally consistent and traditional, passed from generation to generation in essentially unaltered form. The 'culture' concept served as description, explanation, and generalization. The fact that a person did something was data for the description of that culture. What was done could be explained by membership in that culture, and it could be generalized to the single culture assumed to be relevant.

The culture concept that guided earlier ethnographies is now in a shambles. The earlier assumptions about culture, such as its traditional and consistent nature, have been shown to have been in error from the beginning (Wolf 1982). Further, contemporary life makes the assumption that a person is a member of only one culture look hopelessly naive. While the nature of ethnography as a research process endures, it is no longer clear how to describe, explain, or generalize what is learned, nor is it clear what form a report—the ethnographic product—should take. The old concept of culture is no longer adequate to the task. Sect. 3 of this article deals with the problem.

Until this point ethnography has been discussed in the context of anthropology. Because of its longstanding concern with the exploration of previously unknown ways of living, anthropology is the academic discipline with the most elaborate history of ethnographic research. Ethnographic work outside anthropology also exists. For example, predisciplinary efforts such as Tacitus' description of the Germans in Roman times are often cited as a precursor. And ethnographic work in the discipline of sociology also has a long tradition, beginning with work based on Weber's theory of social action, continuing with the symbolic interactionism of the Chicago school and with the development of grounded theory and ethnomethodology in the 1960s.

By now the historical link between anthropology and ethnography has turned complicated in at least two ways. First of all, ethnography is used in a variety of different disciplines—ranging from history to speech communication to organization and management to public health—as a *new* approach, as well as in kindred social sciences such as political science and psychology. Second, the concept now coexists with such related terms as qualitative research, grounded theory, and phenomenology, terms that are also used widely in a number of different research contexts. These multiple uses of 'ethnography' and related terms have further blurred the edges of how ethnography should be defined, a problem dealt with in Sect. 4 of this entry.

In traditional cultural anthropology, then, ethnography had a clear meaning—the process of learning a community's way of life and reporting the results of that learning under the label 'culture.' Beginning in the late twentieth century, many of the assumptions underlying traditional ethnography were called into question—questions amplified by the changing nature of the world we all live in now. Finally, the increasing popularity of ethnography and related nontraditional approaches to research in numerous academic and organizational settings further complicates any attempt to define the term.

This article, then, is built less on a definition than it is on a sample of key issues around the question of what a definition might look like. 'Ethnography' is now a cover term for several debates around the nature of human understanding; debates for which, at the time of writing, no end is in sight. In fact, this might be the major contribution of the term to current social research, a contribution with more historical importance than its use as a label for a discipline-internal activity. If nothing else, this entry alerts the readers new to ethnography and culture that they are stepping into a series of issues rather than a recipe for doing research. Many new to ethnography import outdated notions of ethnography and culture from traditional anthropology into their work, a move that replicates historical mistakes and distorts their results.

2. *Science or Humanity?*

Traditional anthropology has long lived with the contradiction of being *both* a science *and* a humanity. In fact, ethnography makes this contradiction particularly visible. On the methodological level, ethnography seeks new patterns in 'found' data, displaying its kinship with philosophy, history, journalism, and second-language learning, fields typically found in the 'humanities' branch of a university. On the level of theory, ethnography usually deals with issues related to sociology, psychology, economics, and political science, disciplines categorized as 'social sciences.'

The idea of a 'science of society,' as first articulated by Spencer and Comte, linked 'social science' explicitly with the Western Enlightenment tradition. In the classic formulation of this approach, one deduces hypotheses that should be true if a particular theory is true, where a hypothesis is a statement of a relationship among two or more variables. One then operationalizes the variables by specifying what observations one might make or what questions one might ask in order to measure them—i.e., assign a numerical value where

differences in the number represent relevant differences in the phenomena of interest. One selects a sample of a population on some principled basis, the point being to say at the end how confidently one can generalize from the sample to that population. Finally, one specifies a decision procedure so that one can say at the end whether the hypothesis is accepted or rejected. Often a decision procedure involves a statistical test with a cutoff point of statistical significance, significance technically meaning, 'there is no more than a 5 percent (or 1 percent, or some other figure) chance that I'm wrong when I say that the variables in the hypothesis are related in ways beyond what I'd expect by chance.'

Numerous studies in anthropology have revealed the power and value of traditional science in the context of ethnography. (For a good example of methodology from this angle of vision, see Bernard 1988.) Further, other social sciences recognize the importance of testing hypotheses 'cross-culturally,' linking those fields to anthropology. And finally, in a metaphorical sense, much of anthropology serves the purpose of challenging assumptions by comparison among different societies, a 'hypothesis test' of a rather fundamental sort. In fact, one can say that social research done only in one society that generalizes to all of humanity is bad science.

However, much of ethnography does *not* fit the tradition of social science. Consider two example problems. The first—scientific research is objective and replicable. By this is meant that well-designed research, done in the same way in any place by any trained person, will yield the same results. In contrast, ethnographers argue that, for some group X and some ethnographer Y, both the ethnographic process and the ethnographic product will vary as a function of Y as well as a function of X. In other words, an ethnography can take different shapes depending on the biographical and cultural background of the ethnographer. The ethnographer is, in a nutshell, part of the data. It is now a cutting-edge methodological issue—more than one ethnography of X is possible, but not all ethnographies of X are acceptable. The problem is to learn how to specify the difference between the two.

A second problem—the scientific emphasis on control. In traditional science, control is key, from theory through data collection and analysis to decision criteria on whether to accept or reject a hypothesis. When the variable of interest, the dependent variable, changes in value, it must be due to the independent variables and nothing else. Ethnography has a defined starting point, but as it progresses a study is emergent. New concepts are learned that suggest new questions; new knowledge of communication styles suggests new ways of asking them; something someone does opens new avenues of inquiry; new knowledge of social types within the group alters sampling designs; analysis consists of putting new pieces together into patterns rather than breaking them down into measurable variables. The research process is nonlinear, dialectical rather than sequential. An emphasis on control from the outset and throughout the research would eliminate these possibilities.

Many anthropologists now reject the scientific tradition and consider ethnography a humanity rather than a social science (see Geertz 1973 for a classic statement of this position). But the humanities offer no straightforward model for ethnography, either. To offer just a few examples, a look at journalism reveals genre constraints whose *a priori* structural requirements may be as limiting to emergent research as is traditional science. Models of second language learning deal awkwardly, if at all, with the massive amounts of background knowledge implicated in syntax and lexicon, and it is just this knowledge that an ethnographer hopes to learn and represent. Narrative approaches from both history and literature are promising, since much ethnographic data is narrative in form. However, narrative is built on chronological sequence, and ethnography abstracts and generalizes from such sequences.

Ethnography, then, is caught between agreement with general scientific goals and a poor fit with traditional social scientific practice, and it is caught on a research process akin to the humanities that calls for systematic approaches to modeling and validation that those fields do not provide.

What is needed is an epistemology that fits ethnography, a clear sense of how knowledge is obtained and what it looks like in the end. Epistemologies borrowed from either traditional science or traditional humanities are suggestive and helpful, but at the same time inadequate. Three conclusions are clear. First, a proper epistemology will not come from a simple classification—i.e., ethnography is a kind of social science or ethnography is a kind of humanity. Second, the proper epistemology is, as of now, far from established. And third, the development of such an epistemology will be a contentious issue well into the future.

3. *Culture*

The topic of culture is dealt with elsewhere in this encyclopedia. However, the concept is relevant here because 'culture' traditionally has been used to characterize the results of ethnographic research.

In the words of Roy D'Andrade, studying culture today is like studying snow in the middle of an avalanche (cited in Carrithers 1992, an introduction to various views of anthropological research). Traditionally, anthropologists assumed that the small communities they studied constituted a single culture. What people said or did could be described, explained, and generalized by attribution to that single culture, bounded in space and replicated over time.

Any contemporary ethnography now shows that such assumptions no longer hold. Indeed, numerous 'cultures'—global to national to regional to local—might or might not be relevant to the description, explanation, and generalization of a particular ethnographic moment. There are cultures of generation and gender, of nationality and religion, of ethnicity and region, of occupation and leisure-time pursuit, media inspired and driven by tradition, and in the process of creation. Some cultures span the globe, some distribute unevenly across it, and some take shape only in a particular location. Some people enact a particular culture; some resist it; some ignore it. Some 'craft a self' that is a blend of different cultures (the phrase is from Kondo 1990, an excellent example of narrative ethnography). Popular phrases now tag almost anything with 'culture': the 'culture of violence', or the 'culture of capitalism', or the 'culture of poverty.'

Culture can no longer be used as it was in traditional anthropology. Indeed, its use in traditional anthropology was inaccurate even then. The work of Eric Wolf (1982) showed that traditional assumptions were incorrect, even in the nineteenth century when anthropology first appeared as an institutional discipline. Differences among people still lend themselves to ethnographic investigation. But the multiple and simultaneous relevance of different 'cultures,' and the multiple positions of actors vis-à-vis those cultures at different points in time, have turned description, explanation, and generalization into a most difficult problem. Certainly it is now the rare case when any overview of group life can be modeled under a single 'culture' label (Hannerz 1992, Kuper 1999).

The culture problem took another twist with a book entitled *Writing Culture: The Politics and Poetics of Ethnography* (Clifford and Marcus 1986). *Writing Culture* asked why ethnographies were written the way that they were. What genre constraints did students unconsciously absorb as they read the works of their predecessors? And how did these constraints set limits on the images of the 'other,' the world in which they lived, and the role of the ethnographer who did the work?

The book inspired a series of debates that continue to this day. A few key issues can be mentioned here. First, what were the 'politics' of the ethnographer/community relationship as it developed over time? Any ethnography builds on collaborative relationships, more so than traditional images of social science allow. Why doesn't the writing reflect that collaborative process, with control of the final product distributed across all the participants?

Second, any community lives in a world of layered contexts, from local realities up to the global political economy. Traditional ethnographies tend to feature the local situation as if it hangs isolated in space and time. Clearly it doesn't. Regional, national, and global histories help explain how the local community came about, as well as the systems of power that hold it in place. Why don't traditional ethnographies include such material? And what is the proper way to obtain and analyze it, since some crucial data lie outside the awareness of community members who are interviewed and observed?

Third, who is this ethnographer? He or she has a biography, social identities, a history of training, a set of ideological biases, and a vested interest in doing the work and satisfying whoever pays for it. Traditional writing minimized the presence of an ethnographer, if it recognized it at all. In part, the writing reflected notions of traditional science, as discussed earlier. In an objective and replicable study, the identity of the researcher has no influence on the outcome. Now the question is, how and how much of the ethnographer to include in the writing of the results?

These and other issues around the 'politics' of the research implicate the 'poetics' of the writing, as suggested by the subtitle of *Writing Culture*. Traditional ethnographic writing does not handle issues of politics and broader national and global contexts and ethnographer presence. What kind of writing does? Narrative? Legal briefs? Postmodern collage? Or, never mind writing, how might an ethnographic product be represented in a film or in a museum exhibit? Here, as with previous topics discussed in this entry, the questions around 'writing culture' have opened up a variety of new possibilities that simply did not exist in traditional anthropology.

The relevance of multiple 'cultures' and the call to include previously neglected 'political' issues have converted the old concept of culture into a list of issues that, for the near future, will remain under debate.

4. *The Growing Ethnographic Family*

Until recently, ethnography remained the specialty of anthropologists and sociologists. Now interest in ethnographic approaches to research has increased in a number of fields. Anthropologists often react with dismay to these developments, arguing that critical aspects of ethnography and the culture concept get lost in the transfer. More often than not they are right to do so. At the same time, outside anthropology various models of research are being developed that have a 'family resemblance' to ethnography, to use Wittgenstein's terminology. The existence of this new 'family,' together with the indeterminate nature of ethnography within anthropology already discussed in this entry, make for an even more complicated situation.

Consider the term 'qualitative,' the most widely used term to label this family of research. Strictly speaking, 'qualitative' labels only a type of data, propositional rather than numeric in form. Yet 'qualitative' may or may not also imply differences in

methods, analysis, or epistemology. At one extreme, a traditional social scientist might add open-ended questions to a survey, code them with a few concepts derived from prior theory, and announce that 'qualitative research' had been done.

An ethnographer, who would also be called a 'qualitative' researcher, would criticize these data on several grounds. The open-ended questions are too narrow and the researcher invented them. They represent only interview data without any participant observation. No other contextual data are available to constrain interpretations. Codes are taken from prior theory rather than being developed dialectically with the texts themselves. For an ethnographer, these 'qualitative' data are simply alternative measures of prior variables characteristic of traditional science, measures that have little or nothing to do with ethnography.

'Quantitative,' on the other hand, supposedly labels traditional scientific research, but the same ambiguities operate with this term as well. An ethnographer, for example, might use census data as part of their investigation of a community. They might also use prior survey results to link local detail with larger populations. Or they might use a 'natural experiment' approach to organize ethnographic data to test covariation among elements of a discovered pattern. An ethnographer uses quantitative data following a different epistemology when compared to traditional social science, as previously discussed. But 'qualitative' versus 'quantitative' is not a distinction adequate to capture such differences in research.

A second strategy to clarify the nature of the new 'family' is to divide it into types. Introductory textbooks on qualitative research lay out subdivisions such as ethnography, grounded theory, and phenomenology. Such distinctions confuse historical sources of the family with the family itself. Phenomenology, and later developments such as hermeneutics, helps clarify the philosophical foundations of the family. Grounded theory isolates and makes explicit a part of the research process—the development of summary categories from uncontrolled data. Ethnography, as shown earlier, takes from anthropological traditions the notion that long-term intense involvement—participant observation—is a precondition of exploring a community. But these three historical sources are contributions to this new family of research, not separate ways of doing it. Dividing the family into its historical sources does not clarify what it is and what it is becoming, and 'qualitative' won't serve as an adequate label for the new family of research, either.

For the author of this article, the new family is, in fact, an adoption of basic ethnographic epistemology. However, the scope and depth of data and the method of analysis vary widely across different disciplines and problem orientations. Many, probably most, approaches, do *not* feature participant observation as a *sine qua non* of the research.

For ethnographers, this new family poses a problem. Ethnography, as it developed in anthropology, is clearly a historical source and a current member of the family. Most family members are recognizable as instances of ethnographic logic in action. At the same time, for anthropologists, the ethnographic tradition defines the prototype for the family, and departures from this tradition count as a decline in quality. Narrow focus and lack of participant observation are two frequent criticisms of such departures. For many ethnographers, then, the growth of the new family is viewed negatively, as the appropriation of a logic without the disciplinary tradition that developed it. This negative view is complicated because, within contemporary anthropology, traditional ethnography is now viewed as inadequate on several grounds as well (Gupta and Ferguson 1997). The paradox generates much debate among anthropologists.

5. *Conclusion*

Fifty years ago this article would have been much simpler but much less interesting to write. 'Ethnography' labeled both the way that anthropologists did their research and the report that an anthropologist wrote, a report also called a description of the culture of a community. That definition, by the late twentieth century, had mutated into numerous unresolved questions about the nature of one human setting out to understand some others in our diverse, rapidly changing world. These same questions are now of interest in a variety of fields—other social sciences and humanities, artificial intelligence, biology, business/management, and public health, to name a few examples. Ethnography, as practiced in anthropology, has the most elaborate history, the greatest amount of experience with such questions, and its insistence on participant observation remains unique. But what it will become, separately and as a part of the new research family described in the preceding section, remains to be seen.

Ethnology

Ethnology started in the eighteenth century as a systematic attempt to acquire and compare information on those non European populations who did not possess written records of their history and cultural heritage. In the historiography of the social sciences, ethnology represents an early stage in the development of the anthropological disciplines. The meaning of the term, however, is not limited to this historical designation. In contemporary anthropology, ethnology can also refer to a methodology of cross-culturally comparing data on multiple populations. Ethnology in this sense is both distinct from and dependent on ethnography as the primary data gathering by fieldwork conducted in individual societies. In recent decades, the term ethnology has acquired yet another meaning. In a number of European countries, ethnology is prefixed with European and replaces earlier approaches to the study of folklore and the investigation of national culture history.

1. *Ethnology as the Formative Period of Anthropology*

Academic circles at the German universities of Goettingen and Halle first used the term 'ethnology' in the late eighteenth century. Coined as a derivation of the Greek word 'ethnos,' meaning 'a people,' the term 'ethnology' in its most general meaning indicates a scholarly interest in how aggregations of human beings are distinct from each other in terms of material culture, language, religion, moral ideas, or social institutions. Early developments in ethnology also included speculative theories on assumed interrelations between cultural and biologic group differences. In the nineteenth century, ethnology emerged as an exclusively historical line of inquiry, initially supported and brought to public attention by the founding of learned societies in a number of European capitals. This in turn prepared the ground for the inclusion of ethnology as an academic discipline in the curricula of universities first in England, then in Germany and the United States of America (see Schmidt 1924). Ethnology was first considered to be a subfield of anthropology. In the late nineteenth and well into the twentieth century, the umbrella term of anthropology was applied to a much broader domain of scholarly interest than today and included physical anthropology, linguistics, and archeology along with ethnology. Because what has become known as cultural anthropology in the United States of America, and as social anthropology in Great Britain and the Commonwealth countries, grew out of earlier ethnological concerns, ethnology is also to some extent regarded as the predecessor of Anglo–American anthropology.

1.1 *Evolutionism, Diffusionism, and the Historical Method*

In 1888, German-born natural scientist Franz Boas, who during the following decades would initiate and establish cultural anthropology as an academic discipline in the United States, lectured on 'The Aims of Ethnology' before an audience of a German immigrants' civic society in New York City. He identified himself as an ethnologist and defined ethnology's agenda as follows:

> 'The task of ethnology is the study of the total range of phenomena of social life. Language, customs, migrations, bodily characteristics are subjects of our studies. Thus its very first and most immediate object is the study of the history of mankind; not that of civilized nations alone, but that of the whole of mankind, from its earliest traces found in the deposits of the ice age, up to modern times.' (Boas 1940, p. 628)

Coming to ethnology in the late nineteenth century, Boas found himself at the cusp of an important paradigm shift that changed the face of this still young discipline. Up to this point, ethnology had been driven by the impetus to discover the hidden laws of human cultural development. Scholars hoped to do this by aggregating data on as many cultures as possible—both past and present—and by tabulating and classifying them. Findings were supplied either by archeology, itself an emerging discipline, or came from travel accounts, mission reports, and increasingly

also from more sophisticated ethnographic surveys of indigenous groups in Africa, Asia, and the Americas. Most of the nineteenth-century ethnologists attributed the manifestly observable cultural diversity of mankind to what they considered to be different levels of cultural development: the more 'primitive' groups were classified as being still far down on the lowest rungs of the steep ladder of ascent to civilization. At the same time, to the gaze of their more progressed contemporaries these 'savages' personified the earliest evolutionary stages of humanity. Therefore, this approach personified among others, by Edward B. Tylor in England (1832–1917), Lewis Henry Morgan (1818–81) in America, and to some extent by Adolf Bastian (1826–1905) in Germany, was labeled—not by its protagonists, but by later opponents and historiographers—'evolutionism.'

As increasingly more exact and detailed information on non European cultures was made available, many evolutionist generalizations became untenable. At the turn of the twentieth century and already anticipated by Boas in the lecture cited above, a new theory took over that shifted the emphasis away from determining the universal rules of cultural development. Instead, evidence of migration and of contact between groups, and the resulting exchanges and transfers of cultural elements were now taken to be the key to the understanding of human history and cultural diversity. The underlying assumption was that human culture emerged from a single or a small number of origins and the ensuing dispersal of cultural elements came about by migration and diffusion—hence the label of 'diffusionism' that was attributed to this new school. It had its strongest and methodologically innovative proponents among museum ethnologists in Germany (Graebner 1911) who used similarities in the shape and make of pottery vessels, weaponry, ornaments, or other artifacts as a basis to map geographical areas where cultures were assumed to have a shared origin. This enabled German-speaking ethnologists, among them Leo Frobenius (1873–1939) and Pater Wilhelm Schmidt (1868–1954), at the beginning of the twentieth century to lay out a worldwide system of so-called 'Kulturkreise,' areas of shared cultural traits. With their evolutionist predecessors, representatives of diffusionism shared a tendency for sweeping generalizations and a disregard for the cultural meanings associated with the artifacts under scrutiny. They were not interested in the social integration of groups or in the cultural context of customs they used as the basis for their theoretical speculations, rather they treated them as isolates, much as if they were specimens of material culture in a collection's glass case. Also, while insisting on their endeavour being historical in nature, they established a frozen chronology of past cultures rather than dating events and gaining insights into historical processes.

Franz Boas (1858–1942) who had been trained by Bastian in Germany and was appointed a professor at Columbia University in New York City in 1899 rejected not only evolutionism—which had an American stronghold in the Smithsonian Institution's Bureau of American Ethnology in Washington DC—but German diffusionism as well. He founded a new approach, 'the historical method,' that could perhaps best be described as a moderate type of diffusionist ethnology. He and his students, however, shied away from projective theory and, indeed, from generalizations on a grand scale. They built up an enormous database from fieldwork among contemporary North American indigenous populations; their concept of culture areas paid careful attention to proven historical relationships between native American tribal groups and also integrated environmental factors. With this emphasis on 'critical empiricism' (Kuper 1988, p. 143), the Boasians, as his students came to be called who later would become university professors in their own right at the most prestigious American universities, ended the era of speculative ethnology. In Great Britain, evolutionism proved to be more tenuous and was not superseded by diffusionist ideas until the 1920s (see Kuper 1983). However, both in the United States and in England, the term 'ethnology' was gradually eclipsed by the newer designations of cultural anthropology—in America—and its British counterpart of social anthropology, with a focus on culture and on social structure respectively.

2. *Ethnology as Cross-cultural Comparison*

Cross-cultural comparison had already been an indispensable tool for the historical reconstruction of cultural evolution as well as of cultural diffusion, but it was not until the advent of the functionalist school that cross-cultural comparison emerged as the principal methodology of social anthropology. 'By comparing a sufficient number of diverse types we discover uniformities that are more general, and thus may reach to the discovery of principles or laws that are universal in human society,' British social anthropologist Alfred R. Radcliffe-Brown put it succinctly in 1921 (Radcliffe-Brown 1951). Relinquishing the generalizing thrust of earlier social anthropology, later approaches used comparison to inquire into the interplay of variable and invariable factors shaping social relations in a given culture by contrasting it with others like it, often in a controlled sample of regionally equivalent cultural groupings. Meanwhile, in the United States of America, the statistical analysis of nonmaterial cultural data had been elevated to an advanced 'scientific' level by the development of the Human Relations Area Files at Yale University, a project that since 1937 had abstracted and systematized information on cultures around the world from ethnographic reports, and successively created a huge cross-cultural survey (see Moore 1961).

2.1 *Ethnography, Ethnology, Anthropology*

By the end of World War II, the meaning of 'ethnology' had contracted to define but one of the three scholarly practices that form the anthropological enterprise. Ethnography was understood as data-gathering in a single society, usually in a spatially and temporally bounded situation, such as when the fieldworker spends 1 year as a participant observer in a local community and later writes up the findings in a stand-alone, case study-type monograph (also called ethnography). Ethnology, by contrast, utilizes the information collected in a number of ethnographies in order to engage in systematic cross-cultural comparisons between two or more societies. In a report on the status of anthropology in higher education submitted to UNESCO in 1954, French anthropologist Claude Lévi-Strauss defined ethnography, ethnology, and anthropology as three consecutive stages in the production of anthropological knowledge, each building up on the results of the other. While ethnology, to his mind, achieves synthesis by the systematic comparison of ethnographic data across cultures, only anthropology as the third and final stage aspires to theory building with a generalizing impetus, attempting to come to universal statements on the nature of humanity (see Levi-Strauss 1975).

2.2 *The Crisis of Comparativism in Anthropology*

In cultural anthropology in 1960s America, new developments predicated a significant shift away from comparative work in anthropology. Most notably, Clifford Geertz's championing of 'thick description' suggested 'not to generalize across cases but to generalize within them' (Geertz 1973, p. 26) by in-depth immersion in one culture and ethnographic representation of one individual case-study. Criticism of cross-cultural comparativism became increasingly vocal. Comparative methodologies were attacked for their tendency to cut up cultural systems into trans-culturally comparable bits and pieces, with contextual meanings and culturally specific relations getting lost in this process. By treating the cultures under comparison as discrete and separate, cross-cultural comparison in the past tended to deny or downplay influences and linkages between cultures. Also, cross-cultural comparison has been criticized for fixing cultures in time and thus robbing them of their historicity (see Fabian 1983). Another important critique concerns the anthropologist conducting the comparison of at least two, usually multiple non Western cultures and assumes the position of objective observer who is purportedly above or beyond culture. Critics argue that cross-cultural comparison as an operation tends to make invisible power and privilege shaping the hierarchical relations between observer and observed, or between comparer and compared.

In recent decades, many anthropologists have avoided the pitfalls of comparativism by doing away with explicitly cross-cultural perspectives alltogether. At the same time, ethnography stopped being conceived of as merely providing 'raw materials' for comparison and theory building, but as a mode of producing anthropological knowledge became unexpectedly central for the disciplinary identity and epistemology of anthropology. However, anthropologists never completely abandoned comparativism. In recent years, there is a definite move to reassess comparative methodologies in anthropology. New approaches are introduced to strengthen what is considered the inherently critical potential of comparison (see Marcus and Fischer 1986).

3. *European Ethnology*

The disciplinary landscape of European countries is far from uniform. Especially in the social sciences and the humanities, the names of academic disciplines, their boundaries, and their designated domains of scholarly inquiry differ from one country to the next, sometimes even between individual universities and research institutions. Historical developments account for this high degree of variation. A closer look, however, reveals some remarkably consistent patterns. A European phenomenon that in the past has been most strongly articulated in the German-speaking countries is the so-called 'Volkskunde/Völkerkunde split' in anthropology (Gerholm and Hannerz 1982, p. 22) that emerged in the nineteenth century, resulting in two separate anthropological disciplines coexisting in academic teaching and research. Traditionally, those disciplines grouped under the *Volkskunde* heading were concerned with the historical investigation and the cultural construction of a national heritage. Conversely, those disciplines belonging to the *Völkerkunde* category focused on nonEuropean 'primitive' peoples. While the latter scholarly line of inquiry became dominant in those societies marked by colonial expansionism, the former interest led to the establishment of folklore and folklife studies dedicated to the philology and history of national and regional cultures in most of Eastern, Central and Northern Europe.

Since the late 1960s, and intensifying with the transformations in Eastern Europe starting in 1989, both sections of the anthropological enterprise have undergone a marked modernization, in some countries leading to a rapprochement of the disciplines. In Nordic countries, ethnology, formerly a museum science concerned with the material culture of non-European small-scale societies, was transformed into an internationally acclaimed social anthropology, while the label ethnology was appropriated by a historically informed and sociologically acute 'anthropology at home' that has little in common with the folklife studies it emerged from. In the German-

speaking countries of Europe, conversely, the term ethnology was initially adopted by *Völkerkunde*, while many university departments and programs previously called *Volkskunde* acquired new names—cultural studies, European ethnology, cultural anthropology, among others. Their name change signified a shift towards the problem-oriented study of contemporary German, Swiss, or Austrian society informed by new developments in social theory as well as in international anthropology (Greverus 1978). In France, the 'ethnologie contemporaine de la France' represents a new orientation of anthropological inquiry into French society with a strong ethnographic flavor (see Cuisenier and Segalen 1986). In the post-socialist and postcommunist countries of Eastern Europe, new orientations being established could build on the fact that prior to 1989, the discipline of ethnography had integrated scholars working within and outside of Europe. Abandoning the name ethnography that dates back to the 1929 rejection of purportedly 'bourgeois' ethnology by Moscow and Leningrad anthropologists, in the Czech Republic and in Slovakia, at Polish and at Hungarian universities, to cite a few examples, ethnology, cultural anthropology, or combinations of both have been chosen as new designations for anthropological inquiries at home and abroad. Also, in Southern Europe, regional anthropologies are developing that combine research interests in their home countries and regions with the most advanced theoretical developments in international anthropology (for a European survey see Giordano et al. 1990, Giordano and Greverus 1992). These new directions on the European continent have been entering into a dialog with a Europeanist specialization developing in American cultural anthropology and British social anthropology since the 1970s.

As early as 1955, a Europe-wide conference of ethnologists and folklorists in Arnhem, Netherlands, recommended to use the name 'European ethnology' internationally for all disciplines concerned with the anthropological study of European societies. This suggestion was taken up by the founders of a European association, the Société Internationale de Folklore et d'Ethnologie, in 1964 and a Europe-wide journal *Ethnologia Europaea* in 1967. Still, it is obvious that inconsistencies in disciplinary names will persist between and within European societies. However, at the turn of the new millennium in many continental European societies, ethnology not only continues to be widely used as a disciplinary designation, but has been adopted and even reinvented to suggest a new direction taken in the anthropological investigation of European cultures past and present (Kaschuba 1999). As social and cultural anthropology are redefining themselves as the analysis of cultural complexity in a global framework, European ethnology promises to bring this new anthropological approach to the study of European societies and their cultures of late modernity, and might ultimately prove capable of overcoming the old split between intra- and extra-European fields of research in continental anthropology.

Ethnomethodology: General

Ethnomethodology is a mode of inquiry devoted to the study of the practical methods of common sense reasoning used by members of society in the conduct of everyday life. The significance of this seemingly mundane subject matter resides in the fact that

practical reasoning is what enables societal members to make sense of the circumstances in which they find themselves, find ways of acting in relation to those circumstances, and thereby contribute to the production and maintenance of an intelligible social world. Ethnomethodology, as the study of such reasoning practices, is thus concerned with the very foundations of social order.

It should be clear from this brief definition that ethnomethodology is not primarily a theory of social life, nor is it a methodology for the study thereof. It is in the first instance a discipline of inquiry devoted to a distinctive order of phenomena, one that is sometimes understood to be orthogonal to the concerns of mainstream social science. However, these phenomena have important theoretical, methodological, and substantive ramifications, and in the course of elucidating them ethnomethodology has had a major impact across a range of social science disciplines. Although it originated within sociology, ethnomethodology's sphere of influence extends to anthropology, cognitive science, communication, linguistics, psychology, and the philosophy of the social sciences.

Although a few studies appeared in the late 1950s and early 1960s, the nascent approach crystallized and attracted widespread attention in 1967 with the publication of Harold Garfinkel's *Studies in Ethnomethodology*. This was a time of great intellectual ferment in the social sciences, and ethnomethodology contributed in no small way to the revolutions that challenged prevailing theoretical perspectives and methodological approaches. In the domain of sociological theory, ethnomethodology helped end the dominance of the structural functionalist paradigm associated with Talcott Parsons, and led to a major reconceptualization of the theory of action and its relationship to social structure. It was also an important impetus behind the broad-based social constructionist movement that revolutionized theorizing about subjects ranging from deviance to gender. In methodology, ethnomethodological studies challenged the scientistic pretensions of positivistic research methods, and fostered greater sensitivity and self-reflection among methodologists of various stripes. Finally, ethnomethodology inspired numerous research initiatives that revitalized a wide range of social science subfields, including the study of language and social interaction, the inner workings of bureaucratic and people-processing institutions, and the construction of formal scientific knowledge.

1. *Intellectual Origins*

The origins of ethnomethodology can be traced back to seminal research conducted in the late 1940s by Harold Garfinkel in the course of his graduate work in sociology at Harvard University. Garfinkel was a student of Talcott Parsons and he took Parsons' voluntaristic theory of action as a basic frame of reference, but he was also deeply influenced by the phenomenological writings of Alfred Schütz and the teachings of Aaron Gurwitsch. (Sometime later, the ordinary language philosophy of Ludwig Wittgenstein would become another source of inspiration.) The phenomenological enterprise directed Garfinkel's attention to certain fundamental pretheoretical problems posed by Parsons' theory of action, problems which were not adequately addressed within the Parsonian framework. What would later come to be known as 'ethnomethodology' is in large part the result of Garfinkel's sustained effort to confront these problems by empirical means (see *Parsons, Talcott (1902–79)*; *Phenomenology in Human Science*).

Parsons had sought to develop a theory of social action that would solve the Hobbesian problem of order while retaining purposive human agency within its framework. At the same time, he wished to avoid the limitations and pitfalls of strictly utilitarian thinking, which cannot account for the ends toward which action is oriented, and which treats intrinsic rationality as the sole standard governing the selection of means. Parsons' solution centered around the role of moral values in social action—he proposed that, through socialization, such values become internalized and incorporated into the actor's personality, where they guide both the selection of ends of action and the normative means by which they are sought. Insofar as such values are also institutionalized within a society and are shared by societal members, patterned activity and social cohesion will be the natural result.

Parsons' theory places primary emphasis on the motivational wellsprings of action, and in so doing it has relatively little to say about how concrete actions are managed and coordinated in real time. Thus, as Heritage (1987, p. 228) has observed, it is less a theory of action *per se* than a theory of the dispositions that give rise to action. Correspondingly, Parsons' theory fails to give serious consideration to the knowledge and forms of reasoning that actors themselves bring to bear in the course of producing and recognizing actual conduct. This insensitivity to actors' *endogenous* perspectives is exacerbated by Parsons' decision to define rational action in terms of an *exogenous* standard based on consistency with the application of scientific/logico-empirical methods. Any deviation from this standard is regarded as the embodiment of ignorance and error, in which case actors' own explanations of their actions may be dismissed in favor of a 'scientific' explanation cast in the language of norms and values.

Garfinkel recognized that Parsons' motivational solution to the Hobbesian problem of order implicates an analytically prior *cognitive* problem of order, one that cannot be resolved without due consideration to the common sense knowledge and practical reasoning employed by actors themselves. How do actors analyze their circumstances, determine which features are

relevant for present purposes, and grasp what those features 'mean?' How do they know what forms of behavior will be recognized as normatively appropriate under those circumstances? How in other words is the fundamental intelligibility of action and circumstance accomplished? It is questions like these that Garfinkel sought to answer.

2. *Garfinkel's Classic Studies*

Although Garfinkel's central analytic questions were inspired by phenomenology, his way of addressing them was distinctively his own. He eschewed highly interpretive methods involving introspection or free-wheeling *verstehen* in favor of a rigorously empirical approach based on close observation of social behavior. Since the methods of reasoning of interest are those embodied in social activities, they are publicly available to both lay members of society and professional analysts and are, at least in principle, eminently observable.

Analyzing such methods of reasoning-in-action, however, is intrinsically difficult because they are so deeply taken for granted. As an omnipresent resource for the management of social life, practical reasoning is not ordinarily an object of conscious reflection in its own right. Its very familiarity renders it elusive and resistant to analysis.

Garfinkel's ingenious solution to this problem entailed seeking out extraordinary situations in which the sense-making process is foregrounded, exaggerated, and hence rendered conspicuous. For the most part, these situations were engineered by Garfinkel and his associates through a series of experiments and quasi-experimental demonstrations. The situations often involved social actors encountering anomalous events—typically, particular social actions—that are incongruous with a pre-existing or default 'definition of the situation.' In one such experiment, subjects were engaged in a game of tic-tac-toe by experimenters who would erase and reposition the subjects' mark before placing their own mark on the grid. In another experiment, subjects were told to ask yes/no questions of a counselor but, unbeknownst to them, the 'answers' were given according to a random schedule. Elsewhere the focus shifted to incongruities that arise naturalistically rather than experimentally, and to the practices of social actors rather than observers—an example is the study of 'Agnes,' a person whose masculine genitalia and biography were at odds with her claim to female status. Across these examples, incongruity and its management served to throw processes of practical reasoning into sharp relief.

The results revealed that interactants would strive to render the situation as coherent and intelligible, invoking a wide range of background assumptions, contextual knowledge, and other elements of common sense—often in the form of natural language accounts—to this end. Three patterns of response were recurrent. Subjects would either (a) 'normalize' the anomalous event by reinterpreting it as consistent with the prior definition of the situation, (b) 'demonize' the event by treating it as a motivated and morally suspect departure from normality, or (c) reconstitute the environing situation so as to make it congruent with what is ostensibly taking place.

These outcomes demonstrate forcefully that interactants make sense of a given action by considering not only the intrinsic properties of the action itself, but also its relationship to the broader social environment in which it is embedded. The meaning and import of any particular action is thus thoroughly context-dependent. This would be a trivial matter if contexts were autonomous and stable—'the' context of an action could then serve as an archimedian vantage point from which to disambiguate that action. Contexts, however, do not have such transcendent properties—the relevant context at any given moment is derived primarily from the actions through which it is composed, and even a single incongruous action can dramatically alter the context that is understood to be in play. Practical reasoning is thus a dynamic and reflexive process whereby the sense of particular actions and environing social situations are ongoingly adjusted and reconciled with one another. By implication, the experiential reality and temporal persistence of any social situation—whether a game of tic-tac-toe, a course of counseling advice, or a person's sexual status—rests upon a foundation of such reasoning practices.

3. *Theoretical Implications*

Garfinkel's findings amount to a major reconceptualization of the fundamental locus of social order. Most social science theories view social life as organized by structural entities (e.g., social institutions, cultural symbol systems, structures of race, class, and gender, etc.) that stand outside of the flow of events in everyday life and exert a more or less determining influence on the course of those events. Such theories embody what might be thought of as a *top-down* conception of social order. Garfinkel, in contrast, offers a thoroughly *bottom-up* conception, and this theoretical inversion is a natural consequence of his decision to treat social order as a cognitive rather than a Hobbesian problem—not a problem of how conflict is avoided and solidarity maintained, but a problem of how the social world, whatever its character, becomes intelligible and accountable to its members. From this vantage point, every orderly feature of social life is an ongoing contingent accomplishment, the result of members' concerted effort to make those features recognizable to one another and the basis for subsequent action.

This theoretical inversion has further implications for the theory of action, and in particular for the role of social norms (as well as rules, conventions, etc.) in

the conduct of action (Heritage 1984, 1987, Wilson 1971). In the traditional Parsonian view, norms regulate action by specifying what courses of action are appropriate under given circumstances. This view presupposes that situations, norms, and actions are independent entities, with each situation standing outside of the actions contained within it, and predefined norms constraining those actions to unfold along situationally appropriate lines. However, Garfinkel's findings about the nature of practical reasoning suggest that this viewpoint is fundamentally misguided. Far from being independent entities, situations, actions, and norms stand in a co-constitutive or reflexive relationship to one another. Correspondingly, actors are knowledgeable agents at the very center of this process, with the capacity to alter or transform the 'definition of the situation' through their actions, and to decide upon the sense and applicability of the norms deemed relevant to that situation. Thus, the experiential reality of social norms, like every other organized feature of social life, rests upon a foundation of practical reasoning whereby action is produced and rendered intelligible in normative terms. This does not mean that norms are inconsequential for social organization, but their primary significance is constitutive rather than regulative—norms play a crucial role as a resource for imputing meaning and motivation to situated behavior (see *Action, Theories of Social*; *Norms*).

4. *Contemporary Research Initiatives*

Following Garfinkel's classic studies, ethnomethodological research developed in a number of fruitful directions. While some researchers continued to elucidate the generic properties of practical reasoning (e.g., Pollner 1987), most shifted toward examining such reasoning as it is applied in various specialized domains of social life. At the same time, the predominant research methods employed by ethnomethodologists underwent a corresponding shift away from quasi-experimental designs and toward more naturalistic methods involving the direct observation of ordinary conduct. The resulting corpus of studies resists easy summary, but three prominent lines of work will be distinguished.

4.1 *People-processing Institutions*

Ethnomethodologists first explored various organizational environments involved in people processing: schools, public welfare offices, police departments, and so on (e.g., Cicourel 1968, Sudnow 1965, Wieder 1974). These studies repeatedly documented the inadequacy of codified rules, formal procedures, and informal norms as explanations of organizational conduct. Rules and allied phenomena fail to capture the elaborate judgmental work necessary to implement the rules in concrete circumstances, and more generally to perform competently the tasks intrinsic to each setting. These previously unexamined professional competencies and discretionary judgements became the focus of close scrutiny and sustained analysis, shedding new light on the complex inner workings of people-processing institutions.

The findings have important implications for our understanding of organizational decision-making and its products. The institutions under examination routinely generate official designations of persons (e.g., 'criminal,' 'juvenile delinquent,' 'qualified welfare recipient,' etc.) and their actions (e.g., 'burglary,' 'assault,' etc.). Such designations do not result from workers mechanically applying clearly defined criteria to each case, but involve various *ad hoc* considerations guided by common sense knowledge of what outcome would be normal and reasonable under the circumstances. Insofar as the resulting designations form the basis for calculations of official statistics (on rates of crime, mortality, poverty, etc.), these studies also cast doubt on the validity of official statistics and their value for social scientific research (see *Bureaucracy, Sociology of*).

4.2 *Science and Technology*

Ethnomethodologists have also ventured into the laboratory to explore the highly technical competencies that underlie the creation of scientific and mathematical knowledge, and the production and use of technological artifacts. This line of research is most closely associated with the later work of Garfinkel himself and his immediate associates (e.g., Livingston 1986, Lynch 1993). It is reminiscent of Edmund Husserl's later writings on the European sciences in that a primary objective is to elucidate the unexplicated foundations of scientific knowledge. However, where Husserl's enterprise was essentially philosophical in character and retained a phenomenological concern with transcendental consciousness, the ethnomethodological approach proceeds empirically by examining publicly available details of situated 'workbench' practices.

Much research in this vein is concerned with the genesis and reproduction of technical discoveries ranging from physical objects to mathematical theorems. Such discoveries are arrived at, accountably validated, and made intersubjectively available through complex courses of practical reasoning and embodied activity that receive scant attention in scientific texts. This may seem surprising, given that scientists are supposed to document their own methods so as to permit replication, but scientists' methodological descriptions—like all abstracted accounts

of situated action—are necessarily incomplete. Ethnomethodologists thus seek to recover the mundane praxiological foundations of discovering work, and in so doing they re-specify discovered objects as locally produced and naturally accountable achievements. Furthermore, the very concept of discovery is transformed by this research. If physical and mathematical objects are unavoidably intertwined with situated practices, then the discovery of any such object is at the same time the discovery of a substrate of practices through which that object may be accountably produced and reproduced within concrete situations.

Ethnomethodological studies of science and technology hold the promise of yielding findings that represent recognized contributions to the various technical disciplines being studied. Indeed, the practical value of ethnomethodology is increasingly recognized in computer science, software engineering, and human–computer interaction (Suchman 1987, Button 1993) (see *Technology, Anthropology of*; *Truth and Credibility: Science and the Social Study of Science*).

4.3 Talk and Social Interaction

Perhaps the most widespread contemporary variant of ethnomethodology is what has come to be known as *conversation analysis*. This burgeoning field was developed by Harvey Sacks, originally Garfinkel's student and colleague, in collaboration with Emanuel Schegloff and Gail Jefferson (e.g., Sacks 1992, Atkinson and Heritage 1984).

Conversation analysis (henceforth CA) involves the study of practical reasoning as it is put to use in the conduct of spoken interaction. The domain of interaction—what Erving Goffman referred to as *the interaction order*—is more general than any of the specialized institutional domains investigated by ethnomethodologists, for interaction lies at the heart of virtually all of these institutions and extends as well to informal encounters between persons. Moreover, in the history of the human species, interaction developed long before other societal institutions came into being, and is in this respect 'the primordial site of sociality' (Schegloff 1988).

CA differs from other lines of ethnomethodological research not only in substance but in methodology. Conversation analysts rely exclusively on audio- and video-recordings of interactional data, and transcripts that capture the details of interaction as it actually occurs. Such data have numerous advantages—they can be examined repeatedly, analyzed at an unprecedented level of detail, and reproduced in published works so that readers can independently assess the validity of analytic claims.

The resulting research enterprise has generated an impressive array of interlocking and cumulative findings on a wide range of subjects. These include the organization of turn taking, action sequences, lexical choice, the relationship between talk and nonvocal activities, and the collaborative management of various interactional activities (e.g., giving advice, delivering good and bad news, telling troubles, etc.). More recently, researchers have applied the analytic resources of CA to various phenomena that intersect with, and can be informed by, the study of talk-in-interaction. These include how talk is organized in various institutional settings, and how it serves as a medium for the accomplishment of occupational tasks such as medical examinations, classroom lessons, journalistic interviews, trial examinations, and so on (e.g., Boden and Zimemrman 1991, Drew and Heritage 1992). Researchers have also begun to explore how the study of talk-in-interaction can illuminate linguistic phenomena such as grammar (Ochs et al. 1996), as well as medical disorders such as aphasia that manifest themselves at the level of speech (Goodwin 1995, Heeschen and Schegloff 1999).

Ethnonationalism: Cultural Concerns

Claims to national identity based on race, kinship, language, or common culture are described as 'ethnonationalist.' Such ethnonationalist claims have been widespread throughout the modern era. They sometimes extend beyond the construction of identity to the reproduction of enmity, demands that members place the nation ahead of other loyalties, and attempts to purge territories of those defined as foreign. As a result, ethnonationalism is often associated with ethnic violence and projects of ethnic cleansing or genocide. However, ethnic solidarity is also seen by many as basic to national identity as such, and thus to the notion of the nation-state. While this notion is as much contested as defended, it remains influential.

In such usage, ethnonationalism is commonly opposed to civic nationalism. The latter is understood as the loyalty of individual citizens to a state based purely on political identity. Habermas (1998) has theorized this as constitutional patriotism, stressing the extent to which political loyalty is to a set of institutional arrangements rather than a prepolitical culture or other extrapolitical solidarity. Ethnonationalism, in such usage, refers precisely to rooting political identity and obligation in the existence of a prepolitical collective unit—the nation—which achieves political subjectivity by virtue of the state. The legitimacy of the state, in turn, is judged by reference to the interests of the nation.

The contrast of ethnic to civic nationalism is heavily influenced by that of Germany to France (Kohn 1967, Alter 1989). The contrast has been enduring, and has resulted in different understandings of citizenship. France has been much more willing, for example, to use legal mechanisms to grant immigrants French citizenship, while Germany—equally open to immigration in numerical terms—generally refuses its immigrants German citizenship unless they are already ethnic Germans (Brubaker 1992). Other countries vary on the same dimension, but it is important to recognize that the difference is one of proportion and ideological emphasis (Calhoun 1997, Sassen 1999). As Smith (1986, p. 149) has remarked, 'all nations bear the impress of both territorial and ethnic principles and components, and represent an uneasy confluence of a more recent "civic" and a more ancient "genealogical" model of social cultural organization.' Not all scholars accept the distinction or hold it to be sharp; those who do use it often attribute ethnonationalism to countries that are 'late modernizers' (Bendix 1964, Nairn 1998, Schwarzmantel 1991).

Two enduring debates have shaped social science scholarship on ethnonationalism. First, is ethnonationalism an ancient (or historically nonspecific) phenomenon, possibly rooted in 'primordial' social relations, or is it distinctively modern? Relatedly, is it vanishing, enduring, or recurrent? Second, is ethnicity basic to nationalism in general, perhaps even an explanation for nationalism, and is ethnonationalism thus its 'normal' form? Much nationalist ideology has claimed definitive ethnic roots; social scientists are more divided on the question. Beyond these broad questions of orientation, research focuses on a variety of issues from the cultural content of ethnonationalism to explanations of its occurrence, forms of public performance, dynamics of leadership and mobilization, and reasons for violence.

1. *Modernity vs. Primordiality*

A long-running debate in the literature on nationalism pits arguments that it is an extension of ancient ethnicity (Smith 1986, Armstrong 1982, Hutcheson 1994) against those who argue that it is essentially modern (Gellner 1983, Hobsbawm 1990, Greenfeld 1992). Majority scholarly opinion tends toward the latter view, though explanations differ. 'Modernists' variously see nationalism rooted in industrialization (Gellner 1983), state-formation (Tilly 1990, Mann 1993), the rise of new communications media and genres of collective imagination (Deutsch 1966, Anderson 1991), and the development of new rhetorics for collective identity and capacities for collective action (Calhoun 1997). While many favor specific factors as primary explanations, most recognize that several causes are interrelated.

Many nationalists but few scholars see nationalism as ubiquitous in history and simply the 'normal' way of organizing large-scale collective identity. Most social scientists point rather to the variety of political and cultural forms common before the modern era—empires and great religions, for example—and the transformations wrought by the rise of a new kind of

intensive state administration, cultural integration, popular political participation, and international relations. Many of these social scientists argue that nations and nationalism in their modern sense are both new. In particular, they would argue that ethnicity as a way of organizing collective identity underwent at the least a substantial reorganization when it began to be deployed as part of ethnonationalist rhetoric in the modern era. Others, however, including notably Anthony Smith (1986, 1991, 1998) and John Armstrong (1982) argue that there is more continuity in the ethnic core of nations, though they too would agree that modernity transformed—if it did not outright create—nationalism.

The attraction of a claimed ethnic foundation to nations lies largely in the implication that nationhood is in some sense primordial and natural. Nationalists typically claim that their nations are simply given and immutable rather than constructions of recent historical action or tendentious contemporary claims. Much early scholarly writing on nations and nationalism shared in this view and sought to discover which were the 'true' ethnic foundations of nationhood (Skurnowicz 1981, Zacek 1969). It is no doubt ideologically effective to claim that a nation has existed since time immemorial or that its traditions have been passed down intact from heroic founders. In no case, however, does historical or social science research support such a claim. All nations are historically created.

Noting this, one line of research emphasizes the manipulation of popular sentiments by the more or less cynical production of national culture by intellectuals and state building elites. Hobsbawm and Ranger (1983), for example, have collected numerous examples of the ways in which apparently definitive cultural markers of ethnonational identity can in fact be traced to specific acts of creation embedded in political (or sometimes marketing) projects rather than reflecting pre-existing ethnicity. The Scots tartan kilt is a famous example, dating not from the mists of primordial Highland history but from eighteenth century resistance to Anglicization (Trevor-Roper 1983). Likewise, nineteenth century Serbian and Croatian intellectuals strove to divide their common Serbo-Croatian language into two distinct vernaculars with separate literary traditions. But as this example makes clear, it is not obvious that because the 'traditions' of nationalism are 'invented' they are somehow less real or valid (see also Hobsbawn 1990). Anderson (1996, p. 6) finds the same fault with Gellner: 'Gellner is so anxious to show that nationalism masquerades under false pretences that he assimilates "invention" to "fabrication" and "falsity," rather than to "imagining" and "creation".'

Hobsbawm and Ranger imply that long-standing 'primordial' tradition would somehow count as legitimate, while by contrast various nationalist traditions are of recent and perhaps manipulative creation. Many ideologues do claim origins at the dawn of history, but few scholars have doubted that cultural traditions are constantly renewed. What so-called 'primordialists' have argued is that certain identities and traditions—especially those of ethnicity—are *experienced* as primordial (Geertz 1963). Sociologically, thus, what matters is less the antiquity of the contents of tradition, than the efficacy of the process by which certain beliefs and understandings are constituted as unquestioned, immediate knowledge. This has more to do with current bases for the reproduction of culture than with history as such. Ethnicity or cultural traditions are bases for nationalism because they effectively constitute historical memory, because they inculcate it as 'prejudice,' not because the historical origins they claim are accurate (prejudice means, following Gadamer (1981), not just prior to judgment, but constituting the condition of judgment). Moreover, all traditions are 'invented' (or at least in a more diffuse sense, created); none are truly primordial. This was acknowledged, though rather weakly, even by some of the functionalists who emphasized the notion of primordiality and the 'givenness' of cultural identities and traditions (see Eisenstadt 1966, 1973, Geertz 1963, Gellner 1964). All such traditions also are potentially contested and subject to continual reshaping, whether explicit or hidden. Some claims about nationality may fail to persuade because they are too manifestly manipulated by creators, or because the myth that is being proffered does not speak to the circumstances and practical commitments of the people in question.

Notions of nations as acting subjects are distinctively modern, part of a new way of constructing collective identity (Steiner 1988). This said, there is no scholarly agreement about when nationalism began. Greenfeld (1992) dates it from the English Civil War, Anderson (1991) from Latin American independence movements, Alter (1989) from the French Revolution, and Breuilly (1993) and Kedourie (1993) both from German Romanticism and reaction to the French Revolution. Calhoun (1997) suggests that rather than trying to identify a single point of origin, scholars should see nationalism as drawing together several different threads of historical change. As a discursive formation, it took on increasingly clear form through the early modern period and was fully in play by the Napoleonic era.

2. *Nationalism as an Ethnic Phenomenon*

Most prominent twentieth-century analysts of nationalism have sought to challenge the explanation of nationalism by ethnicity. Kohn (1944) and Seton-Watson (1977) stress the crucial role of modern politics, especially the idea of sovereignty. Hobsbawm (1990) treats nationalism as a kind of second-order political movement based on a false consciousness which ethnicity helps to produce but cannot explain

because the deeper roots lie in political economy not culture. The dominant approach in contemporary scholarship treats nationalism largely as an ideological reflection of state formation (Tilly 1975, 1990, Hall 1995, Mann 1993). Gellner (1983) emphasizes industrialization, and also stresses the number of cases of failed or absent nationalisms: ethnic groups which mounted either little or no attempt to become nations in the modern senses. This suggests that even if ethnicity plays a role it cannot be a sufficient explanation (though one imagines the nineteenth-century German Romantics would simply reply that there are strong, historic nations and weak ones destined to fade from the historic stage). Hayes (1931) argues for seeing nationalism as a sort of religion. Hechter (2000) analyzes it in terms of strategic individual action aimed at maximizing mostly economic and political benefits. Kedourie (1993) approaches nationalism as an ideology, and attempts to debunk nationalism by showing the untenability of the German Romantic cultural-ethnic claims. Indeed, in their different ways, all these thinkers have sought to debunk the common claims that nationalists themselves make to long-established ethnic identities.

Against this backdrop, Smith acknowledges that nations cannot be seen as primordial or natural, but nonetheless argues that they are rooted in relatively ancient histories. Smith argues that the origins of modern nationalism lie in the successful bureaucratization of aristocratic *ethnie*, which were able to transform themselves into genuine nations only in the West. In the West, territorial centralization and consolidation went hand in hand with a growing cultural standardization. Nations, Smith thus suggests, are long-term processes, continually re-enacted and reconstructed; they require ethnic cores, homelands, heroes, and golden ages if they are to survive. 'Modern nations and nationalism have only extended and deepened the meanings and scope of older ethnic concepts and structures. Nationalism has certainly universalized these structures and ideals, but modern "civic" nations have not in practice really transcended ethnicity or ethnic sentiments' (Smith 1986, p. 216).

The ethnic similarities and bonds that contribute to the formation of nations may indeed be important and long-standing, but in themselves they do not fully constitute either particular nations or the modern idea of nation. While some critics of ethnic explanations of nationalism emphasize the influence of state formation or other 'master variables,' a number assert that nations are created by nationalism—by this particular form of discourse, political rhetoric, or ideology—not merely passively present and awaiting the contingent address of nationalists (Kedourie 1993, Gellner 1983, Anderson 1991, Chatterjee 1986).

An emphasis on pre-existing ethnicity—even where this is rightly identified—is unable to shed much light on why so many modern movements, policies, ideologies, and conflicts are constituted within the discourse of nationalism. Indeed, as Gellner (1983, pp. 8–18, 61) has suggested, the very self-recognition of ethnicities or cultures as defining identities is distinctively modern. Walker Connor (1994, p. 103) uses a similar point to distinguish ethnic groups as 'potential nations' from real nations: 'While an ethnic group *may*, therefore, be other-defined, the nation *must* be self-defined.'

Explanations of ethnonationalism, thus, need to address the contemporary conditions that make it effective in people's lives, attempts to orient themselves in the world, and actions. Such conditions are of course subject to change and nationalist constructions are apt to change with them. Thus Indian nationalists from the nineteenth century through Nehru were able to make a meaningful (though hardly seamless or uncontested) unity of the welter of subcontinental identities as part of their struggle against the British. The departure of the British from India changed the meaning of Congress nationalism, however, as this became the program of an Indian state, not of those outside official politics who resisted an alien regime. Among other effects of this, a rhetorical space was opened up for 'communal' and other sectional claims that were less readily brought forward in the colonial period (Chatterjee 1994). Similarly, the proliferation of nationalisms in Eastern Europe attendant on the collapse of communist rule involved a 'reframing' of older national identities and nationalist projects; the nationalisms of the 1990s were neither altogether new nor simply resumptions of those that predated communism. The opposition between primordiality and 'mere invention' leaves open a very wide range of historicities within which national and other traditions can exert real force.

In 1871, in one of the most famous essays ever written on nationalism, Ernst Renan (1990, p. 11) grasped the importance of the tensions masked in nationalist invocations of history:

> Forgetting, I would even go so far as to say historical error, is a crucial factor in the creation of a nation, which is why progress in historical studies often constitutes a danger for [the principle of] nationality. Indeed, historical enquiry brings to light deeds of violence which took place at the origin of all political formations, even those whose consequences have been altogether beneficial. Unity is always effected by means of brutality.

The common contrast between France and Germany—the literature's paradigmatic opposition of civic to ethnic nationalism—thus, is between two different styles of invoking history and ethnicity, not radically between nonethnic and ethnic claims. French schoolchildren learn that their commonality is not merely ethnic but achieved in the collective action of the Revolution. German nationalist historians put forward stronger claims for the primacy of common culture and ethnicity partly because their narratives

must help schoolchildren 'forget' that Germans spent most of their history as members of separate polities (often combative and not all very uniform culturally), even while they celebrate the roles of Bismarck and others in unifying Germany.

Like all forms of nationalism, ethnonationalism is partly a matter of narrative construction, the production (and reproduction and revision) of narratives locating the nation's place in history (Bhabha 1990). As Anderson (1991) puts it, nations move through historical time as persons move through biographical time; each may figure in stories like characters in a novel. This is one reason why the continuity of ethnic identities alone does not adequately explain nationalism: The narrative constructions in which it is cast change and potentially transform the meaning of whatever ethnic commonalties may exist. Ironically, the writing of linear historical narratives of national development and claims to primordial national identity often proceed hand in hand. Indeed, the writing of national historical narratives is so embedded in the discourse of nationalism that it almost always depends rhetorically on the presumption of some kind of preexisting national identity in order to give the story a beginning. A claim to primordial national identity is, in fact, a version of nationalist historical narrative.

3. Conclusion

The modern literature on nationalism is centrally structured by debates over the extent to which nationalism is based on and/or explicable by ethnicity. The rhetoric employed by nationalists around the world commonly presents nationality as an extension of ethnicity, but academic analysis often challenges this. Researchers point to the extent to which national identities are based on new cultural creativity, not ancient traditions, or on selective appropriation of ancient traditions. They stress the role of state formation, industrialization, and economic change, of geopolitical pressures and rivalries, of the availability of a globally distributed rhetoric of nationalism, and of the interests of those who promote nationalism. Even if ethnicity is not the primary explanation of nationalism, it still often plays a role—at the very least in ideology. Movements and policies shaped by ethnonationalism are powerful sources of both collective identity and collective conflict in the contemporary world. They do not seem to be declining in significance, but rather to be among the main forms through which people grapple with the challenges and opportunities posed by globalization.

Etymology

'Etymology' is the branch of linguistic science that treats the history of words and their components, with the aim of determining their origin and their derivation. It may also be defined as word history. In this sense one may speak of the etymology of a word.

1. Relation to Historical Linguistics

The term is attested in English from the late fourteenth century, when as in earlier periods the study was aimed at determining the 'true meaning' of words, often with fanciful results. Accurate results were achieved only in the nineteenth century as historical linguistics developed. From that time, historical treatment of the lexicon has gradually come to be dealt with separately from historical treatment of the grammar. Historical linguistics deals with phonology, inflectional morphology, and syntax, while etymology confines its attention to the lexicon and derivational morphology; there has been some overlap. Etymological dictionaries may include entries on affixes like the past participle suffix *-ed*, as in *hoped*, probably because many of these are used as adjectives as well, e.g., in *long hoped* …, but dictionaries generally omit inclusion of the past tense suffix *-ed* and other inflectional affixes.

Although etymology omits treatment of grammatical elements, it relies heavily on historical grammar for phonology and morphology. It may also draw on syntax, as in the treatment of compounds. Advances in etymology have accordingly gone hand-in-hand with advances in historical linguistics.

2. Gradual Development as an Independent Branch

In the early decades of the nineteenth century etymological studies were directed at comparing prior forms in previous periods of the language and related forms in other dialects of that language, often in connection with historical essays, monographs, and grammars. Jacob Grimm (1785–1863) in his Germanic grammar of 1821 set side by side cognates like Greek *treĩs*, Latin *trēs*, Gothic *þṙeis*, Old High German *drī*, and proposed rules for indicating the corresponding consonants, e.g., |**gk t. goth th. ohg d**|. He also recognized discrepancies, such as the differing correspondences with Latin *t* in *frāter*, Gothic *brōþar* and Latin *pater*, Gothic *fadar*. But he did not account for the difference between the medial consonants of the two sets, nor for the vowels. Similarly Friedrich Diez (1794–1876) in his etymological dictionary of the Romance languages (1858) merely brought together related words centering on Italian.

Following etymological investigations as by August Pott (1802–87) (Pott 1836), August Fick (1833–1916) published a comparative dictionary of the Indo-European languages (Fick 1871) half a century after Grimm's grammar. August Schleicher (1821–68) had introduced the practice of providing reconstructed/starred forms (Schleicher 1862). Etymological dictionaries now provided the etymon and history of words rather than comparative lists. Etymology has subsequently been treated independently of historical grammar, as may be exemplified by Walter Skeat's (1835–1912) etymological dictionary of the English language (1909) as well as the comparable German work in 1883 by Friedrich Kluge (1856–1926) (Kluge 1989). They were brought repeatedly up to date, as Kluge's has been with more than twenty editions.

3. Explanation of all Elements of Words

By the end of the nineteenth century etymological essays, monographs, and dictionaries aimed at accounting for all the phonological and morphological changes in the development of words and stating their oldest attainable form. Methodology had become precise in accordance with increased understanding of phonology and morphology. In the fourth decade of the century linguists controlling the increasing knowledge of phonetics accounted for the unchanged *p t k* in Germanic words like *spew*, Latin *spuō*, *stand*, Latin *stāre* by noting their position after fricatives; attention then was directed not only at individual sounds but also at combinations of them. In 1863 Hermann Grassmann (1809–77) (Grassmann 1863) accounted for the discrepancy exemplified in the initial *b* of Sanskrit *bandhati* and that of NE *bind* and similar patterns through establishing that an aspirate was deaspirated in Sanskrit and Greek when a second aspirate occurred in the following syllable. The Indo-European root was accordingly posited as **bhendh-* and the Germanic *b-* was in accordance with the general change posited by Grimm. Attention then was directed at entire words, not merely at individual sounds and their immediate neighbors. After Karl Verner (1846–96) accounted for the voiced *d* in Gothic *fadar* and the voiced rather than voiceless fricatives of other such words by pointing to the position of their accent, as in the Greek cognate *patḗr* (Verner 1875), attention was directed at suprasegmentals as well as segmentals. Subsequently etymological studies treated all the formal elements of words—individual sounds, sounds in combination, and accentuation.

The entry for *father* in Skeat's dictionary, brought up to date in 1909, may serve as an example. After a brief indication of the meaning, 'a male parent,' Skeat provides the Middle English and Old English form *fader*; thereupon he adds the cognates in other Germanic dialects and finally those in some of the Indo-European dialects, concluding with the reconstructed Proto-Indo-European **pater-*. He then lists a few derivatives, e.g., *father-hood*. The entry includes one formal comment, that 'the spelling *fader* is almost universal in Middle English (and) *father* is due to dialectal influence, which changed *-der* to *-ther*.' The entry may illustrate the concentration on the form of individual words characteristic of many etymological dictionaries.

4. The Impact of Expanded Linguistic Studies

While greater control of phonology was being achieved, increasing attention was given to meaning and change of meaning. The results may be illustrated by the entry for the German cognate of *father* in the Kluge dictionary, which has been revised many more times than that of Skeat. After providing formal information, much like the entry of Skeat, the Kluge entry has an additional explanatory statement on the meaning: 'The word refers clearly to the social status of the father (as master of the house) though a more precise etymology is not certain. Beside it there exists in most languages a familiar word, an imitative word (doubtless of child's language) of the type Gothic *atta*, NE *daddy*, French and New High German *Papa*, etc.).' This is followed by a list of cognates in the other present-day Germanic languages and by references to *Patriot*, *Patrizier*, *Vetter*. The entries for these are similar in pattern. They indicate that their etymon may be found under that for *Vater*. The entry for *Vetter* (cousin) also refers to other relationship terms which in turn contain further such references. Even though the kinship system is not provided as such, it may be inferred through the cross-references.

Such entries illustrate that a great deal of attention had been given to the position of words in society; the attention was fostered by the developing fields of dialect geography and sociolinguistics in the latter part of the nineteenth century. There was also more specific concern for the history of nonnative or, as they are generally known, borrowed words, as may be noted from the references under *Vater*. In addition, words were examined by semantic classes, such as the numerals, or wider areas, such as clerical, military, and political terms. The impact of all such relationships was then identified for more precise historical treatment. Conversely the information drawn from such relationships was applied to determine in greater detail the social conditions they revealed.

5. Various Kinds of Imported Words and their Modifications

Influences from other languages may be introduced in a number of ways. Words may be adopted with little change. These are known as 'borrowings.' Examples from the early contacts between Romans and Germanic speakers are words referring to improved transportation and measurement, such as *street*, Latin *strāta* (*via*) 'paved road,' *mile* Latin *mīlle* '1000,' and *inch*, Latin *uncia* 'twelfth.' As in these words, modifications result from differences in pronunciation of individual sounds or in inflectional endings. Modifications may also be made in meanings. The Latin adverb *alibī* 'elsewhere' has been taken over as a noun in English, as has the Latin verb *affīdāvit* 'he has pledged his faith.'

Rather than adoption, a foreign word may be translated, utilizing native elements. Several processes may be involved in such importations. If the foreign word or its elements are rather literally translated, the results are known as 'loan translation' or calques. Examples may be cited from the time when classical

culture and religion were introduced into northern Europe. The word *heathen* 'inhabitant of the heath or countryside' is a translation of the Latin *pāgānus*. Similarly, *gospel* Old English *gōd-spell* 'good story' is a translation of Greek *euaggélion*, also imported as *evangel*.

If the translation is not as exact as in these words, it is referred to as a 'loan rendition.' Examples are prominent in German, in which *Gewissen* corresponds to Latin *conscientia*, *conscience*, *Sauerstoff* to *oxygen*. If the foreign word is taken as a model but not reproduced with similar elements, it is referred to as a 'loan creation,' for example German *Auferstehung*, Latin *resurrectio*, *resurrection*. The meaning of foreign words may be taken over for native words in 'semantic loans.' Words like *God*, *heaven*, *hell*, *Lord* were modified in this way with the introduction of Christianity.

After foreign words or elements are introduced into a language their components may be paired with native components, resulting in 'hybrids.' The native inflectional suffixes of English like the genitive *-s* and the participial *-ing* are used with non-native nouns and verbs; on the other hand, non-native suffixes like *-able* are used with many native English words, as in *doable*.

As another modification, foreign words may be modified to fit the native pattern resulting in 'back formations.' Widely cited examples are *pea* from Old English *pise*, Latin *pisum*, where the *-s* was taken as plural marker, and *cherry*, based on French *cerise*.

These processes involved in etymological explanation may illustrate that etymology is closely related to historical grammar.

6. Relationships Between Etymology, Historical Grammar, and Culture

Etymological investigations contribute information on the phonological or morphological status of languages concerned at a given time. For example, the word *wine* adopted from Latin at the beginning of our era informs us that the initial consonant of *vīnum* was still pronounced as a resonant. When *vine was* later introduced into English, it had been shifted to a fricative. Similarly the borrowing of Latin *catīnus* as *kettle* informs us that vowel mutation in the West Germanic languages took place only later.

Such information is especially important in providing information on the early periods of languages. The importation of Proto-Indo-European words into Proto-Finno-Ugric, e.g., **medhu-* 'honey,' PFU **mete* among other borrowings, and that of PIE **pek'u-* 'cattle' into Proto-North-Caucasian **päHäKwV* among other borrowings, has been taken as evidence that the speakers of Proto-Indo-European were located along the Volga in the fifth millennium BC.

The words affected also inform us of the social and cultural relations between the two sets of speakers. English provides paradigmatic information. The words taken over from Latin at the beginning of our era such as those cited above belong to the everyday vocabulary but suggest greater technical advances for the Latin speakers.

A half century later many words were taken over from Scandinavian, such as *bank*, *car*, *sky* as well as the pronouns *they*, *them*, *their*. Adoption of these words indicates that both sets of speakers shared approximately the same culture.

The sets of words adopted from French and the classical languages after 1000 AD belong in general to advanced facets of society, such as political, clerical, military and, other such spheres. They suggest introduction of items from speakers of a more complex society.

We may regard these three types of borrowings as patterns for interpreting the findings regarding language relationships generally. Importations among the languages of Europe today are comparable to those between Scandinavian and English. Influence of Arabic on Spanish from the tenth century, as of Arabic and Persian on Turkish, is comparable to that of French on English. Historical examination of the lexicon to determine the etymology of its items then not only illuminates the development of languages but also contributes to our understanding of the culture and social situation of their speakers.

Eudaemonism

Following up on the ancient concepts of *eudaimonia* (lit. 'having a good demon'), the notion of 'happiness' has been given a great variety of different meanings. Its semantic space reaches from 'the favor of fate, the advantageous lot, the happy circumstance,' all referring to accidental, external circumstances, to completely achieved goals and the 'good life.' Across this breadth, thus, the term happiness includes that which is outside of the reach of human beings, individual destiny (as in the ancient figure of *Fortuna*, the goddess of fate, who distributes her offerings blindly), as well as a durable state that can be influenced and, in principle, achieved by human action. Precisely the determination of such action, guided by the pursuit of happiness, has long been the basis of ethics and moral philosophy and of their debates about action guided by virtue, which then in turn was to determine and safeguard happiness.

Eudaimonia (*Glückseligkeit*, *prospérité*, happiness) is thus one of the central concepts of ethics and moral philosophy. It has been cast in a variety of ways and points into a number of different directions. Happiness was, for once, conceptualized in subjective terms, with reference to the self (see *Self: History of the Concept*), to the passions and affects, to the realization of one's objectives, or of one's overall life. Second, happiness can be cast in relation to the other, as friendship, love, recognition, as ethically founded intersubjectivity. And finally, there is a conception of happiness that takes all other conceptions for incomplete as long as there is no connection to the community and its political order. Even though this conception found its strongest expression in ancient philosophy, it has by far not disappeared from current discourse. In contrast, it may possibly even be claimed that this conception with its emphasis on justice as a precondition for happiness and the 'good life' presents, just as much as the reference to the self and to the other, an inescapable point of concern and a 'utopian' horizon of the philosophy of happiness.

In sum, then, the conceptualization of happiness shows a temporal tension between fulfillment across all of the life-span, on the one hand, and fulfillment in the sudden and epiphanic moment, on the other. Further, it is marked by a transcendental-religious tension that stretches from revelation, redemption and salvation to joy. It carries with it a political-social-ethical tension between an individualistic view of self-realization and the conception of a good political order. Finally, a tension with regard to a theory of action is unavoidable, a tension that situates the singular human being between the capability to act autonomously and destiny. All these tensions can be traced back, in a variety of ways, to the heritage of Greek reason.

1. *The 'Classical' Tradition*

In the Nicomachean Ethics, engaging with Plato's conception (Wolf 1996), Aristotle links the concept of *eudaimonia* to the three human life-forms: to pleasure, from which most human beings gain their view about what happiness is; to the service of the state; and to life dedicated to philosophy. Because the essence of human life lies in the pursuit of reason, neither profane enjoyment nor politics and the art of governing, but *theorein* is the highest in the hierarchy of human activities, in which *eudaimonia* can be realized. 'Happiness is activity (*energeia*) in accordance with virtue' (X, 7) and 'the highest good reachable for human beings presents itself as the activity of the soul in the sense of its essential prowess (*areté*)' (Aristotle 1934, I, 6, see Heidegger 1992). *Theorein* as an activity is not aiming at the cognition of just anything, but of that which is eternal. As such it is among the human activities the one that is the most persistent of all, independent of changes in the external circumstances. This activity is full of pleasure, it is so even most among all activities—on the one hand, because it is continuous; on the other, because it participates in the eternal that it gets to know. *Theorein* is not confined to any moment; such activity stretches across an entire life. Furthermore, to be active in the sense of *theorein* is a purpose for itself, the final purpose, that which is pursued for its own sake, since it does not produce anything that lies outside of itself; it is self-sufficient. Such autarchy, however, is possible only if the polis has provided the required means so that human activity can develop free of the concern for survival. For Aristotle, happiness is an eminently social and political matter, since under conditions of lack of resources no accomplished life is possible, and it is also not thinkable without friendship, without the relations to others. Thus, happiness is finally possible only within a just political community that is organized on principles of reason.

Aristotle, thus, linked happiness to human essence in need to be actualized, to the relation to others in friendship and to institutionally supported forms of living and acting together. With the disruption of the order of the polis as well as of Hellenic philosophy, in contrast, for the Stoa and for Epicureism (and as well for skepticism), *eudaimonia* becomes a concept that refers to purposes that now reside in that which is available to human beings. *Eudaimonia* is, then, the striving for whatever is available and, vice versa, emphasizes the diminution of demands and the avoidance of pain. The thought that happiness opens itself

towards the humans only in a Stoic relation of radical distance to all that which is not at hand is alien to Epikur; nevertheless he, too, sees happiness neither in *theorein* nor in a goal-directed activity that finds its fulfillment in ethical and theoretical practice. Despite all differences between the ancient Greek schools of thought, they also show commonalities, such as in particular in the connection of virtue and happiness. Ancient Greek philosophies, as Kant stated, follow the same method in rejecting any validity to the assertion that virtue and happiness could be two separate elements of the highest good. They 'consequently sought the unity of the principle in accordance with the rule of identity,' even if they differ in the choice of the fundamental concept. 'The Epicurean said: to be conscious of one's maxim leading to happiness is virtue; the Stoic said: to be conscious of one's virtue is happiness. For the first *prudence* was equivalent to morality; for the second, who chose a higher designation for virtue, *morality* alone was true wisdom' (Kant 1993a, A 200, pp. 239–40/book II, chapter 2, p. 229).

2. *Eudaimonia in the Philosophy of Early Modernity*

Conceptions of happiness in relation to individuals and to society changed profoundly during the period known as early modernity; these changes were part of broader reproblematizations in the moral and social philosophy of the time. Political thinking of this period introduces happiness as a component and as a means of politics and the symmetrical opposition of passion and reason enters into a conceptual relation with virtue and politics. Happiness becomes one of the key concepts of ethical-political thinking during the seventeenth and eighteenth century, a thinking that at the same time reorders the relations between the concepts for affects and those for morality. No longer the affective drives of the human beings are the object under consideration, but rather human actions and the consequences of these actions. Affects as such are considered neither as good nor evil, it is rather individual selfishness and self-love (*amour-propre*) which moves into the center of concern. This focus generates the new problématique of moral philosophy: If it is the case that human beings pursue their happiness on the basis of their drives and affects, then it is the task of moral philosophy to determine how—despite that—a good social order can exist and be maintained.

The new emphasis on the individuals and their interests went along with a reconceptualization of the political. From now on, it was precisely their striving for happiness that made human beings inclined to subject themselves to the laws of the common order. This reasoning emerges in classical form in Thomas Hobbes's (1588–1679) *Leviathan*. Hobbes first determines 'felicity' as the attempt to completely accomplish the objectives of human desires. Since, however, all human beings hope to reach this goal, the one potentially turns into a danger for the other. To avoid such a situation of *bellum omnium contra omnes*, of 'war of every man against every man,' human beings assemble to form a state that itself embodies no longer any conception of happiness or of the good life, but that guards to prevent any situation from arising in which the various strivings for happiness collide in a violent manner.

At the end of this period, during which happiness remains the focal point of theoretical constellations, an attempt is made to indeed erect a polity that is committed to support its members' striving for happiness. The American Declaration of Independence even declares the 'pursuit of happiness' to be a human right (Jefferson 1776). A historically novel compromise is here elaborated between a classic-substantive and an individualistic-instrumental conception of the state: the state respects the autonomy of the individual and the plurality of their views, but does not entirely renounce the proposition of a general guiding idea about the 'good life.' The individuals' striving for happiness—to the protection of which the state has been created, exactly in the sense of the theories of delegation—in its sum produces the common good. This common good, however, is now in a particular way mixed with elements of a Protestant ethic, in which inner-worldly happiness, for example, as economic success, gains divine approval. This unique privileging of the pursuit of happiness as a human right, which cannot be found in European declarations, is rooted in a particular relation between the state and the citizens. It is nevertheless close to European conceptions in another respect, namely in understanding the citizen predominantly as an economic subject, a *bourgeois* in contrast to a *citoyen*, whose pursuit of property needs to be protected by the state, a protection that is considered as being the primary task of the state.

The utilitarianism of the eighteenth and nineteenth century similarly still places happiness in the center of moral and social philosophy (see *Utilitarian Social Thought, History of*). The ethics of utilitarianism considers individual—as well as general—utility as the purpose of action and sets thus 'good' synonymous with 'useful.' Jeremy Bentham (1748–1832) calls for 'the greatest happiness of the greatest number' as the collective goal; by promoting the well-being of all, the well-being of the individual is promoted as well. Morals and legislation are that art to regulate human actions such that to bring forth 'the greatest possible quantity of happiness' (*An Introduction to the Principles of Morals and Legislation* 1789). Drawing on Bentham, John Stuart Mill (1806–73) considers the pursuit of the greatest possible happiness of all as the supreme goal as well (*Utilitarianism* 1861). On the one hand, utilitarism maintained a conception according

to which the pursuit of happiness is the most important motive of human action, and it also kept the link between happiness and politics. What was added were amendments that had become historically unavoidable, namely the view that every human being determines their happiness in their own way and strive for it, and that everybody has the same right to do so. On the other hand, however, what was thus created was an *aporia* between the common good and the diversity of the human pursuits of happiness. This *aporia* was to be dealt with by assuming the comparability of the various individualized and subjectivized pursuits. Measurability and quantification were the tools to make the diverse compatible, since the state's task to pursue the greatest happiness of the greatest number demanded the possibility of adding up the manifoldness of forms of individual happiness. Quantification of happiness is the attempt to maintain a measure for collective happiness by at the same time making only a minimum of substantive assumptions about happiness as such. Utilitarianism had inevitably to fail when radically subjectivized conceptions of happiness were to be compared to each other, measured and sublated in an overall concept of utility.

3. *The Eviction of Happiness from Philosophy: Immanuel Kant*

In continental moral and political philosophy, the most systematic attempt to clarify the relation between action and happiness was undertaken by Immanuel Kant—it was at the same time an attempt with far-reaching consequences for later philosophy. It had long been an objective of moral philosophy to demonstrate that there is no, and could not possibly be any, contradiction between ethical demands on the one side, and the pursuit of happiness (or of utility or interest) on the other. Thus, it had merged virtue and happiness into one, and stated that virtuous action promotes happiness at the same time. Kant radically breaks this connection of interest, virtue, and happiness.

Happiness remains for Kant as well a concept that has a basic influence on human action: 'Happiness is "the satisfaction of all our desires"; *extensive*, in regard to their multiplicity; *intensive*, in regard to their degree; and *protensive*, in regard to their duration' (1974a, II, B 834, p. 677 [p. 518]), '*happiness* is the state of a rational being in the world in the whole of whose existence *everything goes according to his wish and will*, and rests, therefore, on the harmony of nature with his whole end as well as with the essential determining ground of his will' (1993a, A 224–5). This concept, however, is not suitable as a foundation of moral philosophy, according to the following reasoning.

First, happiness can hardly be the true purpose of nature, since in such a case, human action would not be guided by practical reason, steering the will, but subjected to the instincts (1993b, BA 5, p. 20). Second, the concept of happiness cannot be determined unequivocally, since it rests on experience, which is never closed, on the one hand (1993b, BA 46, p. 47, 1993a, A 46, p. 133), and since, on the other hand, the 'idea of happiness' requires an absolute whole, a present and future maximum of well-being. The contradiction between the principled openness of experience and the idea of the accomplishment of happiness cannot be sublated within time. Furthermore, the conception of a reachable maximum of happiness is impossible, for two reasons. No sum of happiness can ever be added up, since only similar perceptions can be added up; feeling, however, is highly variable according to the manifoldness of being touched in the very intricate state of life. In addition, the nature of the human being can never halt and be satisfied in possession and enjoyment. The inclinations change, they grow, and they always leave an even larger emptiness behind them than the one one hoped to fill. (The dynamics of needs and their limitless character (*apeiron*) was already of concern for Hellenic philosophy.) The fact that each human being may have a specific view of happiness, and which furthermore may undergo change in the course of life, puts a further limit to any general determination of happiness. Happiness is 'a subjective basic feeling of enjoyment of dissatisfaction' (1993a, A 46, p. 133); a subjective feeling however, cannot be the foundation of general rules for action. As a consequence, thus, it is not possible to demand the agreement of the pursuit of happiness with moral requirements—which precisely was the former assumption: that namely the pursuit of happiness realizes ethical requirements since happiness resides only in morally virtuous action.

Such subjectivization separates happiness radicality from virtue and ethicality and subordinates it, as an indeterminate inclination, to the categorical imperative. 'Act in such a way that the maxim of your will could always serve as the principle of a general law.' It is no longer the pursuit of happiness that makes an action moral, but only the respect of the moral law and the obedience to duty, since it is only in them that human freedom is anchored. The categorical imperative refers the concept of ethicality back to 'the idea of freedom' (1993b, BA 102–3, p. 84). Free will is nothing but 'autonomy, that is, the property of the will to be its own law' (1993b, BA 97–8, p. 81). Happiness is accidental and not at our disposal, but freedom is effective 'independent of external causes that determine it' (1993b, BA 97–8, p. 81, BA 99–100, pp. 82–3). A human being does not act morally because he or she hopes for happiness—'If *eudaemonia* (the principle of happiness) instead of *eleutheronomia* (the principle of freedom for inner legislation) is set as the foundation, the consequence will be euthanasia (the soft death) of all morality' (1997, AIX, p. 506)—but because he or she follows the principle of freedom of inner legislation. This entails that morality has been

robbed of the foundation on which it could ground itself, that is, the hope for the remuneration for moral action that would arrive at some point. And by implication the pursuit of happiness loses the justification that was derived from its link to morality. Simmel (1989, p. 253) called this the 'mutual independence of ethicality and happiness.' 'If our ethical action,' Simmel wrote, 'were only a detour on the path to happiness, then the point of our freedom would show itself again interwoven with the dependence on the powers of being, without whose favors no happiness could be complete.'

The expulsion of the concept of happiness from the reach of moral philosophy has its counterpart in the eviction of happiness out of the realm of the political. For Kant, freedom has taken the place of happiness as the goal of politics—a concept driven further by romanticism, although setting out from the non-*eudaimonistic* ways of reasoning in transcendental philosophy. Kant's categorical imperative and the ideal of autonomy inherent in it expel the concept of *eudaimonia* from the main lines of philosophical discussion.

4. *Redemption, Happiness, and Political Order*

The emerging social sciences have started out from this rupture and have largely accepted it. In his theory of religiosity and morality, Durkheim re-interprets happiness and recognizes it only in religious experience, in moments of 'collective effervescence,' of self-transcendence and loss of self. Happiness is seen as the experience of being-one-with-oneself or of being submerged in the world, as a 'feeling of strengthening' (Durkheim 1981, p. 291), as the subjective 'oceanic feeling,' which Freud (1994) considers without any comprehension. Simmel, too, considers spiritual salvation (*Seelenheil*) as a state in which complete harmony with the world has been achieved, a state that shows the full liveliness and inner touchability of the perceived, the immediate being (Simmel 1995). 'Happiness, as a relation of transcendence, thus has two fundamental forms. It exists as the experience of either *oneness* or *otherness*, as the dissolution of all difference, or as the apprehension of, and unconditional surrender to, absolute difference' (Ferguson 1992, pp. 11–12). Such experience turns into an articulation of social integration, which at the same time rests on individual feeling and, again, connects the individual with the other and with a 'holy' collectivity, the ideal community of justice.

Within the main line of critical theorizing, that is, in Theodor W. Adorno and Max Horkheimer, the subjectivization of happiness is further radicalized. The foundational character of the aporias that result from the dualism of individual and society is rejected. Instead, the joint attack of liberalism (*bourgeois* ideology) and capitalism is held responsible for the destruction of the link between freedom and happiness.

Happiness is privatized in 'administered society' and under the reign of 'culture industry,' and it becomes the expression of societally determined false consciousness. Due to the horror of the circumstances, individual happiness becomes nothing but the dreadful arrangement of a petty-bourgeois idyll with its swollen sentiment. The *bourgeois* promise of happiness arising from property and possession—already denounced by the romantic critique of the revolution as the abandoning of the shaping of the world according to the ideas of reason in favor of the demands for material happiness on the part of the bourgeoisie—becomes under conditions of inhumanity a curse. The promise of the commodity turns into pale appearance; in the totality of objectivizable socioeconomic relations, the connection between the individual, happiness, and society is interrupted and the promise of happiness only admitted as aesthetic experience (Adorno). But, within the same critical tradition, and by appropriating critically Freud's reflections on the pleasure principle and the reality principle, Herbert Marcuse (1955/1966) aims at developing a social theory that elaborates on a conception of possible happiness and permits the critique of both, the societal circumstances as well as the empirically existing conceptions of happiness. 'The concept (of happiness) denotes a more-than-private, more-than-subjective condition; happiness is not in the mere feeling of satisfaction but in the reality of freedom and satisfaction' (Marcuse 1955/1966, pp. 103–4). The concept of happiness has to be liberated from bourgeois conformism and relativism; even the singular human beings cannot be 'judge of their own happiness' under these circumstances. It is precisely the task of critical analysis to show the 'possibility of a happier real constitution of humanity' beyond the existing 'false happiness.'

In another line of critical thinking, Walter Benjamin turns political time, directed towards happiness, into the key element of his philosophy of history. 'The image of happiness … is tainted by time through and through … In other words, the imagination of happiness resonates inalienably with the one of redemption' (1991a, p. 693). Happiness is here not in the (past) event, but in its possibility, to which a 'weak messianic power' is given; it is recognizable only in its being missed historically (1991a, p. 694). 'The order of the profane has to erect itself with the support of the idea of happiness' (1991b, p. 203)—and in the *Angelus Novus*, Benjamin finds the image for history in which the past, that which is complete (misfortune and misery), and the future, that which has remained incomplete (happiness), get reverted and in which misfortune and misery turn into something incomplete hoping for redemption (1991c, pp. 588–9). Ernst Bloch, too, reinstates the old connection between the individual, passion and society; happiness becomes

again an inalienable part of human being. 'Because hope's grounding in the human drive for happiness is too difficult to be destroyed; and too evidently has it always been the engine of history' (1978, I, p. 515).

Happiness, thus, even though pushed into the private realm since Kant, persistently returns into the political realm—as 'redemption,' 'the principle of hope,' as 'emancipation,' 'undamaged life' and, in the version of existentialist philosophy, as 'authenticity.'

During the past few years, happiness has not only become the object of dubious empirical-quantitative research on levels of satisfaction, but also again a theme of social philosophy, partly by referring to classical liberalism, partly also by returning to ancient traditions. Under terms such as justice, the good life, and self-realization, the question about the societal conditions under which happiness can unfold is again raised. The attempt is, thus, renewed to locate happiness not only in an 'accomplished' relation of the individual to her- or himself, but also in relation to others and to a just societal order.

Hannah Arendt already held a view of political happiness, of 'public happiness,' that could not be equated with the obligation of the state to care for the welfare of its citizens (such a view of *bonheur*, in contrast, is, in her view, coresponsible for the loss of freedom in the course of the French Revolution). In the American Revolution, however, the connection between 'public happiness and political freedom,' which is an 'inalienable part of the structure of a republican community,' could be maintained at least for some period (Arendt 1994, p. 178). The new connection between happiness and freedom made here occurs in the sign of plurality and a public sphere as guardians against both dangers; that namely substantive conceptions of happiness could suffocate freedom or that abstract and atomized freedom empties out any conception of happiness at all.

Drawing on the classical contract theories by John Locke and Jean-Jacques Rousseau and situating himself—often in a rather decontextualized way—in relation to Immanuel Kant, John Rawls develops a 'theory of justice' (1971) for modern, pluralistic and democratically constituted societies. For Rawls's theory, the 'right' enjoys primacy over the 'good,' since value-pluralistic societies will be able to agree only over a minimum set of foundations for what is right, but not over what is good. Rawls, thus, renounces any attempt to formulate a substantive theory of the good life. The starting point of his considerations is the hypothetical construction (the 'intuitive thought') of a society as a fair system of cooperation between free and equal persons. Since these considerations provide the general political framework for the 'good life as justice and fairness,' a human being can for Rawls be called 'happy … during those periods when he is successfully carrying through a rational plan and he is with reason confident that his efforts will come to fruition' (Rawls 1971, p. 550). Rawls ties his theory of justice to a critique of utilitarianism. For him the well-being of people does not depend on the degree to which individual preferences are realized. It is important only that people are provided with the basic means to the same amount. As Martha Nussbaum, however, points out, Rawls did not consider what people do with these goods, to what they are enabled, and whether the space of enablements that thus opens up is not marked by striking inequalities.

Nussbaum (1990, 1993) herself resorts to Aristotle to sketch those political foundations that are to enable all people to lead a good life. She does not advocate any liberal relativism, but rather a universalism, based on an anthropological conception, that refers to needs and capacities which all people across all divides of culture, class, and sex have in common. Such basic needs constitute moral demands; they are an inalienable part of ethics and moral philosophy. At the same time, Nussbaum's perspective aims at pushing back the primacy of reason in moral philosophy, since moral principles had hitherto mostly been anchored in human reason. Her ethics of virtue attempts to counteract the insufficient regard for the particularity of situations in moral theories that are based on general principles. In addition, it aims at integrating emotional dimensions into ethics. To define the concept of virtue more precisely, and not merely to understand it by recourse to rules, a 'superior instance' needs to be found; for Nussbaum this is a theory of the good. Starting out from the 'basic structure of the human form of life' (mortality, corporeality, cognitive abilities, practical reason, sociality, etc.), she develops an 'open list' of the basic capacities of human beings and of the good. She herself characterizes the list as 'vague,' which means that it is open for concretization in each specific cultural context, and then puts specific demands towards politics. The objective of measures taken by the state is that they enable the citizens to choose a good form of leading their lives, to develop their capacities and to live in accordance with practical reason and with their social ties.

In his attempt at clarifying the relations between a moral life and a good life, Seel (1995) similarly defends a 'universalism of the good,' which is not linked to particular forms of society. This universalism, however, is no essentialism that claims the existence of values independent of human volition or raises anthropological facts to the status of values or norms. Seel develops a position that he calls 'reflexive *eudaimonism*' and asks what it entails, from the viewpoint of different people, 'to sensibly lead a succeeding life' (p. 10), defining a 'good life' formally on the basis of moral respect, social recognition and political legitimacy. The incarnation of good human life is a 'life, open to the world and self-determined, the moral and legal protection of which includes a respect for all individuals who are able to have a (however determined) good life' (p. 11).

'Happiness' and 'the good life' are, thus, always also tied to sociocultural circumstances. It remains the task of philosophy as well as of the social sciences to think the—political—conditions under which a good life and happiness stay open as a possibility. Happiness as the relation to oneself, to others, and to the community belongs then to reflection, to experience, and to the dream (Mauzi 1969).

Eugenics as an International Movement

The term eugenics, derived from the Greek *ευγενεσ* (eugenes) was first coined by English mathematician and geographer Francis Galton (1822–1911). In his book *Inquiries into Human Faculty and Its Development* eugenics refers to one born 'good' in stock, hereditarily endowed with noble qualities (Galton 1883, p. 24). Eugenics was the human counterpart of scientific animal and plant breeding.

In his book, Galton lays out all the dimensions that came to characterize eugenics as an ideology and social/political movement during the first half of the twentieth century. These were as follows. (a) Adherence to the methods of selective breeding as applied to the improvement of the human species. (b) A strong belief in the power of heredity in determining physical, physiological, and mental (including personality) traits. (c) An inherent ethnocentrism and racism that included belief in the inferiority of some races or groups and superiority of others (a view extended to ethnic groups and social classes as well). (d) Belief in the power of science, rationally employed, to solve social problems, including ones so seemingly intractable as pauperism, crime, violence, urban decay,

prostitution, alcoholism, and various forms of mental disease, including manic depression and 'feeblemindedness' (retardation).

It took some time after Galton first propounded idea of eugenics for eugenics organizations and activities to emerge around the world, but by the time of World War I (1914) eugenics had become a truly international movement. Thus, the standard historical view of eugenics as a largely British, American, and German phenomenon is inaccurate. Eugenics developed in a variety of national contexts with a wide range of ideological and political programs (Adams 1990, pp. 4–6 and 217–31). The earliest eugenics movements were founded in Germany in 1904, in Britain in 1907, and in the United States in 1908–1910. Other eugenics movements appeared around the world shortly thereafter: in Western Europe between 1910 and 1920: France, Spain, the Scandinavian countries, Finland, Russia, Latin America (Cuba, Brazil, Mexico), in Canada, Africa (particularly South Africa), and Asia (China and Japan). While eugenics clearly originated in its modern form, that is, viewed as a branch of genetics, in the west, its spread around the globe gave it an international flavor that retained some common core of scientific and political beliefs, while developing considerable local differences. Eugenicists themselves were consciously internationalists, arguing that like all science, eugenics knew no national boundaries. Despite this international profile, however, it was in western countries such as the United Sates and, of course, Germany under the Nazi regime (1933–1945), that eugenics as an intellectual and social movement reached its greatest strides and from eugenicists' point of view, enjoyed its greatest ideological and political success.

The international character of eugenics is reflected in the three major international congresses, at which eugenics enthusiasts gathered literally from around the world. The first was held in London in 1912, while the second and third were held in New York (the third congress was held at the American Museum of Natural History) just following the sixth International Congress of Genetics, in 1932). Papers and photographs of exhibits from the second and third congresses fill several impressive volumes.

Although eugenics is often thought of as a politically conservative movement, globally its supporters came from widely divergent political backgrounds. Some, like Charles B. Davenport, Harry H. Laughlin, and Madison Grant in the US, and Eugen Fischer in Germany, were reactionary, while others, such as Britain's J. B. S. Haldane, the United States's H. J. Muller, or Russia's Alexander Serebrovsby, were influential left-wing eugenicists who held socialist or even communist views (Paul 1984, p. 567). Left-wing eugenicists were not necessarily egalitarians, however, and few envisioned a society in which all people were truly 'equal.' Their model was a meritocracy based on inherited biological worth.

1. *Background: Degeneration Theories and the Rise of Eugenics (1890–1914)*

In both the west and east the late nineteenth century saw, for different reasons, a widespread belief that the human species was in various phases of deterioration and decline (Paul 1995). Much of this pervasive pessimism came from observations in the social and political arenas. British eugenicists were particularly concerned with the high fecundity and presumed inherited mental degeneracy of the urban working class, particularly those labeled as 'paupers' or (in Britain) the 'residuum.' By contrast, American eugenicists were more concerned with the number of feebleminded who appeared to be filling the prisons and insane asylums in the wake of urbanization and industrialization after 1865 (the US Civil War) and with the genetic deficiencies of the 'new immigrants' around the turn of the century. In Germany various racial and ethnic groups were thought to harbor an undue proportion of mentally ill, psychotic, psychopathic, and psychiatric members. In France and Brazil where ideas of the inheritance of acquired characteristics held more sway than in most other countries, public health measures, rather than reliance on selective breeding, were seen as the most effective means to combat degeneracy. In Asia, general theories of degeneration spread with the encroaching influence of western imperialism from the 1860s onward. The inability of the Asian populations to ward off imperial penetration or intra-Asian rivalries was seen as partly a result of scientific and technological backwardness and of physical and cultural weakness in the face of the western onslaught.

2. *Eugenics and Scientism*

Eugenics throughout the world was viewed as the application of rational, and 'modern' scientific principles to the solution of age-old social problems. Eugenicists and many of their supporters had a high regard for science and technology, symbols in the western countries of the triumph of enlightenment and rationality, and of modern capitalist control over and exploitation of, nature for human gain. The goal of science was to predict and control, an ideology extended to society at large. The period in which eugenics developed was globally one of great economic, social, and political instability: two major world wars, the dissolution of the great empires of Europe in the wake of rebellions abroad, rapid industrialization in the west, especially the growth of heavy industry, and urbanization, all of which contributed to the rise in such problems as alcoholism, prostitution, crime, mental illness, and social unrest. In the major western countries organized labor gained great strength, leading to increased and bloody conflicts in the period

1890–1940. Communism made major gains during the period, with the Bolshevik Revolution in Russia, the organization of Workers' Councils that took over several cities in Germany after the Armistice in 1918; and with the expansion of such groups in the United States as the International Workers of the World (the IWW, or 'Wobblies') who carried out a successful general strike in Seattle and the northwest in 1919.

Outside of Europe, similar, sometimes related, historical events led to similar responses. Latin America underwent convulsive economic and social change in the wake of the decline of Spanish and rise of North American colonialism. In Asia, the struggle in China and Japan toward 'modernization,' inter-imperial rivalries culminating in the Sino–Japanese War of 1894–95 and the Russo–Japanese war of 1905, all stemmed from growing expansionism related to trade, and control of raw materials and markets between east and west and within rising industrial powers, like Japan, in Asia itself. As in the west, science and technology in Asia were associated with modernism and economic advancement.

As a supposed new 'science,' eugenics meshed well with modernist ideology. Eugenics was based on what was thought to be the cutting edge research in a new science (genetics), was mathematical, experimental, rigorous, and predictive, and purported to apply the principles of science to the solution of previously intractable social problems. Worldwide, it provided an incentive for academically-trained practioners (geneticists) to join the new managerial class that was beginning to apply highly-trained expertise to everything from organizing factory production lines, offices, and schools, to 'scientific' agriculture and not least, human reproduction. Applied to society, eugenics became part of the ideology of 'social engineering' that was replacing the older notion of *laissez-faire* associated with social Darwinism. It was not enough to let nature take its course: scientifically-trained social engineers had to step in and direct that change along national lines. Eugenically, this change involved the guidance of human reproduction to ensure that only those with good heredity passed on their genes to future generations. Eugenics was viewed as the 'control of human evolution.' Eugenicists argued that to control heredity at the source was to be efficient—to prevent problems before they occurred, rather than let them happen and then deal with the consequences. In various forms—either as proposed breeding and sterilization programs, or maternal and other public health proposals, the efficiency argument dominated much of eugenic social rhetoric. In the United States this collage of views and ideas was swept up into a somewhat heterogeneous movement known as Progressivism. Progressives advocated the use of science to solve social problems, and embraced the efficiency movement of Frederick Winslow Taylor (1856–1915), which had been developed in the United States initially in an industrial context. Similar strains and arguments appeared in different forms in eugenics movements around the world.

Since other articles focus on details of various eugenics movements around the world (see *Eugenics in Europe*; *Eugenics as the Basis of Population Policy*; *Eugenics, History of*; *Eugenics in Asia*) this article will focus on the general nature and extent of international eugenics activities, comparing the similarities and differences among the various national movements.

3. *British and American Eugenics, 1880–1940*

British and American eugenics shared a number of intellectual and social concerns, as well as personal contacts. The major importer of eugenics to the United States, Charles B. Davenport (1866–1944), spent part of the year 1899–1900 with Galton and his protégé, Karl Pearson (1857–1935) at University College, London, learning statistics and biometrics and gaining initiation into Galton's 'secular religion of eugenics.' American eugenics thus grew directly out of the vision that Galton, and later Pearson, developed. At the same time, American eugenics developed its own particular twists, especially its early acceptance of particulate, discontinuous and Mendelian concepts of heredity, a relationship not shared by their British counterparts until the later 1920s.

Mendelism notwithstanding, American and British eugenicists shared the basic assumption that such traits as alcoholism, criminality, physical and mental 'defects,' and intelligence, were all biologically inherited, with the worse forms concentrated in the lower classes and among certain races. Horrified by the significantly higher birth-rate of the lower classes, eugenicists in the United States and Britain argued that the observed decline in productivity and 'national efficiency' was due to the increasing number of less-productive social defectives that were being born and were having to be cared for by the state. Eugenics was a scientific approach to improving social efficiency. In Britain, Pearson's largely theoretical orientation to eugenics led him to warn eugenicists to avoid politics. Partly as a result, British eugenicists had much less legislative success than their counterparts in the United States.

In several ways the American movement followed a different trajectory from the movement in Britain: (a) American eugenicists became strong advocates of psychometrics, the burgeoning new school of I.Q. testing, which took it for granted such tests measured an innate, unchanging mental function. While British eugenicists also assumed that mental ability was inherited, they did not employ the I.Q. (or other similar) tests to the same extent as in the United States; (b) Leaders of American eugenics were from the start anxious to play a role in the public arena—in what today would be called formation of public policy.

Eugenicists such as Harry H. Laughlin (1880–1943), Superintendent of the Eugenics Research Office at Cold Spring Harbor, NY translated eugenic principles into social action. Eugenicists lobbied for passage of the Johnson–Reed Act (Immigration Restriction Act) in the United Sates congress in 1924, while Laughlin designed a 'Model Sterilization Law' and eugenicists lobbied for the passage of eugenical sterilization laws in a number of states during the 1920s and 1930s. The first eugenical sterilization laws were passed in the United States (the first was Indiana, 1907) though by the mid-1930s such laws were in place in a number of western countries (Norway, Sweden, Finland, Germany, and Canada). Between 1907 and 1965, some 60,000 people in the United States—mostly in state institutions for the feeble-minded, psychiatric hospitals, and prisons—were sterilized. Like their British counterparts, American eugenicists were highly motivated by the ideas of national efficiency and rational planning (Vecoli 1960, Allen 1986, pp. 255–60).

4. *Eugenics on the Continent: Germany, Scandinavia, and France*

On the continent, eugenics in Germany and Scandinavia shared many features in common, while that in France took its own, unique direction. The German and Scandinavian movements were based strongly on what has been termed notions of 'hard heredity' (i.e., that most mental and moral attributes are rigidly determined by genes at conception), and employed basic concepts of Mendelian genetics. While the ideology of Nordic and Aryan superiority was present in both movements, it represented only one strand, and were not even the most prominent strand prior to the ascendancy of the National Socialists in Germany in 1933. Ideologues of the German movement, such as Fritz Lenz (1887–1976) and Eugen Fischer (1874–1967) were racial purists, but during the Weimar years kept a 'subdued' profile on overtly racial issues. Because racial purity was a cornerstone of the Nazi regime, however, eugenics after 1933 became openly racist and pro-Nordic.

A number of common ideological convictions characterized German eugenics from its pre-1900 days, right down through the 'final solution.' (a) The conviction that *laissez-faire* capitalism was at heart dysgenic because it allowed individuals to reproduce at will, with no concern for the future well-being of society. (b) The belief that Germany's population was degenerating, as evidenced by the debacle of World War I, increases in labor unrest, and social problems such as alcoholism, criminality, prostitution, mental illness, and retardation. (c) A strong belief in the value of a managed society based on scientific expertise. At the same time several features distinguish German eugenics from its counterparts elsewhere. (a) More German eugenicists were drawn from the medical profession than in either England or the United States (Proctor 1988). (b) During the Weimar Republic and later the Nazi regime, eugenics received far more government funding than in most other countries. German geneticists and eugenicists all held posts on important government advisory councils dealing with matters of eugenics and national health (Weindling 1985, pp. 308–9). (c) A major feature of German eugenics, of course, was the subsequent role it came to play in the National Socialist government and the Holocaust, between 1933 and 1945.

Some historians have argued, cogently, that eugenics became so prominent and virulent in Germany because of the humiliation of defeat in World War I and the exacerbating terms of the Treaty of Versailles. Among the factors leading to military defeat, eugenicists argued, was the nation's national degeneracy, the influences of racial impurity, declining birthrates among the intelligentsia, and economically prosperous, and the antieugenic policies associated with socialist egalitarianism (Mosse 1964, pp. 237–40, Meineke 1963, pp. 30–4). Worsening economic conditions due to reparations payments and loss of the mineral-rich Ruhr Valley, gave, among average Germans, added weight to arguments for improving national efficiency by eliminating what the Nazis termed 'useless eaters' or 'lives not worth living.' Eugenics became the scientific rationale for euthanasia and genocide.

All three Scandinavian countries, including Finland, had well-entrenched eugenics movements by the 1920s, those in Norway and Sweden being the largest and most politically successful. Scandinavian eugenics shows much of the character of the other western movements: an emphasis on efficiency, commitment to legislative action, and a strong pro-Aryan and Nordic stance (Broberg and Roll-Hansen 1996). In the period between 1910 and 1925, Scandinavian eugenics was characterized by a strong belief in the superiority of the Nordic races, and thus displayed a nationalist and racist undertone. These took the form of social legislation, particularly the passage of eugenical sterilization laws (Denmark's law was passed in 1919, Norway's in 1934, and Sweden's and Finland's in 1935). The rates of sterilization varied considerably: between 1935 and 1960s Sweden sterilized over 62,000 people—an astonishing figure for a country whose total population at the time was less than 7 million (Roll-Hanson 1996, p. 263). Eugenics achieved its greatest political success in Sweden, though the most vocal international voice from Scandinavia was Jon Alfred Mjøen (1860–1939), a pharmacist turned eugenic activist. Although shunned by many in his own country for his racist views, Mjøen was viewed as a major theoretician by eugenicists in Sweden and Denmark. Nonetheless, Scandinavian eugenics as a whole never adopted the virulent Nordic racism found among Nazi elements in Germany. As advanced

welfare states, the Scandinavian countries also couched their eugenics proposals in terms of 'national efficiency.' Hit hard by the same economic problems faced by other countries during the interwar period, and especially after 1929, the Scandinavian countries were seeking to reduce state expenditures wherever possible, and the supposedly hereditarily defective were a likely target.

5. *Eugenics in France*

The French, as other Europeans, harbored a growing concern about what was perceived as the degeneration of society, in France's case associated with a declining birth rate and loss of military hegemony on the continent after the Franco–Prussian war of 1870. French eugenics also embraced as strongly as elsewhere the idea of rational management by scientifically trained experts, especially in areas of social policy. Like other countries during the same period, France was beset with a variety of economic, social, and political problems that called for sweeping changes in both public attitudes and government policy (Thomson 1960, pp. 173–86). Before, but especially after, World War I, class struggle accelerated, in such publicly visible forms as large-scale strikes (Tilly et al. 1975, pp. 71–6). Like Germany, eugenics in France was strongly supported by members of the medical, including public health, professions. French eugenics differed from that in England, the United States, and Germany, however, in three very important ways. (a) The presence of a strong Enlightenment tradition of radical social theory and practice laid greater emphasis than elsewhere on environmental, as opposed to biological, determinants of human behavior. (b) Concomitant with their emphasis on the environment, though not directly deriving from it, French biologists maintained a strong commitment to neo-Lamarckian concepts of heredity, that is, the direct inheritance of environmentally induced variations. Consequently, eugenicists in France did not emphasize Mendelian genetics and other more strictly biological factors such as Darwinian natural selection. (c) The strong influence of the Catholic church, especially with regard to matters of reproduction, caused French eugenicists for the most part to avoid advocating measures such as contraception, sterilization, or abortion to deal with actual or potential defectives (especially after the Papal Bull, *Casti connubi* in 1930, which condemned eugenical sterilization). The effect of the church position was to widen an already-existing division within the eugenicists' ranks: between liberal and conservative and between pro- and antisterilization forces. Thus, French eugenicists never attained the unity necessary to lobby effectively for specific eugenic measures at the legislative levels.

6. *Eugenics in Russia*

The development of a distinct eugenics movement in Russia was apparent in the period just before the onset of the Bolshevik Revolution (1917). Russian eugenicists drew more of their inspiration and direction from the movements in the United States and Germany than elsewhere. Although eugenics, along with what might be called more strictly human genetics, was widely discussed in the Soviet Union, the eugenics movement there was confined almost wholly to the decade between 1920 and 1930 (Graham 1977, p. 1145). Increasingly viewed as racist and elitist in the political sphere, eugenics was disbanded even before the rise of neo-Lamarckism and the Lysenkoist movement in the 1930s and 1940s. Yet many enthusiastic and committed Bolsheviks saw no conflict between eugenical principles and socialism (Graham 1977, p. 1146). Indeed, many younger communists found eugenic ideals completely compatible with Marxism, providing a rational and materialist base to their visionary hopes for the scientific reconstruction of society.

Like the movements in England, the United States, and Germany, Russian eugenics at first was closely allied with Mendelian genetics. Although Russian eugenicists eventually moved away from negative toward more positive programs, as in Europe and the United States, they began with the deep forebodings of racial degeneration. As in other countries, in Russia after the revolution, eugenicists propounded a technocratic vision of social engineering by scientifically trained experts. It was only because of a strong Marxist opposition to technocracy that such a vision did not persist as long in Russian eugenics as it did elsewhere.

Like their counterparts elsewhere, soviet eugenicists hoped to apply both positive and negative eugenic measures to improvement of the human species. Based on a survey of the state sterilization laws in the United States, Russian eugenicists such as Nikolai Kol'stsov (1872–1940) argued for large-scale sterilizations of the unfit to improve the genetic character of the Russian people. Since birth control or sterilization were viewed as both morally questionable as well as dysgenic, negative eugenics, especially sterilization, never developed a wide following in the USSR.

A more viable option for pursuit of eugenic goals after 1917 was emphasis on the widespread belief in neo-Lamarckian inheritance. Like biologists and eugenicists in France, many Soviet geneticists and eugenicists adhered to some form of the inheritance of acquired characteristics. At the time, neo-Lamarckian views were accepted by many biologists around the world. Pioneer student of human genetics, Solom G. Levit (1894–c.1938), argued that neo-Lamarckism alone allowed for the rapid improvement in human health and social behavior that eugenics called for. If the gene was as fixed an entity as classical Mendelian genetics suggested, there was little chance of creating

the new soviet human being by eugenical means. Moreover, eugenicists were accused of propounding a hard-line concept of heredity to the total neglect of social and economic factors (Graham 1977, p. 1150). Eugenicists seemed to be reducing human beings to genetic machines whose consciousness was determined by their biology, not by their socioeconomic circumstances. As a result of these growing doubts, and the advent of the debate between Lysenkoists and Mendelians, by 1930 eugenics in the Soviet Union had been labeled reactionary and technocratic, and the major journal, *The Russian Journal of Eugenics*, was disbanded. More clearly than perhaps in other countries the fate of eugenics in Russia was uniquely tied to the turbulent period of history in which it rose and fell.

7. *Eugenics in Latin America*

The existence of significant eugenics movements in non-European and non-Anglo-Saxon contexts has been ignored by historians of science until quite recently (Stepan 1991). Eugenics movements in Latin America rose to prominence between the world wars and commanded considerable attention within the worldwide eugenics community. Interest in eugenics stimulated some of the first genetics courses in Latin American universities, and was often an important factor in child welfare, maternal health, infectious disease, and immigration legislation in the various countries (Stepan 1990, p. 110). Eugenics was also discussed vigorously at various Latin American scientific and public health conferences, as well as being the focus of two specific Pan-American conferences of its own (Cuba in 1927 and Argentina in 1934). A special eugenics society, the *Fédération International Latine des Sociétés d'Eugénique*, was founded in 1936 under the leadership of Corrado Gini, a well-known Italian eugenicist and president of the Italian society of Genetics and Eugenics. The *Fèdèration* held one international congress, in Paris in 1937. Moreover, leaders of eugenics movements in other countries expressed keen interest in the developments in Latin America. Not only Gini in Italy, but also Davenport and Laughlin in the United States, offered considerable encouragement to fledgling societies in Cuba and Mexico.

One of the most important differences between Latin American and western eugenics was the political economy of neocolonial 'underdevelopment' in which most Latin American countries existed in the first decades of the twentieth century. Although just beginning to experience industrialization and urbanization after World War I, Brazil, for example, was still largely an agricultural country with an impoverished rural population that was illiterate and dominated by the Catholic church. Much of the land was held as plantations by local family oligarchies and foreign investors who produced more for export than local consumption. The country was ruled by a tiny elite largely educated abroad. Biology, such as existed, was housed only in medical schools and agricultural stations. Historian Nancy Stepan has pointed to the highly mixed racial composition of most South American countries as a factor differentiating the Brazilian eugenics movement from that in Europe or the United States (Stepan 1990, p. 11).

Four specific factors helped to make eugenics attractive in the period after 1920 in countries such as Brazil (Stepan 1990, pp. 112–4). (a) A rising new nationalism and sense of independence gained from the war experience. The collapse of Germany, whose science and culture had been so much admired in Brazil and other Latin American countries before the war, generated a new sense of independence about what Latin Americans could accomplish on their own. (b) There was increased recognition of 'the social question,' that is, the appalling poverty and poor health of the working and peasant classes. After 1915 the combination of poverty, massive migrations, and immigration from abroad (particularly Italy) produced a radicalization of politics. A large-scale strike in 1917 was met with brutal repression by the government and industry leaders. Under these circumstances, eugenics began to play the same role as it had in the United States and Britain: a means of breeding out the biological defectives who were claimed to be the cause of such disruptions. (c) Growing enthusiasm for science, and particularly biological science, as a means of economic and social progress, especially in the area of public health, had been imported into Latin America from Europe and the United States. As in both France and Germany, eugenics in Latin America was easily incorporated by an expanding medical profession eager to assert its own power and expertise in generating new or reformed public health policy. (d) Finally, the widespread racial intermixing (between Indian, African, and European) that characterized most Latin American countries raised the specter of race suicide and impending degeneracy.

After starting from a more anthropological and public health perspective, by the mid-1920s a new generation of eugenicists had begun to apply Mendelian genetics to formulate Latin American eugenics policies. Greatly stimulated by the visit of American geneticist Theodosius Dobzhansky (1900–1975) to Brazil in 1943, eugenicists in Latin America, unlike their US or German counterparts, used genetics to argue that miscegenation, like crossing different strains of animals and plants, could produce superior, not inferior or 'mongrel,' lines. With such divisions in their ranks, however, eugenicists in Latin America could not speak with one voice. Yet, despite strong antiracist views advocated by Mendelian eugenicists, racism, and marginalization of the continent's black

and Indian populations continued with full force in the face of largely foreign-dominated economic, political, and social expansion.

The Latin American experience illustrates the quite different path that eugenics could take in an environment far removed from the centers of scientific advancement, one in which scientific ideas were derived largely from outside. The strong orientation of most Latin American eugenics to personal and public hygiene, as well as to nutrition and medical care, clearly reflects the existence of widespread poverty, malnutrition, and disease (hookworm, malaria, yellow fever) among the vast and largely rural populations. With economic and health problems of such magnitude, issues of race and race-mixture were less central among Latin American eugenicists than among their counterparts in the industrialized world.

8. *Eugenics in Asia*

Scholars studying the history of modern Asian science have pointed out that eugenics had a role to play in many of those societies. Moreover, it was not merely western eugenics imported and imposed on Asian society *carte blanche*. In both China and Japan, eugenics fitted well with movements for the increased promotion of science and technology associated with the 'modernization.' Mendelian genetics was introduced to both China and Japan in the early decades of the twentieth century through Western scientists who traveled to Asia, as well as by Asian scientists who came to work in laboratories in the West. Unlike their Western counterparts, eugenicists in both China and Japan relied less on a formal, organized set of genetic theories, promoting eugenics primarily as a 'modern' way of dealing with traditional problems.

For Chinese 'progressives,' eugenics became a way of grounding the calls for social and economic reform in science, and thus in the principle of rational, social control. Eugenics promoted a naturalistic view of society, based on human biology. Chinese adopted the 'soft' approach to heredity, one in which biological inheritance could be significantly molded by environmental factors. Not exactly relying on Lamarckian notions of inheritance of acquired characteristics, during the 1920s and 1930s, Chinese eugenicists emphasized the importance of education, public health, and other social measures, along with reproductive control. There was relatively little in the way of statistical or genetic research carried out by eugenicists in Republican China. As elsewhere, eugenics in China was particularly supported by the rising professional middle classes.

In Japan, during the early decades of the twentieth century, eugenics was linked closely with movements for birth control, sex education, and public health. In this context, conditions such as venereal disease, tuberculosis, alcoholism, and leprosy were all considered inherited and eugenicists argued they should fall under the same regulations as those governing public health matters. Here too, as in the West, eugenics was seen as a scientific means of combating social and moral degeneracy. Japanese eugenicists were successful in 1935 in getting the Imperial Diet to pass a Racial Eugenics Protection bill which favored the sterilization of hereditarily mental defectives. A sterilization law based on the German 1933 law (in turn based on model laws in the United States) was drafted in 1936, but a fully comprehensive eugenics law was not adopted until 1940.

Ironically, although eugenics was on the wane in the West after World War II, it became more prominent in China and Japan during that same period. Various laws and regulations in China focused on limiting family size, culminating in the 1978 'One Child' law that has raised considerable controversy both inside and outside of China. In Japan, a full-scale Eugenical Protection Law was passed in 1948, allowing for involuntary sterilization (by 1996 over 16,000 such operations had been carried out).

9. *Conclusion*

Although the term eugenics was used worldwide, eugenic movements in various countries were shaped by local economic, social, political, and cultural factors, and thus differed from one another in substantial ways. It has become clear that, as a movement, eugenics was not monolithic. Although tied to rigidly hereditarian Mendelian genetics in the United States, Scandinavia, and somewhat later in England and Germany, eugenics was more aligned with neo-Lamarckian views of inheritance in France, Latin America, and the Soviet Union. In their orientation toward various social issues and proposed solutions, eugenicists also varied considerably from country to country. In some, such as the United States and Germany, concern with racial issues played a prominent role especially in Germany after the Nazi takeover in 1933. In the United States and Germany, concern with the ill-effects of race-crossing was widespread while in countries such as Brazil, race mixture was considered by some eugenicists to be a source of biological improvement. For British eugenicists, the supposed degeneration apparent among the lower classes was the counterpart of the supposed inferiority of racial and ethnic groups in the United States. In all three cases, it was the economically dispossessed who formed the focal point of eugenicists' fears, and the targets of their programs.

Eugenics movements also differed widely in the social policies that were brought forward. In those countries such as France, Brazil, and to some extent the Soviet Union, where a more neo-Lamarckian view

prevailed and where the medical profession was more actively involved in eugenics, proposals tended to focus on environmental reforms, particularly with regard to public health. In those countries such as the United States and Britain, and especially Germany after 1933, where more strictly Mendelian views were predominant, segregation and/or sterilization of supposed 'defectives,' as well as immigration restriction, were more commonly proposed solutions.

It should be pointed out that the scientific basis for eugenical claims—that complex behavioral, personality, and mental traits are inherited in a 'hard-wired' fashion, and particularly that they follow Mendelian patterns of inheritance—has never found strong empirical support. Most eugenicists had a simplistic understanding of Mendelian genetics, and persistently ignored environmental inputs into determining social traits. Various geneticists in the West, such as Thomas Hunt Morgan (1866–1945) or Herbert Spencer Jennings (1868–1947) strongly criticized the genetic claims on which eugenics was based, but their public critiques came late in the movement and appear to have done little to stop it.

Underlying all the differences, eugenics movements worldwide shared a concern for efficiency, the ideology of scientific management, the role of middle-class experts in establishing social and political policy, and a strong faith in science. Underlying all of this, however, in almost all eugenics movements, was a powerful undercurrent of apprehension about the supposed degenerating biological quality of the human species. Eugenics programs, from California to the Baltic Sea, were aimed at increasing the biological worth of the human species by applying the latest biological and medical knowledge. That such knowledge was often incomplete or flawed ultimately brought the eugenic tree to bear a bitter fruit.

Eugenics as the Basis of Population Policy

Population policy refers to control of human reproduction by legislation or other official means for a given population of people (state, nation, social class, etc.). It involves setting goals for such population

parameters as total size, maintenance of stability, and rates of growth. Population policy includes programs such as the privately funded contraception program introduced into India in the 1950s by the Rockefeller Foundation, and publicly-funded programs such as those promoted throughout the Third World by the United States Agency for International Development and by China's official policy limiting families to two children. Although we are accustomed to thinking of population policies being aimed at reducing birth rate, policies such as the Catholic Church's opposition to contraception that increase birth rate, also represents a form of population policy.

Population policy should be distinguished from what is known as family planning or birth control. The latter refers to decisions within a given family regarding when to start having children, how many children to have, their spacing apart, etc. Organizationally, in the West family planning is represented by groups such as Planned Parenthood, but occurs through a variety of individual channels in most cultures. Population policy and family planning have areas of overlap in that population policy can only be effected at the level of the individual reproductive process. Both population policy and family planning/birth control include efforts to increase as well as decrease birth rate.

In Western Europe and the United States in the twentieth century population policy has often been associated with eugenics. The term 'Eugenics,' derived from the Greek *εὐγενής*, or *eugenes*, and was first coined by English statistician Francis Galton (1822–1911) in his book *Inquiries into Human Faculty and Its Development* to refer to one born 'good in stock, hereditarily endowed with noble qualities' (Galton 1883). As an intellectual and social movement in the early twentieth century, eugenics came to mean, in the words of one of its strongest American supporters Charles B. Davenport (1866–1944), 'the science of human improvement by better breeding' (Davenport 1910). For both Galton and Davenport, better breeding implied improving the hereditary quality of the human species by the scientific principles of heredity. Eugenics was the human counterpart of scientific animal and plant husbandry. It seemed ironic to eugenicists that human beings paid such careful attention to the pedigrees of their farm and domestic stock, while ignoring the pedigrees of their children.

Eugenicists wanted to develop population policies that dealt not only with quantity but also the quality of children being born. In this sense they sought to increase the reproductive rate of that segment of the population deemed to be biologically (meaning genetically) well-endowed (positive eugenics), and limit or prevent the reproduction of that segment of the population deemed to be biologically inferior or degenerate (negative eugenics). Eugenicists were concerned about what they saw as the increased reproductive rate of inferior (meaning working class and lower socioeconomic) classes, compared to superior people (meaning the middle and upper classes). While they were concerned with the inheritance of physical abnormalities such as hemophilia, color-blindness, brachydactyly (shortened digits), and debilitating diseases such as Huntington's chorea (all recognized to be genetic prior to 1910), eugenicists were ultimately more interested in human behavioral and personality traits—including mental ability, mental illness, 'moral degeneracy,' and criminality, to list only a few—all of which they claimed were genetically determined to a significant degree. Eugenics represented one of the earliest theories in the twentieth century to be based on biological, or genetic determinism (the idea that genes determine more of what a person is like, both in personality as well as in physical traits, than environment; eugenics took the side of 'nature' in the long-standing nature-nurture debate).

Although the term 'eugenics' and the idea behind it were Galton's, he himself did not found a movement either to develop eugenics as a 'science' or to put its principles into practice. Eugenics movements did not begin to arise in various countries of Europe or the United States until the first decade of the twentieth century, nor did they become generally effective in promoting social and political programs nationally or internationally until after 1910. The earliest eugenics movements were founded in Germany in 1904, in Britain in 1907, and in the United States in 1908–10. Other eugenics movements appeared subsequently around the world: in Western Europe (France, Norway, Spain), Russia, Latin America (Cuba, Brazil, Mexico), in Canada, and Asia (Japan). However, it was in the United States, Britain, and Germany where eugenics as an intellectual and social movement reached its greatest strides and from eugenicists' point of view, greatest ideological and political results.

One of the acknowledged leaders of eugenics on an international level was American Charles B. Davenport. Although somewhat eccentric, Davenport was a highly respected biologist, with a Ph.D. from Harvard (1891), where he subsequently served on the faculty for a decade (1891–1900). Between 1900 and 1904 he taught at the University of Chicago before obtaining funds from the Carnegie Institution of Washington to establish his own research laboratory, the Station for the Experimental Study of Evolution (SESE) at Cold Spring Harbor, Long Island (New York). In 1909 Davenport convinced the Harriman family of New York to establish a second institution, the Eugenics Record Office (ERO), also at Cold Spring Harbor to serve as a center for eugenical research, a clearing-house for exchange of eugenic information, a repository for eugenic data, and an organizational center for eugenic education and propaganda. Heading the ERO was Davenport's chief administrative aide, Harry Hamilton Laughlin, formerly a teacher of agricultural sciences at the Kirksville Normal School in Missouri.

In its claim to be scientific, eugenics drew heavily on the newly discovered work of Gregor Mendel, the Moravian monk who, in 1866, had published a paper on breeding patterns in peas. Although ignored for the next 35 years, in 1900 Mendel's paper was recognized for its path breaking approach to the problems of heredity by three investigators, more or less independently. By the time of World War I the Mendelian principles of heredity were being applied with great success to many varieties of animals and plants, including humans. It was in this atmosphere that eugenics flourished. It was hailed as a scientific solution to recurrent social problems. If alcoholism, criminality, pauperism, and feeblemindedness were all determined by genes, then the way to eliminate these problems would be to prevent the reproduction of those individuals thought to carry those genes. As eugenic ideas spread, other centers of eugenics activity arose in the United States, England, and in Europe: the Eugenics Research Association (ERA) and the American Eugenic Society (AES), both in the US, the Eugenics Education Society (England), and the Gesellschaft für Rassenhygiene (Society for Racial Hygiene) in Germany, among many others.

1. *Eugenic Research: Its Aims and Problems*

Since eugenicists could not carry out planned matings in the manner of laboratory geneticists, the family pedigree chart was the main analytical means for displaying and analyzing data on the heredity of one or another trait. Information was collected from among a group of relatives, and it was displayed as a family pedigree chart, emphasizing that traits ran in families and thus how heredity influenced many behavioral, personality, and mental traits (see Table 1). Although Davenport was acknowledged in many ways as the intellectual and scientific leader of American eugenics, his research was often naive, careless, and overstated. Even Galton and his protégé Karl Pearson, felt that despite Davenport's enthusiasm, he was 'not a clear, strong thinker' (Kevles 1985). His claim that complex mental and behavioral traits were almost exclusively controlled by one or two Mendelian genes, ignored the complexity of human mental development and claimed that thalassophilia, or 'love of the sea,' was a sex-linked Mendelian recessive appearing in the families of prominent US naval officers (Davenport 1919). That the condition must be sex-linked was clear to Davenport, since in pedigree after pedigree only males in the various families he studied became naval officers. When one of his friends, a professional psychiatrist, criticized him for lumping complex human behaviors into single categories such as 'insanity,' Davenport dismissed the criticism as uninformed (Kevles 1985). Such simplistic Mendelian arguments were then extended from individuals to large groups as a way of explaining the differences between racial, ethnic, and national groups.

Table 1
Some *lists of proposed human races* (compiled from Coon 1962, Cohen 1991, and Molnar 1997)

Author	N of races	Races proposed
Linnaeus (1735)	6	europaeus, asiaticus, afer, americanus, ferus, monstruosus
Buffon (1749)	6	laplander, tartar, south asiatic, european, ethiopian, american
Blumenbach (1795)	5	caucasian, mongolian, ethiopian, american, malay
Cuvier (1828)	3	caucasoid, negroid, mongoloid
Deniker (1900)	29	
Weinert (1935)	17	
Von Eickstedt (1937)	38	
Biasutti (1959)	53	
Coon (1962)	5	congoid, capoid, caucasoid, mongoloid, australoid

Because of their concern with the apparent rise in 'feeblemindedness' eugenicists embraced the nascent psychometric movement (intelligence testing) starting as early as 1912. In that year Henry H. Goddard administered a version of the French Binet-Simon test to immigrants at Ellis Island. Although the Binet-Simon test was intended to measure only an individual's mental functioning at a given point in time, Goddard and a host of psychometricians in the United States, England, and Germany considered that it also measured innate, or genetically determined intelligence. Goddard coined the term 'feeblemindedness' (which he claimed was genetic) to refer to those people who scored below a given level (70) on his tests, and claimed that it 'was a condition of the mind or brain which is transmitted as regularly and surely as color of hair or eyes' (Kevles 1985). It was Goddard who carried out the famous study of the Kallikak family, showing what was presumed to be the hereditary effects of feeblemindedness and degeneracy (Goddard 1912). Most of the early psychometricians such as Lewis Terman and Robert Yerkes were members of the American Eugenics Society, while both Yerkes and Terman sat on the Society's Committee on Psychometrics. For eugenicists, the new mental tests were seen as a precise, quantitative tool for measuring an otherwise elusive, but fundamental human trait. Like their British professional, middle-class counterparts, psychometricians felt that the scientifically-trained expert could at last solve with rational and scientific methods the social problems that muddle headed politicians and social workers had been unable to solve during the preceding century.

A major problem with eugenic research was that it quickly fell behind the work being done by geneticists in laboratories throughout the world. By the 1920s many geneticists had come to recognize that genes (collectively, known as the organism's genotype) interact with one another (a phenomenon known as epistasis) and with the environment to produce any given trait (the organism's phenotype). The interaction of genes with one another and environmental factors (for example, temperature, drugs, diet) was found to

alter the gene's expression in profound ways, yielding a variety of alternative phenotypes from the same genotype. Even the position of a gene along the length of its chromosome turned out to affect the way that gene is expressed. This malleability, or plasticity, of the genotype-phenotype relationship meant that even knowing the genotype of the offspring at conception did not provide a certain means of predicting the phenotype. Eugenicists' understanding of Mendelian heredity seems to have become frozen in time somewhere around 1910–5. While they coat-tailed on much of the exciting new work in genetics in the 1920s and 1930s, it is apparent that many eugenicists did not really understand it fully, or take to heart its implications for their social programs.

2. *Eugenics and Legislation of Reproductive Policy*

In the United States Harry H. Laughlin was particularly active in lobbying for the passage of a number of state eugenical sterilization laws in the 1920s and 1930s (Chase 1977, Kühl 1993). Indeed, Laughlin drew up a 'Model Sterilization Law' that served as a prototype from which each state could derive its own modified version (Laughlin 1920). Although the earliest such laws had been passed before World War I, the majority was established during the interwar period (Reilly 1992). Eugenical sterilization was aimed specifically at those individuals in mental or penal institutions who, from family pedigree analysis, were considered likely to give birth to 'socially defective' offspring. Sterilization could be ordered only after a patient had been examined by a eugenics committee, usually composed of a lawyer or family member representing the individual, a judge, and a doctor or other eugenic 'expert' (Reilly 1992).

Between 1907 (when the first such law was put into effect in Indiana) and 1941, over 38,000 eugenical sterilizations were performed in the United States, with California leading all other states (Reilly 1992). By the early 1960s, the number had risen to some 60,000 (Robitscher 1973). The most famous of the sterilization cases in the US was that of Carrie Buck in Virginia. When Virginia passed its eugenical sterilization law in 1924, a test case was arranged the next year to determine if the law was constitutional. Buck *vs* Bell was tried in 1925 in the Virginia Circuit Court (Lombardo 1985). When the lower court ruled in favor of the law, an appeal was sent to the Supreme Court of the United States, where Justice Oliver Wendell Holmes wrote the majority report. In upholding the lower court ruling, Holmes made his oft-repeated assertion: 'Three generations of imbeciles are enough.' More to the legal point, Holmes claimed that: 'The principle that sustains compulsory vaccination is broad enough to cover cutting the Fallopian tubes' (Reilly 1992). Laughlin's model sterilization law also served as the basis for a similar law in Germany passed by the National Socialist government in 1933 (Chase 1977). For this effort, as well as for his enthusiastic support of Nazi eugenic programs, Laughlin was awarded an honorary doctorate from Heidelberg University on the occasion of its 550th anniversary celebration in 1936: three years after the Nazis had come to power and two years after their sweeping sterilization act had gone into effect (Allen 1987).

3. *Criticism of Eugenics, 1925–50*

Almost from the beginning many of the basic premises of eugenics were brought under critical scrutiny by biologists, medical doctors, social workers, and lay persons from all walks of life. Among the first and most important critics from the biological side was Thomas Hunt Morgan, the *Drosophila* geneticist at Columbia University and, in 1933 the first recipient of the Nobel Prize for work done in genetics, and one of the earliest members of the Committee on Animal Breeding of the American Breeders' Association (a Committee that had taken on itself organizing the first eugenic activities in the US). In a personal letter sent to his close friend Davenport in 1915, Morgan resigned from the Committee, explaining that the claims being made on behalf of eugenics were exaggerated beyond what any scientific evidence could support (Allen 1978). Although Morgan did not criticize eugenical work in print at the time, from 1925 on, starting with his book *Evolution and Genetics* (Morgan 1925) he publicly chastised eugenicists for lumping many mental/behavioral conditions together under a rubric like 'feeblemindedness' and treating it as if it had a single underlying cause. Especially critical, he noted, was the fact that personality and social traits were the most malleable of our characteristics, and hence the most difficult in which to tease apart the relative contributions of heredity and environment:

> The important point … is that mental traits in man are those that are most often the product of the environment which obscures to a large extent their inheritance, or at least makes very difficult their study (Morgan 1925).

The pedigree charts on which Mendelian analyses were based, were also strongly criticized by Morgan and others as giving the impression of tracing genetically determined transmission when, of course, they equally well could be interpreted as showing culturally-determined effects:

> The pedigrees that have been published showing a long history of social misconduct, crime alcoholism, debauchery and venereal disease are open to the same criticism from a genetic point of view; for it is obvious that these groups of individuals have lived under demoralizing social conditions

> that might swamp a family of average persons. It is not surprising that, once begun from whatever cause, the effects may be to a large extent communicated [socially] rather than inherited [genetically] (Morgan 1925).

Pedigree charts do not separate 'nature' from 'nurture.'

Other geneticists followed suit. Raymond Pearl, a geneticist and supporter of general eugenical principles at Johns Hopkins University, also voiced public criticism of eugenicists claims, especially those regarding the supposed biological inferiority of various racial and ethnic groups (Pearl 1927). Along with his colleague Herbert Spencer Jennings, Pearl felt that propagandists like Laughlin, Madison Grant, and others made claims that went far beyond any reasonable evidence (Barkan 1992). Jennings devoted the better part of the ensuing decade (after 1924) to lecturing all over the United States about the dangers of oversimplified and racially based eugenical claims. H. J. Muller, a student of Morgan's, and later himself to become a Nobel laureate in genetics, delivered a searing attack on 'old style' eugenics at the Third International Eugenics Congress in New York City in 1932 (Muller 1932). Muller, who still harbored strong eugenical beliefs, argued that until the economic and social environment could be equalized it would be impossible to know how much of any individual's 'social inadequacy' was due to heredity and how much to environment (see also Ward 1935, and for a review, Paul 1984). Much of feeblemindedness might be due to poor maternal diet during pregnancy or during the early years of childhood, or to maternal drug and alcohol use; although these effects might appear at a superficial glance to be genetic, they had nothing to do with defective germ plasm. The same point was made also by influential Danish plant breeder Wilhelm Johannsen, who wrote:

> There is no reason to assume that the weak and sickly would represent the genetically inferior stock: they could be individuals of the same [hereditary] value as children from higher social classes who are better cared for (Hansen, in Broberg and Roll-Hansen 1995).

English mathematician/geneticist and sometime eugenics critic Lancelot Hogben made one of the clearest statements at the time about the over-simplified concept of genetics that informed much of the eugenics movement:

> No statement about a genetic difference has any scientific meaning unless it includes or implies a *specification of the environment* in which it manifests itself in a particular manner (Ward 1935).

In 1934, a special blue-ribbon committee of the British government published the Brock Report (named for its chairman, Laurence B. Brock, head of the Joint Committee on Mental Deficiency), outlining difficulties in determining the relative contribution of genetics to mental deficiency. Among others, the Committee included Ronald A. Fisher, himself a staunch eugenicist but also one of the world's foremost statisticians and population geneticists. The Brock Report agreed with the criticisms of eugenics put forward a few years earlier by Lionel Penrose, who had demonstrated that the category of 'feeblemindedness' was ill-defined; was used carelessly and indiscriminately to cover a host of mental problems; was caused in many cases by disease and social deprivation; and for the most part little was known of the genetic cause of mental disability (Kevles 1985). As the Brock Report stated:

> the more closely individual records are examined the more difficult it becomes to fix on one cause to the exclusion of others, or to say with certainty that the genetic endowment of any individual is such that it must produce a given result (Kevles 1985).

An even more comprehensive and devastating critique of the whole range of eugenic claims was published by the American Neurological Association in the mid-1930s, just a few years after the appearance of the Brock Report (Myerson et al. 1936). Work for the book was funded by the Carnegie Foundation through the New York Academy of Sciences. Like the Brock Report the findings of the Myerson Committee found that by the mid-1930s abundant evidence was available throwing into doubt such well-accepted eugenical beliefs as: (a) the vast number of mental and moral/personality traits are genetically determined; (b) environment (upbringing) plays a relatively minor role in the development of mental and personality traits; and (c) sterilization is the most effective means of reducing the frequency of socially inadequate behavior in future generations.

The Myerson Committee supported many of the general conclusions of the Brock Report. Citing the work of Morgan, Jennings, and others in the US, and that of J. B. S. Haldane in England the authors argued that we do not know 'enough about the mental diseases and the effects of the social structure to manipulate in a successful way the procreation of the race' (Myerson et al. 1936). The level of genetic knowledge was too slight to formulate any social policies or carry out any specific manipulations guaranteed to alter the genetic basis of future generations.

More specifically, Myerson et al. found that eugenicists consistently downplayed the role of the environment in the development of mental and behavioral problems, even when it seemed obvious that social and economic conditions must be playing a highly significant role. H. S. Jennings at Johns Hopkins University made the same point, emphasizing that 'environment' included the internal, cellular, as well as external environment in affecting how genes were expressed. Even if a person is clearly shown to have a genetic defect, as in hereditary thyroid deficiencies, Jennings argued, the condition can be treated

with dietary and/or drug supplements, which can restore normal function. A whole host of human anatomical and physiological conditions that were clearly genetic did not need to be debilitating or limiting to the individual, according to Jennings, because in many cases we possess the technological means to restore, or at least compensate for, the genetic defect. Genetics, according to Jennings, was not destiny (Jennings 1927). For eugenicists, however, it was, and this remained one of the underlying assumptions of hereditarian thinking from the past to the present.

On the eve of World War II (literally one week before), another strong criticism of eugenical thinking emerged as the 'Geneticists' Manifesto,' a document signed in early August, 1939, by a group of geneticists assembled in Edinburgh at the VIIth International Congress of Genetics. Among the major initiators were J. B. S. Haldane and Lancelot Hogben (England), and Hermann Joseph Muller (United States). The Manifesto put forth Muller's argument that from a genetics point of view as long as vast disparities in wealth and access to resources continued to exist in Western societies, no claims could be made about the relative contribution of heredity over environment to human mental capacity and social behavior (Chase 1977). They condemned racialist thinking, especially the attempt to rank races with respect to one another on the basis of genetic worth. The geneticists who initiated and signed the Manifesto were among the most well-known and respected workers in the field during the twentieth century.

In the period after World War II overt criticisms of eugenics and eugenical thinking became more widespread. Revelation of Nazi atrocities committed in the name of eugenics played an important role in this change of attitude. In addition, hard-line eugenicists such as Davenport, Laughlin, Grant, and others on the American scene were retired or deceased by the end of the war, and were replaced by what historian Daniel J. Kevles has dubbed moderate, or 'reform eugenicists.' Although it might be questioned how really 'reformed' these eugenicists were, it is clear they were more knowledgeable about the nuances of what traits genes might and might not control, less overtly racist, and more modest in their claims for what eugenics might accomplish. Partly because of the criticism, it was difficult for the field of human genetics to get a fresh start after the war, and many geneticists shied away from dealing with human heredity (Kevles 1985, pp. 193ff., Ludmerer 1972). Textbooks and other writings on human genetics were careful to distinguish themselves from old style eugenic thinking (Ludmerer 1972). Laurence H. Snyder's *Human Genetics* (1951), for example, stated clearly: 'We should hesitate at accepting without careful analysis the claims and recommendations that are present in a large portion of the eugenics literature.' An understanding of the historical development of the eugenics movement, Snyder went on to say, would suggest 'why professionally trained geneticists, on the whole, have given relatively little support to eugenic theories and programs' (Ludmerer 1972). Anthropologist and prolific popular writer Ashley Montague echoed the same feeling in his 1959 *Human Heredity* when he wrote that much unfortunate public policy—by which he meant immigration restriction and state sterilization laws—had been based on 'the ill-considered, prejudiced, and unscientific judgments of the late Harry Laughlin … Madison Grant … and Charles Benedict Davenport' (Montague 1959, pp. 25–6). And, in 1960, the American Medical Association came out with a report, *A Reappraisal of Eugenic Sterilization Laws*, that called into question virtually all the assumptions of the old eugenic movement.

Despite these severe criticisms, eugenics continued to thrive in the Scandinavian countries and especially in Nazi Germany (Proctor 1988). After passage of the sterilization laws in 1934, the Nazi government enacted the first of the infamous Nüremberg Laws in 1935, dismissing Jewish and half-Jewish citizens from state jobs (including all university positions) and prohibiting marriage between Aryans and Jews and other 'non-Nordic' groups. Doctors were required to report to the Reich Health Department cases of what they deemed to be hereditary diseases among their patients. After the large-scale deportation to concentration camps, many doctors became involved in a variety of genetic and other studies, including painful and deadly experiments, on twins. All in all, the Nazis carried eugenic principles further than in any other country of Western Europe or North America.

4. *Later Development of the American Eugenics Movement*

The period of greatest growth and political influence of eugenics ideology in the United States occurred between 1920 and 1935. By the mid-1930s American eugenics began to experience a decline in general popularity and in political effectiveness (Haller 1963, Ludmerer 1972, Paul 1995). Scholars have disagreed on the extent to which the movement went into 'decline' in the United States, or the reasons for its change of fortune. Clearly, both the depression of 1929–33 and reports of Nazi eugenics in the American press played some part in a general disaffection with eugenical principles. In the depression people without jobs became 'paupers' and 'social inadequates' overnight with no change in their genetic make-up, while in Germany the wholesale sterilization of those deemed biologically inferior demonstrated the logical conclusion to which eugenic principles could lead.

An additional factor may have been the recognition that American eugenicists were out of touch with the most recent findings of laboratory genetics. Davenport and Laughlin's simple unit-character concept did not

square with recent experimental data suggesting that most traits were produced by the interaction of many genes, and that the evidence for a genetic basis of complex human social behaviors was almost non-existent. Nonetheless, it is the opinion of historian of science Diane Paul, among others, that neither the scientific criticisms nor the pre-war use of eugenics by the Nazi government had much influence on the movement's decline. More specifically, G. E. Allen argues that a major cause for the decline of eugenics was that the movement had served the purposes of the economic elites (Rockefellers, Harrimans, Kelloggs, Carnegies) whose philanthropies had supported it. That function was to try and bring science to bear on the solution of social problems in a period rocked by violent labor-capital confrontations, and by the rise of a variety of social problems engendered by rapid industrialization and urbanization (Allen 1986). Whatever the exact causes, what has been labeled 'mainline' or 'old-style' eugenics was losing favor in the US and England especially, by the late 1930s; symbolically, the Carnegie Institution of Washington withdrew funding for the Eugenics Record Office by late 1939, and it closed on December 31 of that year (Allen 1986). Secretary of the American Eugenics Society, Frederick Osborn, retired railway executive and nephew of American Museum of Natural History President, Henry Fairfield Osborn (a wealthy-elite New York family who supported eugenics in a variety of ways), has been described as a 'moderate' among eugenicists, perhaps a misleading term but nonetheless signaling the different twist that he gave to eugenics in the postwar period (Mehler 1988). That approach did not involve a rejection of eugenic ideology or goals, but a toning down of the overtly racist claims and simplistic genetic analyses put forward by Davenport, Laughlin, Grant, and others of their generation. The face of eugenics had begun to change, even if the principles at its core remained largely the same.

5. *Eugenics and Population Control*

As early as 1926 Raymond Pearl of Johns Hopkins University claimed that eugenicists had focused too much attention on the quality of offspring from particular (usually 'degenerate') families, and had lost sight of the equally important issue of the rapid birth rate of the biologically 'degenerate' at home and abroad. In a series of scientific and popular articles he began to articulate the ideology of population control. While critical of much of the current eugenical propaganda, Pearl did not disavow basic eugenical principles. He simply emphasized the importance of quantitative as well as qualitative considerations.

In the aftermath of World War II the United States emerged as a contender for global power, inheriting the mantle of international economic and political involvement that had previously been carried by the British and, to a lesser extent, the French. In 1952 President Dwight D. Eisenhower formed a blue-ribbon panel, headed by David Rockefeller of the Chase National (later Chase-Manhattan) Bank, to evaluate the future prospects for US industrial and commercial expansion around the world. In the same year, the Rockefeller Foundation organized a conference in Williamsburg, Virginia, under the direction of John D. Rockefeller III, to study what Pearl had highlighted as the 'population problem.'

The blue-ribbon panel concluded that the single greatest obstacle to US industrial expansion (meaning access to cheap raw materials, labor, and ultimately markets) was the rapid population growth occurring in most Third World countries. Such population increases not only required the retention of more of countries' raw materials (including agricultural products) at home, but also fueled local revolutionary movements aimed at eliminating foreign control. Not surprisingly, the Williamsburg conference called for the formation of an organization to look into methods for controlling population growth. Out of this meeting came the proposal for establishing the Population Council, with Rockefeller funds and John D. III himself as President. Frederick Osborn, still Secretary of the American Eugenics Society at the time, soon took over as Council President, running both organizations out of his office in Rockefeller Center in New York.

One of the first major projects of the Council was the funding of investigations of various forms of birth control, including the IUD (intra-uterine device), and eventually, the first birth-control pill (Watkins 1998). Initial trials in Puerto Rico beginning in April 1956, led to field studies in other Third World countries such as India and Pakistan. One of the major incentives used to promote these studies was the economic benefit that would accrue to families that had fewer children. That such pilot population control movements encountered considerable resistance in the countries where they were introduced, suggested that local people saw the matter quite differently. The programs provided a lesson in the cultural and social components of reproductive life. For many in agricultural, Third World countries, large families were the only way to insure some manner of economic survival. Children worked on farms at an early age, and thus more than earned their 'keep,' while large families often provided the only form of old-age insurance in countries that lacked programs for the elderly. This lesson is still one to be learned by leading political and many environmental and conservation groups, who continue to advocate population control as the major agenda for Third World countries. Today, for example, the United States Agency for International Development, a branch of the State Department, devotes a significant portion of its budget to its Population Office. Programs emerging from

USAID support population control programs in over 20 Third World countries. Eugenic ideology is still providing as a basis for population policy throughout much of the industrialized world.

Eugenics, History of

Eugenics is the theory and practice of improving human heredity, typically through control of reproduction. Although the concept is very old, stretching back at least to the ancient Greeks, the modern movement dates to the nineteenth century when Francis Galton, a British polymath and first cousin of Charles Darwin, decided it was time for humans to learn from the breeders of horses and cattle and take human evolution into their own hands. In 1883, Galton termed this project 'eugenics,' from the Greek *eugenes* for 'well-born.' He defined it broadly as 'the science of improving stock, which is by no means confined to questions of judicious mating, but which … takes cognisance of all influences that tend in however remote degree to give the more suitable races or strains of blood a better chance of prevailing speedily over the less suitable than they otherwise would have had.' A conventional distinction contrasts 'positive' eugenics, which promotes breeding by those possessed of superior hereditary qualities, with 'negative' eugenics, which deters breeding by those with physical, mental, or moral defects.

1. Eugenics before Galton

Abandonment or outright killing of deformed infants was practiced in the ancient world, although both the rationale for and the extent of infanticide are matters

of controversy (Roper 1913, Riddle 1992, pp. 10–15). Infanticide of defective infants was approved by both Plato and Aristotle; indeed, the latter thought it should be mandated by law.

Eugenics is central to Plato's *Republic*. Written in the fifth century BC, it describes a utopia in which the family is replaced by a community of wives and children. Mating within the Guardian class is tightly controlled. According to Socrates, the Rulers would never allow unregulated unions. Such a practice would be 'a profanation in a state whose citizens lead the good life' (Cornford 1941, p. 157). In a dialogue whose theme will be often reprised, Socrates constructs an analogy between human and animal breeding. Just as we breed from the best of our sporting dogs and game birds, he argues, we should ensure that among our own flock, there be as many unions of the best, and as few of the inferior, as possible. Plato's analogy, which was further elaborated in the *Laws*, influenced the seventeenth-century Dominican Monk, Tomasso Campanella. His *City of the Sun* (1623) describes a utopia where children are bred for the good of the commonwealth, and whose inhabitants are scornful of those who neglect the breeding of their own kind.

2. *From Galton to the 1930s*

2.1 *Charles Darwin and Evolutionary Thought*

Campanella notwithstanding, proposals to control human heredity faded with the advent of Christianity. They re-emerged following publication of Darwin's *Origin of Species* (1859). Darwin argued that evolution occurred through a process of fierce competition in which organisms with advantageous traits would tend to survive and reproduce their kind, while the ill-adapted would leave few if any progeny. He and his contemporaries viewed this process as a progressive force that tended toward the constant physical and mental improvement of organic beings. But many Victorians worried that natural selection was no longer at work in their own species since modern medicine, charity, and other humanitarian measures prevented the culling of the physically and mentally weak. Moreover, it seemed as though the worst elements of society now were breeding at a much faster rate than the best. Darwin expressed a common middle-class anxiety about the 'differential birthrate' when he remarked in *The Descent of Man* (1871) that if various checks 'do not prevent the reckless, the vicious, and the otherwise inferior members of society from increasing at a quicker rate than the better class of men, the nation will retrograde, as has occurred too often in the history of the world. We must remember that progress is no invariable rule.' Darwin himself did not advocate any practical measures to counter the anti-selective forces of modern society. But in 1865, his cousin Galton published the first modern eugenics manifesto, 'Hereditary talent and character.'

2.2 *Galton's Argument*

Galton aimed to prove that human mental, moral, and temperamental traits, and not just physical ones, were transmitted from parents to offspring. These traits included a gregarious personality, a truthful or courageous character, a liking for alcohol or drugs or gambling, a tendency to pauperism or crimes of violence or fraud. He was particularly concerned to prove the heritability of traits making for success.

His method was simple, if from a contemporary perspective naive. Consulting biographical dictionaries, he established that fathers who had achieved eminence in various fields were much more likely than members of the public at large to have had fathers who were themselves eminent; in short, that distinction ran in families. Of course Galton knew that individuals also inherit social advantages, and he conceded that this might explain success in certain fields. No admirer of the landed aristocracy, which still dominated parliament, the army, and civil service, Galton noted that 'many men who have succeeded as statesmen would have been nobodies had they been born into a lower rank of life' (quoted in Jones 1998, p. 7). But in the 'open fields' of science, literature, and the law, individuals without talent would surely fail, no matter how distinguished their families, while conversely, the talented would succeed, no matter how unfavorable their background. Unfortunately, it seemed that those with the most talent were the least prolific. Galton argued that there was an urgent need to reverse this trend. However, he offered no specific measures to accomplish this end, only the conviction that if everyone could be made to see the importance of breeding, 'some way or other' would be found to get the job done.

2.3 *Changing Views of Heredity*

Galton believed that the hereditary material was transmitted intact from one generation to another. However, his contemporaries were 'Lamarckians,' who assumed that characteristics acquired by organisms during their lifetime (primarily through the use and disuse of particular organs) could be transmitted to their offspring.

The 'Lamarckian' or 'soft' view of heredity blurs the distinction between nature and nurture, since it assumes that inherited traits can be suppressed or redirected by changing the conditions of life. Thus, even if social problems such as criminality, promiscuity, or pauperism resulted from poor heredity, the solution could reside in improved nutrition, education, or other social reforms. But if heredity is impervious to

environmental changes, the only way to eliminate the problems it caused would be through selective breeding.

Galton lacked experimental evidence for his assumption that heredity was fixed. But in 1883, the German cytologist August Weismann (1834–1914) was able to distinguish germ cells, which are present in the gonads and give rise to sperm and ova, from somatic cells, which are present in all the other tissues of the body. Weismann argued that only the somatic cells could be affected by the environment, whereas the germ cells would be transmitted intact from generation to generation. Thus, no matter how hard individual parents worked to improve their minds or bodies, or whatever social reforms might be instituted, no child would be born healthier, or more equable, virtuous, musical, athletic, or smarter as a result.

2.4 Eugenics Becomes Popular

Galton's work initially received a lukewarm reception, especially in the popular press. But after the turn of the century, eugenics caught on. Between 1890 and 1930, eugenics movements of some form developed in over 30 countries, encompassing Central and South as well as North America, and Asia as well as Europe (Adams 1990). The greatest impact, however, was felt in the United States, Canada, Britain, Germany, and Scandinavia—predominantly Protestant countries in which Weismann's 'hard' view of heredity prevailed.

Eugenics societies drew most of their members from the professional middle classes: doctors, lawyers, teachers, social workers, ministers. Numerous demographic studies seemed to demonstrate that workers and agricultural laborers had more children than the middle and upper-middle classes, with those living in the worst conditions producing the largest families (actual patterns of fertility are a matter of dispute; see Szreter 1996).

Of particular concern was the ostensibly rapid increase in the number of 'feebleminded.' In 1910, the psychologist Henry H. Goddard proposed a three-tiered grading system for mental deficiency. Those with a mental age of one or two he termed 'idiots,' those with a mental age of three to seven 'imbeciles,' and those with a mental age between nine and 12 'morons' (Zenderland 1999). Members of the 'high-grade feebleminded' or 'moron' class posed the greatest threat to society since they could not easily be differentiated from normal persons. Unlike idiots and imbeciles, they were often physically fit and attractive, and thus had no trouble either finding mates or producing children. But lacking foresight and self-restraint, and unable to distinguish right from wrong, they easily fell into lives of pauperism, alcoholism, sexual promiscuity, and crime. Exhibits at museums, expositions, and state fairs described the disastrous consequences of allowing reproduction by these defectives to go unchecked.

On the basis of pedigree studies demonstrating the passage of traits in several generations of the same family (such as Goddard's 'Kallikaks') feeblemindedness was judged to be heritable. According to the best science of the day, feeblemindedness resulted from a single recessive gene. It thus initially seemed that the trait could be eliminated if its possessors were prevented from breeding. By the 1920s, that optimistic assessment was shown to be wrong, since most of the offending genes would be hidden in apparently normal carriers. Policies such as eugenic segregation or sterilization, which targeted only those affected, would thus work much more slowly than had been thought. But most eugenicists reasoned that even a small reduction was better than none (Paul and Spencer 1995).

Modern scholarship has challenged the once-conventional identification of eugenics with political conservatism and support of the social status quo. Many eugenicists were indeed reactionary. But eugenics was also deployed in support of a variety of progressive causes. In China, eugenics flourished during the Republican Era, where it was invoked by modernizers in their efforts to counter tradition (Dikötter 1998). In Europe and North America, pacifists claimed that war destroyed the strongest and bravest of men, thus weakening the race (Crook 1994). Although many Fabian and even some Marxian socialists worried that the worst were outbreeding the best, they turned this concern into a case for social and economic change, arguing that only in a society that abolished economic inequality would it be possible to distinguish genetic value from environmental good fortune (see Kevles 1995, Paul 1998, Grossmann 1995). These Left eugenicists criticized the racial and class bias that informed the 'mainstream' eugenics movements. In their view, the real problem was the high reproductive rates among the least prudent and foresighted of every class.

While many eugenicists were socially conservative, sex reformers invoked eugenics in support of access to birth control, legalization of divorce and abortion, and radical changes in gender roles, including expansion of educational and employment opportunities for women (who were often drawn to the eugenics cause; for example, nearly half the members of the British Eugenics Education Society were female: see Soloway 1990, p. 1280, Hall 1998; on Weimar Germany see Grossmann 1995; on Spain see Cleminson 1994). Birth-control advocates argued that access to contraception would allow poor women, of inferior heredity, to voluntarily limit their births. According to Margaret Sanger, 'funds that should be used to raise the standard of our civilization are diverted to maintenance of those who should never have been born.' (Opponents countered that contraception would be used disproportionately by the middle-class.) Even 'free love' or abolition of marriage was promoted on

the grounds that marriage was often based on class or other genetically-irrelevant factors (see Paul 1995, pp. 91–2, Hansen 1996).

2.5 Eugenic Measures

Until recently, studies of eugenics focused almost exclusively on Britain and the US. Since the 1980s, however, the focus has greatly broadened to include Canada, Latin America, Germany, Russia, France, Spain, Scandinavia, Australia, China, and Japan, among other countries and regions. As a result, historians now understand that eugenics took quite different forms in different places. In the Latin countries, where Lamarckianism was strong, race-mixing common, and Catholicism the dominant religion, concern with biological degeneration did not result in calls for sterilization of defectives. In France, the 'puericulture' movement, spearheaded by Adolphe Pinard, stressed the value of breast feeding and of improved diet and more rest for pregnant women, as well as a premarital examination law to prevent dysgenic unions among those individuals with hereditary defects. In these countries, environmental and hereditary improvement were generally thought to be mutually reinforcing, rather than at odds (on France, see Schneider 1990; on Latin America, see Stepan 1991).

Even in North America and the Protestant countries of Europe, eugenics encompassed a wide range of activities. In Britain, where the modern movement originated, there was no effort to pass coercive legislation (which would have been politically impractical, in part due to the strength of the Labour Party, which viewed eugenics as hostile to workers). Following Galton's lead, the Eugenics Education Society emphasized the need to convince their compatriots of the value of controlling reproduction. Thus, eugenics consisted primarily of education and propaganda, such as the Pauper Pedigree Project, which compiled family trees of typical degenerate families (Mazumdar 1992).

Coercive measures were adopted elsewhere. Beginning in 1907, when Indiana authorized the compulsory sterilization of 'criminals, idiots, rapists, and imbeciles,' sterilization laws were passed in over 30 American states, two Canadian provinces, all the Scandinavian countries, Estonia, Germany, and Japan. In the US, opposition from the Catholic Church, concern that the procedure (vasectomy in men, tubal ligation in women) would promote sexual promiscuity and venereal disease, and especially legal challenges to the constitutionality of state laws, originally limited the number of sterilizations (Reilly 1991). To address the legal issues, Harry Laughlin, Superintendent of the Eugenics Record Office at Cold Spring Harbor, New York (the center of the organized eugenics movement in the US), drafted a model law. Its use by the state of Virginia was tested in the 1927 case of *Buck v. Bell*. In his famous decision in that case, Justice Oliver Wendell Holmes wrote: 'It is better for all the world if, instead of waiting to execute degenerate offspring for their crime, or to let them starve for their imbecility, society can prevent those who are manifestly unfit from continuing their kind … . Three generations of imbeciles is enough.' In the aftermath of the case, a dozen states revised existing laws or enacted new ones. (However, more than half the 60,000 legal sterilizations were performed in California.)

In the US, concerns about deterioration had been heightened by the results of the mental testing program initiated by the army during World War I. Psychologists tested more than 1.75 million recruits and concluded that nearly half the white draft was feeble-minded, with blacks and recent immigrants scoring worst. The testing program thus exacerbated anxiety about the quality of immigrants from Southern and Eastern Europe, whose numbers increased dramatically beginning in the 1880s. The newcomers from Russia, Poland, Italy, and the Balkans were anyway resented for their cultural and linguistic differences, support for big-city political machines, and willingness to work for low wages. Eugenicists added that they were also of poor stock, and that mixing with older-stock Americans would produce biological degeneration. In the first decade of the century, Theodore Roosevelt had warned repeatedly that old-stock Americans were losing a desperate 'war of the cradle' with lesser breeds, a theme that recurred frequently in both academic and popular literature. In 1924, President Calvin Coolidge signed into law the Immigration Restriction Act, which restricted entrants from any European country to two percent of the foreign-born of the same national origin recorded in the 1890 census, that is, before the massive influx of new immigrants.

American developments were noted in Germany, where a draft law permitting sterilization with the consent of the person involved or their guardian had been drafted at the end of the Weimar Republic. In *Mein Kampf*, Adolf Hitler had characterized National Socialism as 'applied biology.' The Nazi government quickly passed a compulsory law, which extended to a wide range of ostensibly genetic conditions. The law was often praised by non-German commentators for its procedural safeguards (although these were often disregarded in practice). Approximately 400,000 Germans were eventually sterilized under the Nazi regime (Bock 1986, pp. 230–46).

In 1939, the Nazis instituted a euthanasia program aimed at eliminating the 'useless eaters' in mental hospitals. Neither the sterilization nor euthanasia policies were racially-oriented. But soon after the Nazis came to power, they enacted the first of the Nuremberg laws, which forbade Germans to marry Jews and others of 'inferior blood.' Other actions targeting Jews, Gypsies, the offspring of German

mothers and black French soldiers, and other reviled groups followed, culminating in the Holocaust. The Nazis also instituted a number of 'positive' eugenics measures, including the *Lebensborn* program, which allowed single and married women who passed a racial test to give birth in special SS maternity homes.

Events in Germany were watched closely in Scandinavia, where many eugenicists were critical of Nazi racism, but impressed by the sterilization law. Denmark, Sweden, Norway, Finland, and Iceland passed laws of their own, virtually without dissent (Broberg and Roll-Hansen 1996). Support for sterilization reflected fears about degeneration that were shared by elites elsewhere in Europe and in America. It also reflected the Social Democratic emphasis on communal responsibilities, as well as the view that a state that has taken on the responsibility of caring for its citizens must limit the numbers of those who will burden it.

Opposition to compulsory sterilization did not necessarily imply wholesale opposition to eugenics. In fact, most critics took for granted that mentally deficient individuals should be persuaded or prevented from breeding. The issue was how best to achieve this end. Skeptics variously charged that the laws promoted promiscuity, were ineffective, were based on unfounded assumptions about the heredity of mental defect or criminality, and were inevitably biased in their application. A common concern was that sterilization would provide a cheap substitute for the more desirable policies of segregation, training, and community supervision.

Even the Catholic Church—the most powerful foe of sterilization—was not opposed to eugenics *tout court* (much less committed to the view that procreation is a private matter). In his 1930 encyclical *Casti Connubi*, Pope Pius XI conceded that eugenics must 'be accepted, provided lawful and upright methods are employed within the proper limits,' although he denounced sterilization as an illegitimate usurping by the state of power over the bodies of its subjects. In the same encyclical, the Pope condemned contraception and abortion, and noted that private individuals are also barred from tampering with their bodies in order to prevent procreation.

3. *The Decline of Eugenics*

In the aftermath of World War II, eugenics fell from favor. Historians once attributed its decline in large part to the progress of genetics. In the conventional view, which still informs much popular writing on the subject, it became increasingly clear that traits were usually the product not of one but of several genes, that these genes acted in complex ways with each other and with the environment, and that selection against undesirable traits could not in fact eliminate them. As a result, support for programs of selective breeding inevitably waned. From this standpoint, eugenics was unable to withstand its encounter with scientific fact. However, most recent historiography emphasizes that the scientific developments said to have eroded support for eugenics occurred in the 1910s, long before it became disreputable, and that the researchers responsible for these discoveries were themselves eugenics enthusiasts.

Eugenics' decline seems to be linked most closely to a shift in the social climate resulting from revelations of Nazi atrocities—crimes that had been justified by the ostensible biological need to protect and purify the German race. The result was a backlash against eugenics, including its underlying hereditarianism. In the 1950s, genetic explanations of individual and group differences fell from favor. Although the reign of 'cultural determinism' was short-lived (Nelkin and Lindee 1995, pp. 34–7), eugenics' reputation never recovered. It was now equated with its most barbarous manifestations, viewed as inherently racist and reactionary, as well as scientifically shoddy.

In fact, not all eugenics was racist. Even in Germany, the movement originally had been dominated by technocratic elitists, not racial purists, and some prominent eugenicists were Jewish (Weiss 1988, Weingart et al. 1988, Weindling 1989). In the US, the subjects of the pedigree studies, such as Goddard's 'Kallikaks,' were all white and Anglo-Saxon (Rafter 1988). Nor was eugenics invariably supportive of the status quo, as its popularity among Fabian socialists, architects of the Scandinavian Social Democratic welfare states, and a host of sex reformers indicates. Moreover, many eugenicists, especially in Britain, opposed coercion. Following Galton's lead, they instead supported educational and propagandistic measures. Thus racism, class-bias, social conservatism, and violations of individual liberty—while prominent aspects of the history of eugenics—were not constitutive of it (Wikler 1998). However, the new historiography, which stresses eugenics' complexity and diversity, has so far had little impact on popular perceptions of the subject.

Eugenics in Asia

Eugenics, a term coined in 1883 by the English scientist Francis Galton, had its heyday during the first half of the twentieth century. Its proponents claimed that breeding principles such as assortative mating and artificial selection could improve the quality of human offspring. 'Positive eugenics' would ensure that individuals with above-average abilities would breed at a higher rate than ordinary people. 'Negative eugenics' would restrict the reproduction of inferior people, while those having subnormal abilities would have to be physically prevented from perpetuating their 'infirmities.' Mainline eugenicists assumed that intellectual capacity and behavioral traits were inherited and could not be significantly enhanced by education. Supporters included not only scientists, in particular geneticists, but also social reformers, journalists, and other members of the emerging liberal professions. Until recently, however, it was often assumed that eugenics only appealed to extreme right-wing thinkers or organisations in Germany or the United States, as the multifarious dimensions and extraordinary appeal of eugenics to individuals of very different social backgrounds, political convictions, and national affiliations was ignored.

Far from being a politically conservative and scientifically spurious set of beliefs which remained confined to the Nazi era, eugenics belonged to the political vocabulary of many modernizing forces between the two World Wars. It was not only supported by scientific societies, pressure groups, and political institutions in such different countries as France, Brazil, and Sweden, but also developed a large following in Asia, in particular in China and Japan.

1. *China*

Eugenics in Asia is sometimes dismissed as a derivative manifestation of a more 'authentic' dis-

course in 'the West,' a misleading interpretation which can only impoverish our understanding of the complexities of cultural and intellectual encounters between population groups around the world. When the history of eugenics is explored in a variety of cultural, social, and political contexts, it resists any reductive explanation, an observation which is all the more true as the less familiar shores of China and Japan come under investigation. As in European cultures, popular hereditarian notions—encapsulated in such sayings as 'Like begets like'—helped the emergence and acceptance of eugenic ideas in Asia. Well before Darwin's time, experts in China had attained a sophisticated level of knowledge about selection and breeding, particularly in botany and in goldfish. On the other hand, many medical publications discussed in great detail ways of improving the physical quality of a line of descent while also highlighting the medical dangers to future offspring of careless reproduction. Patrilineal culture, in which reproduction was represented as a potentially dangerous process that should be carefully regulated in order to enhance the possibilities of engendering healthy male descendants, permeated traditional medical literature in imperial China. The individual, seen in relationship to the lineage, was held to be responsible not only for his or her own reproductive behavior, but also for the health of future offspring.

Interest in eugenics, however, only appeared in China in the wake of the reform movement of the 1890s, which openly sought to challenge imperial institutions and orthodox ideology. In search of wealth and power after the country's disastrous defeat against Japan in 1894–5, reform-minded scholars used Darwinian theories—inspired by Herbert Spencer and T. H. Huxley—to propose a radically new political vision based on faith in progress. Slogans such as 'survival of the fittest' and 'struggle for existence' became popular in China, increasingly represented as a 'race' which ought to be strengthened in its confrontation with imperialist countries. Public health, individual hygiene, even sexual behavior were targeted by reformers such as Kang Youwei and Liang Qichao as areas in need of state regulation in order to ensure the 'survival of the race' in a context of international competition. Only after the collapse of the empire in 1911 and its substitution by a republic, however, did eugenics develop a much wider following.

Eugenics in republican China (1911–49), as in other countries during the interwar period, was not so much a clear set of scientific principles, as a 'modern' way of talking about social problems in biologizing terms: politicians with mutually incompatible beliefs and scientists with opposed interests could all selectively appropriate eugenics to portray society as an organic body which had to be guided by biological laws. Eugenics gave scientific authority to social fears and moral panics and provided an overarching rationale for welfare policies in China. Powered by the prestige of science, it allowed modernizing elites in China to represent their prescriptive claims about social order as objective statements irrevocably grounded in the laws of nature. Eugenics promoted a biologising vision of society in which the reproductive rights of individuals were subordinated to the rights of an abstract organic collectivity.

Eugenic discourse had different meanings to different social groups in different contexts: it was appropriated and used in a variety of ways to accommodate radically divergent purposes and interests, being flexible enough to unite individuals or constituencies with contradictory agendas. One of the major dividing lines within eugenic discourse was that between a hard approach to heredity, based on genetics in Britain and Germany, and a soft approach combining an emphasis on the environment with hereditarian explanations.

The soft approach to eugenics was common in republican China as well as in other countries as diverse as Brazil and France. Professional groups in China campaigned for better public education in social hygiene and sexual health in the name of race improvement. Moreover, unlike researchers in countries which pursued a hard Mendelian approach, supporters of eugenics in China did not produce significant biological research or statistical studies. An emphasis on the virtues of education accounts for the relative absence in republican China of formal institutions, official organs, or professional organisations centerd around the promotion of eugenic ideals. Rather than emanating from a solid organisational foundation, eugenic discourse was supported by a variety of voices in the social field: it attracted popular journalists, social reformers, medical writers, sex educators, university professors, and political ideologues, all attempting to promote medical knowledge and reproductive health for the sake of a more eugenic nation.

Eugenics was actively supported by members of the professional classes, in particular intellectuals, university teachers, sociologists, and biologists, and cut across most political positions, from the fascist core of the Guomindang to the communist theories of Chen Duxiu. Cheap textbooks on heredity and genetics explained to the public the dangers of racial degeneration. Primers, self-study manuals, cheap pamphlets, and 'ABC' introductions to mainline eugenics were published throughout the 1920s. Hereditary principles, endowing sex with a biological responsibility for future generations, were thought to further highlight the need for social discipline. In the 1930s, eugenic discourses became increasingly common in medical circles, 'degeneration' and 'racial hygiene' being the catchwords of the day. There is little evidence, however, to show that the widespread interest in eugenic ideas was translated into actual practice before the advent of a socialist regime, although some isolated cases, such as the execution of

lepers by the police in Guangdong province in the 1930s, point to a more radical approach in questions of public health during the Nanjing decade.

The Second World War, followed by the civil war between the Communist Party and the Guomindang from 1945 to 1949, was the main reason why eugenic ideas did not achieve institutional form. The Committee for the Study of Population Policies, organized by the Ministry of Social Affairs in 1941, was the first official attempt to approach eugenics systematically. It recommended the segregation of physically and mentally handicapped persons from the normal population for what was called 'cultural advancement and racial rejuvenation.' Because people were recognized as being unequally endowed, the report advocated a differential birth-rate: 'Thus viewed,' said the report, 'some individuals may have children, others not.' The committee—whose members included Chen Da and Pan Guangdan—also encouraged the use of sterilization for the racial rejuvenation of the country and recommended that '(s)teps should be taken to segregate persons of hereditary defects, physical or mental, from the normal population' (Dikötter 1998).

After the communist victory in 1949, the class bias of eugenics was systematically condemned, while genetics was denounced as 'bourgeois science.' As in the Soviet Union, Lysenko's doctrine became dominant in the 1950s and 1960s while Mendelian laws of inheritance and T. H. Morgan's chromosome theory were rejected for ideological reasons. This trend was only reversed after the accession of Deng Xiaoping to power in 1978. Medical experts and population specialists were put into powerful positions as official policies aimed at the limitation of births were initiated by the government. Besides the one-child family program, by which the government only in exceptional circumstances allows parents to have more than one or occasionally two children, an important component of these policies has been the improvement of the quality of newborn babies.

The one-child family policy has effectively prepared the terrain for a better acceptance of eugenic legislation among large sectors of the urban population: many families which are allowed to have one child only are keen to avoid 'defective' births themselves. A prolific medical discourse has responded to the general public's concern for healthy offspring, a virtuous child, or even a genetically improved line of descent. Numerous pamphlets of scientific vulgarization thus dispense advice on the art of engendering a prodigy child, suggesting that the eugenist vision of the government is shared to a great extent by a population which is anxious to avoid what are called 'inferior births.'

As the result of such consensus, local regulations have been passed virtually unopposed in a number of provinces and cities since the late 1980s. On November 25, 1988, the Standing Committee of the National People's Congress of Gansu Province passed the country's first law prohibiting mentally retarded people from having children. According to the law, those mentally retarded people whose condition was either inherited or a consequence of marriage between close relatives were not allowed to have children; no mentally retarded people were allowed to get married unless they had undergone sterilization surgery; those who had married before the promulgation of the law were also to undergo sterilization surgery; and pregnant women suffering from mental retardation were required to have their pregnancies terminated. Individuals who violated the law by allowing mentally retarded people to have children would be punished by both administrative and economic means. A similar law was enacted by Liaoning province in February 1990, while Zhejiang province passed a law on the preservation of 'eugenic health' in June 1992 to combat the increasing incidence of 'cretins,' who were estimated to number more than 300,000. The Henan eugenics law of 1992 requires that if one partner in a married couple suffers from a 'chronic mental disorder' such as schizophrenia or manic depression, that partner shall be sterilized. The implementation of such sterilization laws at the provincial level is advanced by a system of incentives and disincentives. People who refuse to be sterilized or anyone who impedes the sterilization of another may be subject to penalties. For example, Henan's eugenics law requires prompt reporting of those diagnozed as 'needing to be sterilised' who refuse to accept the operation. Differential fines for noncompliance with 'eugenic measures' are imposed for rural and urban residents.

Under pressure from a variety of lobbies, mainly family planning experts and geneticists, the provincial laws finally culminated in the People's Republic of China passing eugenic legislation at the national level at the beginning of 1995. The law aims to prevent 'inferior births' from becoming a burden on the state and society. Renamed Maternal and Infant Health Law after protests against a preliminary draft entitled Eugenics Law (*Youshengfa*), it supports the systematic 'implementation of premarital medical check-ups' in order to detect whether one partner in a couple suffers from a 'serious hereditary,' venereal, or reproductive disorder, a 'relevant mental disorder,' or a 'legal contagious disease': it asserts that those 'deemed unsuitable for reproduction' should be urged to undergo sterilization or abortion, or to remain celibate, in order to prevent 'inferior births.' During pregnancy, medical testing will be compulsory and can be followed by termination if the foetus is found to have a serious disorder.

In the absence of any detailed studies by social-anthropologists and population experts, concrete information on the implementation of eugenic laws is missing. Foreign observers, however, have underlined that the implementation of eugenic legislation not only undermines the rights of the person vis-à-vis the state, but it is based on controversial if not antiquated

theories of human heredity (O'Brien 1996, Lancet 1995, Nature 1994).

2. Japan

In Japan, eugenics developed gradually after modernizing intellectuals encountered evolutionary theories in the works of Charles Darwin and Herbert Spencer in the 1880s. In the wake of the Meiji revolution (1868), science and technology were perceived to be the key to national defence in an era of intense imperialism. As in many other countries, racial improvement became a popular notion among leading intellectuals who viewed the world in terms of a 'struggle for existence' among competing 'races.' Belief that individual reproductive decisions should be controlled by the state in the name of collective health flourished during the first half of the twentieth century. In the 1910s, works on eugenics by Umino Kōtoku, Nagai Hisomu, and Saitō Shigesaburō appeared, closely related to an increased interest in birth control, sex education, and public health.

Specialized journals were also established in the 1920s, both the *Yūzenikkusu* (Eugenics) and the *Yūsei Undō* (Eugenics Movement) being crucial in spreading eugenic discourse to a wider audience. As in China, belief in the power of heredity led many followers of the eugenics movement to view venereal disease, tuberculosis, leprosy, and alcoholism as heritable conditions which should be strictly administered by the state in order to prevent the increase of 'inferior offspring.' Eugenics became part of such widely discussed themes as evolution, degeneration, civilization, and modernity, and touched on a wide variety of emerging fields like maternity, psychiatry, criminology, public health, and sex education.

In Japan, too, the orthodox Mendelian roots of eugenics were often disregarded in favor of a more flexible approach to eugenics which emphasized belief in the transmission of acquired characteristics. Contrary to China, however, eugenic ideas provided a rationale for welfare policies with deep institutional and legal ramifications. A first attempt to implement eugenic legislation took the form of an appeal to the Imperial Diet in the early 1920s (Matsubara 1998). Proposed by the New Women's Federation, the petition sought to legally restrict the marriage of individuals with venereal diseases as a means of strengthening the nation. Despite support from leading intellectuals as well as members of the Imperial Diet, the petition was not adopted. Only in 1934–5 was a Racial Eugenics Protection Bill introduced by the Imperial Diet, which proposed the sterilization of persons with mental and physical diseases deemed to be hereditary, including serious criminals who were claimed to transmit their 'bad traits' to their descendants. The Japanese Association of Racial Hygiene, on the other hand, campaigned for a eugenics law limiting sterilization to patients with hereditary diseases. Headed by Nagai Hisomu, the group drafted a sterilization bill in 1936 based on the German Sterilization Law of 1933. Only in 1940, however, was a National Eugenic Bill passed, its enactment leading to heated controversy among government representatives and members of the medical professions. Objections came both from nationalists defending the need of the state to increase its population and from geneticists questioning the scientific validity of eugenics. While the Bill came into effect a year later, the government was compelled to prevent the enforcement of eugenic sterilization: by the end of the Second World War, only 454 operations were performed under the eugenics law.

After Japan's defeat in the Second World War, questions of 'racial survival' surfaced again in the context of occupation by the Allied Powers (Matsubara 1998). As abortion was legalized, a broad consensus emerged within medical and political circles around the need to prevent not only 'inferior descendants,' but also the reproduction of patients deemed to have 'infectious diseases' such as leprosy and non-hereditary mental disorders in the name of 'eugenic protection.' Supported by conservative advocates as well as socialist politicians, the Eugenics Protection Law (*Yūsei hogohō*) of 1948 gave legitimacy to eugenic sterilisation without the consent of the patients considered. The law remained the foundation for eugenic sterilisations throughout the second half of the twentieth century: involuntary operations reached over 16,500 cases by 1996, while a further 1,500 leprosy sufferers segregated in sanatoriums had been sterilized with consent by 1992. In 1996, the law was finally revised and renamed Maternal Protection Law, while the eugenic clauses on sterilization and abortion were deleted. Even after these legal changes, however, the government refused to critically examine the practice of compulsory sterilization on eugenic grounds, despite the severe criticisms from a variety of civil rights groups (Norgren 1998).

3. Conclusion

The legacy of eugenics is still highly visible today in many countries, including in the less researched parts of the world outside 'the West.' As the examples of China and Japan demonstrate, eugenic ideas elaborated during the first half of the twentieth century continue to carry scientific and legal credibility. While crude eugenic programs sponsored by the state may have become less frequent today, eugenic ideas are prominent in contemporary debates about new medical techniques for isolating and manipulating genes. During the heyday of eugenics, assumptions about 'race,' gender, and class pervaded genetic research: with the revolution in human genetics since the end of

the twentieth century, social and political factors continue to exert formidable influences on scientific research. Eugenic laws have been passed at the provincial and national level in China, a country which has curbed the reproductive freedoms and civil rights of individuals on behalf of the 'public good.' Even in democratic countries like Japan, however, marginalized people may be treated in a discriminatory way, as social prejudice and economic interest influence the genetic information made available to families, employers, hospitals, insurance companies, or welfare systems. As much as 'ethnicity' is a concept which is sometimes used as a thinly disguised substitute for the outdated notion of 'race,' discredited eugenic ideas have thrived on rather than suffered from the revolution in human genetics in some parts of the world: East Asia is no exception.

Eugenics in Europe

Eugenics were practiced as early as in the Classical Greek era. Spartans were known for throwing abnormal newborns into the Kaiada, a wild ravine. Plato in the *Republic* (459D) stated that rulers should permit the best men to mate with the best women for procreation, while in the *Laws* he compared animal breeding to that of humans, rulers playing the part of shepherds in the amelioration of their breeds. Inspired by Plato, Tomasso Campanella wrote of a eugenic utopia, the *City of the Sun* (1623). Actually, Francis Galton (1822–1911), a cousin of Charles Darwin and a man of many talents (explorer, anthropologist, statistician, student of heredity), was the modern founder of eugenics. This term derived from the Greek 'eugenes,' meaning 'from good birth.' Galton first spoke of eugenics in 1883, one year after Darwin's death, defining it as the study of the elements, controlled by society, which may improve the physical or mental racial qualities of future generations.

Galton started with the study of human intelligence. In two articles written in 1865 and expanded into a book, *Hereditary Genius*, in 1869, he investigated the hereditary origin of mental ability by accumulating data on important men and their relatives. Darwin was impressed by his half-cousin's work and wrote: 'We now know, through the admirable labours of Mr. Galton that genius … tends to be inherited.' However, Darwin was ambivalent on eugenics. While being convinced from Galton's writings on the inheritance of intelligence, he did not advocate a programme of genetic amelioration. He thought that one of the higher qualities of humans is 'sympathy,' namely sentimental closeness to other human beings, especially those suffering, and this was contrary to all attitudes of 'social Darwinism,' which aimed at the improvement of society by letting the laws of natural selection operate against the poor and the needy. Darwin never promoted or approved of such social policies. Eugenics and social Darwinism achieved their prominence after Darwin's death.

1. England

Galton assembled data indicating that many human characteristics, physical as well as social (ranging from pauperism to mental illness), were inherited. In the International Health Exhibition of 1884 Galton established an Anthropometric Laboratory and assembled metrical data. He also remarked that, in England, individuals with lower intelligence seemed to have more offspring than those with higher intelligence and thus in future generations intelligence (being inherited) was condemned to decline. Lower classes were formed by more fertile but less intelligent individuals. Adequate measures would become necessary to prevent the decline of society. Darwin noted that higher fertility combined in lower classes with higher mortality, so a population's intelligence would not change, but he did remark on cases (as in ancient Greece and in Spain) where, according to him, such a

reduction took place and explained the decline of these powerful nations.

We should distinguish two different sorts of social Darwinism, the holistic and the individualistic. The individualistic considers the competition between individuals within a society or population, while the holistic the competition between races, states, and societies. The first is linked to proposals for eugenic measures within society, the second to racism.

Two students of Galton continued his tradition of combining anthropology and eugenics, the biometricians Karl Pearson (1857–1936) and W. F. R. Weldon (1860–1906). Pearson became Professor at University College, London, and headed the Galton Eugenics Laboratory (which included the Eugenics Record Office) and the Biometrical Laboratory. Both Pearson and his friend Weldon were Darwinists and eugenicists but anti-Mendelians. In 1907 the Eugenics Education Society was founded, with seven branches in different English towns plus one in Australia. Galton was convinced to accept the honorary presidency, while the son of Darwin, Major Leonard Darwin, became president (from 1911 to 1928). Many important scientists, professors (among them John Maynard Keynes, later famous as an economist), social radicals as well as conservative public figures, such as George Bernard Shaw, Havelock Ellis, H. G. Wells, Harold Laski, Winston Churchill were in favor of eugenics or became active members of the Society. In 1926 it was renamed The Eugenics Society. In 1912 the First International Congress of Eugenics was organized in London with the participation of Societies or representative committees from Sweden, Norway, Russia, Switzerland, Germany, Poland, Italy, France, and other countries.

The history of the eugenic movement in England is connected strongly with that of the USA; they behaved as communicating vessels. The concern caused by the greater fertility of individuals with lower mental capacities was great, especially after observations were reported suggesting that the majority of recruits for the Boer War did not perform well in mental tests. The French psychologist, Alfred Binet, invented a test, which was perfected by his colleague Theodore Simon. The Binet–Simon test was used to estimate the 'intelligence quotient' (IQ) and investigate its inheritance. In 1913, with an overwhelming majority (only three votes were cast against it, among them that of the liberal Josiah Wedgwood), the British House of Commons approved the Mental Deficiency Bill, in which the different categories of feebleminded were recognized. Measures of segregation were compulsory only for extreme cases, to avoid their procreation. Sterilization was not mentioned. English society was reluctant to impose extreme eugenic measures. England did not include minorities (as later was the case in Germany) or immigrants (as was the case in the USA). The concern was for the urban poor strata, the middle and upper classes found repulsive any extreme repressive measure. Leonard Darwin avoided including them in discussion. Catholics were opposed to eugenic action as were the Labour party, Liberals, and Conservatives (Churchill was afraid that eugenic measures could undermine population growth), while the eugenic group was not homogeneous. Pearson never joined the Society, which soon became dominated by Mendelians. Important scientists, such as the American geneticist T. H. Morgan and the English scholars J. B. S. Haldane, Julian Huxley, and Lancelot Hogben, were opposed to extreme measures.

On the other hand, socialists and members of the Fabian society tended to be favorable to eugenic practices. In 1926, Pearson started the journal *Annals of Eugenics*. Two International Congresses of Eugenics were held in New York, the second in 1923 and the third in 1932, the latter attracting a very small audience. In 1933 Ronald Fisher (1810–1962), a mathematical geneticist and statistician, who demonstrated that Mendelian genetics was compatible with Darwinian selection, even essential to explain the evolutionary process, was appointed to the Galton Eugenic Professorship, succeeding Pearson. Fisher was a strong supporter of eugenics, and a major part of his epoch-making book, *The Genetical Theory of Natural Selection* was devoted to eugenics.

Lionel S. Penrose, a polymath physician and human geneticist, who embarked on the study of the genetics of mental deficiency, succeeded Fisher in 1945 to the Galton Eugenics Professorship. Penrose soon realized that in a few cases of mental deficiency, the genetic etiology was clear and due to a simple gene. In many cases, however, there was an interaction between environmental influences and genetic predispositions. Penrose was critical of the work of the psychologist Cyril Burt on the inheritance of IQ. He disliked eugenics. Penrose might be considered as a turning point in the shift from eugenics to human genetics. Actually, in 1954 he changed the title of *Annals of Eugenics* to *Annals of Human Genetics* and dropped the word Eugenics from the name of his chair. This shift was strengthened by the postwar revelation of eugenic and racist German atrocities. In 1950, UNESCO issued a strong declaration on the concept of human races and against racism signed by well-known and respected evolutionists such as the Americans Herman Muller, and Theodosius Dobzhansky, and the Englishman, Julian Huxley.

The growth of knowledge about human genetics was impressive. Blood groups, enzyme studies, and the cytological etiology of several abnormal syndromes are many of the subjects that marked the flourishing of this field, first in Britain, later in Europe and the USA. With the development, after World War II, of human population and statistical genetics, genetic counseling became feasible. The advent, in the 1970s/1980s, of molecular techniques made possible early detection of carriers of genes causing serious abnormalities and pathologies, and allowed early

abortions. However, this part of the history, although following naturally from the ideas and preoccupations of eugenics, belongs to a different subject.

2. *France*

The case of France is different. In France, the belief in Lamarckian inheritance of acquired characters (while Darwinism was not widely accepted) influenced the development of eugenics. Two major themes played a decisive role, the depopulation of France, and the degeneration of its population. For the first time, in 1854, deaths exceeded births and, although this was not repeated, in the following years the birth rate steadily declined. This combined with the disastrous outcome of the 1870 Franco-Prussian war, was of great concern to demographers, politicians and the common people. Unlike France, the population of Germany increased. The German general von Moltke was reported to have said that France was losing a battle every day because of its declining birth rate.

Depopulation did not permit the neo-Malthusian movement, active in the last quarter of the nineteenth century, to play an important role. The natalist movement, on the contrary, was very popular and influential (the demographer Jacques Bertillon was one of its founders and its most vocal representative). Natalists preached control of the family but emphasized guidance towards its growth. While neo-Malthusians tended to be socialists and libertarian, natalists tended to be Catholics and in 1920 succeeded in having a law passed banning the sales and advertisement of birth control devices. In 1939, a second law encouraged the creation of large families.

France differed further from England in terms of the development of 'solidarism,' an ideology combining individual freedom with state intervention on behalf of social justice. Cooperation rather than competition was emphasized. This was an alternative to English or American social Darwinism. Important public figures participated in the movement, which was the expression of the official philosophy of the French Third Republic. Leon Bourgeois, ex-prime minister, and member of the Senate, identified with the solidarity movement, and became honorary president of the French Eugenics Society. Another member of the solidarity movement, the biologist Edmont Perrier (1844–1921), became president of the French Consultative Committee to the First Eugenics Congress in London, and later the first president of the French Eugenics Society.

A rather general consensus, popularized in the literature of that time, was that the French population was tending to degenerate. Emile Zola, in his novels about the Rougon-Macquart family, insisted on this trend of decline and decadence. The degeneration was attributed to several causes, of which alcoholism, tuberculosis, and venereal diseases were considered to be the most prominent. An environmental amelioration (in a Lamarckian spirit) could rescue, if not the patients, at least their progeny (since it was believed that all three conditions had a strong hereditary component).

An amateur anthropologist, Georges Vacher de Lapouge (1854–1936), ostracized from the French scientific institutional system, promoted racist and eugenic ideas, observing that a very small number of males of absolute perfection and worthy of perpetuating the race could inseminate all females! Lapouge was more appreciated in the USA and Germany than in his own country.

Adolphe Pinard (1844–1934), professor at the Medical faculty in Paris, and a well-known obstetrician, together with his student, demonstrated that pregnant women having proper shelter and food, and not being obliged to work during the last three months of pregnancy delivered newborns weighing on average 300 g more than those working during these last months. Pinard's aim was to improve the next generation by improving physical conditions and the art of raising children, what he called 'puericulture.' Pinard first distinguished an extrauterine puericulture (the raising of the newborn and the baby) and an intrauterine one (improving the conditions of the pregnant women). Later, in 1899, he extended his concept of puericulture, to apply before procreation. This reflected his concern for the hereditary component. Then in spirit, puericulture joined eugenics. Even so, the emphasis was on education, and supportive of premarital examination. Women and men should choose their mates for procreation; mothers should stay near their children. The teachings of Pinard had great influence in France at the beginning of the twentieth century, his theories were taught in schools, while his book was translated in Romania, Spain, Belgium, and Italy (Latin and Catholic countries).

The French delegation to the First Eugenics Congress in London in 1912 was the starting point for the founding of the French Eugenic Society in December of the same year. Perrrier was elected President; Pinard, Louis Landouzy (dean of the medical Faculty in Paris), and Frederic Houssay (1860–1920, professor at the Faculty of Science) Vice Presidents; Eugene Apert (1868–1940, pediatrician), Secretary, and Lucien March (1859–1933, demographer, head of the Statistique Génèrale), Treasurer. Another important member was Charles Richet (1850–1935), professor of physiology and Nobel laureate for his work on anaphylaxis, and science popularizer, who replaced Landouzy after his death. Richet believed that the influence of the environment was small and to improve the quality of the population he strongly supported negative eugenic measures. The natalist and politician Adolphe Landry, in the same year, stated the contrary position, that sterilization and marriage restrictions were repugnant to the need for liberty and

French individualism. The number of founding members of the Society exceeded 100. The Society was very active before World War I, holding meetings every month and publishing a journal, first by itself, and later as part of the bulletin of the Ecole d'Anthropologie in Paris. During the war, the Society stopped its activities, which were resumed in 1920. Heavy human losses during the war (about a million) affected the thinking of many of its members; thus, after the war the emphasis switched to positive eugenics combined with a Lamarckian outlook. Social hygiene became the prime concern, and institutions dealing with public health were founded and strengthened. The Rockefeller Foundation financed an antituberculosis programme in France. However, some eugenicists did not put aside the idea of a premarital examination and a proposal for such legislation was first raised in 1920 by Georges Schreiber. In 1926 Pinard presented to the Chamber of Deputies a bill on premarital examination. This bill was amended repeatedly (Pinard's version was very mild), resulting in a delaying as its vote. The last amendments and a new bill proposal in the Senate, in 1932, were not voted for. Opposition from the Catholics (especially Edouard Jordan) helped to achieve this demand. A Papal encyclical, issued in the last days of 1930 and dealing with Christian marriage (*Casti Conubi*), condemned eugenic practices. Thus, only under the Vichy regime was the premarital examination implemented, by a decree in December 1942, which was amended the following year. An influential personality in the 1930s was the physician and aristocrat Just Sicard de Pauzoles (1872–1968). He defended class-based eugenics (lower classes were multiplying faster, but their genetic quality was poor) and a method for estimating human genetic capital in monetary terms. He was one of the few eugenicists who survived World War II scientifically.

In the 1930s, the depression and the arrival of numerous immigrants, triggered the expression of racist attitudes. France had a long tradition in this matter. Both monogenists (believing in a single origin of all human 'races' such as Buffon and Gobineau) and polygenists (Voltaire, Le Bon, Taine) expressed racist opinions. Joseph Alfred de Gobineau (1816–82) is considered a prominent racist. Ernest Renant (1823–92) stated that 'a very small quantity of noble blood infused into a population suffices to ennoble it.' Gustave Le Bon (1841–1931) tended to identify the hierarchy of races with those of gender and class, believing that the lower social strata corresponded to primitive man. Lastly, Hippolyte Taine's (1828–93) beliefs could be interpreted as a critique of the enlightment (man does not exist, but *men*) and as revealing racist attitudes. The Dreyfus affair, at the beginning of the twentieth century, displayed the attitude of a significant part of the French society towards those considered alien. In the 1930s the skull index started being replaced by the frequency of ABO blood groups. Immigrants should be accepted, according to some scientists, on the basis of the similarity of the frequency of blood groups in the population of their origin to that of French people.

During the Vichy period, German Nazism influenced France: von Verscheuer and Fischer spoke in Paris on the German racial legislation. Well-known racists were placed in key positions. However, the Eugenic Society was disbanded. An important figure during this period, Alexis Carrel (1873–1944), a physician with a successful career in the USA and Nobel laureate for his work in experimental life-support of organs, in his book, *Man, the Unknown*, supported euthanasia for the insane and those guilty of criminal acts. The Vichy regime agreed to create a foundation, proposed by Carrel and headed by him, dealing with eugenics. After the war, in November 1945, the French provisional government, by an ordinance, upheld the Vichy regime decree on premarital examination.

3. *Germany*

The corresponding term for eugenics in Germany was *Rassenhygiene*. Eugenic thought originated in this country partly from social Darwinism, and partly from a concern to increase the population size of the German nation and partly from a racist ideology related to the concept of the Aryan or Nordic race. Racism had a long tradition in Germany. It was imported from England by George II, king of England and elector of Hanover, who formed a cultural bridge between England and Germany. He founded the University of Göttingen early in the eighteenth century, where during the last third of it Professor Johann Friedrich Blumenbach taught racism. Eugenicists in Germany formed a heterogenous group, some accepting and others rejecting the racist ideology. Those opposing proposed the term *Rassehygiene*, the use of the singular for *Rasse* indicating the entire human population. At the end of the nineteenth century, Germany experienced social problems resulting from its fast industrialization. In this atmosphere of social change, of increased criminality, alcoholism, and prostitution, the German middle and upper classes favoured a new '*Sozialpolitik*' in the form of race hygiene, thus solving social problems in an economical way. Physicians played a major role in this, and they were inspired by the Haeckelian version, the selectionist variety of social Darwinism. The influence of August Weismann caused the Lamarckian alternative (the welfare state) to decline. Two major founding figures must be mentioned at this point, Alfred Ploetz (1860–1940) and Wilhelm Schallmayer (1857–1919). Ploetz studied economics and medicine. He was an enthusiast of Germany's Teutonic past and coined the term *Rassenhygiene* as a German synonym for eugenics. He was concerned with the improvement of the

hereditary quality of the population as well as its increase to an optimal size. He believed in a germ plasm selection—that is, selection before birth—in order to improve the population genetically without resorting to inhumane practices. In 1904 he founded the journal *Archiv für Rassenkunde und Gesellschaftsbiologie* (a journal in which not only leading biologists published but also some racists), and in 1905 the society for Race Hygiene. Schallmayer, in opposition to Ploetz, rejected racist ideology. He was a physician influenced by the writings of Karl Marx, and a Darwinist. Being deceived by the possibility of curing mental diseases, he adopted a eugenic approach, supported marriage restrictions for the insane, the feebleminded, alcoholics and others, but opposing state legislation for them.

The Society for Race Hygiene was founded in 1905 by Ploetz, the psychiatrists Anastasius Nordenholz (his brother-in-law), Ernst Ruedin (1874–1952), and the ethologist Richard Thurnwald (1869–1954). It was dominated by physicians, and formed local groups in Berlin and in Munich. Among the practical measures it proposed, in 1910, were the establishment of a counterbalance to the state protection of the feebleminded and the weak, the isolation of them, and the imposition of marriage restrictions so that they would not procreate as well as the control of immigration from 'inferior elements.' The German people, it seems were not ready to accept mandatory sterilization. Some eugenicists recommended the creation of work colonies, which were probably precursors of the concentration (labor) camps.

In the face of deterioration of the international climate before World War I, in which France and Russia would be allies against Germany, special emphasis was given to birth polity and the rejection of neo-Malthusian proposals. After the war, the Weimar Republic (1918–33) succeeded the Wilhelmine era. During this period, the same preoccupations continued, namely race hygiene, population degeneration, and its size increase. After the death of Schallmayer and the retirement of Ploetz, Fritz Lenz (1887–1976) played a major role. A physician, influenced by Weismann, and a member of the Munich chapter, he became known as the co-author of a treatise on human genetics and eugenics. He was a racist and a sexist, believing that races had physical characteristics which could change under the influence of natural selection, but most importantly were their spiritual characters, which permitted race valuation. The Aryan race (especially its Nordic or German strand) reached the highest point in his scale. Jews were not considered to be very different from the German Aryans, but this did not prevent him from later collaborating willingly with the Nazis. He considered himself a student of Ploetz. Weismann's influence directed him to adopt non-Lamarckian practices for population improvement. He was conservative politically but also a strong supporter of meritocracy. Ruedin and other members of the Munich branch sympathized with Lenz's views. In general, the Munich branch succeeded in dominating that of Berlin, which was more progressive politically.

Scientific journals and the creation of institutions (research centers, university positions) gave increased status to eugenics. Lenz became professor of race hygiene in Munich in 1923, and Ruedin director of a research institute for psychiatry in Munich in 1931. The Rockefeller Foundation financed the creation of the Kaiser Wilhelm Institute for Anthropology, Human Heredity and Eugenics in Berlin in 1927 headed by Eugen Fischer (1874–1967). Fischer, a docent in anatomy at Freiburg, investigated in 1908 the bastards produced between Boer men and Hottentot women in South Africa and their progeny, and in 1913 published a book about them. He stated that such mixing of blood produced inferior individuals. Later he was considered as the expert on the products of racial mixing. The economic crisis and depression of 1929 put an end to the welfare state by which the Weimar Republic had tried to counter Bolshevism. As a means of alleviation of state charges, the implementation of eugenic measures was considered seriously: the creation of work colonies for the unfit was discussed again and a law on sterilization was drafted. Although there was general support for this law, the 1930 Papal encyclical prevented its enactment. It was implemented in the Nazi period (1933–45), when extreme racist practices were combined with eugenic ones. Despite the fact that racism was not always connected to eugenics, it is clear that compulsory sterilization and euthanasia were measures first proposed by eugenicists, and these constituted the inspiration for mass killings. Actually Nazis, as they characteristically put it, considered these measures to be 'applied biology.' Eugenisists who did not support racist practices (such as Ostermann and Muckermann) were removed from their posts. The Society for Race Hygiene came under state control, Ruedin was appointed as its head and given the authority to have officials and heads of the branches. The membership of the Society was restricted to German Aryans, and excluded Jews. Eugen Fischer was appointed head of the Berlin Institute of Anthropology and in 1933 was named rector of the University of Berlin. Another important figure was Otmar von Verschuer (1896–1969), a human geneticist, who fist occupied the position of head of the human genetics division under Fischer (Lenz occupying that of eugenics). Subsequently, he held a professorship at the University of Frankfurt and finally, in 1942, succeeded Fisher on the latter's retirement. Lenz, who previously regarded Jews as being nearly equal to Germans, kept silent under the Nazis and changed the text of his treatise in a subsequent edition to accord with the partly line. Along with many others, he collaborated willingly with the regime. About one-third of the physicians became members of the Nazi party, and several took

an active part in sterilization and 'euthanasia' projects. Although few scientists were involved directly in such projects (mainly, SS and party members were employed), all seemed to be aware of what was going on. In July 1933 a law permitting mandatory sterilization for the feebleminded was enacted, as well as for those suffering from mental illnesses and other 'hereditary' afflictions. A committee formed by Lenz, Ploetz and Ruedin was the highest expert authority and made the final decision on every case. From 1934 to 1939 (when apparently this practice was discontinued) between 200,000 and 400,000 individuals, probably 350,000, were sterilized without their consent, or even their knowledge. At least 367 women and 70 men died from postsurgical complications after such operations. In 1937, 385 children from German mothers and coloured fathers from among French colonial troops who occupied the Rhineland, were sterilized. In 1938 euthanasia by starvation was practiced in the mental hospital in Helborn. Euthanasia was applied in order not to waste money and valuable work on those designated as 'useless eaters.' About 100,000 individuals were eliminated in this way.

In 1934, several university professors and lawyers helped to draft the Nuremberg laws for the protection of the racial purity of the German race. Marriages and extramarital affairs of Germans with Jews were prohibited. Fischer, at the end of a meeting, thanked Hitler for giving geneticists the opportunity, through these laws, to make the results of their research useful to the general public! A law for euthanasia was drafted by Lenz, but apparently 'euthanasia' was practiced 'secretely' in labor camps for Jews, gypsies, some Slavs, and, of course, homosexuals, and socialists. The Holocaust was planned carefully by Hitler and Himmler. Some physicians experimented on those destined to die, or collected their organs and dispatched them to the Institute in Berlin, among them the well-known Dr Josef Mengele (1911–84), an assistant of von Verschuer at that time. It is estimated that at least 70,000 mental patients, 5–6 million Jews (mostly German, eastern and Balkan Jews) and an unknown number of gypsies, Slavs, and others were gassed. Thus it is not surprising that in Germany, after the war, population genetics was a taboo subject, and until the 1980s only one chair of evolution and population genetics existed (at the University of Tübingen).

4. *Switzerland and the Scandinavian Countries*

Along with some of the states of the USA, Switzerland was of the first countries to pass a law for compulsory sterilization, in 1927. Even as late as the early 1950s, recidivist rapists were given a choice, either to be castrated and go free, or suffer life imprisonment. In the 1930s, influenced by the USA, and especially by Germany, Scandinavian countries passed sterilization laws. Denmark permitted voluntary sterilization in 1929 and extended it to coerce the feebleminded in 1934, Norway legalized sterilization in 1934, Sweden the same year, Finland in 1935, and Iceland in 1938. A Baltic state, Estonia, passed such a law in 1936. These laws should be seen as part of welfare state policies rather than connected with the racial cleansing of Nazi Germany. However, it seems that such laws continued to be implemented well after the end of World War II, and the sterilization was performed without permission or even the knowledge of those being subjected to it. Mental defectives and asocial subjects were treated in the same way. In Denmark between 1929 and 1945 some 3,800 persons were sterilized.

5. *Russia*

Eugenics was introduced from England in 1875. Geneticists and biologists played the major roles, joined by physicians. Two young biologists, Nikolai Konstantinovich Kol'tsov (1892–1940) and Yuri Alexandrovich Filipshenko (1882–1930) were instrumental. After the Revolution and the civil war (1917–22) several opportunities were open to young scientists. Kol'tzov was named professor at the two universities in Moscow, while Filipshenko, a year after his thesis (1917), became professor at Petrograd University and the following year director of the Laboratory of Genetics and Experimental Biology.

Kol'tsov had created a privately funded Institute of Experimental biology in 1916. In a rhetorical declaration he stated that socialism was bound to earthly life and eugenics were an attempt to achieve perfect order in relations between people, thus (following Galton) he claimed it was similar to a religion, giving meaning to life. Using eugenics, he secured from N. Semashko, his friend and Commissar of Public Health, funds for his Institute. Semashko and others adapted German 'social hygiene' to a Soviet-style enterprise. In 1920 Kol'tsov founded the Russian Eugenics Society, which he controlled, since most of its members were his students and collaborators. He was therefore elected as president and served at the society's bureau with two other members, the psychiatrist T. I. Yudin and the anthropologist V. V. Bunak. Bunak, his student the geneticist A. S. Serebrovsky (1892–1948) and M. V. Volotskoi (1893–1944), were all Kol'tsov's protégés. In 1922 the Society started *The Russian Eugenics Journal*. Finally, at the Brussels' meeting in 1922, the Society became a member of the International Commission of Eugenics. Several eugenic societies were created in other cities in the Soviet Union and became affiliated with that in Moscow; one was created by Filipshenko in Petrograd, others in Odessa, Saratov, and Sverdlovsk. Filipshenko approached the Academy of Sciences and established a Bureau of Eugenics under its auspices, to which he appointed his students Diakonov, Lusis, Lepin,

Zuitin, Dob(r)zhansky, Kerkis, and Medvedev. The Bureau issued a *Bulletin* (1921–25); it later became the Bureau of Genetics and Eugenics (1925–27).

Since both Filipshenko and Kol'tsov were adepts in Mendelian and later in Morgan's genetics, eugenics in Russia had close links to classical genetics. In the mid 1920s Pavlov, a well known Lamarckian, was convinced by Kol'tsov and his wife that his data could be better interpreted by Mendelian genetics. This was a major victory for genetics in Russia. The research agenda of eugenics was to establish genealogies of talented individuals; the investigation of the heredity of criminality, alcoholism, schizophrenia, and manic depression, as well as of several bodily abnormalities and malfunctions (goiter, hernia). It also included demographic and statistical inquiries in general population studies.

In an attempt to provide a local origin to eugenics, Russians attributed it to the neglected writer, Florinsky. Subsequently they tried to render it 'socialist' or 'Bolshevik' to differentiate it from 'bourgeois' or 'capitalist' eugenics. With this attempt, Russian geneticists tried to protect their field from persecution and to secure state funds. To label eugenics as a scientific religion or an international movement did not help much; they should have presented material results in public health, or expectations of beneficial results. Young scientists devoted to Marxism and having an influence on the party helped in this respect. One of them, M. V. Volotskoi, became secretary of the Moscow society, another was A. S. Serebrovsky. In 1923 Volotskoi proposed a negative eugenic measure: sterilization of defective individuals. Vasectomy was used widely in the USA, as it was easily performed and was not a castration. In women, salpingectomy was a more complicated operation. This proposal met with heavy criticism, formulated by Filipshenko, and was finally rejected on moral grounds and because during those years the USSR witnessed an important population implosion due to the wars and famine. Deaths exceeded births. In one of the eugenic societies a proposal was approved also to eliminate abortions.

Supporters of Lamarckism were numerous in Russia, especially among those following the party line. Inheritance of acquired characters was thought to fit with Marxism and permit the improvement of society through concrete social actions. The Viennese biologist and strong supporter of this kind of inheritance, Paul Kammerer, was considered a hero, his books were translated and circulated widely, and the Communist Academy invited him to head a laboratory. His suicide was presented as part of a capitalist plot. Volotskoi originally supported Lamarckism. A physician, Soloman G. Levit (1884–1938) joined Volotskoi in this. Filipshenko, in the same year (1925), by himself and together with H. J. Muller criticized Lamarckism and demonstrated that it was scientifically unacceptable. He pointed out (as did Haldane in England) that if Lamarckism was right, proletarians were at a great disadvantage, bearing the unfavourable influences of generations of slavery. Serebrovsky tried to reconcile the negative attitude towards eugenics with this confrontation. He argued that, while genetics was a science, eugenics was a social enterprise influenced by the ideology of the class of its supporters; therefore each class created its own eugenics, but, whatever the case might be, bourgeois or socialist eugenics, it should be based on the objective science of genetics. Thus Serebrovsky distinguished '*antropogenetika*,' human genetics (*anthropos* means '*man*' in Greek), a scientific field, from eugenics, which was not a science. In 1927 the American geneticist, H. J. Muller, student of Morgan and a communist, demonstrated that irradiation by X-rays was mutagenic. This implied that genetic traits could be changed by an environmental agent and be manipulated for eugenic purposes (at that time it was not known that most of the mutations are harmful). This helped the conversion of Levit to Mendelism under the influence of his fellow Marxist, Serebrovsky. Serebrovsky made a new proposal in 1928, to provide a Bolshevik form of eugenics, the use of genetically recommended sperm in artificial inseminations to produce a great number of children. He remarked that 'one talented and viable producer could have up to 1,000 children' and 'that various women would be proud of the successes and achievements in this … production of new human beings.' Serebrovsky had worked in a zootechnical station on a project for amelioration of poultry and was aware of the technique, devised by Ilia I. Ivanov (1870–1932), for the artificial insemination of sheep, cows, and eventually of poultry. Serebrovsky's *antropotechnika* was obviously inspired from *zootechnika*. Vacher de Lapouge in France had proposed a similar measure in 1896, and later Muller, inspired by Serebrovsky, also proposed the eugenic use of artificial insemination. It was positive eugenics: the dissemination of valuable inherited traits. The proposal met with satirical comments.

The beginning of the Stalinist era (1929–32) with its great purges and the Bolshevization of the Academy of Sciences marked the end of the eugenics movement. In Leningrad, Filipshenko withdrew his interest in the movement from the mid-1920s and in 1930 he was relieved of his university duties and his department was disbanded. He died suddenly in the same year, from meningitis. In 1930, the Russian Eugenics Society was disbanded and its journal suspended. The Eugenics Section of the Kol'tsov Institute was abolished. Filipshenko's successor, N. I. Vavilov, the well-known plant geneticist, and a student of Bateson, regrouped the geneticists that were left, together with plant specialists. Technocrats were suspected of having bourgeois influences; a new generation of Marxists, especially those having a proletarian background, replaced them. Kol'tsov, in anticipation of difficulties to come, made some changes: He turned to medical genetics and included Marxists on his staff. His

Institute had two important groups, one headed by Serebrovsky, another by S. S. Chetverikov. Serebrovsky left the Institute in 1927, and Chetverikov was arrested and sent to exile in 1929. In 1930, Kol'tsov was removed from his teaching duties; and his department was disbanded and replaced by a Genetics Department headed by Serebrovsky. In 1933, Kol'tsov re-established his genetics division by bringing in a new geneticist of proletarian origin, N. Dubinin. In 1928, Kol'tsov created a Society for the Study of Racial Pathology and the Geographical Distribution of Diseases and became its president. From the beginning of the 1930s, eugenics was no longer considered a legitimate field, therefore former eugenic researchers moved to medical research.

Levit became director of the Biomedical Institute in 1930. He was working at this Institute from 1928 and had established an Office of Human Heredity and Constitution. In 1930–1, on Rockefeller Fellowships, Levit and Agol worked in Muller's laboratory in Texas. On his return, Levit continued to work at the Institute, and in 1934, at a conference alongside Muller, Kol'tsov and others, an expansion of medical genetics, was called for. In 1935, the Institute was renamed the Maxim Gorky Research Institute of Medical Genetics, and A. R. Luria headed its psychology division. Muller, a convinced communist, visited Russia for the first time in 1922, and returned in 1932. During his first stay he advanced genetic studies, bringing with him *Drosophila* cultures, and visiting Kol'tsov Institute and Serebrovsky's poultry station. Muller was interested in eugenics from 1910. In 1932 he accepted an offer from Vavilov to head a laboratory in Leningrad. In 1935 he published his book *Out of the Night: A Biologist's View of the Future*, where he expounded his eugenics views and the artificial fertilization programme. It seems that he arrived in the USSR in order to implement his eugenics programme. In 1936, he sent Stalin a copy of his book and a letter supporting his plan, arguing that eugenics would ensure the triumph of socialism. This letter had extremely negative consequences. A student of Muller's was arrested. The speakers at a session of the Lenin All-Union Academy of Agricultural Sciences, Vavilov, Serebrovsky and Muller defended genetics. Muller did not follow the advice he was given, to avoid mentioning human genetics. At this meeting Serebrovsky was heavily attacked by Lysenkoists. It seems that Stalin had read the transcription of Muller's talk and disliked it. Muller had to leave Russia for fear of being arrested too. After that, a Kol'tsov student, N. K. Beliaev, was arrested and shot. The translator of Muller's book into Russian was also shot, while Levit lost his position as director of the Gorky Institute, was arrested in 1938 and executed. In 1938, Kol'tsov was removed from his position and died in 1940 from a heart attack. The next day, his wife committed suicide. In 1938 Lysenko was elected as a member of the Academy of Sciences (the charges against Kol'tsov were formulated to secure the election of Lysenko, Kol'tsov also being a candidate for the same position) and the Soviet government and party gave him full support from 1940 to 1965. In 1940, Vavilov was arrested, along with his close friends and colleagues, G. D. Karpeshenko and G. A. Levitsky. All died in prison during the war (1942–3). During this quarter century, genetics became an illegal topic, but it did survive in a few centers which Lysenko could not control. It reappeared after Lysenkoism was repudiated in 1965; but not the eugenics movement, which the Nazis atrocities had thoroughly disqualified.

Europe, Archaeology of

European archaeology is the study of the material culture left by inhabitants of the European continent anywhere from three million years ago until the beginning of the Middle Ages. These people were as mixed ethnically as they were culturally and made their homes in Europe's diverse microregions and microclimatic zones. In their wake, they left a large legacy of material traces and it is from these traces that archaeologists can reconstruct the complex patterns of their lives. As a science, European archaeology got its start during the Renaissance, when the classical world was rediscovered. But it was not until the end of the nineteenth century, when typology, classification, systematic excavation, and relative chronology emerged, that archaeology became an academic discipline. By the twentieth century, European archaeology's major tenets had been established as had conflicting schools of archaeological thought (see archaeological theory). When the Iron Curtain fell in 1989, European archaeology experienced a new rupture. Terrain that was once impenetrable and colleagues and research that for decades had been unreachable suddenly became available. This exchange has both incited rich dialogue and stirred stimulating controversy. Spectacular recent finds such as the Iceman in the Austrian Alps and technological advances such as the ability to analyze prehistoric DNA are revolutionizing archaeology and promise to bring exciting new breakthroughs in the twenty-first century.

This article is divided into five parts, each of which outlines the major chronological and cultural shifts in European pre- and protohistory. Also included are major finds that significantly altered or enriched knowledge of the past.

1. *Europe's Origins—the Paleolithic and the Mesolithic*

The first European hominids belonged to the group *Homo erectus* and migrated from Africa about 1.8 million years ago. Cyclical changes in ice sheets caused them to move frequently. Archaeologically, this period, the oldest in hominid history, is known as the Lower Paleolithic. The second period, the Middle Paleolithic, occurred when *Homo erectus* was replaced by *Homo sapiens neanderthalensis* about 130,000 years ago. Unlike their ancestors, these new hominids buried their dead. Several Neanderthal graves have been found with grave goods, indicating that these hominids had some sort of belief system with notions of an after-life. The Neanderthals hunted, gathered, and scavenged.

The Middle Paleolithic ended when *Homo sapiens neanderthalensis* were rapidly replaced by *Homo sapiens sapiens*, the first modern humans. *Homo sapiens sapiens*, whose anatomic structure is the same as ours, emerged in Europe around 40,000 years ago, and soon spread throughout the continent. Their movement was probably facilitated by the steady disappearance of the ice sheet and marks the beginning of the Upper Paleolithic. During this time, stone technology advanced and archaeologists have identified four varieties of flint tools which they believe represent distinct societies of hunter–gatherers. They are: Aurignacian, Gravettian, Solutrean, and Magdalenian. Cave paintings found at Upper Paleolithic sites offer proof of artistic activity and the ability of *Homo sapiens sapiens* to think symbolically. The paintings mainly depict animals, however abstract patterns of lines and squares are also present. Two sites—Altamira in northern Spain and Lascaux and Cosquer in southern France dating from c. 30,000 BC—offer particularly vivid examples. Equally elaborate are the carved female figurines depicted with exaggerated breasts, stomachs, buttocks, and thighs. They have been found all over Europe, the best example being the Venus of Willendorf.

The Mesolithic is the first period of the Holocene and comes at the end of the Ice Age. Its chronology varies according to region, but it dates from about 10,000–5,000 BC. As the ice sheet disappeared, hunter–gatherers began to inhabit forest land and open tundra that had earlier been unlivable. Warmer temperatures also stimulated great changes in fauna. Mammoths became extinct, reindeer moved north and were replaced by forest-dwelling creatures like red deer, roe deer, and wild boar. In a few regions, a complex settlement and economic pattern emerged which involved a base camp and a number of small, specialized activity camps. In some cases, like in Ertebölle, coastal resources were exploited, while in Star Carr, hunting red deer, roe deer, and aurochs became a specialized task. At Lepenski Vir, located at the Iron Gate of the Danube Gorge, finely worked flint objects, rounded stone sculptures, and trapezoid houses demonstrate the aesthetics of these hunter–gatherers. Overall, the Mesolithic is characterized by an ability to adapt to and exploit diverse environmental climates for personal gain. It is marked by a series of technological innovations, most notably the microlithization of flint tools. These tools were used as projectile points and as components in other tools. In some regions, such as southern Scandinavia and the eastern part of the Baltic Sea, a hunting and gathering economy continued long after farming was introduced in Europe.

2. *The Emergence of Farming and Social Complexity: The Neolithic and the Copper Age*

The Neolithic is often identified by the appearance of domestic animals and crops. This huge change revolu-

tionized European history. It is accompanied by an increase in the size and complexity of settlements as well as the use of pottery and polished stone tools, and in some regions, the erection of elaborate monuments. During the Neolithic, people began to view the world in a whole new way. Farming revolutionized ways of life and subsistence. The human diet shifted from an almost total dependence on wild animals to a diet based primarily on cereals and domesticated animals. Sedentary life had demographic consequences and as populations increased, society became more complex and stratified.

Early Neolithic communities came to Europe from the Near East and Anatolia around 7,000 BC, and first settled in the southeastern part of the continent in Greece and the Balkans. As in Anatolia, subsistence was based on emmer, wheat, sheep, goats, pigs and cattle. Farmers inhabited open settlements and lived in free-standing, rectangular houses. Some settlements were inhabited for long periods and the constant building and rebuilding led to the emergence of large settlement mounds (tells). From these southeastern settlements, Neolithic communities dispersed across Europe. The movement went in two general directions: To the north and north-west and to the west along the Mediterranean coast. The process of colonization varied tremendously, as did the adoption of domesticates. In southern Scandinavia and the British Isles, for example, it occurred around 4,000 BC, while in central Germany, it occurred about 1,300 years earlier. The western route of Neolithic colonization led along the Mediterranean coast to southern Iberia and southern France, both of which were colonized around 5,500 BC. These routes have been identified closely with the spread of Impressed Ware Pottery. From the Mediterranean, domestication and farming moved northward along the Atlantic coast into the Parisian Basin. Here, the southern route met the northern route. This route, which followed the Danube through Central Europe, is associated with Linear Pottery and showed advances in the use of long-houses, incised decorated pottery and the shoe-last adze for clearing forests. By 5,300 BC, the Neolithization of continental Europe was complete. The most significant pottery emerged from the Chasseen culture in France, the Michelsberg culture between the Rhine delta and the Alps and the Trichterbecher culture in northern and eastern Europe. Along the Atlantic coast, from Portugal in the south, the Orkney Isles and Scandinavia in the north, and Poland in the east, large megaliths in the form of standing stones, stone circles, henges, and cursus monuments have been found. During the fifth millennium BC, copper metallurgy was introduced into southeastern Europe, specifically in the Balkans and the Carpathian Basin. This period, which lasted from 4,500 to 2,500 BC, is hence known as the Copper Age.

Economic changes such as the introduction of the wheel and plow, wool production, and the increased use of animals for specialized tasks occurred. Together, this is known as the Secondary Product Revolution. At this time, more emphasis was placed on creating cemeteries than on erecting domestic structures. Cemeteries were a means of establishing group identity and instilling a sense of belonging. A spectacular example of this is in Varna on the Black Sea coast of Bulgaria. Here, individual graves featured sophisticated gold and copper work. By 3,000 BC, the explosion of new innovations ruptured traditional lifestyles across the continent and change occurred rapidly. As wealth became portable, emphasis shifted from places to people and from collective to personal possessions. A symbol of this change is Corded Ware pottery, which is decorated with impressed cords. Such pottery has been found in male graves located under circular mounds across Northern and Central Europe.

In addition to the pottery, men were found in single graves accompanied by stone battleaxes. This has both been interpreted as a sign of the importance of fighting and drinking and of individualization within a stratified society. A second type of pottery, handless drinking-cups know as Bell-Beakers, appeared concurrently and slightly later in the expansive area from Scotland to Sicily and Spain to Central Europe. Graves were flat graves and in some regions also individual round mounds and, along with Bell-Beakers, contained daggers and archery equipment such as triangular barbed-flint arrowheads and wrist guards of fine stone. The vast distribution of the Bell-Beakers across temperate Europe and the Mediterranean indicates an increasingly mobile lifestyle that arrived just as traditional social structures disintegrated.

3. *The Emergence of Elites: The Bronze Age*

During the second millennium BC, bronze became the universal medium of ordinary objects and also of prestige. Horses and wheeled vehicles, textiles, amber necklaces, and metal dress-pins for clipping wool clothing emerged as visible signs of wealth. Trade in bronze expanded and bronze became popular for manufacturing weapons, ornaments and tools. Most importantly, metallurgy shifted as copper became regularly alloyed and tin began to replace arsenic. Although copper is relatively rare as a naturally occurring material, tin is even rarer and the creation and circulation of bronze objects depended on regular supplies of both. This led to the rise of leading centers of metalwork, each of which made technical advances in bronze casting that were widely diffused and adopted. As techniques of war changed, so did the types of weapons used. New bronze weapons and designs spread across the continent.

In Central Europe, in a region known as the Carpathian Basin, where the Únětice culture flourished, large hoards of bronze objects and magnificent burial mounds filled with gold and bronze objects have been uncovered. The influence of these communities stretched from Denmark to Italy to Greece, and to some degree, the British Isles. In the western Mediterranean, similar developments around 2,200 BC spawned the establishment of new centers along the coast of the Iberian Peninsular. Here, hilltop settlements containing rectangular houses and streets were surrounded by stone walls. These settlements lasted throughout the second millennium and are called El Agrar. The proximity of urban cultures in the Eastern Mediterranean also provided alternative centers of trade and exposure to novel eating and drinking habits, clothing, furniture, means of transport, prestige ornaments, and weaponry.

Demand for bronze by the populations of the northpontic steppes spurred trade and soon communication and exchange networks were established. North of the Caspian Sea, new grave architecture that included timber-built underground chambers known as Timber Grave culture was found. Eastward, the closely-related Andronovo culture perfected the use of horses and created a horse-driven chariot complete with a bridle-bit with spiked cheek pieces made of antler. At the timber-grave cemetery of Sintashta in the southern Urals, shaft graves similar to those of Mycenae were found containing wheeled chariots and horses.

When the palatial societies of the eastern Mediterranean collapsed after 1,300 BC, dramatic changes swept across Europe. This period is known as the late Bronze Age and is characterized by hill-forts, flat cemeteries, scrap hoards, and votive finds from rivers. The most striking sign of the changes is the almost-universal shift from burying the dead in graves to cremating them and putting their ashes in pits or funerary urns. The period lasts until c. 800 BC and has been named the 'Urnfield Period.' It is a transitory time, a phase in between the Bronze and the Iron Age, in which economic, social, military, and religious changes that are of pivotal importance in the formation of historic Europe occurred. For the first time, swords, spearheads, armor, safety pins, and certain ornaments from central and northern Europe appeared in the Mediterranean. Hilltop forts and stockades on lower ground became popular around 1,100 BC and lasted until c. 550 BC. At Biskupin, near Bydogszcz in Poland, a fortified settlement island with thirteen parallel rows of houses divided by roads and encircled by a rampart were excavated. The layout resonates communal order and indicates the presence of a coercive power. Throughout the period, exchange networks allowed goods to travel over vast distances and for the first time salt from the Austrian Alps and other places emerged as a valuable trade commodity. Hallstatt, the richest cemetery of the period, sits on top of a salt mine. Spiritual life also took on great importance and the bird became a beloved symbol. Figurines in the shape of birds have been found, as have numerous pots, cauldrons, and cult wagons with bird applications. Numerous rock carvings with engravings of humans, animals, boats and a variety of symbols were found in Sweden (Tanum), the Alps at Val Camonica north of Brescia, and on Monte Bego near Bordighera. The abundance of swords, daggers, spearheads, arrowheads, and armor found indicate the importance of war and the extensive choices available to the warrior.

4. From Chieftain to 'State' Organization in Celtic Europe: The Iron Age

By 600 BC, iron became the standard material for tools and weapons, while bronze was used for high quality art products. The explosion of trading ports around the Mediterranean provided a strong incentive for European development. Mediterranean goods were sought avidly and the most valuable ones were acquired by the wealthy as proof of their exalted status. The valleys of the Rhone and Saône provided easy access to the region from Burgundy to southern Germany. This west Hallstatt zone was pivotal as it spanned the upper courses of the Seine, Saône, Rhine, and Danube rivers and directly linked the continent north of the Alps. Greek-led trade intensified through the colony of Massalia in the sixth century and the elite in this northern zone controlled trade of exotic Mediterranean products, including prestige equipment for wine-drinking rituals of the Greek symposium. Large valuables, such as the human-sized bronze crater from Vix, were imported and were exchanged for local products and slaves. The native elite maintained full control of these exchanges and likely held lavish feasts and gift exchanges among important chieftains, including the famous chief from Hochdorf. At graves, social prestige was demonstrated by the inclusion of costly sets of wine-drinking equipment and other exotic gear with the dead. Funerary rituals took place in large-scale religious structures surrounding burial mounds. At Glauberg in Hessen, a kilometer-long ceremonial path leading to a grave from the early La Tène period was recently discovered. Hilltops also emerged as prime locations for defended residences for the nobility. At Mount Lassois in Burgundy and at the Heuneburg in Germany, huge quantities of Mediterranean luxury goods were found. The Heuneburg was surrounded by a mud-brick wall built on dry stone footings with forward-projecting rectangular bastions. This technique, common enough in the Greek world, was totally alien to temperate Europe, and is a striking example of how avidly the European elite adopted Mediterranean achievements, even when they were impractical for the

climate. In the east, in Slovenia, a second group of less wealthy communities known as the east Hallstatt zone arose from the eighth to the fifth centuries. They were characterized by fortified settlements such as Magdalenska Gora, Vače, and Stična and large cemeteries with aristocratic graves furnished with sheet bronze body armor and decorated situlae.

The rise of a new warrior elite and the drying up of the market for luxury goods in the early fifth century destabilized the east and west Hallstatt systems and by the middle of the fifth century caused their demise. A new, northern elite arose and relied on native craftsmen to produce luxury goods. Numerous late fifth century elite tombs have been found containing locally-made masterpieces of Celtic-style art. Schools of creative metalworkers emerged during this period and their work led to the creation of the first truly Pan-European art style, known as Celtic or La Tène art. A rapid population increase, evident in the growth in the number of cemeteries, ensued and shook the social equilibrium. Over time, the system collapsed and resulted in a widespread migration. Late fifth- and early fourth-century cemeteries which extend south into the Po Valley and east along the Danube into Hungary trace the path of this migration. Some early groups also crossed the great Hungarian plains and settled in Transylvania. In the Marne–Moselle region, elite burials continued at Somme-Bionne, Reinheim, and Waldalgesheim. But overall, the number of cemeteries decreased, indicating migration. In the tombs, young men were usually found accompanied by spears, swords and shields. Wealthier men had bronze helmets and some possessed two-wheeled chariots. It is these warriors, called 'Gauls' or 'Celts,' who, in tens of thousands, made their way across Europe seeking new lands to conquer and settlements to plunder. The Celtic migrations between 450 to 200 BC can be traced archaeologically across Europe through the La Tène culture, which is characterized by art depicting mobility, upheaval, and turbulence.

The northern limit of La Tène culture lay at the mouth of the Rhine and across southern Germany and northern Italy to the Carpathians. Further east, the Celts were well-established in the lower Danube region. In the early fourth century, they began moving eastward into Transylvania and in the third century they pushed into southern Thrace and Greece. In the north-east, Celtic groups crossed the Prut and Dnestr, exploiting the power vacuum left by the decline of the Scythians. One of the few surviving pieces of silver made during the disrupted Celtic period is the Gundestrup cauldron found in Jutland. The puzzle of this elaborate cauldron encapsulates the complexity of these migrations. The techniques used to make it are typically Augustian Thracian. Some of the figures on it, such as a warrior wearing a bird-crested helmet look Celtic, while other motifs are reminiscent of steppe shamanism. The cauldron was probably carried north as booty by raiding Germans.

5. *Center and Periphery: Barbarian Europe and the Roman Empire*

For Rome, the Rhine River marked an ethnic divide between the Celts to the south and the Germans to the north. In reality, tribes on both sides of the river had integrated to such a degree that few ethnic differences existed. Wealth derived from constant access to particularly fertile land and did not build up in the hands of any single group. Status could, however, be acquired by acts of bravery and leadership in raids. Power at this time lay with the elite and was measured by entourage and the ability to bestow patronage. The elites formed the tribal council. Caesar overran Gaul fairly easily because the Gauls were a settled people with a well-developed agricultural base and tribes centrally located on permanent defended settlements known as oppida. Oppida were the first urban centers in temperate Europe and have been found from France to Serbia. At Manching in southern Germany, the settlement was densely built up with regularly laid out timber buildings aligned along straight, ordered streets. A wide range of craft skills were practiced and coins were minted. Commodities such as wheel-turned pottery, glass beads, bracelets, and ironwork of every kind was done on an industrial scale. In oppida like Bibracte, cargoes of wine amphorae were exchanged with the local aristocracy for slaves and other commodities. This stability made Gaulish society soft and vulnerable. Germans were the opposite. Mobility and warfare were central to their lives and they had few southern luxuries. Since they had no oppida to protect, they could simply retreat and disappear. The Roman Empire desperately needed a continuous supply of raw materials and manpower. As its frontiers continued to expand, valuable metals and other commodities arrived. Rome's greatest dependence lay in its need for slaves to keep the Roman system working. The scale of the slave trade was enormous. Judging from the distribution maps of artifacts in Free Germania, Romans traded coins extensively, but also traded sets of metal vessels used for wine-drinking rituals, buckets, situlae, and jugs. In this zone, a number of rich burial sites known as Lübsow were found. The graves contained extraordinary luxury goods, indicating that the dead were members of the elite, who, by virtue of their rank, were able to acquire a set of the most costly Roman items. Such local elite served as middle men between the Roman world and the Baltic region. This system of socioeconomic zones continued until the middle of the second century AD, when population expansion, social instability, and folk movements in Central Europe built up and pressured tribes along the frontier. They then threatened the stability of the Empire. The territory occupied by the warrior burials coincides with the region from which the Burgundians and Vandals are thought to have emerged. The first recorded indications of the growing problem came in AD 162 when a frontier tribe, the

Chatti, attempted to migrate south into Roman territory. A few years later, the Longobardi and Marcomanni crossed the Danube into transdanubian Hungary. This was followed by even more massive movements by other tribes. These events, and the Marcomannic War fought by Rome between 166 and 180 AD, mark the beginning of a wave of migrations which within three centuries destroyed the Empire and laid the groundwork for the formation of medieval Europe.

Europe: Sociocultural Aspects

1. The Term 'Europe'

In ancient Greece, the term Europe evoked legendary or divine characters from the mythological universe, rather than a geographic site. The Greek geographer Strabo (58 BC–AD 25), who lived under the Roman emperors Augustus and Tiberius, gave the first detailed description of the favorable climatic and natural conditions in which European populations lived. Strabo contended that these populations were intellectually superior to those of other continents. The Roman Empire however was never particularly Eurocentric. In those days, it was seen as a tricontinental entity, socially and culturally composite, whose hub was the Mediterranean, which the Latin knew as 'Mare Nostrum.'

The term Europe took on a more political and sociocultural connotation during the Carolingian period (seventh to eighth centuries). According to a medieval anonymous chronicle, the soldiers led by Charles Martel who fought victoriously against the Arabs at Poitiers (732) were 'European.' At this time, the notion of Europe was assimilated with the Frankish Kingdom, and the idea of Europe as a political-spiritual entity developed along with the expansion of Arab–Muslim settlements north of the Strait of Gibraltar.

One of the recurrent themes of various subsequent concepts of Europe as an 'imagined community' (Anderson 1983) can be identified *in statu nascendi* from the latter observation. They are characterized almost without exception by a scheme in which the notion of Europe appears together with another contrastive term. In most cases, it is a dichotomy or bipolarity, rather than a comparison between what Europe is reckoned to be and what is supposedly its opposite. This 'European self-awareness,' as de Rougemont (1990) calls it, becomes even more tangible at the time of geographical discoveries and the first colonial conquests.

From an anthropological point of view, Europe discovers itself by discovering and conquering the rest of the world. Between 'Europe' and 'Anti-Europe,' which from time to time could be Arab–Muslim culture or Asia, Africa, or the Orient, there is a reflective relationship in which the former identifies its basic traits through a presumed diametrical difference with the latter. Balthazar Gracian (1601–1658) coins the famous phrase 'Europe is the admirable face of the world.' Following the same train of thought, the *Grand Dictionnaire historique de Louis de Moreri* (published in 1674) illustrates the European traits that have allowed them to overpower the people of other continents. It is quite surprising to read statements in this publication that seem to foreshadow the stereotypes of German 'Völkerpsychologie,' as well as American studies on 'modal personality' and 'national character.' Similar arguments were expressed more briefly and clearly by Carl von Linné (1707–1778); the Swedish naturalist describes the 'Homo Europaeus' as 'subtle' and 'creative' while Asians are 'melancholic' and 'miserly' and Africans are 'sly' and 'lazy.'

During the *ère des philosophes*, almost all the eighteenth century's great thinkers—Montesquieu, Voltaire, Jean-Jacques Rousseau, Ferdinando Galiani, Melchior-Gaspar de Jovellanos, Antoine de Condorcet, Edward Gibbon, Edmund Burke—pondered over a 'European peculiarity.' Their dissertations share a common denominator: a scheme, usually bipolar, in which at least one other term of comparison appears besides Europe. Thus, the main question for most of the above-mentioned authors is: how is it that European nations are the only ones that have reached such levels of civilization, while the

'other' societies are still savage, primitive, or barbarian? Leaving aside the answers, almost all eighteenth century texts on Europe draw either implicit or explicit parallels and hierarchies between 'us' and 'them,' between 'Europe' and 'Anti-Europe.'

During the nineteenth century, the notion of Europe took on an increasingly hegemonic connotation. The century was characterized by a bold optimism that turned out to be an awful self-deception. In historical terms, European 'élites' surprisingly had underestimated the changes that had been going on beyond their continent. They had overlooked that there had been the American 'Great Transformation,' or the Japanese development model spurred by the emperor Mutsuhito (1852–1912), who had opened his country to foreign commerce. It is no surprise that the term Europe was being increasingly used as a synonym of 'civilization' and 'progress' (Schmitt 1974). From a European point of view, the Old Continent was the only one that could establish a 'civilizing movement' to 'break through the darkness that enfolds whole populations' as Leopold II (1835–1909), King of the Belgians, stated in a solemn speech in 1876. For this typical representative of the time, European colonial expansion in the heart of the 'Anti-Europe' at that moment, namely Africa, was 'a crusade worthy of this century of progress.'

Nineteenth-century certainties were curtailed radically by the World War I, which the German philosopher Karl Löwith (1897–1973) keenly called 'the first European civil war' (Löwith 1990); by the critical analysis of the nationalistic and totalitarian frenzy between the two World Wars; by World War II traumas; and finally by the melancholic awareness of crumbling colonial empires. Europe as a nation became less triumphalist and much more defensive. After 1945, Europe was perceived as suffering from a chronic economic, cultural, and above all political and military fragility. This intrinsic deficiency could be checked only by a strong synergy between all the continent's components sharing the same fate. In this respect, the French sociologist Edyan Morin (1987) has fittingly spoken about Europe as a '*Schicksalsgemeinschaft*,' a term first used by the Austro-Marxist theorist Otto Bauer (1881–1938). From a sociological point of view, the 'European fragility' concept implies a 'menace' coming from external hostile forces. Each community, especially if it is a '*Schicksalsgemeinschaft*,' is strengthened or crystallized if under pressure from an actual or presumed enemy. The part of Europe that after the World War II was not under Soviet control always reverted to the 'Anti-Europe' theme to emphasize who the 'menace' was. From 1945 until 1989, while Europe was establishing its first joint institutions, the leading 'Anti-Europe' 'menace' was the Soviet and communist sphere.

The fall of the Berlin Wall (1989) and the subsequent disintegration of the opposing blocs coincided with the birth of a new European institution, the European Union (EU). A 'fragile' and 'menaced' Europe is still a common perception on the Old Continent despite this new highly specialized and official legal apparatus. Behind this defensive attitude some authoritative, though overly severe, 'Euro-skeptic' critics detect the danger of the creation of a 'European fortress' that wishes only to defend an acquired economic standing threatened by supposed external 'menaces.' At the end of the twentieth century, the bipolarity between 'Europe' and 'Anti-Europe' still exists. Now 'Anti-Europe' is mainly the planet's boundless south: its migratory waves towards the Old Continent, its high demographic rates, and political-religious conflicts.

2. *What Europe is Not: Some Misleading and Dangerous Ideas*

During the twentieth century, notions of Europe with powerful ideological implications have been spread occasionally; yet, they can hardly endure historical, sociological, and anthropological analysis. The idea of 'European civilization' as a 'monolithic' entity was most popular and politically relevant. 'European civilization' was seen as the bulwark of Christianity. This concept of Europe was an ideological backbone of antidemocratic political movements. Although under many aspects admittedly in conflict with Christian doctrine and ecclesiastic institutions, German Nazism and Italian Fascism envisioned themselves as the upholders of 'European civilization' and strenuous paladins of 'Christianity' particularly against Soviet Bolshevism, which was stigmatized as 'Asian,' hence 'alien' to Europe. Other regimes with similar ideological backgrounds, such as authoritarian and dictatorial governments and movements in Central and East European countries as well as Francoism in Spain and Salazarism in Portugal, resorted to analogous ideas.

Europe as a 'united civilization' embodied in the 'Christian Occident' is an idea that can still be traced in present-day European extreme rightists, such as the French *Front National* and neo-Nazi and neo-Fascist fringes in Germany, Austria, and Italy. These movements resort to similar concepts to assert their hostility towards immigration, especially from Islamic and/or non-European countries. It is a dangerous idea, since it implies the pursuit of cultural, denominational, and maybe even ethnic homogeneity based upon the 'exclusion strategy' and the 'purity myth,' which caused so many of Europe's tragedies during the twentieth century. This vision of Europe is misleading since it is far from the continent's past as well as present social realities.

3. *Europe: A System of 'Historical Regions'*

The German philosopher Ernst Bloch (1885–1977) advises us not to turn a highly differentiated social

entity as Europe into a sum of 'cultural areas' because this would turn 'History…into a circus (with) three or more (separate) rings' (Bloch 1985). Europe must be considered a system of strictly (inter)dependent yet structurally diverse 'historical regions.' Hungarian historian Szücs (1983) was the first one to apply a strictly scientific method to the problem of Europe's internal frontiers, to pose the question of its historical divisions, and consequently of its sociostructural differences.

Szücs stresses that from the early Middle Ages, Europe began to differentiate socioeconomically giving rise to two different poles: '*Europa occidentalis*' and '*Europa orientalis*.' The border could be a line running from the Elbe River (socioeconomic boundary line between western and eastern Germany) to the Leitha River (for many centuries a previous frontier between Austria and Hungary). A second economic and sociostructural division, which includes all societies involved in the Great Schism (1054), came to pass between the eleventh and fourteenth century. Thus, there are three 'historical regions' with very diverse socioeconomic, political, and cultural characteristics. The first one includes the territory from the Atlantic to the above-mentioned Elbe–Leitha ideal line: more or less Carolingian Europe, today believed to be the quintessence of Western Europe. The central 'historical region' east of the Elbe–Leitha line but west of the eastern and southern borders of the original kingdoms of Hungary and Poland (Grand Duchy of Lithuania included) approximately overlaps with what is known today as mid-Eastern Europe, also called *Mitteleuropa*. Everything east of the Baltic–Black Sea line or south of the Carpathians is East Europe proper.

Szücs' arguments are relevant for the social sciences because they reveal how processes dating back to a remote past have created enduring economic, sociostructural, and cultural differences in Europe; however, his hypothesis of at least three 'historical regions' must be broadened and specified. It is useful to add Wallerstein's analysis of Europe incorporated in the 'world- system,' yet divided into 'core' and peripheries' (Wallerstein 1974). A new system to organize and manage the economy arose and spread between 1450 and 1640. Max Weber labeled this new system rational capitalism. According to Wallerstein (1974), as well as to the French historian Braudel (1979) amongst others, expansionist movements are inherent to this new model of economic and social behavior. The capitalist economy's worldwide expansion implies new relationships between economic partners, that is, societies, states, regions, towns, etc. These new relationships entail a new international division of labor that will permeate social structures and cultural models of all the societies involved.

The international division of labor within the 'world-system' is also based on a systematic separation between core and peripheries. Europe at first, and then the whole world, came to be divided into a number of regions. Some of these underwent a historical acceleration, quickly modernizing most of their socioeconomic structure, while others suffered centuries of socioeconomic stagnation if not growing impoverishment. The following classification highlights roles of Europe's 'historical regions' within the new international division of labor.

3.1 Northwestern Europe

The first core of the 'world-system' ensued from this region. Steady decline of the feudal system, early establishment of an extended net of self-governing towns (*freie Reichstädte*, *comuni*, etc.), striking capital accumulation followed by important technological changes culminating in the 'industrial revolution,' the rise of strong territorial states with more culturally homogeneous populations, colonial expansion outside Europe: these are only some of the most evident processes marking the socioeconomic and cultural structure of this 'historical region.' From the onset, it included southern England, France, Flanders, Holland, and the westernmost part of Germany. Northern Spain and Northern Italy, other areas of Germany and most of Switzerland, Austria, Bohemia, and Scandinavia joined the core in subsequent periods.

3.2 Mediterranean Europe

This 'historical region,' for centuries the continent's socioeconomic and cultural hub, was turned into a vast periphery by the new international division of labor. It provided the core with foodstuffs and raw materials for the growing textile industry. From a socioeconomic point of view, the area comprising Portugal, Spain, and Italy was ruled by a system of latifundistic wheat monoculture and/or stock-farming with an absentee owner aristocracy. The vast properties were administered by large tenants who sublet to smaller ones, who in turn would sublease to the smallest peasants. This long renting-chain led to a devastating fragmentation. Too many people without a productive activity lived exclusively off the land and the backs of those who actually tilled it.

Even though the banking system, rational capitalism's pillar, was developed in Renaissance Italy, and the two Iberian States were the first to rely on imperial colonies, Mediterranean Europe's structure was rooted in agrarian societies and economies from the sixteenth century up to most of the twentieth century. The rising bourgeoisie of this 'historical region' did not play a specific role, nor did it have its own specific economic behavior. Its ideal was to imitate the aristocracy. This matched the economic and social behavior of such categories of tenants as the *señoritos* in Andalusia, La Mancha, and Extremadura, or the *gabelloti* and *galantuomini* in Sicily and

southern Italy, who were inclined to a passive existence based on the principle of 'dignified idleness.'

3.3 Central-east Europe

This 'historical region,' with few exceptions, lies between the two ideal boundaries traced by Szücs. It is Europe's second vast periphery and has been one of the core's major suppliers of foodstuffs. The typical socioeconomic scenery of Europe's second periphery is in western and eastern Prussia, the Baltic countries, the Hungarian plain, and the Romanian Danube plain besides Poland's so-called eastern territories (most of which were lost after World War II). In these boundless areas were the landed estates of Central-east Europe's aristocracy: major Polish and Hungarian noble families, Baltic overlords of Germanic ancestry, and Romanian boyars. The institution of serfdom was the rule in these estates nearly up to the end of the nineteenth century. In fact, rather than being abolished, serfdom relationships were revived in what historians call the 'second serfdom.' Great landowners introduced new farming methods in order to increase crops, mainly cereals, bringing down harsher labor and life circumstances on peasants. Central-east European 'second serfdom' was also accompanied by the formation of new groups of great landowners with a strong 'corporate spirit' and staunch political and socio-economic ambitions such as the Prussian *Junker*, Polish *Szlachta*, and Hungarian 'gentry.'

3.4 Southeast Europe

This 'historical region' includes mainly the Balkans (except Romania). The Ottoman Empire which dominated it for almost 500 years became a part of the 'world-system' only during the eighteenth century, that is, during its manifest decadence. However, even under Ottoman domination the Balkans was a poor periphery, on the precarious border between the Ottoman and Austro–Hungarian empires. Therefore, the circumstances of this 'historical region' should not be compared to other more flourishing socioeconomic areas of the Ottoman Empire such as parts of Syria or Egypt. To make matters worse, in the Balkans there was a degeneration of the patrimonial system based on 'tax-farming.' The Balkans' destiny within the 'world-system' was to become a 'periphery of the periphery.'

3.5 East Europe

In Europe's third 'historical region,' according to Szücs' classification, there is mainly Russian territory west of the Urals, except the areas south of the Carpathians. During its first centuries this enormous country was an 'external area' as regards to the 'world-system,' with a distinctive socioeconomic structure. A communitarian land property regime and a peculiar patrimonialism by which an imperial 'official' 'arrogated' property administrated on behalf of the tsar, were the socioeconomic structure's cornerstone. Historians compared the situation engendered by such a structural peculiarity, which lasted up to the Russian Revolution (1917), to a 'bog of misery' (Riasanovsky 1984). However, East Europe's gradual integration in the 'world-system,' beginning in the eighteenth century, remained incomplete. Russia continued to be a European 'external area' and never became a real periphery or a core-state, as the other 'historical regions' already described.

3.6 '*Historical Regions*' and Present Socio-economic Gaps

The establishment of the 'world-system' and the growth of a new international division of labor, which have molded the European core and peripheries, are the primary components of an epochal historical change whose socioeconomic and cultural consequences are still visible to this day.

The gaps that appeared between Europe's 'historical regions' during the formation of the 'world-system' are still plain to see. The north–south gap mirrors past historical sociostructural and economic differences between the core and the Mediterranean periphery. To date, even the integration of these two 'historical regions' within the European Union has not eliminated the gap. The so-called 'enlargement towards the East' of the European Union is a problematic issue due specifically to east–west discrepancies (and not only to 50 years of socialism) that embody old boundaries between the European nucleus and the central–east periphery. The Balkan situation, which is characterized by feeble industrialization and incomplete modernization, is due to the fact that for centuries this area was a periphery of the periphery. Finally, present-day Russia with its distinct 'development model' torn between capitalistic borrowings and (pre)Socialist communitarist revivals, is adhering to its typical 'tradition' of lingering on the borders of the 'world-system.' The core–periphery gaps are detectable not only interregionally but also within states. In fact, states that straddle 'historical regions' have strongly 'dualistic' societies, economies, and cultures. For example, Italy is divided into north and south; Spain has discrepancies between Catalonia and Spanish Basque Country on one side, and the rest of the country on the other; in former Czechoslovakia there were differences between Bohemia and Slovakia; in former Yugoslavia, Slovenia, and Croatia were more connected to the core while Serbia, Bosnia, and Macedonia belonged to the southeast periphery.

3.7 Perceived Gaps and Peripheral Knowledge

Core–periphery gaps go beyond structural data. They are also 'lived,' therefore 'perceived' and 'constructed'

realities. In European peripheries, especially among the intellectual élites, there is an awareness of the 'marginality' if not the 'backwardness' of one's country or its 'historical region.' However, there is also a strong belief that one's 'nation' or 'people' has outstanding 'excellence' and 'virtues.' 'Peripheral élites' have been coping with the discrepancy between their nation's perceived socioeconomic 'inferiority' and its presumed spiritual and moral 'superiority' since just before the formation of their respective nation-states. European peripheries' ruling classes' interpretation of this apparent contradiction has been remarkably ambivalent as regards to relationships with the core as a socioeconomic and cultural complex. Quoting Bendix's terminology, the core is looked upon as a 'reference society' with which there is both an 'identification' and a 'distinction' relationship (Bendix 1978). Emulation of the core is encouraged while dissociation is maintained as well. Over the past 150 years, almost every European periphery underwent major modernization processes, emulating the core, which included all aspects of society. However, these processes were accompanied by 'archaistic' counter-trends (agrarian populist movements, nationalisms, etc.) which instead glorified what was deemed to be the 'past,' 'tradition,' 'culture,' 'identity' of one's group. Modernization drives and nativistic revivals were both at work.

A modernization drive basically means 'Europeanization,' particularly of politics (establishment of parliamentary institutions and legal systems), the economy (industrialization), culture (more theaters, art museums, avant-garde arts, etc.), and even everyday life (new habits, conventions, and ephemeral fads from the capitals of 'reference societies'—Paris, Vienna, or Berlin). Nativistic revival means stressing one's 'difference' to be distinguished from the core, and revitalizing 'imagined' social institutions, guardians and bearers of 'primordial virtues,' such as the village, rural community, medieval municipality, or guilds.

4. *Europe and the Sociocultural Order of Nation-states*

Since the nineteenth century, capitalist economic expansion in 'world-system' Europe has been accompanied by a proliferation of nation-states. They were established (except in the United Kingdom) through a combination or a separate use of two main models conceived in France and Germany first (Brubaker 1992). Notwithstanding some differences, both concepts are based on the doctrine by which each 'nation' is entitled to its own territorial state and each state must include only one 'nation.'

Because of this ideal, the last two centuries have been marked by repeated efforts to make single national territories more and more ethnically and culturally homogeneous. Already from the twelfth to the seventeenth century, Western Europe was overrun by several homogenization waves in the shape of religious conflicts and persecutions. Even in the more culturally homogeneous nation-states of Western Europe such as France, however, assimilation processes continued to the end of the nineteenth century (Weber 1976). In Central and East Europe by contrast, where the doctrine was applied only after the downfall of the multicultural empires, the processes of 'ethnocultural recomposition' aimed at 'ethnic purity' have been implemented only during the nineteenth and twentieth century, through a series of boundary revisions, forced assimilations, expulsions, aimed and planned immigrations, deportations, ethnic wars, and genocides.

Four main periods can be identified in the various processes of 'ethnic separation' that over the last two centuries concerned the European nation-states, especially in the central and eastern parts of the continent. The first period was predominantly in the Balkans, immediately after the creation of the first nation-states in the nineteenth century. Vast population groups of Turkish origin or merely of Islamic faith were forced to leave the region. As administrators of the Ottoman Empire, some indeed represented the hated occupiers, but members of social strata that had little in common with the ruling class were also expelled. During the great 'Crisis in the Orient,' which led to the bloody Russian–Turkish war, from 1875 to 1878, a million and a half people were repatriated.

The second virulent phase took place between 1913 and 1925. It was characterized by the forced transfer of whole minority groups, yet it was internationally recognized and guaranteed. In diplomatic language, it was euphemistically termed 'population exchange.' Substantial groups of Albanians from Kosovo and western Macedonia were transferred to Turkey after the Balkan Wars (1913) mainly because of their religion. Particularly after the creation of the Kingdom of Yugoslavia, the Islamic populations were replaced with Serbian, Montenegrin, Croatian, and Slovenian people. The 'population exchange' between Greece and Turkey was even more dramatic. The Treaty of Lausanne in 1923 ratified a series of reciprocal expulsions and hasty repatriations caused by the Greek military catastrophe during the campaign in Asia Minor. After the defeat, Greece was overrun by refugees from the coasts of western Anatolia, plus the Greeks from the Black Sea area and the Caucasus who had fled the new Bolshevik regime's repressions. A country with 4.5 million inhabitants faced the arrival of 1.3 million refugees. At the same time, the 'population exchange' provided for the departure of Turks and Albanians.

The third phase of 'ethnic homogenization' includes the decade between 1940 and 1950, marked by the Nazi policy of annihilation, transfer, and expulsion of whole ethnic groups, and by Stalinist deportations and

purges. Along with the holocaust of the so-called 'transnational minorities,' that is, Jews and Roma, there were massive population movements in Central and East Europe. Eleven and a half million Germans were expelled from the *Ostgebiete* (eastern territories) while three million Poles, particularly from the regions absorbed by the Soviet Union after World War II, were settled in Silesia and in the southern portion of eastern Prussia. Thus, Poland became an almost monoethnic country.

The treaties between Czechoslovakia and Hungary and between the latter and Yugoslavia, which also provided for reciprocal 'population exchanges,' date back to the same period. Finally, Stalin consolidated his conquests in the western part of the Soviet Union through a policy of 'planned mobility.' This involved the deportation of populations considered 'accomplices of the enemy,' therefore 'traitors of the great patriotic war' (Latvians, Lithuanians, Estonians, etc.), to Siberia or central Asia. It also involved replacing them with more 'reliable' immigrants, mainly of Slavic origin.

The fourth virulent phase of 'ethnic homogenization' is the wave of 'ethnic separations' that has devastated Central and East Europe over the past 15 years. It can be traced back to Socialist Bulgaria with its approach to minority problems. In the second half of the 1980s, the Bulgarian solution was to expel and/or forcibly assimilate 'ethnic Turks.' The phase continued with the disintegration of the three countries born after World War I through a multiethnic and multinational 'logic'; Yugoslavia, the Soviet Union, and Czechoslovakia. The resulting new and old states are all based on the nation-state principle. This latest wave of 'separations,' which aims at the homogenization of territories with highly differentiated ethnic structures and claimed by one or more 'nations,' continued in the 1990s in Bosnia and Kosovo, and may not yet have come to an end, particularly in the Balkans and former Soviet Europe.

5. *'Postnational' Europe in the Making?*

Over the last 50 years of the twentieth century, there were major population movements in Europe; this is the most outstanding characteristic of this period. These migrations for economic (job seekers) or political, that is, humanitarian (asylum seekers), reasons have affected Western Europe more than Central-east Europe. Until 1989, Soviet hegemony in this area allowed only a limited and often planned mobility, even though immigrant laborers were not totally lacking (Vietnamese in Bulgaria, former Czechoslovakia, German Democratic Republic, and the USSR as well). Within the EU and its previous community institutions a gradual, albeit slow, frontier abatement amongst member states has made transnational mobility easier. From the end of the 1950s, unprecedented numbers of laborers from the Mediterranean and Southeast peripheries (Italy, Spain, Portugal, Greece, and former Yugoslavia) reached the core (France, Germany, Austria, Switzerland, Benelux, United Kingdom, and Scandinavia). Here they found jobs in industry and in fields that are not sought after by the 'autochthonous' population because they are considered low status activities. From the 1970s on, these immigrants were joined by an increasing amount of laborers from the Mediterranean area bordering on the Old Continent (Turkey and Maghreb). Although to date some countries such as Germany and Switzerland challenge this denomination, northwestern European countries became 'immigration societies' in this period, notwithstanding strict measures introduced in the early 1970s regulating foreigners' permanent entry.

The circumstances in Euro-Mediterranean former 'emigration societies' (Italy, Spain, Portugal, Greece), which in the meantime have become 'immigration countries' instead, are slightly different from Northwestern Europe's situation. Migration is mainly from so-called Third World countries (Sub-Saharan Africa, Southeast Asia, China, the Indian subcontinent, Latin America, etc.), and from the continent's most underdeveloped areas (Albania). From the end of the 1980s, however, what became known as 'mass unemployment' worsened in all Western Europe. Therefore, recruitment of foreign workers fell drastically while political and humanitarian immigration increased.

At the same time, large numbers of migrants reached the core from non-European regions and former Socialist bloc countries after the fall of the Berlin Wall (1989) and the subsequent opening of frontiers. Facing a difficult socio-political transformation and an unstable economy, Central-east Europe is not the preferred destination for these migrants, who regard it only as a stopover on their way to Western Europe. Therefore, former 'Real Socialism' countries become a temporary 'buffer zone.'

The above-mentioned migratory circumstances have called into question the sociocultural order created by nation-states that is based on the ideal of a mono-ethnic territory. The growing presence of diasporas, transnational groups, creolized communities, and deterritorialized collectivities in Europe's social and cultural setting, plus minorities' emphatic claims and demands (linguistic, religious, and ethnic), have fired discussions on nation-state adequacy and the need for 'postnational' organizations with new types of 'transnational' or 'multiple' citizenships, as Ferry (1992), Pierré-Caps (1995), and Kleger (1997) foresee.

However, such projects will be for the twenty-first century. For the time being the nation-state is the political and sociocultural standard, both internationally and regionally, from which different types of autonomism, Euro-regionalism, federalism, 'devolution,' and separatism (Catalonia, Galicia, Spanish

Basque Country, Corsica, Flanders, Walloon Provinces, Scotland, 'Padania,' etc.) continue to draw inspiration when they seek an organizational form for their ambitions.

European Integration

European integration is the product of the selective pooling of national sovereignty, or ultimate jurisdiction over a body politic, by postwar European nation-states (see *Sovereignty: Political*). Many regional organizations exist to promote and foster cooperation in Europe, above all the European Union (EU, formerly known as the European Economic Community, European Community or Common Market). From its origins in the 1950s, the EU expanded from six to 15 member states, with most of the rest of Europe seeking to join by the end of the twentieth century (see Table 1). The EU maintained close links to a variety of other organizations which promote or foster European cooperation, such as NATO, the Organization for Security and Cooperation in Europe (OSCE), and the European Bank for Reconstruction and Development. But the EU was by far the most powerful, important, and successful manifestation of European integration.

Table 1
The European Union's member states and applicants

Member states	Year of accession
Belgium, France, (West) Germany, Italy, Luxembourg, Netherlands	1957
Denmark, Ireland, United Kingdom	1973
Greece	1981
Portugal, Spain	1986
Austria, Finland, Sweden	1995
Applicants	
Bulgaria, Cyprus, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, Romania, Slovakia, Slovenia, Turkey	As of 2000

1. European Integration and Political Science

European integration poses daunting challenges to political science as a discipline. The EU's supranational character, particularly the legal superiority of its legislation over its member states' national laws, is replicated in no other international organization (see *International Organization*). The EU defies traditional conceptions of nation-states as atomized, self-sufficient units that resist interdependence and engage in alliances strictly on an *ad hoc* basis (see *Interdependence: Political*; *International Relations: Theories*). The Union is based on international treaties, but ones that function as a sort of constitution for a quasi-federalist system of government (Weiler 1999). Nonetheless, the EU sustains more than it supersedes the nation-state in Europe. It is plausible to argue that it has acted to strengthen—and not weaken—postwar European states by fostering economic growth and recovery, providing a bulwark against the Soviet bloc, and enhancing Europe's role in international affairs (Milward 1992).

European integration has been subject to frequent stops and starts. The EU rarely has shaken free of

tensions between distinct national interests and shared economic interdependence. However, a series of revisions to the EU's Treaties—four in 15 years after the mid-1980s—had the general effect of more closely binding together the Union's member states, strengthening its common institutions, and adding to its policy remit. It also encouraged the emergence of EU studies as a subdiscipline in its own right.

2. *European Policies and Politics*

Over time, the politics of the EU have become far more like the domestic politics of its member states, and less like the international politics of relations between states (Wallace and Wallace 2000). The primary reason for the emergence of the EU as a polity in its own right has been political will to create an internal or 'single' European market, free of barriers to internal trade and constituting the world's largest single capitalist market. The ambition to create an internal market was reflected in the EU's founding treaties, but began to be realized only after the Single European Act (SEA) effectively relaunched European integration in the late 1980s, following a period of deep stagnation and 'Eurosclerosis.'

Throughout this period, the European Court of Justice remained the ultimate arbiter of legal disputes, and many of its decisions advanced European integration as a political project. The EU's hybrid executive/civil service, the European Commission, retained exclusive powers to propose legislation. However, the SEA (ratified in 1987) substantially altered the Union's institutions and rules governing relations between them. Before the late 1980s most EU legislation required the unanimous agreement of the Council of Ministers, the EU's main legislative body offering representation to all member states. After the SEA, renewed political commitment to the internal market combined with extended majority voting on the Council—with each member state given a weighted number of votes based roughly on population—transformed European integration. Increased majority voting significantly empowered the Commission, which also achieved considerable autonomy in a number of policy sectors, including agriculture and competition policy. The volume of EU legislation mushroomed after 1987 and the Union developed a range of new policies, mostly in areas linked to the internal market such as environmental protection, research, and the development of its poorer regions. It even developed ambitions to create a single currency to take the internal market, and European integration, a major step further (see McNamara 1998).

Meanwhile, EU decision making became increasingly complex and protean. Council deliberations remained mostly closed, a dizzying variety of different decision rules applied to different policies, and polls reflected popular apathy or cynicism with the EU. The growing perception that European integration needed to be democratized allowed the European Parliament (EP) to gain in strength and stature. In 1979, it was directly elected for the first time. By the early 1990s, it had been made a legal colegislator with the Council in many policy areas (including the internal market). However, EP elections attracted low voter turnouts and the Parliament remained an ill-disciplined institution that engaged in effective collective action only rarely. The EU was far from being a parliamentary democracy. Its lack of either a government or opposition made it difficult to apply majoritarian methods of democratic control (see *Accountability*: *Political*).

EU Treaty revisions in the 1990s made the Union, on balance, an even more complex institution. The Maastricht Treaty (ratified in 1993) upgraded the EP's powers but also created two new 'pillars' to foster intergovernmental cooperation between member states on foreign and justice/home affairs policies, creating new (almost purely unanimous) decision procedures and sidelining the EU's supranational institutions. Neither pillar enjoyed much success, with the EU's performance during the Bosnian war in the mid-1990s particularly criticized despite the Maastricht Treaty's sanction of a new 'Common Foreign and Security Policy.' Very limited progress on justice and home affairs cooperation eventually led to a more powerful role for the EU's institutions in this area, but according to an entirely new set of decision rules not previously used in any other EU policy sector.

The Maastricht Treaty also set a firm timetable and entry criteria for monetary union. Most governments that wished to join the single currency were forced to slash their public budgets and embrace austerity when Europe was suffering through its worst recession since the 1930s. The drive to monetary union, along with the EU's failure in Bosnia, further dampened popular enthusiasm for European integration.

The Amsterdam Treaty (ratified in 1999) mostly tinkered at the margins of the EU's constitutional settlement, despite intense pressures to enlarge the EU to take in new democracies in Central and Eastern Europe. Qualified majority voting was extended to very few new policy areas even though it was impossible to imagine that a future EU of 25–30 member states could achieve unanimity very often. The inevitable effect was to raise doubts about the future political unity of a much larger and more diverse EU, particularly one that offered membership to new Central and Eastern European states which were far less modern or wealthy than its existing members.

3. *The Study of European Integration*

The study of early post-War institution building in Europe was dominated by functionalists (or 'neo-functionalists,' see Haas 1958), broadly in line with the rise of structural functionalism as a general theory of

social science. Neofunctionalism assumed that European integration was driven primarily by the need for states to cooperate in noncontroversial, technical sectors in order to grow their economies. It predicted that integration in selected areas of policy would 'spill over' into separate but related sectors, for both functional and political reasons, thus giving integration a self-sustaining character. It was assumed that the European experience of integration would be replicated in other parts of the world.

The stagnation of European integration in the late 1960s and 1970s led neofunctionalism, and EU studies more generally, to fall into disrepute. The reinvigoration of integration in Europe in the 1980s prompted an enormous increase in academic interest in the EU. Eventually, debates between advocates of liberal theories of international relations (Moravcsik 1998) and institutionalist theories of political organization (Armstrong and Bulmer 1998) came to dominate EU studies (see Puchala 1999). Liberal intergovernmentalism theorized that European integration was the outcome of the pursuit of economic advantage by rational state agents, with the EU's supranational institutions only granted as much power as was needed to seal bargains between them. Institutionalists countered that European integration was highly path-dependent, produced many unanticipated consequences, and was uncontrollable by states in important respects (see *Institutionalism*). Few advocates of either theory sought to disavow neofunctionalism altogether, particularly given the development of the EU's own system of law, powers of enforcement, and money.

Recent scholarship on European integration reflects consensus that the EU has evolved into a distinctive polity with multiple levels which is like no other in existence (see Marks et al. 1996). On the one hand, its rise to become one of the most important sources of public policy in Europe has prompted the application of conceptual tools associated with policy analysis in national (especially federal) contexts (Peterson and Bomberg 1999). On the other, the *sui generis* nature of the EU creates an '*N* of 1' problem: the EU is not a readily comparable case for most general theories or methodologies of social science. One effect is that scholarship on the EU is often subject to bitter criticism by nonspecialists, in part because it is viewed as nonscientific and atheoretical. However, a related problem is that European integration generally and the EU specifically are so complex as to resist simple generalizations and often comprehension by anyone but devoted students.

4. *Future Theory, and Research*

In some respects, the EU is becoming less *sui generis*, particularly given new regional economic projects in the Americas and Asia (see *Regional Integration*). The Union is likely to become the subject of more normative theory and research, as its perceived success makes it a model for other experiments in regional cooperation. The creation of the Euro has attracted a further group of scholars—monetary economists—to EU studies, and the Union's inevitable enlargement makes it a primary focus for scholars specializing in Central and Eastern Europe. International relations scholars preoccupied with military or 'strategic studies' are also likely to find the EU impossible to ignore as it seeks to develop its own military capability in the early twenty-first century.

In theoretical terms, scholarship on globalization increasingly offers insight into what the EU does, how and why (see *Globalization: Political Aspects*). Most EU policies are designed either to defend European interests in an increasingly global economy, or soften the nefarious effects of globalization. On balance, the continuing structural shift in power from states to markets encourages continued European integration. The EU is the most successful experiment in international cooperation in modern history. However, the enlargement of the EU is likely to transform the Union fundamentally, in ways that challenge the notion that ever closer European unity is inevitable.

European Religion

The concept of Europe—whether considered geographically or culturally—is not self-evident. While the Western, coastal edge is clear enough, the distinctiveness of Europe within the Eurasian land mass

is less so. The first part of this article will consider the relevance of the religious factor to the definitional question; it will also outline the major confessional divisions *within* the continent. The second section will look at the patterns of religious life in different parts of Europe, underlining the contrasts between 'hard' and 'soft' indicators of religion in this respect. The final section deals with the bewildering variety of church–state relationships in modern Europe.

1. *The Religious Boundaries of Europe*

The complexities involved in the concept of Europe are clearly outlined by Davies (1996). In the early modern period, the idea of Europe gradually disentangled itself from the concept of 'Christendom,' a process in which the religious factor played a decisive role. As the nations of Europe endured centuries of religious war, they were disinclined to remind themselves of what they supposed to have in common: the notion of Europe provided a more neutral alternative. A longer historical perspective reveals, however, that Christendom had itself been divided long before the early modern period: between an Orthodox East (centered first in Constantinople and then in Moscow) and a Catholic West (centered in Rome), a dispute which came to a head for a mixture of theological and political reasons in the eleventh century.

The central question of Europe's self-understanding is closely connected to this division: should this or should it not include Russia, an Orthodox, economically backward, and slavophile state? This article will include Russia, but will at the same time emphasize the distinctiveness of the Orthodox part of the continent. Such distinctiveness takes the form of a markedly different cultural heritage. The nations associated with Western Christianity have, for example, experienced the Renaissance, the Reformation, the scientific revolution, the Enlightenment, and the Romantic revival (and take these pivotal movements for granted). Countries further east have been through an equally formative, but entirely different historical evolution. For them the ebb and flow of Islam has been of greater significance. Indeed, it is possible to argue that the concept of Europe finally gives way to something else as Orthodoxy gives way to Islam, on a line which has fluctuated over centuries and continues, from time to time, to play a crucial and not always peaceful role in the establishment of identities. The 1990s disputes between Russia and Chechnya or between Armenia and Azerbaijan are cases in point.

Given its long-term cultural significance, the boundary between Catholic and Orthodox is of more importance in understanding Europe's religious life than the much more recent division between communist and noncommunist Europe. With this in mind, it is useful to introduce the terms 'East' and 'central' Europe when dealing with the former communist countries. East Europe (European Russia, Romania, Bulgaria, Serbia, and Macedonia) belong to the Orthodox tradition, whereas the central European countries (the Baltic states, Poland, the former East Germany. the Czech Republic, Slovakia, Hungary, Slovenia, and Croatia) developed within Western Catholicism. It is only in the postwar period that they have been separated from the economic and cultural traditions of the West. The position of Greece is anomalous in this respect; it is the only Orthodox country within the European Union. In a much longer timescale, the contribution of Greek culture to the understanding of what it means to be European in the Western sense can hardly be overestimated.

The border between 'East' and 'central' Europe is, however, as problematic as any other, for on it are found the Greek Catholic or Uniate churches—those, in other words, which have been received under the jurisdiction of Rome, but which retain their own ritual, practice, and canon law. In the emergent identities of this part of Europe, moreover (notably in the Ukraine and in Belarus), the Uniate churches are of considerable importance. Further south and in a rather different way, Bosnia-Herzogovina is uncomfortably pincered between Orthodox Serbia and Catholic Croatia, a situation rendered all the more complex by the presence of a sizable Muslim population dating from the time of the Ottoman occupation.

So much for the east–west boundaries of Europe. The subsequent divisions of the west into areas or nations which are primarily Catholic or Protestant (or combinations of the two) are inseparable historically from the emergence of the nation state as the dominant form of Europe's political life. The processes by which such divisions occurred are highly complex, involving economic, social, political, as well as religious issues. Which of these led to the others and how the whole thing was set in motion in the first place is the subject of an ongoing debate among historians, themselves of different persuasions. What remains indisputable, however, is an unprecedented upheaval in the ordering of Christian society in the sixteenth century; an upheaval which included the emergence of separate political entities or nation states, some of which expressed their independence from papal interference in the form of a state church.

Part of the ambiguity regarding the whole historical process lies in the understanding of the term 'Reformation.' Does this imply innovation and the breaking of new ground? Or does it involve a return to and rediscovery of primitive excellence? Were those who endorsed the theological changes taking place at this time looking primarily for radical change or for conservative independence? Motives were mixed. The more conservative interpretation, however, was bound to appeal to those political rulers anxious to establish independence from external authority, but with a careful eye on stability within. Both were possible

within the Lutheran concept of a 'godly prince.' Sometimes the prince had jurisdiction over a whole kingdom or kingdoms. Such was the case in Scandinavia where Lutheranism became embodied in the state churches of Northern Europe. Elsewhere the process was far more local and concerned relatively small patches of land. The German case exemplifies the latter, leading to patterns which are not only extant but influential some 400 years later.

The Reformation took different forms in different places. In addition to Lutheranism, parts of Europe—notably the Swiss, the Dutch, the Scots, some Germans, some Hungarians and Czechs and a small but significant minority of French people—were attracted first by Ulrich Zwingli, but then by Jean Calvin, towards a more rigorous version of Protestantism. Calvinism was both more radical and more restrained: radical in the sense of a new kind of theology based on the doctrines of predestination and redemption, but restrained in terms of its stringent moral codes. The effect of this particular combination on the subsequent economic development of Europe has provided inexhaustible material for an ongoing debate among historians and sociologists alike.

Broadly speaking West Europe divided itself into a Catholic South (Spain, Portugal, Italy, France, but including Belgium and Ireland), a Protestant North (Scandinavia and Scotland), with a range of 'mixed' countries in between (England and Wales, Northern Ireland, The Netherlands, and Germany). Central Europe exemplifies similar categories, though the geography is rather more complicated. Lithuania, Poland, Slovakia, Slovenia, and Croatia are firmly Catholic; Estonia and Latvia are Lutheran and relate closely to their Scandinavian neighbors (a commonality strongly re-emphasized as the Baltic Republics regained their political independence); Hungary and the Czech Republic, finally, are rather more mixed (primarily Catholic but with significant Protestant minorities). In other words, boundaries gradually emerged all over Europe dividing one nation from another, one region from another, and one kind of Christianity from another. Boundaries, moreover, imply dominance as well as difference. Majorities and minorities were, and still are, created depending on the precise location of the line in question. One of the most arbitrary in recent years has been the line that divides Northern Ireland from the Irish Republic.

2. *Patterns of Religious Life in Europe*

The European Values System Study Group (EVSSG) provides a principal source of data for this section (Barker et al. 1992). Using careful sampling techniques, the EVSSG aims at an accurate mapping of social and moral values across Europe. The first study was carried out in 1981, the second in 1990 and a third—unavailable at the time of writing—in 1999. Initially only some countries in West Europe were involved, a coverage which quickly extended to most of Europe and beyond. The following discussion starts with West Europe; East and central Europe will be dealt with subsequently.

There are, broadly speaking, five religious indicators within the EVSSG data: denominational allegiance, reported church attendance, attitudes towards the church, indicators of religious belief, and some measurement of subjective religious disposition. These variables have considerable potential: they can be correlated with one another and with a wide range of sociodemographic data. In this respect the survey shows commendable awareness of the complexity of religious phenomena and the need to bear in mind more than one dimension within a nation's religious life. What emerges in practice, however, with respect to these multiple indicators is a clustering of two types of variable: on the one hand, those concerned with feelings, experience, and the more numinous religious beliefs; on the other, those which measure religious orthodoxy, ritual participation, and institutional attachment.

It is, moreover, the latter (the more orthodox indicators of religious attachment) which display, most obviously, an undeniable degree of secularization throughout Western Europe. In contrast, the former (the less institutional indicators) demonstrate considerable persistence in some aspects of religious life. Bearing this in mind—it seems more accurate to suggest that West Europeans remain, by and large, unchurched populations rather than simply secular. For a marked falling-off in religious attendance (especially in the Protestant North) has not resulted yet in a parallel abdication of religious belief. In short, many Europeans have ceased to belong to their religious institutions in any meaningful sense, but they have not abandoned, so far, their underlying religious aspirations (Davie 2000).

Two short parentheses are important in this connection. The first may seem obvious, but the situation of believing without belonging (if such it may be called) should not be taken for granted. This widespread, though fluctuating, characteristic within European religion in the late twentieth century must be examined, probed, and questioned. The second point illustrates the need for caution. At the same time it introduces the contrasting situation in parts of East and central Europe where believing without belonging was not the norm. Indeed, prior to 1989, the two variables were (in some places at least) reversed, for the nonbeliever quite consciously used Mass attendance as one way of expressing disapproval of an unpopular regime. The Polish case is the most obvious illustration of this tendency (Michel 1998).

Returning to the West European data and beginning to probe more deeply, there is further evidence of consistency in the shapes or profiles of religiosity which have been obtained across a wide variety of

European countries. Whatever the overall level of belief in any given country, for example, the following variables—belief in God, in a soul, in heaven, in life after death, in the devil, in hell and in sin—almost always come out in the same order. Correlations between religious indices and socioeconomic variables confirm the existence of socioreligious patterning across national boundaries. The correlation with age is particularly striking, and raises the future shape of European religion. Indeed, it prompts the most searching question of the study: is it the case that West Europe is experiencing a permanent generational shift with respect to religious behavior, rather than a manifestation of the normal life-cycle? The EVSSG findings seem to indicate that this might be so. Data from the 1990 restudy reinforce this point.

So much for the similarities across West Europe. What about the differences? The first and most obvious of these lies between the notably more religious, and Catholic, countries of Southern Europe and the less religious countries of the Protestant North. This variation holds across almost every indicator; indeed, they are inter-related. Levels of practice, for example, are markedly higher in Italy, Spain, Belgium, and Ireland (closer in its religious life to continental Europe than to Britain) than they are elsewhere. Not surprisingly, one effect of regular Mass attendance is a corresponding strength in the traditional orthodoxies through most of Catholic Europe.

There are, however, exceptions to this rule, and at this point it is necessary to point to the limitations in the EVSSG data. There is no way of telling from the data why a particular country should be similar to or different from its neighbors. France, for example, displays a different profile from the other Catholic countries (with markedly lower levels of practice), a contrast that cannot be explained without reference to the specificities of French history. Other exceptions to a European pattern, or patterns, should be looked at in a similar light; notably, the countries which do not conform to the believing without belonging framework. Conspicuous here are the two Irelands in both of which practice as well as belief remains unusually high. Within central Europe, the Polish case reflects a similar pattern. As ever, there are historico-political reasons for these exceptions.

A crucial point concludes this section. It concerns the patterns of practice and belief in East and central Europe and their possible future(s). In making this assessment, it is important once again to remember the distinctiveness of Orthodoxy, a form of belief which contains within itself a greater degree of diversity than is possible in the Western churches (it is more inclusive). It is also different in its relationship to political power (see below). The profiles of religion in East (and indeed central) Europe are, moreover, not only varied but volatile—in some places the indices rise sharply after 1989, in others less so. With this in mind it is probably too soon to answer the key question. Will Eastern Europe follow the West into a state of relative religious indifference (increasingly unusual in the modern world) or will this part of Europe emerge a distinct alternative, following its own religious trajectory? Only time will tell.

3. *Church–State Relationships*

A broad brush profile of religion in West Europe provides the background for a more detailed discussion of church and state relationships; these in turn constitute the parameters within which religious life on a national level takes place. It is helpful to set a discussion of church–state relationships within the following framework, taken from Martin's seminal work on the evolution of secularization in the Western world (Martin 1978). Following Martin, Europe is a unity by virtue of having possessed one Caesar and one God (the legacy of the Judaeo-Christian tradition); it is a diversity by the existence of nations. The patterns of European religion derive from the ongoing tensions and partnerships between religion and the search for national integrity and identity. These tensions and partnerships have resulted in a bewildering variety of church–state relationships within the continent as a whole.

In Western Europe, such relationships range from the state churches of Northern Europe, through the pillarized cultures in The Netherlands and Belgium, to the considerable diversity contained within the United Kingdom and Ireland (including a Calvinist national church in Scotland, an Anglican establishment in England, assorted nonconformity in Wales, and a technically secular but heavily Catholic state in Ireland). Germany is a biconfessional state in which both the Lutheran and Catholic churches remain important public bodies. Latin Europe includes the privileged Catholic churches of Italy, Spain, and Portugal and the rather different situation in France (the only European nation, for example, with a rigorously secular school system in addition to the state itself). In this part of Europe (and especially in France), anticlericalism has a historically important role—itself diminishing as the Catholic hegemony declines.

In East and central Europe, it is necessary to start with the autocephalous churches of Orthodox Europe, closely aligned with political power over centuries (of which Russia is the prime example). In central Europe there are examples (notably Poland) of the Catholic Church becoming the effective carrier of an *alternative* memory in the communist period; elsewhere—in Hungaria and Czechoslovakia—the churches were more compromised. The Lutheran churches (in, for example, Estonia or the former East Germany) all but collapsed altogether—notwithstanding the outstanding courage of individual believers. In all these cases, the postcommunist period brings a new set of chal-

lenges in terms of church–state relationships and the associated privileges.

Indeed, in a whole variety of ways, the Europe that is emerging as the twenty-first century dawns is a rapidly changing place. From a religious point of view, one of the most significant evolutions is undoubtedly the increasing representation of faiths other than Christian. Analytical concepts must evolve accordingly. European religion is giving way to the 'religions of Europe'; a continent which now houses a significant representation of Muslims, Sikhs, Hindus, and Buddhists in addition to the Jewish communities which have played such a crucial role in Europe's recent history. Martin's tension between unity and diversity remains paramount, though in forms that are peculiar to late modern rather than early modern European society.

A final section of the population should be mentioned in conclusion: the sizable minority of Europeans who declare that they have no religion and are not affiliated to any religious institution. A striking but overlooked factor within this significant minority is its internal diversity. Not only does it vary from the cautiously agnostic to the aggressively atheist, it is unevenly present in different European nations and in different socioeconomic groups. From a sociological point of view, the lack of material concerning this significant minority is striking.

European Union Law

The European Union was established by the Treaty on European Union, signed at Maastricht on February 7, 1992 (Official Journal of the European Community – OJ – 1992 C 224/1). It relates to three areas commonly called the pillars of the Union. The first consists of the Communities, which are often thought to be a single Community but are, in fact, three Communities: the European Community (EC) established as the European Economic Community by the Treaty of Rome of March 25, 1957 (United Nations Treaty Series – UNTS – Vol. 298, p. 11), the European Coal and Steel Community (ECSC) established by the Treaty of Paris of April 18, 1951 (UNTS Vol. 261, p. 140), and the European Atomic Energy Community (EURATOM) established by a separate Treaty of Rome of March 24, 1957 (UNTS Vol. 298, p. 167). While these Communities are invested with supranational powers, the second and third pillars of the European Union are constituted by policies and forms of intergovernmental cooperation in the fields of 'common foreign and security policy' and 'co-operation in the fields of justice and home affairs,' renamed 'police and judicial co-operation in criminal matters' by the Treaty of Amsterdam of October 2, 1997 (OJ 1997 C 340/1). The three Communities were set up by six founding member states (Belgium, France, Germany, Italy, Luxembourg, and the Netherlands) but later accessions (Austria, Denmark, Finland, Great Britain, Greece, Ireland, Portugal, Spain, and Sweden) have made the Community grow to 15 member states. A further extension of the Community towards central and eastern Europe is foreseeable. The success of this integration is almost entirely due to the transfer of sovereign powers to the three original communities and in particular to the European Community. The following article will therefore essentially deal with European Community law.

1. A Community Based Upon the Rule of Law

As the Court of Justice has repeatedly held, the European Community is a 'Community based on the rule of law, in as much as neither its member states nor its institutions can avoid a review of whether the measures adopted by them are in conformity with the basic constitutional charter, the Treaty' (Case C-2/88 Imm. – *Zwartveld* – [1990] European Court Reports (ECR) I – 3365 para. 16). In comparison with previous models for the peaceful cooperation and integration of states, the Community approach is outright revolutionary. While political considerations and diplomacy still have a great impact on the settlement of conflicts between member states, national sovereignty is no longer unlimited. States have to respect Community law lest violations are ascertained by the Court of Justice. Access to the Court is not limited to the member states and the institutions of the Community, legal proceedings may also be commenced by national courts of law which can request a preliminary ruling concerning the interpretation or the validity of Com-

munity Acts (article (art.) 234 EC). The enforcement of Community law is thus indirectly entrusted, beyond national governments, to a great number of national judges. While a change of government policy usually threatens to undermine the application or even the existence of international obligations which states have assumed under traditional treaties, Community law is much more stable due to its decentralized enforcement. An agreement of some, or even all, member state governments not to comply with certain Community acts would fail sooner or later as long as it is not embodied in an amendment of the basic Treaty which, however, has to be ratified by the parliaments of all member states. The repercussions on national policies are clear: member states are compeled to conduct their policies within the Community institutions. The pursuit of a separate policy outside that framework will often meet with opposition from Community law and the agencies called upon to enforce it. Within the Community institutions it is, however, almost impossible to pursue a policy of segregation. Thus, the rule of law established by the Treaty of Rome has narrowed the political margin of discretion left to the member states and has channeled their policies towards integration.

2. *Institutions*

Under art. 7 EC the tasks of the Community are carried out by five institutions: the European Parliament, the Council, the Commission, the Court of Justice, and the Court of Auditors. In addition, arts. 8 and 9 EC provide for a European Central Bank and a European Investment Bank.

In the political process, only the European Parliament, the Council, and the Commission are involved. While the traditional model of the Western constitution provides for a separation of legislative and executive powers between parliament and government, the respective roles of the three European Institutions are more complicated. The Commission may originally have been conceived as a kind of European executive which had to implement the integration program of the Treaty. But this task implies wide margins of political discretion, concerning both the priorities and the content of the measures to be adopted. Moreover, the Commission is the only institution which is entitled under the Treaty to initiate legislative proceedings. It is therefore a political heavyweight in the integration process. The governments of the member states have the right to nominate one or, in the case of bigger member states, two members of the Commission who are, however, completely independent in the performance of their duties (arts. 213 s. EC).

It is up to the Council to represent the interests of member states within the Community. The Council consists of a representative of each member state. While each representative may veto a decision where unanimity is required, the votes of the Council members are weighted in accordance with the size of the member state where the Treaty requires a decision taken by qualified majority (art. 205 EC).

The European Parliament was initially named the Assembly and had very little weight in the legislative process, its rights being limited to mere consultation. However, various amendments to the Treaty have improved the legal situation of the Parliament and thereby increased its political influence. As of 2000, its members are elected by direct universal suffrage (art. 190 EC), which however grants a much greater relative weight to the votes stemming from small member states like Luxembourg than to those originating in big member states like Germany. While the rights of the Parliament are still limited to mere consultation in some areas, such as immigration policy (art. 67 EC), most legislative acts now have to be approved by both the Council and the Parliament in the so-called codetermination procedure under art. 251 EC. The Parliament still lacks the power to initiate legislation by its own motions.

3. *Legislative Powers of the Community*

The Community has no inherent powers, it can only act within the limits of the powers conferred upon it by the member states in the Treaty (art. 5 (1) EC). However, the effect of that limitation is mitigated by three factors: first, the Court of Justice interprets the empowering provisions of the Treaty in a wide manner; second, the Treaty contains provisions such as art. 308 EC that confer upon the Community an open-ended power; and third, by the doctrine of implied powers, the Court of Justice has extended the Community's powers even beyond the limits imposed by the Treaty to international commitments insofar as they help to protect the uniform application of Community legislation vis-à-vis third states (Case 22/70 – ERTA – [1971] ECR 263 para. 28).

The exercise of Community competence is further limited by the principles of subsidiarity and proportionality (arts. 5 (2) and (3) EC). The legal significance of the principle of subsidiarity is rather limited as compared with its sweeping use in political discussions. It does not relate to the objectives of a Community action which have to be established in conformity with the Treaty by the political institutions. Subsidiarity pertains only to the question of whether such objectives can better be achieved by the Community than by the member states, the so-called comparative efficiency test. It is highly questionable whether the Court of Justice is in a better position than the political institutions of the Community to decide upon that issue. This may be different in the case of the

principle of proportionality which prohibits the Community from taking action that goes beyond what is necessary to achieve the objectives of the Treaty. In the context of the basic freedoms (see Sect. 6), the Court of Justice has in fact frequently assessed the proportionality of national restrictions imposed by member states.

4. *Sources of Community Law*

It is common to distinguish primary and secondary, or derivative, Community law. The primary law of the Community consists of the founding treaties indicated in the introductory paragraph of this article and some additional international conventions. Moreover, the general principles common to the laws of the member states are sometimes classified as part of the primary Community law. These general principles are explicitly referred to in art. 288 (2) EC in the context of the noncontractual liability of the Community for damage caused by its institutions or by its servants; the Court of Justice considers the general principles as a source of law even outside that field and has recourse to them in other matters, too. However, if the distinction between primary and secondary sources of law indicates a ranking, it would appear that only certain general principles such as the fundamental rights can actually count among the primary sources of Community law. Whatever the status of the general principles may be, they allow for the flexibility that every legal system needs in order to adjust to new and unforeseen situations.

Article 249 EC lists five types of secondary sources of Community law: regulations, directives, decisions, recommendations, and opinions. While recommendations and opinions are not binding, most Community acts are adopted either in the form of a regulation or a directive. Regulations are directly applicable in all member states which means that the Community can impose obligations on, and grant rights to, the citizens of the member states without the intervention of national legislators. As opposed to that, a directive is binding only upon each member state to which it is addressed, and only as to the result to be achieved; to have any effect on the citizens of the Community it must be implemented by member states in accordance with the forms and methods of their legal systems (art. 249 (3) EC). It soon turned out that member states are sometimes slow or reluctant to implement directives. In a long line of cases the Court of Justice has therefore extended their effects: national laws, even if enacted prior to the directive, have to be interpreted so as to conform with it (Case 14/83 – *von Colson* – [1984] ECR 1891 para. 26); insofar as the directive is sufficiently precise and deals with 'vertical' relations involving the defaulting member state it may even be applied directly by the national courts and authorities (Case 8/81 – *Becker* – [1982] ECR 53 para. 24 s.); while such a direct effect is not admitted in 'horizontal' relations (Case C-91/92 – *Faccini Dori* – [1994] ECR I-3325 paras. 22 seq.), the private party suffering loss from the non-implementation of the directive may invoke the defaulting member state's government liability (see Sect. 5). Although case law has approximated the directive to the regulation, the differences are still conspicuous: the regulation creates uniform law whose appearance is the same in all member states, the directive provides for a harmony of solutions at best, but even after that harmonization it is still difficult to assess the precise state of the law in other member states in the area at issue.

It is generally acknowledged, and has been affirmed on various occasions by the Court of Justice, that Community law is a separate legal system distinct from both international law and the national laws of the member states. Ever since the leading case *van Gend and Loos* was decided in 1963, the Court has also stressed the need for a uniform application of Community law in all member states (case 26/62, [1963] ECR 1). Two consequences follow from this premise: Community law has to be interpreted autonomously, i.e., without reference to definitions established in national law; moreover, as recognized in *van Gend and Loos*, Community law must be given direct effect and precedence over national law in so far as the Community provisions are sufficiently clear and unambiguous. In the course of time the conditions for direct effect were watered down. At the end of the twentieth century, direct effect is the norm rather than the exception; it applies to many Treaty provisions, to regulations, and even to many directives (see above in this Sect.). By the doctrine of direct effect the Court of Justice has obliged the national courts to enforce Community law, a duty which has been accepted over time by the national judiciaries.

5. *Ensuring Compliance with Community Law*

Both the Community institutions and the member states must comply with Community law. The Community institutions are subject to legal review in respect of their acts and their failure to act (arts. 230, 232 EC). In case of a violation of its laws committed by the Community or by its servants the Community may incur liability under art. 288 (2) EC. With regard to the member states, the Treaty ensures their compliance with Community law in a much less comprehensive way. Under arts. 226 and 227 EC the Commission and other member states are entitled to bring a violation before the Court of Justice. In practice, only the Commission has made use of this right. The Treaty does not provide for a direct right of action of individuals who complain of a violation of Community law committed by a member state, nor does it

establish the liability of member states for such violations. Both gaps have been filled by judge-made law. By the aforementioned doctrine of direct effect the Court has enabled and instructed the national courts to disregard national provisions which violate Community law. Private parties may therefore invoke Community law in national courts, which can ask the Court of Justice for a preliminary ruling under art. 234 EC if they have doubts about the interpretation of the relevant Community provisions. In addition, the Court of Justice has established the member state's liability for violations of Community law. Insofar as the respective member state has manifestly and gravely disregarded the limits of its political discretion it has to compensate private individuals who have suffered loss as a consequence of that violation. This concerns in particular the cases of a continuous breach of the obligation to implement a directive (cases C-46/93 and 48/93 – *Brasserie du Pêcheur vs. Germany and R. vs. Secretary for Transport, ex parte Factortame* – [1996] ECR I – 29; cases C-187 et al. – *Dillenkofer vs. Germany* – [1996] ECR I – 4845).

6. *Principles of the Internal Market*

Among the various Community policies listed in art. 3 EC the establishment of the Common Market which was later renamed the Internal Market is of central significance. With regard to other policies, the Treaty either limits Community activities to 'a contribution' to efforts made by the member states (e.g., health protection, education, consumer protection), contains vague indications as to the direction of a Community policy (economic and social cohesion, research, trans-european networks), or empowers the Community only to conduct a policy in a given area without indicating any targets (agriculture, transport, environment, energy). As opposed to these policies, the establishment of a Common or Internal Market is not only unequivocal objective stated in arts. 2, 3, and 14 EC, but the basic principles of such a market are also spelt out in clear and operative rules throughout the Treaty. Thus, art. 14 (2) EC defines the Internal Market as 'an area without internal frontiers in which the free movement of goods, persons, services and capital is ensured.' These basic freedoms are guaranteed in further provisions of the Treaty which the Court of Justice has interpreted as producing direct effects. National provisions which subject certain markets and activities to regulations in the interest of consumers, of the safety, of the environment, etc. are therefore regarded as restrictions of the basic Community freedoms and will be approved only if mandatory requirements of the public interest so command (case 120/78 – *Cassis de Dijon* – [1979] ECR 649 paras. 8, 9). By elaborating, in a long line of cases, both the basic rule of free movement and the exception in favor of national restrictions the Court of Justice effectively paved the way for the deregulation of many markets in Europe in the 1980s and 1990s. While political and economic discussions on deregulation were often deadlocked, a single judgment of the Court of Justice would announce a new deal for further negotiations. The case law being inspired by a strong stance against all kinds of discrimination on grounds of nationality (art. 12 EC), the Court has effectively opened national markets to competitors from other member states.

The basic freedoms are directed against restrictions imposed by states. Their implementation extends the scope of private liberties to engage in certain activities, but individuals and companies are not compelled actually to exercise them. Market actors may instead fear the intensification of competition and therefore try to maintain by private agreement the barriers to market access which were previously ordered by national legislation. The risk of such anticompetitive agreements and practices had been foreseen by the founders of the Community who explicitly provided for the prohibition of anticompetitive agreements and abuses of monopoly powers in arts. 81 and 82 EC. The enforcement of competition law which is entrusted to the Commission and to National Competition Authorities must be regarded as complementary to the basic freedoms: while the latter purport to open up the markets by removing national restrictions, the former are meant to protect that competition against private restrictions.

While the basic freedoms have been implemented to a large extent, the Internal Market is far from being a reality in many sectors. This is due to a great number of remaining and sometimes hidden obstacles. Thus, while nationality requirements for certain jobs have been abolished all over Europe, it is still lawful for member states to require a particular type of qualification which, in the absence of harmonization in the field of education, can hardly be acquired by foreigners in other member states; consequently, access to those professions and trades is still closed for foreign applicants. Another impediment to the implementation of the Internal Market consists in the diversities relating to the legal framework of transactions, in particular in civil and commercial law; they deter many small traders from making use of their basic freedoms. While the Community is empowered to approximate the laws of the member states for the purposes of the Internal Market (art. 95 EC), it makes slow progress in that area.

7. *Fundamental Rights*

The EC Treaty does not contain a list of unalterable rights. While some fundamental rights of that type are guaranteed by single provisions scattered over the

Treaty such as prohibitions of discrimination or the basic freedoms, their scope is limited. It is therefore possible that secondary Community legislation infringes private rights which are protected by fundamental rights granted by national constitutions. In respect of such situations the German constitutional court indicated that it would subject secondary Community legislation to the basic rights granted by the German constitution as long as the Community had not developed a charter of basic rights of its own. A constitutional dispute between the Community and some member states appeared inevitable. As a response the European Court of Justice started to acknowledge the fundamental rights flowing from the constitutional traditions common to the member states and from the European Convention on Human Rights (UNTS Vol. 213, p. 221) as an integral part of the general principles of law protected by the Court (case 11/70 – *Internationale Handelsgesellschaft* – [1970] ECR 1125 at 1134). An attempt of the Community to accede to the European Convention on Human Rights failed when the Court ruled that the Community lacks the relevant power without an amendment to the Community treaties (opinion 2/94 – ECHR – [1996] ECR I – 1759). At present, a written affirmation of fundamental rights is absent in Community law, while the Treaty on European Union provides in art. 6 (2) that the Union shall respect fundamental rights as guaranteed by the European Convention on Human Rights and as they result from the constitutional traditions common to the member states. This assertion is of doubtful significance and does not go beyond the case law of the European Court of Justice.

Euthanasia

1. Introduction

In the original Greek, 'euthanasia' meant 'good dying' (*eu thanatos*). First used by Greek poets from about 400 BC onwards, the term was adopted by Greek and Roman philosophers and historians to denote a death that comes quickly and without great and prolonged suffering. The term 'euthanasia' was not used for the intervention, medical or otherwise, to ease a patient's death or to end his or her suffering. Such intervention cannot, however, have been uncommon in antiquity, since assisting a patient's suicide was explicitly ruled out in the so-called Hippocratic oath. Whoever swore this oath (probably the members of a small Pythagorean sect of physicians) committed him- or herself to 'give no deadly medicine to anyone if asked, nor suggest any such counsel.'

In modern times, the meaning of the concept has considerably changed. Though its core meaning of 'good dying' was preserved, it no longer refers to the quality (however defined) of the process of dying as such, but to the cooperation of someone else (the physician, the priest, or others) in making death easier for the dying. Francis Bacon, in a passage of his *De dignitate et augmentis scientiarum* (1623), was the first to distinguish two kinds of assistance to which, according to him, a dying patient has a claim, *euthanasia interior*, the 'spiritual preparation of the soul' for death, and *euthanasia exterior*, 'whereby the dying may pass more easily and quietly out of life' (Bacon 1857, p. 387). Bacon's point was that the purely spiritual preparation provided by the priest was not enough.

What should be introduced was what we now call palliative medicine, the systematic effort to relieve pain and suffering of the dying by medical means. Euthanasia in this sense, Bacon insisted, was not only a natural part of the duties of the physician but also a requirement of plain humanity. Though psychological and spiritual assistance in dying is by now recognized as one of the central elements in the care for the dying (often, however, neglected in practice), the modern concept of euthanasia includes the 'easing of death'

only in so far as this is effected by the application or nonapplication of medical means.

2. Five Types of Euthanasia

The principal meanings of the term 'euthanasia' in ethical and legal discussion correspond to the various forms medical assistance in dying can take.

(a) Relieving suffering by palliative care, e.g., by giving pain-killing drugs and suppressing symptoms such as vomiting or shortness of breath. Palliative care for the dying is rarely referred to as 'euthanasia' in the absence of the more typical practices (b) and (c). However, the term 'indirect euthanasia' is generally applied to cases in which medical interventions aimed at relieving suffering (such as administering drugs or operating on a patient to make the dying process more tolerable) cause the patient's death.

(b) Forgoing life-sustaining medical treatment (either by not initiating treatment or by terminating it at some point) where this implies that the patient dies at an earlier date than he or she would if treatment were continued and where the intention is wholly or primarily to reduce the patient's suffering. This form of euthanasia is commonly referred to as 'passive euthanasia,' irrespective of whether withholding or withdrawing life-sustaining treatment is explicitly requested by the patient.

(c) Actively hastening death to shorten suffering, either by killing the patient ('active euthanasia'), by assisting the patient to kill himself ('assisted suicide'), or by putting the patient in a prolonged state of unconsciousness (e.g., by giving him or her a strong dose of narcotics) with the intention to withdraw life-sustaining treatment while the patient is in this state ('terminal sedation').

Interest in euthanasia of these three types has grown in proportion to the growth of modern medicine and its capacities to maintain life-functions in states of terminal disease and in reaction to a widespread tendency of physicians to preserve life in situations of imminent death at the cost of severe suffering. Political impulses towards making euthanasia a patient right continue to come primarily from the euthanasia and 'right-to-die' societies that have developed all over the world (the British 'Voluntary Euthanasia Legalization Society' was founded in 1935, the 'Euthanasia Society of America' in 1938). They vary, however, in the forms of euthanasia they want to see legalized by law and professional codes. All societies, including the Hospice movement, advocate the extension and improvement of psychological and palliative care for the dying as well as passive euthanasia where this is explicitly requested by the patient. The differences between them concern the extent to which they advocate active euthanasia (as well as the related forms of assisted suicide and terminal sedation). While for the Hospice movement (Twycross 1995) it has become a matter of principle to reject active euthanasia and assisted suicide, most euthanasia societies demand the legalization both of (physician-) assisted suicide and active euthanasia under what might be called the 'paradigmatic euthanasia conditions': (a) the patient is in an irreversible state of terminal illness, (b) the patient suffers intolerably, (c) the patient explicitly wishes to die, (d) this wish is not only momentary but constant. A number of societies, however, favor assisted suicide over active euthanasia as a more unambiguous expression of the patient's autonomous will. At present, an officially approved and legal practice of active euthanasia exists in The Netherlands, an officially approved and legal practice of physician-assisted suicide in the state of Oregon, USA.

The common element of these three variants of euthanasia is that the primary and ultimate aim of giving euthanasia is the relief of suffering, either from physical pain or from other inconveniences of the patient's condition. Shortening the life of the patient is either intended as a means to that end (active euthanasia, passive euthanasia, assisted suicide) or accepted as a side effect (indirect euthanasia). This common element is lacking in practices (d) and (e).

(d) Withholding life-sustaining treatment from a patient in a persistent state of unconsciousness (as in so-called *coma vigile*) with the resulting (and mostly intended) death of the patient. In cases of this sort, the intention cannot be to relieve the patient's suffering because an unconscious patient cannot experience suffering. (There is, however, a residual unclarity on this point. A minority of neurologists think that there is a small chance that consciousness in these patients survives.) Euthanasia in these cases is generally justified either by the patient's presumed will not be kept alive in a persistent state of unconsciousness (as documented, e.g., by an advance directive), by the insistence of the family distressed by a treatment they often see as degrading and contrary to human dignity, or, in advanced stages, by considerations of medical futility (studies have shown that the probability of an 'awakening' from a so-called 'vegetative state' is about 1 percent after one year). Relevant jurisdiction in the US and the UK shows a tendency to allow the withdrawal of life-sustaining treatment after several years of 'persistent vegetative state' with the approval of the family.

(e) Ending the lives of adults and children seen as a burden to society or to parents. In German speaking countries, the German equivalent to the term 'euthanasia' inevitably evokes the National Socialist practice of killing children with malformations and the inmates of psychiatric hospitals and is normally replaced, in reference to practices (a)–(d), by *Sterbehilfe* (assistance in dying). Moreover, memories of the NS-'Euthanasie' explain at least part of the violent resistance, especially in German speaking countries, to philosophical justifications of infanticide (such as by Peter Singer, Singer 1993, Chap. 7). The motives

behind the killing, with the cooperation of their physicians, of 70,000 patients of psychiatric institutions from 1940 to 1941 were partly economic (one criterion of selection was whether patients were able to work), partly an ideology of racial purity.

After stopping the active killing in 1941 a further 90,000 patients were exterminated by 'softer' methods such as undernourishing (Benzenhöfer 1999, p. 129). Calling these killings 'euthanasia' was a deliberate euphemism, as was the term '*lebensunwert*' (unworthy of living) used by the authors Binding and Hoche in a seminal book as early as 1920 and suggesting a poor subjective quality of life (the opposite of 'a life worth living') but in fact expressing an objective judgement about the usefulness of a life to society. Ideas of a selective killing of 'useless' lives have their roots in the Social Darwinism of the late nineteenth century, though there are important earlier philosophical models. A rigid eugenic policy involving compulsory abortion and exposition of 'weak' children (probably on the Spartan model) were a central characteristic of Plato's *Republic*. A curious blending of euthanasia in the sense of relieving suffering and euthanasia in the sense of getting rid of people seen as a burden occurs in Thomas Morus' *Utopia* (1516), where priests and state officials persuade the terminally ill to kill themselves rather than to 'survive their own death.'

3. *Ethical Problems*

While euthanasia in sense (a) is almost universally accepted and euthanasia in sense (e) almost universally rejected by medical ethics and medical law, ethical and legal discussion of euthanasia in each of the other meanings is highly controversial and of a particular emotional quality. There are at least four controversial issues.

(a) How to resolve the conflict between the *principle of patient autonomy* and the *best interest principle* in euthanasia situations. According to the principle of patient autonomy, medical treatment (except in emergency situations) must be based on the informed consent of the patient. If the patient is unconscious or otherwise unable to give valid consent, physicians are required to take into account the presumed consent of the patient, as indicated by written or oral advance directives, by the views expressed by the patient about how he or she would like to be treated in relevant situations and what else can be inferred from the patient's beliefs and world-view. But the physician is also bound by the best interest principle which says that he or she should further the well-being of the patient in the best possible way. This is generally taken to entail an obligation to relieve suffering even without an explicit request. Generally, this principle is taken to be weighty enough to justify shortening the life of a patient with terminal illness if the intention of the physician is exclusively or primarily to relieve suffering.

Problems arise whenever the two principles come into conflict, as when a patient refuses an operation which, in all probability, would save his or her life at an acceptable level of subjective quality of life, whereas following his refusal would lead to instant death. There is considerable consensus among medical ethicists that a medical paternalism (i.e., treating the patient against his or her will, see Van De Veer 1986, Chap. 5) is objectionable even in cases of markedly 'unreasonable' patient wishes except when there is evidence that the patient is not sufficiently informed about his or her prospects, that his or her will is distorted by neurosis, psychosis, or excessive affect, or proves to be unstable under information. Though, on the best interest principle, the physician is called upon to persuade the patient to revise his or her decision, it is widely agreed that the physician should not resort to deception to change the patient's will, since this undermines trust and infringes patient autonomy no less than compulsory treatment would.

(b) Whether actively discontinuing treatment (e.g., by turning the switch of a respirator) is normatively equivalent to strict inaction (e.g., by 'freezing' oxygen pressure on a level that is insufficient for the patient to survive). Ethicists and jurists predominantly take both modes of action to be normatively equivalent. They see no morally significant difference between 'active' and 'passive' discontinuing nor between not starting treatment and terminating treatment. (Discontinuing treatment with the result or the intention of a patient's death in a euthanasia situation generally counts as 'passive' even if involving positive action because the state of the patient is merely restored to the condition in which it was before treatment.) There is, however, a considerable psychological difference. Physicians and nurses find it much easier to let a patient die 'passively' because causality is attributed to external factors instead of one's own behavior.

(c) Whether active killing should be allowed to doctors (or to others) in euthanasia situations. Voluntary active euthanasia, i.e., actively killing a patient to end his or her suffering on the patient's explicit wish is an attractive option because of substantial doubts whether all states of suffering in the last phase of a patient's life (e.g., in some forms of end-stage cancer) can be effectively relieved by discontinuing treatment and palliative measures. Furthermore, many of the ethical arguments against active euthanasia on the level of principles suffer from the fact that they attribute much more normative weight to the distinction between activity (killing) and passivity (letting die) than is thought acceptable, and indeed desirable, in other medical contexts where the physician has not only a duty not to do harm but also a duty to treat. In particular, the question arises how the acceptance of indirect euthanasia (which also involves active intervention) by most legislatures can be made consistent with the rejection of voluntary active euthanasia. The crucial difference is that death is intended as a *means* to

reducing suffering in the latter, while it is accepted as a *side effect* in the former. This difference is regarded as highly relevant by the doctrine of 'double effect' of Catholic moral theology, but not generally by legal systems.

More compelling arguments against legalizing active euthanasia are pragmatic considerations of potential misuse and abuse. Establishing a practice of active euthanasia risks that the autonomy of the patient is overruled by the wishes of relatives, the standards of the medical profession, and the interests of society. In The Netherlands, the only country where active euthanasia is openly practiced, along with a publicly approved practice of voluntary euthanasia (about 2,300 cases per year), there goes a secret practice of nonvoluntary euthanasia (about 1,000 cases per year) which deliberately disregards the procedural rules laid down by the Royal Dutch Medical Association. Though far from proving that a practice of voluntary euthanasia necessarily has a practice of nonvoluntary euthanasia in its wake, the opponents of the legalization of active euthanasia have a point in quoting the 'Dutch experience' (see Thomasma and Marshall 1998) as a warning. Surely, physician-assisted suicide (which is only rarely practiced in the Netherlands) is, wherever it is possible, preferable as an alternative to voluntary euthanasia, not least because it asserts the autonomy of the patient (see Quill 1993).

4. Social Research on Euthanasia

Social science studies about the practice of passive and active euthanasia have begun to be undertaken only recently, partly after the model of the Dutch Remmelink report which was done in 1990–1 at the request of the Dutch government in preparation of euthanasia legislation. This nationwide study included interviews with 405 physicians (carried out by 30 experienced physicians and five other academics) and a questionnaire study with the physicians of a sample of 7,000 recently deceased persons. The main result of this study was a surprisingly high incidence of euthanasia in The Netherlands prior to regulation. Fifty-four percent of the physicians interviewed confirmed that they had practiced active euthanasia or assisted suicide on request of patients and a further 34 percent said that they could conceive of situations in which they would be prepared to do so (van der Maas et al. 1991, p. 669). Twenty-seven percent said that at some time they had ended a patient's life without his or her explicit request and a further 32 percent said that they would prepared to do so under appropriate circumstances. Five years later the study was repeated showing that the situation in The Netherlands had changed only slightly (van der Maas et al. 1996). Substantially lower figures were found in an Australian and a British questionnaire study in which 29 percent (12 percent) of all doctors who returned a completed questionnaire confirmed that they had taken active steps to end a patient's life. A large proportion of the British respondents (46 percent) said, however, that they would consider taking active steps to bring about death if it was legal to do so (Kuhse and Singer 1988, p. 623, Ward and Tate 1994, p. 1332). The importance of cultural factors is highlighted by the contrast between figures for The Netherlands and for Germany, where active euthanasia is still largely a taboo and where questionnaire studies show that the proportion of physicians practicing active euthanasia is maximally 5 percent (Kirschner and Elkeles 1998, p. 251).

D. Birnbacher

Evans-Pritchard, Sir Edward E (1902–73)

Modern anthropology, born in the imagination of the educated classes of Western Europe and the USA in the late nineteenth century, owes its parentage to several ways of witnessing and recording the world beyond their immediate horizon. There were already high quality travelers tales, scientific expeditions mounted to investigate natural history (including direct observations of humanity), and political reports on the troublesome borders of empire. Early professional anthropologists experimented within this framework, and various emphases developed in specific national traditions. In the UK, by the second half of the twentieth century a distinctive combination of personal engagement, systematic research aims within the broad field of social science, and relevance to the affairs of state produced the discipline that became proud to carry the label 'British social anthropology.' Edward Evans-Pritchard was a key architect of this discipline's style and success, both intellectually and institutionally, and achieved perhaps a surprising degree of academic recognition for anthroplogy across the humanities and social sciences. The particular timing of his education and his career meant that he was able to take full advantage of the opportunities of the high colonial period in Africa for his primary research. The expansion of the British University system after the Second World War meant that he was able to promote the institutional development of his discipline. His synthesis was not, however, primarily dependent upon 'participant observation' of culture and human life as such (as had been emphasized by Malinowski) nor upon the need for defining a 'natural science of society' (which had so concerned Radcliffe-Brown). Evans-Pritchard's intellectual ambitions for anthropology sprang rather from an imaginative interest in long-term history and in philosophy, an interest traceable back to his student days and earliest publications.

Edward Evans-Pritchard was born at Crowbridge in Sussex on 21 September 1902, the son of an Anglican clergyman. He attended Winchester College, from which he entered Exeter College at Oxford University in 1921. His family background was less conventional, however, than this account might indicate, as his father was from Caernarvon and spoke Welsh, while his mother's family came from Liverpool. Nor was his time as an undergraduate at Oxford spent very conventionally; he found his obligatory studies of history, mainly about kings and battles, somewhat constricting. Exeter College was, however, already established as a focus for anthropological activities, as a result of the enthusiasms of R. R. Marett, University Reader in Social Anthropology and later Rector of the College, and Evans-Pritchard met many anthropologists there. It is extremely likely that he also attended lectures, almost certainly on Roman Britain but also possibly on philosophy, by the young R.G. Collingwood, then regarded as an unconventional and slightly 'extra-curricular' lecturer but very popular among students. Evans-Pritchard was a little later to review Collingwood's *Roman Britain* (for details see Beidelman 1974); warmly endorsing what we would call today its 'socio-cultural' approach to the everyday life and practices of the ordinary folk.

Drawn by the promise of working with experienced field anthropologists, Evans-Pritchard moved on to study at the London School of Economics and Social Science in 1924. C. G. Seligman was already teaching there, and Bronislaw Malinowski arrived the same year. C.G. Seligman, with his wife Brenda, had been engaged in anthropological work for the government of the Anglo-Egyptian Sudan since 1910, but they were beginning to seek others to continue their project, and Evans-Pritchard seized his opportunity. After completing a required survey in the southern Blue Nile region in 1926 he was allowed a free hand in embarking on his own project to study the Azande kingdoms of the equatorial forests bordering the Congo basin in the south-west. This field research, together with a series of visits between 1930 and 1936 to the very different region of the upper Nile flood-plains inhabited by the Nuer, whose reputation for being a 'difficult' and elusive people far outweighed anything else known about them, laid the foundation for Evans-Pritchard's later career and his shaping of the discipline of social anthropology. He did have the experience of teaching at King Fuad University in Cairo from 1930 to 1934, and at this time published a series of critical, theoretical papers which foreshadowed some of his mature work (for details see Beidelman 1974). A steady output of ethnographic articles mainly on the Azande and the Nuer also appeared through the 1930s, and indeed in the case of the Azande continued to appear throughout his life. But it was the two monographs appearing at the end of the decade which confirmed Evans-Pritchard's outstanding position in anthropology and enabled him, after the War, to re-launch his discipline. They were *Witchcraft, Oracles, and Magic among the Azande* (1937) and *The Nuer: A Description of the Modes of Livelihood and Political Institutions of a Nilotic People* (1940), both published by the Clarendon Press in Oxford, who successfully pleaded the need to obtain a subsidy in each case from the Sudan Government.

While Evans-Pritchard's best-known ethnographic work was carried out in the Sudan, he also undertook field research in several other countries, partly as a result of the War. He was commissioned in the Sudan

Defence Force in 1940, and fought alongside locally recruited militia in Anuak country on the Ethiopian border. In 1942 he was posted to Libya, where he served in the British Military Administration following the liberation of that country from Italian occupation. His investigations of the Bedouin tribes of the interior bore fruit in his book the *Sanusi of Cyrenaica* (1949), an explicitly historical treatment of some of the ideas about segmentary social relations which he had worked out for the Nuer. By the time the War was over, Evans-Pritchard had achieved a greater ethnographic range than any of his British predecessors. There was also an innovative quality to his analytical writings. It was during the period from the late 1930s to the late1940s too that other key events in his life took place. In 1939 he married Ioma Heaton-Nicholls, daughter of the South African high commissioner in London, with whom he raised a lively family of five children. In 1944 he became a Roman Catholic, and returning to Britain at the end of the War, was appointed in 1945 to a Readership in Cambridge and then in 1946 to the Chair of Social Anthropology in Oxford, in succession to A. R. Radcliffe-Brown. He immediately established a high profile position, both for himself and for the now rapidly-expanding subject, becoming president of the Royal Anthropological Institute (1949–51), a founder (1946) and later first life president of the Association of Social Anthropologists of the Commonwealth, and a Fellow of the British Academy (1956). He retired in 1970, and his outstanding life's contribution was recognized with a knighthood in 1971. He died at his home in Oxford, on 11 September 1973. Even before his death, Evans-Pritchard had become something of a living legend, a 'household name' in anthropology. His works helped to define his subject to successive generations of students, and indeed still do so.

Evans-Pritchard's major achievement was to establish social anthropology after the War as a respected member of the humane disciplines, engaging on more equal terms than previously (at least in Britain) with the concerns of linguists, philosophers, historians, theologians, and political theorists. In achieving this distinctive character (which sustains the subject still) some distance had to be created between the 'new' social anthropology on the one hand and the 'old' museums together with 'physical' or biological anthropology on the other. Moreover, a clear identity had to be forged in respect of sociology, which in its new post-War vigor was seen as a richer cousin and tremendous rival (and indeed still is, especially in claims to public funding). Here, the emphasis lay on anthropology's qualitative appreciation of *relational structures and processes* in social life: in the principles behind the uses of language and the creation of meaning in interaction; behind the choreography of kinship and marriage, and the patterning of religious and symbolic practice; and behind the workings of authority, power, and political strife.

The Azande analysis (Evans-Pritchard 1937) immediately struck chords; for example, Collingwood referred to it in his *Principles of Art* (Collingwood 1938). After the War, the book became widely influential in the debate opening up within philosophy over the socially and historically placed foundations of what could be understood as knowledge. It also resonated with the more flexible approaches being taken by historians towards the social context of 'witchcraft' phenomena in the European and American past. Because of its pace and well-constructed storyline, the book easily moved into teaching syllabuses and has always been popular with students. An abridged edition appeared in 1976, mainly to serve teaching courses, and sales are still healthy. The Azande and their doggedly 'rational' and clever way of monitoring and justifying the operation of their oracles (still quite surprising to many readers) have helped to define what modern anthropology is about. They have certainly entered almost every textbook on the subject published since the War. Ironically, however, the appeal of the Azande has more recently converged with new and easy forms of cultural relativism which lead students to ask 'Why shouldn't the Azande believe in witchcraft, if it suits their way of life, and who am I to criticize them?' This is not Evans-Pritchard's line; on the contrary, he shows how most ordinary Azande themselves are not at all comfortable with the presence of witchcraft. It is those in powerful and privileged positions who focus on the idea, as the source of suffering and death, and turn their accusations on the relatively helpless. Sometimes-cruel kings and princes ultimately control the oracles. Even at the household level only senior men have access to them, while women constitute a large proportion of the accused. Evans-Pritchard's analysis is explicitly set in a political and historical context that offers a more nuanced reading than that of simple relativism, and ultimately, it can be argued that this extra depth is what gives the text its lasting qualities.

The Nuer, as a people, and *The Nuer* as Evans-Pritchard's first book on them, next entered the life and language of academic anthropology (Evans-Pritchard 1940). This was the first time that 'œcology' had explicitly been selected for analysis in a field monograph. It was also the first analytical field study of the political principles behind patterns of hostility and alliance between apparently unrelated groups of mobile herders, here cast in a strong idiom of moral obligation invoked through the situational rhetoric of paternal descent. Also for the first time, structured conceptions of space, and of time, were shown to have a social dimension and to constitute an overall framework of shared understandings within which political action was cast and could be 'read' by an observer. The book offered quite a different vision of 'social structure' from the empiricism of Radcliffe-Brown, and, significantly, has since been interpreted as a forerunner of the abstract 'structuralism' associated

especially with Lévi-Strauss; Louis Dumont (in his introduction to the French translation, 1975) even claimed that it had not been properly appreciated by English-speaking anthropologists. *The Nuer* nevertheless served as model and inspiration to a wide range of field studies of 'segmentary' political systems both in Africa and elsewhere. With its successors *Kinship and Marriage among the Nuer* (Evans-Pritchard 1951a, written as a companion text and explicitly focusing on kinship rather than politics) and *Nuer Religion* (Evans-Pritchard 1956) it provoked a considerable industry of 're-analysis', criticism, and comment. The secondary debates flourished in American and British anthropology for some decades until fresh field research began to alter the position of 'the Nuer' within anthropology by asking questions about them and their social world from a different standpoint than that of Evans-Pritchard's founding texts, taking into account aspects of social interconnection across the wider region of the southern Sudan and the longer-term as well as post-colonial social history of North East Africa as a whole and its on-going struggles.

The Nuer, along with the collection on *African Political Systems* co-edited with Meyer Fortes which appeared in the same year, marked the birth of the subdiscipline of field-based political anthropology and a new dialogue with the growing subject of political science. The final volume in Evans-Pritchard's trilogy devoted to the Nuer also helped create a subdiscipline, in this case the field-based anthropology of religion, and also established a new base-line for conversations with a neighboring discipline. *Nuer Religion* (1956) was written quite provocatively as a challenge to academic theology, requiring its specialists as well as a wider readership in religious studies to take tribal systems of belief and practice seriously. Evans-Pritchard's presentation of Nuer trust in *kwoth*, the Spirit of the above, has the schematic character of a creed, but at the same time a lived and shared reality. He portrays for us in almost biblical tone an elemental confrontation between God and Man, demanding recognition across the gulf between the historical religions and their sacred texts on the one hand and the worlds they often denigrate on the other as erring paganism or blind custom. The work is presented as social analysis, emphasizing how diversity of perception and representation reflects the relativity of points of view within Nuer society as established in his first book, and it draws the line (explicitly) at entering the subjectivity of religious experience. A turn towards this very subjectivity, however, has been at the heart of more recent work in the anthropology of religion, opening up avenues to the anthropological study of the major world religions in their lived reality.

Evans-Pritchard's use of ethnographic data from his field research in advancing fresh analysis was innovative and brilliant. To appreciate his 'theories' or 'methods' we need, indeed, to engage with his concrete analyses. However, Evans-Pritchard did set out in the 1950s what he clearly intended as a new horizon for social anthropology. He made explicit his life-long sympathy for the historian's perspective and his ambition to establish social anthropology as 'a kind of historiography,' a comparative study of the forms of social life which did not caricature those forms as mere empirical data but recognized their moral character and their participation in the same historical world as that of the observer (see for example Evans-Pritchard 1951b, 1962). He specifically evoked R.G. Collingwood's vision of what 'history' could be (Collingwood 1946) in sketching his own ambitions for social anthropology, and also followed Collingwood's example in drawing up a new academic lineage for his disciplinary field as he saw it.

It has sometimes been suggested that Evans-Pritchard's style of anthropology could be glossed as 'the translation of culture,' and indeed this was adopted as the title of one of the main volumes of essays offered to him on his retirement in 1970 (Beidelman 1971). However, as a gloss on his overall repositioning of anthropology this phrase sits a little uncomfortably, deriving more from late twentieth-century ideas of 'culture' difference than from the disciplined comparison of social forms towards which Evans-Pritchard strove, taking his inspiration from the French sociological school of Durkheim, and especially perhaps from the historically comparative work of Marcel Mauss. Among other initiatives in the 1950s, Evans-Pritchard sponsored a series of translations of classic essays from the *Année Sociologique*, starting with Mauss's essay on *The Gift* (1954), which remains a foundation text in the teaching of anthropology, especially economic anthropology, and is clearly about more than the 'translation of culture.' Evans-Pritchard was certainly concerned with translation, but essentially as a craftsman in handling the subtleties of language as such, as for example in his elegant paper on *sanza*, the way in which Azande employ proverbs in double-talk (1962), or in his treatments of poetry and oral literature. A project he undertook with colleagues in the 1960s was the launching of the Oxford Library of African Literature, a series that flourished over the following two decades, and had considerable influence in developing anthropology's openness to art, performance, narrative, and the uses of textual material generally.

The lasting significance of Evans-Pritchard's legacy lies partly in its successful move away from simple observer's empiricism and a narrowly-based definition of the subject-matter of anthropology, towards an engagement with key debates in history, politics, literary criticism, philosophy, theology, and religious studies (for evaluations, see, for example, Barnes 1987, Douglas 1980). At the same time, these subjects have come increasingly to recognize the value of empirical inquiry into the lives, opinions, memories, and practices of people living 'in the world,' while the feminist critique and new fields such as gender studies,

cultural, and media studies have adopted many ideas from anthropology. They have also helped to give a new lease of life to the idea of 'ethnography' as a reflexive engagement with the world.

Meanwhile, anthropology has moved firmly from the 'tribal periphery' towards the comparative study of the major civilizations, including the practice of the world religions; it is now tackling modern economic ideas and international development, urban life, and global processes. A generation of anthropologists born long after Evans-Pritchard's era have naturally sought to refashion and refresh the subject in the fast-changing world of the late twentieth century, and various lines of criticism have been directed towards his work. Along with his contemporaries, he has been taken to task for not keeping more of an intellectual distance from the colonial situation in which anthropology had such a privileged position. He has been criticized for being too impressionistic in his ethnographic portrayals, for not adopting a more differentiated view of the peoples he was studying, and not attending more carefully to the specifics of their lives. He has been accused of using a patronizing tone and perpetuating character stereotypes. On the question of religion, he has been accused of presenting Nuer beliefs as too biblical and the people as too pious. He has also had his fair share of accusations over 'male bias.' Details of his Nuer ethnography (though rarely of his accounts of the Azande) have been combed over and reanalyzed in order to support various more 'rigorous' accounts based on modern social or psychological theories. Evans-Pritchard himself rarely responded directly to these criticisms. From the mid-1960s on, in common with others whose lives had become involved in the Sudan in one way or another, he was shocked and angry about the deepening civil war in the country and its effect on people he remembered, and who remembered him. Perhaps partly because of this he had no taste for picking over his earlier writings. He developed various enthusiasms for both radical and conservative causes, and seemed to enjoy his growing reputation for eccentricity (see Lienhardt's memoir, 1974). Age added a more of a waspish tone to his famous wit and camaraderie, while the debates over his work were left to others.

With hindsight, and the turn of another century, it can be seen that Evans-Pritchard's work remains a source of inspiration despite the broadside against 'functionalism' and imperial collusion. He was 'accused' of working for the Sudan government, but at the time he was aware of the contradictions of his position and engaged in debate with the colonial authorities (Johnson 1982). He put very vividly those paradoxes of multiple belonging or 'positionality' which the modern student ponders, focusing in a still helpful way on the relativity of 'self and other' in the making of personal and group identities, as we might rephrase the relevance of segmentary theory today. He placed 'dialogue' both between the Azande themselves and between himself and his informants firmly at the heart of the analysis of knowledge and belief that he carried out among them. He also respected, explicitly, the privacy and inner religious consciousness of the Nuer whose world became in so many other ways public property through his work. It is clearly true that in many respects Evans-Pritchard failed to take 'colonialism' into account in his analyses, or to allow for historical change; but then again, looking back, he is foremost among those who worked to re-orient anthropology towards history. His treatment of field research was never as an end in itself; field research was only one of many methods, including many of those scholarly methods standard to history and the social sciences, to be drawn into anthropological analysis.

Moreover, Evans-Pritchard's anthropology was broader, in practice, than many imagine, including for example the sensitive use of informants' own accounts about relations between men and women among the Azande—long before gender or sexuality had become an academic topic (1974). Nor was he confined to work in 'social' anthropology alone; he made quite extensive collections of ethnographic objects, musical recordings, and photographs, now mostly deposited in the Pitt Rivers Museum in Oxford. In Britain, social anthropology has sought to reestablish debates with the study of material culture, art and music on the museum side and also with medical and biological anthropology. Evans-Pritchard's work remains a source of questions relevant to these new debates. His achievement of a distinctive intellectual tradition within the humanities for 'social anthropology' in the mid-twentieth century provided a momentum from which the discipline in the broader sense is still benefiting. His memory continues to be honored, most recently with the establishment of an annual series of Evans-Pritchard Lectures at All Souls College, Oxford, in 1999.

Event History Analysis: Applications

'Event history analysis' studies a collection of units, each moving among a finite (usually small) number of states. An example is individuals who are moving from unemployment to employment. In this article, various examples of event history applications are presented, the concepts and advantages of event history analysis are demonstrated, and practical complications are addressed.

1. *Examples of Continuous-time, Discrete-state Processes*

Event history analysis is the study of processes that are characterized in the following general way: (a) there is a collection of units (which may be individuals, organizations, societies, etc.), each moving among a finite (usually small) number of states; (b) these changes (or events) may occur at any point in time (i.e., they are not restricted to predetermined points in time); and (c) there are time-constant and/or time-varying factors influencing the timing of events. Examples are workers who move between unemployment and employment; men and women who enter into consensual unions or marriages; companies that are founded or closed down; governments that break down; people who are mobile between different regions or nation states; consumers who switch from one brand to another; prisoners who are released and commit another crime; people, who show certain types of verbal and nonverbal behaviors in social interactions; students who drop out of school; incidences of racial and ethnic confrontation, protest, riot and attack; people who show signs of psychoses or neuroses; patients who switch between the states 'healthy' and 'diseased,' and so on. In event history analysis, the central characteristics of the underlying stochastic process is mirrored in the specific way theoretical and mathematical models are built, data are collected, and the estimation and evaluation of models is done.

2. *Different Observation Plans*

In event history analysis the special importance of broader research design issues has been stressed. In particular, different observation plans have been used to collect information on the continuous-time, discrete-state substantive process. These various schemes produce different types of data that constrain the statistical analysis in different ways: cross-sectional data, event count data, event sequence data, panel data, and event history data.

The cross-sectional observation design is still the most common form of data collection in many fields. A cross-sectional sample is only a 'snapshot' taken on the continuous-time, discrete-state substantive process (e.g., the jobs of people at the time of the interview). Event history analysis has shown that one must be very cautious in drawing inferences about explanatory variables on the basis of such data because, implicitly or explicitly, social researchers have to assume that the process under study is in some kind of equilibrium. Equilibrium means that the state probabilities are fairly trendless and the relationships among the variables are quite stable over time. Therefore, an equilibrium of the process requires that the inflows to and the outflows from each of the discrete states be equal over time to a large extent. This is a strong assumption that is not very often justified in the social and behavioral sciences (see Blossfeld and Rohwer 1995).

A comparatively rare type of data on changes of the process are event count data (Andersen et al. 1993). They record the number of different types of events for each unit in an interval (e.g., the number of racial and ethnic confrontations, protests, riots or attacks in a period of 10 years). Event sequence data provide even more information. They record the sequence of specific states occupied by each unit over time (e.g., see *Event Sequence Analysis: Methods*). The temporal data most often available to the scientist are panel data. They provide information on the same units of analysis at a series of discrete points in time. In other words, there is only information on the states of the units at

predetermined survey points and the course of the process between the survey points remains unknown. Panel data certainly contain more information than cross-sectional data, but involve well-known distortions created by the method itself (e.g., panel bias, attrition of sample). In addition, causal inferences based on panel approaches are much more complicated than has been generally acknowledged (Blossfeld and Rohwer 1995). With regard to the continuous-time, discrete-state substantive process, panel analysis is particularly sensitive to the length of the time intervals between the waves relative to the speed of the process. They can be too short, so that too few state transitions will be observed, or too long, so that it is difficult to establish a time-order between the events.

The event oriented observation design records the complete sequence of states occupied by each unit and the timing of changes among these states. For example, an event history of job mobility consists of more or less detailed information about each of the jobs and the exact beginning and ending dates of each job. Thus, this is the most complete information one can get on the continuous-time, discrete-state substantive process. Such event history data are often collected retrospectively with life history studies. Life history studies are normally cheaper than panel studies and have the advantage that they code the data into one framework of codes and meaning. But retrospective studies also suffer from several limitations (see Blossfeld and Rohwer 1995). In particular, data concerning motivational, attitudinal, cognitive, or affective states are difficult (or even impossible) to collect retrospectively because the respondents can hardly recall the timing of changes in these states accurately. Also the retrospective collection of behavioral data has a high potential for bias because of its strong reliance on autobiographic memory. To reduce these problems of data collection, modern panel studies (e.g., the Panel Study of Income Dynamics (PSID) in the USA, the British Household and Panel Survey (BHPS) in the UK, or the Sozio-oekonomisches Panel (SOEP) in Germany) use a mixed design which provides traditional panel data and retrospectively collects event history data for the period before the first panel wave and between the successive panel waves.

3. *Event History Analysis*

Event history analysis, originally developed as independent applications of mathematical probability theory in demography (e.g., the classical life table analysis and the product-limit estimator of Kaplan and Meier (1958), reliability engineering, and biostatistics (e.g., the path-breaking semiparametric regression model for survival data of David Cox (1972) has gained increasing importance in the social and behavioral sciences (see Tuma and Hannan 1984, Blossfeld et al. 1989, Lancaster 1990, Andersen et al. 1993, Blossfeld and Rohwer 1995) since the early 80s. Due to the development and application of these methods in various disciplines, the terminology is normally not easily accessible to the user. Central definitions are therefore given first.

3.1 *Basic Terminology*

Event history analysis studies transitions across a set of discrete states, including the length of time intervals between entry to and exit from specific states. The basic analytical framework is a state space and a time axis. The choice of the time axis or clock (e.g., age, experience, marriage duration, etc.) used in the analysis must be based on theoretical considerations and affects the statistical model. Dependent on practical and theoretical reasons, there are event history methods using a discrete (Yamaguchi 1991, Vermunt 1997) or continuous time axis (Tuma and Hannan 1984, Blossfeld et al. 1989, Courgeau and Lelièvre 1992, Blossfeld and Rohwer 1995). Discrete-time event history models are, however, special cases of continuous-time models and are therefore not further discussed here. An episode, spell, waiting time, or duration—terms that are used interchangeably in the literature—is the time span a unit of analysis (e.g., an individual) spends in a specific state. The states are discrete and usually small in number. The definition of a set of possible states, called the state space, is also dependent on substantive considerations. Thus, a careful, theoretically driven choice of the time axis and design of state space are crucial because they are often serious sources of mis-specification.

The most restricted event history model is based on a process with only a single episode and two states (an origin state j and a destination state k). An example may be the duration of first marriage until the end of the marriage, for whatever reason (separation, divorce, death). In the single episode case each unit of analysis that entered into the origin state is represented by one episode. Event history models are called multistate models, if more than one destination state exists. Models for the special case with a single origin state but two or more destination states are also called models with competing events or risks. For example, a housewife might become 'unemployed' (meaning entering into the state 'looking for work'), or start being 'full-time' or 'part-time employed.' If more than one event is possible (i.e., if there are repeated events or transitions over the observation period), the term multi-episode model is used. For example, an employment career normally consists of a series of job shifts.

3.2 *Censoring*

Observations of event histories are often censored. Censoring occurs when the information about the

duration in the origin state is incompletely recorded. An episode is fully censored on the left, if starting and ending times of a spell are located before the beginning of an observation period (e.g., before the first panel wave) and it is partially censored on the left, if the length of time a unit has already spent in the origin state is unknown. This is typically the case in panel studies, if individuals' job episodes at the time of a first panel wave is known but no further information about the history of the job is collected. Left censoring is normally a difficult problem because it is not possible to take the effects of the unknown episodes into account. It is only without problems, if the assumption of a Markov process is justified (i.e., if the transition rates do not depend on the duration in the origin state).

The usual kind of censoring, however, is right-censoring. In this case the end of the episode is not observed but the observation of the episode is terminated at an arbitrary point in time. This type of censoring typically occurs in life course studies at the time of the retrospective interviews or in panel studies at the time of the last panel wave. Because the timing of the end of the observation window is normally determined independently from the substantive process under study, this type of right censoring is unproblematic and can easily be handled with event history methods (Kalbfleisch and Prentice 1980—type I censoring). Finally, episodes might be completely censored on the right. In other words, entry into and exit from the duration occurs after the observation period. This type of censoring normally happens in retrospective life history studies in which individuals of various birth cohorts can only be observed over very different spans of life. To avoid sample selection bias, such models have to take into account variables controlling for the selection, for example, by including birth cohort dummy variables (see Yamaguchi 1991).

3.3 The Transition Rate

The central concept of event history analysis is the transition rate. Because of the various origins of event history analysis in the different disciplines, the transition rate is also called the hazard rate, intensity rate, failure rate, transition intensity, risk function, or mortality rate:

$$r(t) = \lim_{t' \to t} \Pr(t \leqslant T < t' | T \geqslant t)/(t'-t) \qquad (1)$$

The transition rate provides a local, time-related description of how the process evolves over time. It can be interpreted as the propensity (or intensity) to change from an origin state to a destination state, at time t. But one should note that this propensity is defined in relation to a risk set ($T \geqslant t$) at t, i.e., the set of units that still can experience the event because they have not yet had the event before t.

3.4 Statistical Models

The central idea in event history analysis is to make the transition rate, which describes a process evolving in time, dependent on time (t) and on a set of covariates, x:

$$r(t) = g(t, x) \qquad (2)$$

The causal interpretation (see *Causation (Theories and Models): Conceptions in the Social Sciences*) of the transition rate requires that we take the temporal order in which the processes evolve very seriously. In other words, at any given point in time, t, the transition rate $r(t)$ can be made dependent on conditions that happened to occur in the past (i.e., before t), but not on what is the case at t or in the future after t.

There are several possibilities to specify the functional relationship g (see Blossfeld and Rohwer 1995). For example, the exponential model, which normally serves as a baseline model, assumes that the transition rate can vary with different constellations of covariates x, but that the rates are time-constant. The piecewise constant exponential model allows the transition rate to vary across fixed time periods with period-specific effects of covariates. There are also different parametric models which are based on specific shapes of the time-dependence (e.g., the Gompertz-Makeham, Weibull, Sickle, Log-logistic, Log-normal, or Gamma model). If the time-shape of the base-line hazard rate is unspecified, and only possible effects of covariates x are estimated, the model is called a semi-parametric or partial likelihood model (Cox 1972). Finally, there are also models of unobserved heterogeneity in which the transition rate can be made dependent on the observed covariates x, the duration t, and a stochastic error term.

4. Parallel and Interdependent Processes

The most important scientific progress permitted by event history analysis is based on the opportunity to include explicitly measured time-varying covariates in transition rate models (see Blossfeld and Rohwer 1995). These covariates can change their values over process time in an analysis. Time-varying covariates can be qualitative or quantitative, and may stay constant for finite periods of time or change continuously. From a substantive point of view, time-varying covariates can be conceptualized as observations of the sample path of parallel processes. These processes can operate at different levels. In sociology, for example, (a) there can be parallel processes at the level of the individual's different domains of life (e.g., one may ask how upward and downward moves in an individual's job career influence his/her family trajectory); (b) there may be parallel processes at the level of some few individuals interacting with each other

(e.g., one might study the effect of the career of the husband on his wife's labor force participation); (c) there may be parallel processes at the intermediate level (e.g., one can analyze how organizational growth influences career advancement or changing household structure determines women's labor force participation); (d) there may be parallel processes at the macro level (e.g., one may be interested in the effect of changes in the business cycle on family formation or career advancement); and (e) there may be any combination of such processes of type (a) to (d). For example, in the study of life-course, cohort and period effects, time-dependent covariates at different levels (see below) must be included simultaneously (multi-level analysis).

In dealing with such systems of parallel processes, the issue of reverse causation (see *Causation (Theories and Models): Conceptions in the Social Sciences*) is often addressed in the methodological literature (see, e.g., Kalbfleisch and Prentice 1980, Tuma and Hannan 1984, Blossfeld et al. 1989, Yamaguchi 1991, Courgeau and Lelièvre 1992). Reverse causation refers to the (direct or indirect) effect of the dependent process on the independent covariate process(es). Reverse causation is often seen as a problem because the effect of a time-dependent covariate on the transition rate is confounded with a feedback effect of the dependent process on the values of the time-dependent covariate. However, Blossfeld and Rohwer (1995) have developed a causal approach to the analysis of interdependent processes that also works in the case of interdependence, too. For example, if two interdependent processes, Y_t^A and Y_t^B, are given, a change in Y_t^A at any (specific) point in time t' may be modeled as being depend on the history of both processes up to, but not including t'. Or stated in another way: what happens with Y_t^A at any point in time t' is conditionally independent of what happens with Y_t^B at t', conditional on the history of the joint process $Y_t = (Y_t^A, Y_t^B)$ up to, but not including, t ('principle of conditional independence'). Of course, the same reasoning can be applied if one focuses on Y_t^B instead of Y_t^A as the 'dependent variable.' Beginning with a transition rate model for the joint process, $Y_t = (Y_t^A, Y_t^B)$, and assuming the principle of conditional independence, the likelihood for this model can then be factorized into a product of the likelihoods for two separate models: a transition rate model for Y_t^A which is dependent on Y_t^B as a time-dependent covariate, and a transition rate model for Y_t^B, which is dependent on Y_t^A as a time-dependent covariate. From a technical point of view, there is therefore no need to distinguish between defined, ancillary, and internal covariates (see, e.g., Kalbfleisch and Prentice 1980) because all of these time-varying covariate types can be treated in the estimation procedure. Estimating the effects of time-varying processes on the transition rate can easily be achieved by applying the method of episode splitting (see Blossfeld and Rohwer 1995).

5. *Unobserved Heterogeneity*

Unfortunately, researchers are not always able to include all the important covariates into an event history analysis. These unobserved differences between subpopulations can lead to apparent time dependence at the population level and additional identification problems. There exists a fairly large literature on mis-specified models in general. In particular, there have been several proposals to deal with unobserved heterogeneity in transition rate models (so-called frailty models) (see, e.g., Blossfeld and Rohwer 1995).

6. *Illustrative Applications*

The following three applications illustrate the technical strength of event history models in different substantive contexts.

6.1 *A Multi-level Analysis of Life-course, Cohort, and Period Effects in Career Mobility*

Any standard statistical analysis using age, year of birth (as a cohort measure), and chronological year of measurement (as a period measure) leads to an identification problem (age = year of measurement–year of birth). The technical solution to that problem often is to assume that at least one of these measures is constant over time or to apply arbitrary statistical constraints. Blossfeld (1986) in an event history study of career mobility of German men approached this problem from a more substantive point of view. He suggested to rely more on explicit measures for the theoretically important macro effects of cohort and period and used 14 time series from official statistics indicating the long-term development of the labor market structure in Germany. Based on factor analysis, he first reduced the 14 highly correlated time series to two orthogonal macro factors which represented the 'monotonic trend in the level of modernization' and the 'cyclic changes in labor market conditions' and then matched these macro data to individual event career data to conduct a multi-level analysis. To represent the changing conditions under which cohorts enter the labor market, Blossfeld used the factor scores of these two factors at the year men entered the labor force. To introduce period as a time-dependent covariate, he used the method of episode splitting. In accordance with this method, the original job episodes were split into sub-episodes every year so that the factor scores of the two macro factors could be updated in each job episode for all employed men every year. Modeling cohort and period effects this way not only provides more direct and valid measures of the explanatory concepts, but also results in the

disappearance of the problem of non-estimable parameters above. It was, therefore, not necessary to impose (in substantive terms normally unjustifiable) constraints on the parameters to identify life-course, cohort, and period effects.

6.2 *Parallel Processes at the Level of the Individual: Women's Rising Educational and Career Investments, and Changes in the Process of Family Formation*

Using event history models, Blossfeld and Huinink assessed the hypothesis of the 'new home economics' that women's rising educational and career investments will lead to a decline in marriage and motherhood (see Blossfeld and Rohwer 1995, p. 143). Because the accumulation of educational and career resources is a lifetime process, they analyzed it as a dynamic process over the life course. To model the changes in the accumulation of qualifications over the life course, Blossfeld and Huinink updated a time-varying covariate 'level of education' at the age when a woman obtained a particular educational rank in the hierarchy. They also generated a time-dependent dummy variable indicating whether or not a woman is attending the educational system at a specific age. Finally, for the dynamic modeling of job-specific investments in human capital over the life course, Blossfeld and Huinink have developed a specific time-dependent labor force experience measure, which they called 'career resources.' The time-dependent increments and final levels of this measure were designed to reflect the 'quality of each job' and the respective 'employment durations.' The time-dependent measure also took into account that career resources are declining when women interrupted their employment career. Blossfeld and Huinink applied the method of episode splitting to include these various time-dependent dimensions of education and career together with additional control variables in the rate equation. The results of their longitudinal analysis were surprising: contrary to the expectations of the economic approach to the family, women's entry into marriage obviously was independent of women's level of education and their career resources. Equally surprisingly, the effect of women's level of education on the rate of their first birth was even positive. An explanation for the positive effect on the timing of first birth is easily demonstrated with an event history model: women who remain in school longer and attain high qualifications are first shifting their fertility decisions to higher ages, and then, they are subject to pressure not only from the potential increase in medical problems connected with having children late, but also from societal age norms. Thus the higher the educational attainment level the stronger the catching-up effect. This application demonstrates that the standard empirical support for the economic theory of the family claimed on the basis of cross-sectional data might be misleading. Cross-sectional data do not permit a differentiation between the time-dependent effect of accumulation of human capital over the life course and the time-dependent effect of participation in the educational system.

6.3 *A Causal Approach to Interdependent Systems: The Effects of Pregnancy on Entry into Marriage for Couples Living in Consensual Unions*

Finally, the application of a causal approach to interdependent systems is demonstrated by Blossfeld and Rohwer in an analysis of the effect of pregnancy on entry into marriage in Germany (see Blossfeld and Rohwer 1995, p. 157). This study shows that the effect of a fertility event on entry into marriage is highly time dependent: It starts to rise at some time shortly after conception (thus there is some time lag involved between cause and effect), increases during pregnancy to a maximum at around seven to eight months after conception, and then decreases again reaching a level even below the starting level at around six months after the birth of the child. Thus, the dynamic interdependence of fertility and nuptiality mainly occurs in a very specific phase of the life course and the unfolding effect of fertility on nuptiality is highly dynamic over time. Of course, standard statistical applications based on cross-sectional observation can be hardly used to analyse such situations in a meaningful way. However, in event history analysis, there is an easy way to approach that problem. One can use a series of time-dependent dummy variables each indicating a month since the occurrence of conception (the causal event). They show that the effects of the time-dependent dummy variable at first increase, reach a maximum, and then decrease again. Thus, starting with conception, there is an increasing normative pressure to avoid an illegitimate birth that increases the marriage rate, particularly for people who are already 'ready for marriage.' But with an increasing number of marriages, the composition of the group of still unmarried couples shifts towards couples being 'less ready for marriage' or being 'not ready for marriage,' which, of course, decreases the fertility effect again. This is an important result not only in substantive terms; the methodological lesson for event history analysis is also revealing. One should be very careful in modeling qualitative parallel processes with only one dummy variable (e.g., in the current application using only the time of conception, or the time of birth for the switch of the time-dependent covariate) because the effect itself might be highly time-dependent. For example, Blossfeld and Rohwer show that the fertility effect disappears completely, when the time-dependent covariate is switched at the time of birth because then a period with a low marriage rate up to the time of discovery of conception and a period with a high marriage rate during pregnancy is aggre-

gated and compared with a period of low rate after the birth of the child.

Event-history Analysis in Continuous Time

1. Introduction

Event history analysis deals with data obtained by observing individuals over time focusing on events occurring for the individuals. Thus, typical outcome data consist on *times of occurrence* of events and on the *types of events* which occurred. Frequently, an event may be considered as a *transition* from one state to another and, therefore, *multistate models* will often provide a relevant modeling framework for event history data. Multistate models are discussed from several points of view in the books by Andersen et al. (1993), Blossfeld and Rohwer (1995), and Courgeau and Lelièvre (1992); see Hougaard (1999) and Commenges (1999) for recent surveys.

There are two broad purposes of event history modeling: *analysis* where the interest is in the statistical modeling of each individual transition, including its possible dependence on internal or external covariates, and *synthesis* where the combination of several transitions is described via suitable summary measures.

2. Survival Data

The simplest multistate model is the two-state model for survival data with one transient state '0: alive' and one absorbing state '1: dead,' see Fig. 1. In general, an *absorbing* state is a state from which further transitions cannot occur while a *transient* state is a state which is not absorbing. The observation for a given individual will here in the simplest form consist of a random variable, say T, representing the time from a given origin (time 0) to the occurrence of the event 'death.' The distribution of T may be characterized by the probability distribution function $F(t) = \text{Prob}(T \leqslant t)$ or, equivalently, by the survival distribution function $S(t) = 1 - F(t) = \text{Prob}(T > t)$. It is seen that $S(t)$ and $F(t)$, respectively, correspond to the probabilities of being in state 0 or 1 at time t. If every individual is assumed to be in state 0 at time 0 then $F(t)$ is also the *transition probability* from state 0 to state 1 for the time interval from 0 to t. In continuous time the distribution of T may also be characterized by the *hazard rate function*

$$\alpha(t) = -\mathrm{d}\log S(t)/\mathrm{d}t = \lim_{\Delta t \to 0} \frac{\text{Prob}(T \leqslant t + \Delta t | T \geqslant t)}{\Delta t},$$

that is

$$S(t) = \exp\left(-\int_0^t \alpha(u)\mathrm{d}u \right)$$

Thus, $\alpha(\cdot)$ is the *transition intensity* from state 0 to state 1, that is, the instantaneous probability per time unit of going from state 0 to state 1.

In general, event history analysis deals with inference for transition intensities and transition probabilities in multistate models. This includes estimation and hypothesis tests for these quantities and analysis of regression models where these quantities are related to (possibly time-dependent) explanatory variables observed for the individuals under study. Most frequently, multistate models are defined by their transition intensities from which transition probabilities may or may not be derived depending on the modeling assumptions.

Figure 1
The two-state model for survival data

A typical feature of event history analysis is the inability to observe complete event histories, for example, by the end of the observation period all individuals under study may not have reached an absorbing state. In survival analysis this would correspond to individuals still being alive by the end of the study and this kind of *incomplete observation* is known as *right-censoring*. Furthermore, all individuals may not have been observed from the same time origin. This kind of incomplete observation where individuals are only observed conditionally on not having reached an absorbing state by the time of initiation of the study is known as *left-truncation*. Restricting attention to right-censoring a crucial problem is whether the available incomplete data enables one to make valid inference on parameters in the multistate model for the complete data. The condition for this is known as *independent* right-censoring and the interpretation is that a sample observed after independent right-censoring is 'representative' for the population without censoring. This means that individuals who are censored should have neither lower nor higher risk of future events than individuals who are not censored (see, e.g., Andersen et al. 1993, Chap. III, Kalbfleisch and Prentice 1980, p. 120).

Right-censoring may be caused by a number of different mechanisms. Suppose, for example, that one is interested in the disease specific mortality for patients suffering from a given disease like skin cancer and followed from their times of diagnosis (time 0). Then right-censoring may be caused by:

(a) a patient still being alive by the time of closure of the study,

(b) a patient being lost to follow-up,

(c) a patient dying from causes other than skin cancer.

In case (a) there are usually no reasons to believe that censoring should not be independent since the time of closure of a study can most often be assumed independent of the process observed. In case (b) one may be suspicious that patients lost to follow-up could be individuals who generally feel well (or the opposite) and, therefore, do not want to take part in a study any more and this could lead to *dependent* censoring. Situation (c) is more tricky since here the population without censoring is quite hypothetical: it is hardly reasonable to think of a population of skin cancer patients for whom it is impossible to die from other causes. This fact has consequences for how to choose an appropriate model in this situation and a relevant model to consider could be a *competing risks model*, see Fig. 2.

The problem is that even though it may be possible to make valid inference for the single cause-specific hazard $\alpha_1(t)$ of dying from skin cancer by using methods for survival data and treating deaths from other causes as right-censored observations then, in order to evaluate the survival probability for skin-cancer patients, the intensity of dying from other causes is also needed. In Sect. 3 we return to the relationship between the two cause-specific hazards and the transition probabilities in Fig. 2. The conclusion is that a *partial model specification* where the hazard, $\alpha_2(t)$, of dying from other causes is not modeled may suffice for some, but not all, purposes and a multistate model like the one depicted in Fig. 2 can be a sensible model to study in spite of the fact that focus may be on a single transition. Partial model specification is further discussed in Sect. 5.

3. *Multistate Models*

In this section, we will present a number of different multistate models including the two-state model for survival data and the competing risks model introduced in Sect. 2. We will begin with a few definitions. Some of the definitions are formulated loosely but they may all be made rigorous within the framework of so-called *marked point processes* (Andersen et al. 1993, Chap. III, Arjas and Haara 1984).

A multistate process is a stochastic process $(X(t), t \in \mathscr{T})$ with a finite state space $\mathscr{S} = \{1, \ldots, p\}$ and with right-continuous sample paths: $X(t+) = X(t)$. Here, $\mathscr{T} = [0, \tau]$ or $[0, \tau)$ with $\tau \leqslant +\infty$. The process has *initial distribution* $\pi_h(0) = \text{Prob}(X(0) = h)$, $h \in \mathscr{S}$. A multistate process $X(\cdot)$ generates a *history* $\mathscr{X}_t$ consisting of the observation of the process in the interval $[0, t]$. Relative to this history we may define *transition probabilities* by

$$P_{hj}(s, t) = \text{Prob}(X(t) = j | X(s) = h, \mathscr{X}_{s^-})$$

for $h, j \in \mathscr{S}$, $s, t \in \mathscr{T}$, $s \leqslant t$, and *transition intensities* by the derivatives

$$\alpha_{hj}(t) = \lim_{\Delta t \to 0} P_{hj}(t, t + \Delta t)/\Delta t$$

which we shall assume exist. Some transition intensities may be 0 for all t. Graphically, multistate models may be illustrated using diagrams like Fig. 1 or 2 with boxes representing the states and with arrows between the states representing the possible transitions, that is, the nonzero transition intensities (Hoem 1976, Andersen et al. 1993, Sect. I.3). A state $h \in \mathscr{S}$ is *absorbing* if for all $t \in \mathscr{T}$, $j \in \mathscr{S}$, $j \neq h$, $\alpha_{hj}(t) = 0$; otherwise h is *transient*. The *state probabilities* $\pi_h(t) = \text{Prob}(X(t) = h)$ are given by

$$\pi_h(t) = \sum_{j \in \mathscr{S}} \pi_j(0) P_{jh}(0, t)$$

Notice that both the $P_{hj}(\cdot, \cdot)$, the $\pi_h(\cdot)$, and the $\alpha_{hj}(\cdot)$ depend on both the probability measure Prob and on the history. Sometimes one is interested in considering an extended history which also includes observed *covariates*. If only time-fixed covariates Z are studied then the observed history is $\mathscr{F}_t = \mathscr{X}_t \vee \mathscr{Z}_0$ whereas

Figure 2
Competing risks model for skin cancer (s.c.) mortality (o.c. ~ other causes)

time-dependent covariates $Z(t)$ give rise to an extended history of the form $\mathscr{F}_t = \mathscr{X}_t \vee \mathscr{Z}_t$ where in both cases $\mathscr{Z}_t$ is the history generated by the covariates in $[0, t]$. We shall here focus on the *purely endogeneous* case where $\mathscr{Z}_t \subset \mathscr{X}_t \vee \mathscr{Z}_0$, i.e. the covariates are either all time-fixed or the random development of the time-dependent covariates is fully specified by the history of the process itself (see, however, Sect. 5).

3.1 The Two-state Model for Survival Data

This model, illustrated in Fig. 1, has $p = 2$ states and only one possible transition from state 0 to state 1. The corresponding transition intensity $\alpha_{01}(t)$ is given by the hazard rate function $\alpha(t)$, while $\alpha_{10}(t) = 0$ for all t, that is, state 1 is absorbing. The initial distribution is degenerate in 0: $\pi_0(0) = 1$. The process is *Markovian*, cf. Sect. 5.1. Covariates may be entered into the model using a regression model for $\alpha(\cdot)$.

3.2 The Competing Risks Model

This model has one transient state '0: alive' and a number, k, of absorbing states, state h, $h = 1,\ldots, k$ corresponding to 'death from cause h.' Thus, there are $p = k+1$ states. The model is illustrated for $k = 2$ in Fig. 2. The transition intensities $\alpha_{0h}(t)$ for $h = 1,\ldots,k$ are given by the cause-specific hazard functions

$$\alpha_h(t) = \lim_{\Delta t \to 0} \text{Prob}(\textit{Dead from cause } h \textit{ by } t+\Delta t | T \geqslant t)/\Delta t$$

where T is the survival time. The initial distribution is degenerate in 0, the only transient state of the model, that is, $\alpha_{hj}(t) = 0$ for all $h \neq 0$ and all j. The transition probabilities are given by

$$P_{00}(0, t) = S(t) = \text{Prob}(T > t) = \exp\left(-\int_0^t \sum_{h=1}^{k} \alpha_h(u)\mathrm{d}u \right)$$

Figure 3
The illness–death or disability model

Figure 4
Unidirectional illness–death model

and

$$P_{0h}(0, t) = \int_0^t S(u-)\alpha_h(u)\mathrm{d}u,\ h = 1,\ldots, k$$

like the simple two-state model ($k = 1$) the competing risks model is Markovian and covariates may be included into the model via regression models for the cause-specific hazards.

3.3 The Illness–Death model

This model is illustrated in Fig. 3, which by now should be almost self-explanatory. Often the time t is the age of the individual, and usually individuals will be assumed to be in state 0 at $t = 0$. However, individuals will not always be observed from $t = 0$ as shall be further discussed in Sect. 5 below regarding observational patterns. The mortality $\alpha_{12}(t)$ of the diseased (the *lethality*) may sometimes depend on duration d since entry to state 1 in addition to the dependence on 'age' t. (Notice that, despite the notation, $\alpha_{12}(t)$ then depends on the *random* time of the most recent transition into 1.) If $\alpha_{12}(t)$ does not depend on d the process is Markovian, otherwise it is a *semi-Markov process*, which is clearly purely endogeneous.

In Fig. 3 we have indicated the possibility of *reversibility*: the transition back from state 1 to 0 is possible. It will turn out that the simple unidirectional model in Fig. 4, is rather easier to analyse statistically. Thus, the transition probabilities in this model have simple explicit expressions

$$P_{00}(s, t) = \exp\left(-\int_s^t (\alpha_{02}(u) + \alpha_{01}(u))\mathrm{d}u \right)$$

Figure 5
A model for marriage and dissolution

Figure 6
Interaction between life history events

and (in the Markovian case)

$$P_{01}(s, t) = \int_s^t P_{00}(s, u-)\alpha_{01}(u)P_{11}(u, t)\mathrm{d}u$$

where

$$P_{11}(s, t) = \exp\left(-\int_s^t \alpha_{12}(u)\mathrm{d}u \right)$$

For this reason, and because of the desire to have a more detailed description, the reversible illness–death model is sometimes replaced by a model with one state for each new 'disease.' An example from nuptiality is indicated by Fig. 5, where the possible transition from each state to death is omitted from the figure. (Only finitely many states are assumed!)

3.4 Interaction Between Life-history Events

This Markov model, illustrated in Fig. 6 describes the joint behavior of two life events A and B; if $\alpha_{0B} = \alpha_{A,AB}$ but $\alpha_{0A} \neq \alpha_{B,AB}$, A is called *locally dependent* on B but B is not locally dependent on A. The temporal order of events allows for this *asymmetric* concept of dependence which yields more information for drawing causal inference than the standard symmetric association concepts from cross-sectional studies. Similar duration dependence as in the illness–death process might be added. A model of this type was discussed by Aalen et al. (1980) for a study of interaction between menopause and a certain chronic skin disease (see also Blossfeld and Rohwer 1995 and Courgeau and Lelièvre (1992).

Figure 7
A model for events following bone marrow transplantation: acute and chronic graft-vs.-host disease, relapse and death

3.5 Bone Marrow Transplantation

A model combining most of the above features has been studied in detail (e.g., Klein et al. 1993, Keiding et al. 2000) as describing some of the possible states of a leukemia patient following bone marrow transplantation, see Fig. 7.

Patients have been given various kinds of therapy to temporarily keep the disease down, they are said to be in *remission*. In our context these patients are followed since bone marrow transplantation ($t = 0$), initially considered in state 0. Two different types of complications are considered: acute graft-vs.-host disease (A), chronic graft-vs.-host disease (C), and a special state AC is defined for those patients acquiring both A and C. Patients are followed until relapse of the leukemia (R) or death (D) while still in remission. Relapsed patients are not followed further in this context. If all transition rates depend only on time t since transplantation, we have again a Markov process, but various kinds of duration dependence (semi-Markov process models) may also be relevant.

4. Counting Process Representation, Likelihood

Assume that multistate processes $X_i(t)$ such as described in Sect. 3 are observed over intervals $[0, \tau_i]$ for individuals $i = 1,\ldots, n$. In this section, we will assume that τ_i is a fixed (i.e., nonrandom) time of termination of observation for individual i. Random right-censoring (Sect. 2) is treated in Sect. 6. Since $X_i(t)$ is constant between transitions, it is equivalent to record $X_i(0)$ and the *counting processes*

$$N_{hj}^i(t) = \#(\text{direct transitions } h \to j \text{ in } [0, t] \text{ for } i)$$

described by the times T_{hj}^{ik} of these transitions, where

$$0 < T_{hj}^{i1} < \ldots < T_{hj}^{iN_{hj}^i(\tau_i)} \leqslant \tau_i$$

Let $N_{hj}(t) = \sum_{i=1}^n N_{hj}^i(t)$.

It will turn out to be useful to also introduce $Y_h^i(t) = I\{X_i(t-) = h\}$ and $Y_h(t) = \#$ (individuals 'at risk' in state h at time $t-$) $= \sum_{i=1}^n Y_h^i(t)$. Note that, for

$t > \tau_i$, $N^i_{hj}(t) = N^i_{hj}(\tau_i)$ and $Y^i_h(t) = 0$; these can thus be considered to be defined on $(0, \infty)$.

For individual i denote the initial distribution $(\pi^i_h(0))$, the density of time-fixed covariates $f(Z_i)$, and the transition intensities $\alpha^i_{hj}(t)$, then the *likelihood* is

$$\prod_{i=1}^{n} f(Z_i)\pi_{X_i(0)} \prod_{h \neq j} \prod_{k=1}^{N^i_{hj}(\tau_i)} \alpha^i_{hj}(T^{ik}_{hj}) \exp\left(-\int_0^{\tau_i} \alpha^i_{hj}(t) Y^i_h(t) \mathrm{d}t \right).$$

It is very common to condition on Z_i and on the initial values $X_i(0)$ (the distribution of which may often be degenerate anyway), and consequently omit the factors $f(Z_i)\pi_{X_i(0)}$ from the likelihood. We shall do so without further comment in the sequel.

Recall from above that the notation $\alpha^i_{hj}(t)$ represents possible dependence of the transition intensity on the whole history $\mathscr{X}^i_t$ of the process. Thus, $\alpha^i_{hj}(t)$ may well contain covariates and other random elements, as already exemplified.

5. *Statistical Model Specification*

As indicated in the introduction the first purpose of event history analysis is to gain insight into the dynamics of the processes by quantifying transition intensities and perhaps assessing their dependence on covariates, possibly using various stratifications. Sometimes additional functionals are useful, particularly various types of *transition probabilities* obtained by integrating certain functions of the transition intensities. A final purpose may be *prediction*, both as illustration of the dynamics and for concrete practical purposes.

5.1 *Markov Processes*

The most important class of models is the (continuous time) *Markov process* $X(t)$ on a finite state space $\mathscr{S} = \{1, \ldots, p\}$ where the dependence of $\alpha^i_{hj}(t)$ on the history $\mathscr{X}_t$ introduced at the beginning of Sect. 3 is only via the current state of $X(t)$ (and possibly via time-fixed covariates). Statistical models usually are obtained by specifying the class of transition intensities $(\alpha^i_{hj}(t))$ for each individual i.

5.1.1 Constant and piecewise constant transition intensities. The simplest class of models is obtained by keeping the transition rates *constant*: $\alpha^i_{hj}(t) = \alpha^i_{hj}$. *Piecewise constant* intensities

$$\alpha^i_{hj}(t) = \alpha^{i(k)}_{hj}, \quad t_{k-1} < t \leqslant t_k, \quad t_0 = 0$$

form the next step up, and both of these choices are of widespread use, particularly in large studies in econometrics, epidemiology, sociology, and demography.

For ease of notation focus on the case with constant intensities and assume first that all individuals have the same transition intensities, $\alpha^i_{hj} = \alpha_{hj}$. The likelihood then simplifies to

$$\prod_{h \neq j} \alpha_{hj}^{N_{hj}(\tau)} e^{-\alpha_{hj} S_h}$$

where $\tau = \max_i \tau_i$ and

$$S_h = \sum_i \int_0^{\tau_i} Y^i_h(t) \mathrm{d}t$$

Since this likelihood looks like one resulting from observing $N_{hj}(\tau)$ events in a Poisson process with intensity α_{hj} observed over the interval $(0, S_h)$, except that here S_h is random, this likelihood, and even the model, are often associated with Poisson's name. Maximum likelihood estimation is elementary, yielding

$$\hat{\alpha}_{hj} = N_{hj}(\tau)/S_h$$

the classical *occurrence/exposure rate*. Asymptotic inference may be obtained from the information

$$-D^2 \log L = N_{hj}(\tau)/\alpha^2_{hj}$$

yielding a variance estimate

$$\mathrm{Var}(\hat{\alpha}_{hj}) \sim \alpha^2_{hj}/N_{hj}(\tau) \sim N_{hj}(\tau)/S^2_h$$

Inclusion of time-fixed covariates conveniently is achieved log-linearly

$$\alpha^i_{hj} = \alpha_{0hj} e^{\beta'_{hj} Z_i}$$

The Poisson likelihood easily accommodates this in what is often termed Poisson regression models, which may be treated using standard generalized linear model software.

Transition probabilities for the constant and piecewise constant Markov process models are explicit functions of the transition intensities (e.g., Chiang 1968), allowing direct 'plug-in' maximum likelihood estimation, as well as calculation of standard error estimates via the delta method.

5.1.2 Other parametric models for the transition intensities. Although the piecewise constant model is often sufficient to describe the dependence of intensities on time, other possibilities exist. Certain mathematical functions of time may generate the

model, such as the Gompertz–Makeham model for mortality

$$\alpha(t) = \alpha + \beta\gamma^t$$

but except for mortality studies in actuarial and some demographic contexts such parametric models are used rather little. One reason for this may be the powerful development of methodology for 'nonparametric' statistical inference, where $\alpha_{hj}(t)$ is left unspecified.

5.1.3 Freely varying ('nonparametric') transition intensities. Assume first that the transition intensities are the same for all individuals but that they are allowed to vary freely with time: $\alpha^i_{hj}(t) = \alpha_{hj}(t)$. Statistical inference is then conveniently phrased in terms of the counting process approach pioneered by Aalen (1976, 1978) (see Andersen et al. 1993 for a detailed exposition). Estimators (which may be given a nonparametric maximum likelihood interpretation) of the integrated intensities

$$A_{hj}(t) = \int_0^t \alpha_{hj}(u)\mathrm{d}u$$

are obtained as the *Nelson–Aalen estimators*

$$\hat{A}_{hj}(t) = \int_0^t \frac{J_h(u)}{Y_h(u)} dN_{hj}(u) = \sum_i \sum_{k:0 < T^{ik}_{hj} < t} \frac{1}{Y_h(T^{ik}_{hj})}$$

$J_h(u) = I\{Y_h(u) > 0\}$, with variance estimators

$$\hat{\sigma}^2(\hat{A}_{hj}(t)) = \int_0^t \frac{J_h(u)}{Y_h(u)^2} dN_{hj}(u) = \sum_i \sum_{k:0 < T^{ik}_{hj} < t} \frac{1}{Y_h(T^{ik}_{hj})^2}$$

An elaborate mathematical theory based on stochastic integrals and martingales is available to study exact and asymptotic properties of these estimators.

When estimates are desired of the transition intensities $\alpha_{hj}(t)$ themselves rather than their integrals, *smoothing* techniques are necessary.

An important feature of the nonparametric approach is its elegant generalization (due to Aalen and Johansen 1978), to estimating *transition probabilities*. The basic tool is the (matrix) *product-integral*. Let I be the identity matrix and G a matrix-valued function. The corresponding product–integral is defined as

$$\Pi_0^t(I + G(ds)) = \lim_{\max|t_v - t_{v-1}| \to 0} \prod (I + G(t_v) - G(t_{v-1}))$$

where $0 = t_0 < t_1 < \ldots < t_n = t$ is a partition of $[0, t]$. In particular, if G is continuous and scalar

$$\Pi_0^t(1 + G(ds)) = e^{G(t) - G(0)}$$

and if G is a scalar step function

$$\Pi_0^t(1 + G(ds)) = \prod_{k=1}^{K} (1 + \Delta G(t_{(k)}))$$

where $t_{(0)} = 0$ and $0 < t_{(1)} < \ldots < t_{(K)} \leqslant t$ are the jump times of G and

$$\prod G(t_{(k)}) = G(t_{(k)}) - G(t_{(k-1)})$$

Define

$$\alpha nn(t) = -\sum_{j \neq h} \alpha_{hj}(t)$$

and the intensity matrix function

$$A(t) = ((\int_0^t \alpha hj(u)du))$$

then the matrix $P(s, t) = ((P_{hj}(s, t)))$ of transition probabilities

$$P_{hj}(s, t) = \mathrm{Prob}(X_i(t) = j | X_i(s) = h)$$

is given by

$$P(s, t) = \Pi_s^t(I + A(\mathrm{d}u))$$

The *Aalen–Johansen* estimator of $P(s, t)$ is obtained by plugging the matrix of Nelson–Aalen estimators $(\hat{A}_{hj}(t))$ into this formula

$$\hat{P}(s, t) = \Pi_s^t(I + \hat{A}(du))$$

For the simple two-state model for survival data $\hat{P}_{00}(0, t)$ reduces to the classical Kaplan and Meier (1958) estimator $\hat{S}(t) = \prod T_i \leqslant t(1 - dN_{01}(T_i)/Y_0(T_i))$ of the survival function $S(t)$.

As documented in detail by Andersen et al. (1993, Sect. IV. 4), there is a well-developed theory, again based on stochastic integrals and martingales, about the asymptotic properties of the Aalen–Johansen estimator.

5.1.4 Semiparametric regression Markov models. For Markov models with several states, there will often be too little empirical basis for estimating freely

varying transition intensities between all states, so that more parsimonious models are required. One possibility (demonstrated in detail by Klein et al. 1993 and Keiding et al. 1999 for the bone marrow transplant example above) is to postulate that transition intensities *into* a state are proportional: $\alpha_{hj}(t) = \alpha_{0j}(t)e^{\beta_h}$ for all (relevant) h. The statistical analysis of this model is equivalent to a Cox regression model with time-dependent covariates indicating the departure state h.

The Cox model (proposed by Cox (1972a, 1972b) for survival data and for renewal processes, respectively), may also be used for including covariates not depending on time, this preserving the Markov property. The consequent generalization of the Aalen–Johansen estimator was studied by Andersen et al. (1991b, 1993, p. 512 ff.) and implemented for the bone marrow transplant problems just mentioned.

5.2 Beyond Markov Processes

The most important deviations from the Markov property in practice are various kinds of *duration dependence*, where transition intensities depend on other time origins that $t = 0$, typically the time at entry to the present state. There are two main approaches to handling these.

As long as transition intensities depend only on one time origin each (e.g., all intensities depend only on duration in the present state), a model for the multistate process may be obtained by combining independent submodels for each transition intensity. These may, in turn, be modeled as constant or piecewise constant or by non- or semiparametric models, and as long as there is a unidirectional flow in the model, transition probabilities are still straightforward explicit functionals which may be estimated by plugging in the intensity estimates. Variance calculations may, however, become less direct.

More elaborate models will include several time origins (such as both age, disease duration, duration since marriage dissolution), often in piecewise constant intensity models or semiparametric regression models such as the Cox model. An example concerning mortality of diabetics with or without nephropathy was studied by Andersen (1988), see also the consequences for Danish life insurance premiums (Ramlau-Hansen et al. 1987).

The heterogeneity between individuals cannot always be accounted for by *observed* covariates, and at least some residual heterogeneity will have to be modeled as random variation. An important class of models here is the multiplicative *frailty models*, obtained by postulating random (usually transition-specific) *frailties* W^i_{hj}, and conditional transition intensities

$$\alpha^i_{hj}(t|W^i_{hj}) = \alpha_{0hj}(t)W^i_{hj}e^{\beta' z_i}$$

5.3 Hypothetical Calculations in Multistate Models

As mentioned earlier, there is often considerable interest in studying the consequences of the estimated transition intensities by calculating summary measures such as transition probabilities. When a full model has been estimated, this can be done not only of the model observed 'in this world.' Rather, the consequences of an assumed (or fitted) multistate model may be usefully further illustrated by calculating transition probabilities in hypothetical models obtained by changing some of the parameters. An elaborate example of this was given by Keiding et al. (2000) for the bone marrow transplantation context, but similar calculations have been performed in the competing risks model ever since the first discussion by Bernoulli 1760 of the effect on population mortality of removing smallpox through vaccination. The interpretational justification of such calculations was discussed heatedly, particularly in the 1970s (see Gail 1975, Prentice et al. 1978, and Kalbfleisch and Prentice 1980, Chap. 7).

Hoem (1969b) derived a simple expression for the modified transition probability in the following particular Markov process situation. Assume the state space $\mathscr{S} = \{1,\ldots, p\} = \mathscr{K} \cup \mathscr{R} = \{1,\ldots k\} \cup \{k+1,\ldots, p\}$, where all states $h \in \mathscr{R}$ are absorbing.

Let $P_{hj}(s, t)$ be the transition probabilities corresponding to transition intensities $\alpha_{hj}(t)$ and $Q_{hj}(s, t)$ these corresponding to intensities

$$\rho_{hj}(t) = \begin{cases} \alpha_{hj}(t), & j \in \mathscr{K} \\ 0, & j \in \mathscr{R} \end{cases}$$

Then if $\alpha_{h\mathscr{R}}(t) = \sum_{j \in \mathscr{R}} \alpha_{hj}(t)$ is independent of h (non-selective occurrence of the events in $\mathscr{R}$), we get

$$P_{hj}(s, t) = Q_{hj}(s, t) \exp\left(-\int_s^t \alpha_{h\mathscr{R}}(u)\mathrm{d}u \right)$$

for $h \in \mathscr{K}$, $j \in \mathscr{K}$, $h \neq j$, $s < t$. A partial converse of this result by Cohen (1972) is that if

$$P_{hj}(s, t) = Q_{hj}(s, t) \sum_{j \in \mathscr{K}} P_{hj}(s, t)$$

for all $h \in \mathscr{K}$, $j \in \mathscr{K}$, $s < t$, then $\alpha_{h\mathscr{R}}(t)$, does not depend on $h \in \mathscr{K}$.

5.4 Partial Model Specification

We have so far assumed that the multistate model was completely specified through statistical modeling of all transition intensities and a specific probability mechanism for the combination of these into transition probabilities. In a series of papers, (Pepe 1991, Pepe et al. 1991, Pepe and Mori 1993, Couper and Pepe 1997), Pepe and co-workers have developed estimates of certain functionals in multistate models without as-

suming a full probability structure. One example is the *prevalence* of a transient condition indicated by state c defined as

$$P_{0c}(0, t)/\sum_{j \in T} P_{0j}(0, t)$$

where T is the set of transient states and 0 is a fixed 'initial' state. The idea is to estimate numerator and denominator separately by simple linear combinations of Kaplan–Meier estimates. Easily applicable variance estimates are then available which in one recent application (Klein et al. 2000) showed that the precision of the Pepe approach was close to the more elaborate (and restrictive) complete Markov model.

Another example of partial model specification occurs when the model contains time-dependent covariates which are not purely endogenous. In fact, for time-fixed covariates we just (cf. Sect. 4) conditioned on their observed values without specifying their distribution $f(Z_i)$, but for time-dependent covariates such a conditioning is more tricky. Formally, the likelihood will contain factors for the stochastic development of $Z_i(t)$ given the history $\mathscr{F}_{t^-} = \mathscr{X}_{t^-} \vee \mathscr{Z}_{t^-}$ and the likelihood described in Sect. 4 is not the full likelihood but only a partial likelihood for the parameters for the transition intensities $\alpha^i_{hj}(t)$. This means that inference for the transition *intensities* may be based on this partial likelihood whereas the transition *probabilities* typically will depend also on the parameters in the model for $Z_i(t)$.

Thus, if the model contains time-dependent covariates which are not purely endogenous then transition probabilities cannot be estimated using only a partial model specification. A joint model for the multistate process $X_i(t)$ and the time-dependent covariates $Z_i(t)$ is needed. When $Z_i(t)$ only takes a finite number of values this joint model could, again, be a multistate model where $Z_i(t)$ is now endogenous (e.g., Andersen 1986, Andersen et al. 1991b). An example of a more general joint model was presented by Wulfsohn and Tsiatis (1997).

6. *Observational Patterns*

As emphasized in the introduction, event history models rarely are observed completely. Some patterns of incomplete observation are more easily handled than others, and this final section aims at introducing some of the more important classes.

6.1 *Delayed Entry and Right Censoring*

Most of the statistical methods introduced in this article depend directly or indirectly on the likelihood representation of Sect. 4.

Two patterns of incomplete observations are particularly easily tractable, because they lead to only minor modification of the likelihood: *Delayed entry* where individual i enters at some time V_i and *right censoring* where nothing is known about i after some time U_i. Both V_i and U_i may be random although only dependent on the previous history of the process (see, e.g., Andersen et al. 1993 for precise specification of this and further discussion). The reason for the particular tractability of these mechanisms is that the 'at risk' indicator $Y^i_h(t) = I\{X_i(t-) = h\}$ just needs to be amended to

$$Y^i_h(t) = I\{X_i(t-) = h,\ V_i < t \leqslant U_i\}$$

the statistical methods then all go through.

6.2 *Interval Censoring*

An important class of incomplete observational patterns consists in the times of some (but often not all) transitions not being known exactly but only up to an interval, e.g. between visits to a clinic or between censuses. (The *number* of transitions usually is assumed known precisely.) A classical approach in demography (Hoem 1969a) is to approximate the 'exposure'

$$S^i_h = \int_{V_i}^{U_i \wedge \tau_i} Y^i_h(t)\mathrm{d}t$$

another to impute values in the observation interval for the time at risk. Systematic studies of nonparametric maximum likelihood estimation under interval censoring of the healthy $\rightarrow$ diseased transition in the unidirectional illness–death model are by Frydman (1992, 1995), Joly et al. (1999), and Gaüzère (2000). Kay (1986) and Andersen et al. (1991a) exemplified interval-censored observation in the reversible illness–death model, using piecewise constant intensity models.

6.3 *Conditioning in Multistate Models*

Many observational patterns in event history analysis may be described by conditional distributions in simpler models, which often describe 'direct' observations that are practically unobtainable. A prime example is the left truncation just described, another *right truncation* with widespread use in studies of AIDS patients whose development is often observed conditional on having contracted the disease before the study entry. For general discussions see Kalbfleisch and Lawless (1989), Keiding and Gill (1990), and Gross and Huber-Carol (1992). A more elaborate

application of such retrospective observational plans obtained by conditioning in an underlying 'prospective' Markov process model was documented by Aalen et al. (1980) for the four state interaction of life history events example described above (Fig. 6). These authors relied heavily on the concise but important general framework of Hoem (1969b). We shall here briefly outline how this methodology works for a simple example of retrospective incidence estimation, obtained from the Markov illness–death model without recovery illustrated in Fig. 4. Assume that we study a random sample of individuals alive at same fixed age u: for those who had by then contracted the disease the age at which this happened is recorded. The observed multistate model has state space $\mathscr{K} = \{0, 1\}$ and transition probabilities

$$Q_{hj}(s, t) = \text{Prob}\{X(t) = j | X(s) = h, X(u) \neq 2\}$$

for $h, j \in \{0, 1\}$ and $0 < s < t < u$. We get

$$Q_{hj}(s, t) = P_{hj}(s, t) \frac{P_{j\mathscr{K}}(t, u)}{P_{h\mathscr{K}}(t, u)}$$

where $P_{hj}(s, t)$ are the transition probabilities in the original illness–death process and $P_{h\mathscr{K}} = P_{h0} + P_{h1}$. Hoem (1969b) used the term *purged* for the conditional Markov process on $\mathscr{K}$ with transition probabilities $Q_{hj}(s, t)$. The transition intensity of the purged process is

$$\lambda_{01}(t) = \alpha_{01}(t) \frac{P_{11}(t, u)}{P_{1\mathscr{K}}(t, u)}$$

and it may be proved that if the mortality of the diseased is never smaller than that of the healthy, that is, $\alpha_{02}(t) \leqslant \alpha_{12}(t)$ for all $t \leqslant u$, then $\lambda_{01}(t) \leqslant \alpha_{01}(t)$, with equality if and only if $\alpha_{02}(t) \equiv \alpha_{12}(t)$. This documents the intuitively obvious result, that the retrospective study will underestimate the disease incidence because of *survivor selection*. Andersen and Green 1985 used such methodology to study robustness of diabetes incidence estimates in a situation where diabetics were only observed conditionally on not emigrating before a certain age.

6.3.1 Competing risks revised. The controversial calculation in the competing risks model (Fig. 2) is the transition probability $P_{01}(0, t)$, the probability that event 1 has happened before time t. In addition to the direct calculation (in epidemiology often called the 'cumulative incidence rate'), it is (surprisingly) common to calculate the hypothetical probability in a model obtained by setting $\alpha_2(t) \equiv 0$ (cf. the classical smallpox application by Bernoulli 1760) quoted above). Pepe and Mori (1993) discussed these as well as the third possibility, calculating the *conditional* transition probability $\text{Prob}(X(t) = 1 | X(0) = 0, X(t) \neq 2)$; the analysis is very similar to that just shown for the retrospective incidence estimation.

6.3.2 The prevalent cohort study. An important sampling frame for the illness–death model without recovery is the *prevalent cohort study* where a cross-sectional sample of diseased is taken at a fixed calendar time. Keiding (1992) (see also Lund 2000), discussed the conditions for correct inference on mortality $\alpha_{12}(t)$ based on follow-up of the diseased, studied under left-truncation, and compared with inference based on the *length-biased* durations which include the retrospective time from disease onset, as well as to the *forward recurrence time* from sampling to death, assuming stationarity.

A comprehensive substantive discussion of biases in prevalent cohorts was given by Brookmeyer (1998). Retrospective estimation of incidence based on the disease onset information of the survivors and independent lethality information was exemplified by Keiding et al. (1989), see also Ogata et al. (2000).

6.4 Some Other Partial Information Designs

Sometimes interval censoring is extreme: in a cross-sectional study it is for all individuals only known whether or not an event has happened at age of sampling. Such *current-status data* were discussed in detail by Diamond and McDonald (1992), Keiding (1991), and Keiding et al. (1996), and there is an elaborate recent mathematical-statistical development in this area (see, e.g., Groeneboom and Wellner 1992, Lin et al. 1998). For *time to pregnancy* data, Keiding et al. (1999) proposed using the *current duration* elapsed so far; under suitable stationarity conditions this distribution can be considered a backward recurrence time.

7. Concluding Remarks

We have attempted to provide an exposition of current problems and solutions in event history analysis in continuous time. The probability models are continuous-time nonhomogeneous Markov processes and generalizations, the main statistical techniques are log-linear intensity models as well as non and semiparametric counting process-based models. It is emphasized that event history analysis often also includes a

'synthesis' phase and that considerable care (and consequent methodological innovation) is motivated by the many indirect observational patterns.

Event-history Analysis: Selectivity

1. Introduction

The general purpose of the analysis of event history data is to explain why certain individuals are at a higher risk of experiencing the event(s) of interest than others. This can be accomplished by using special types of methods which, depending on the field in which they are applied, are called failure-time models, life-time models, survival models, transition-rate models, response-time models, event history models, duration models, or hazard models. Here, the terms event history model and hazard model are used interchangeably.

In hazard models, the risk of experiencing an event within a short time interval is regressed on a set of covariates. Two special features distinguish hazard models from other types of regression models: they make it possible to include censored observations in the analysis and to use time-varying explanatory variables. Censoring is, in fact, a form of partially missing information: On the one hand, it is known that the event did not occur during a given period of time, but, on the other hand, the time at which the event occurred is unknown. Time-varying covariates are covariates that may change their value during the observation period. The possibility of including covariates which may change their value in the regression model makes it possible to perform a truly dynamic analysis.

In the context of the analysis of survival and event history data, the problem of unobserved heterogeneity, or the bias caused by not being able to include particular important explanatory variables in the regression model, has received a great deal of attention. This is not surprising because this phenomenon, which is also referred to as selectivity or frailty, may have a much larger impact in hazard models than in other types of regression models: Unobserved heterogeneity may introduce, among other things, downwards bias in the time effects, spurious effects of time-varying covariates, spurious time-covariate interaction effects, as well as dependence between competing risks and repeatable events. This may be true even if the unobserved heterogeneity is uncorrelated with the values of the observed covariates at the start of the process under study. Several model-based approaches have been proposed to correct for unobserved heterogeneity.

2. State, Event, Duration, and Risk Period

In order to understand the nature of even history data and the purpose of event history analysis, it is important to understand the following four elementary concepts: state, event, duration, and risk period. These concepts are illustrated below using an example from the analyses of marital histories.

The first step in the analysis of event histories is to define the relevant states which are distinguished. The states are the categories of the 'dependent' variable the dynamics of which we want to explain. At every particular point in time, each person occupies exactly one state. In the analysis of marital histories, four states are generally distinguished: never married, married, divorced, and widow(er). The set of possible states is sometimes also called the state space.

An event is a transition from one state to another, that is, from an origin state to a destination state. In

this context, a possible event is 'first marriage,' which can be defined as the transition from the origin state, never married, to the destination state, married. Other possible events are: a divorce, becoming a widow(er), and a non-first marriage. It is important to note that the states which are distinguished determine the definition of possible events. If only the states married and not married were distinguished, none of the above-mentioned events could have been defined. In that case, the only events that could be defined would be marriage and marriage dissolution.

Another important concept is the risk period. Clearly, not all persons can experience each of the events under study at every point in time. To be able to experience a particular event, one must occupy the origin state defining the event, that is, one must be at risk of the event concerned. The period that someone is at risk of a particular event, or exposed to a particular risk, is called the risk period. For example, someone can only experience a divorce when he or she is married. Thus, only married persons are at risk of a divorce. Furthermore, the risk period(s) for a divorce are the period(s) that a subject is married. A strongly related concept is the risk set. The risk set at a particular point in time is formed by all subjects who are at risk of experiencing the event concerned at that point in time.

Using these concepts, event history analysis can be defined as the analysis of the duration of the non-occurrence of an event during the risk period. When the event of interest is 'first marriage,' the analysis concerns the duration of nonoccurrence of a first marriage, in other words, the time that individuals remained in the state of never being married. In practice, as will be demonstrated below, the dependent variable in event history models is not duration or time itself but a rate. Therefore, event history analysis can also be defined as the analysis of rates of occurrence of the event during the risk period. In the first marriage example, an event history model concerns a person's marriage rate during the period that he/she is in the state of never having been married.

3. *Basic Statistical Concepts*

The manner in which the basic statistical concepts of event history models are defined depends on whether the time variable T, indicating the duration of non-occurrence of an event, is assumed to be continuous or discrete. Even though it seems logical to assume T to be a continuous variable, in many situations this assumption is not realistic. First, it may happen that T is not measured accurately enough to be treated as strictly continuous. This occurs, for example, when the duration variable in a study on the timing of the first birth is measured in completed years instead of months or days. Second, the events of interest can sometimes only occur at particular points in time. Such an intrinsically discrete T occurs, for example, in studies on voting behavior.

Suppose that we are interested in explaining individual differences in women's timing of the first birth. In that case, the event is having a first child, which can be defined as the transition from the origin state, no children, to the destination state, one child. This is an example of what is called a single non-repeatable event, where the term single reflects that the origin state no children can only be left by one type of event, and the term non-repeatable indicates that the event can occur only once. Below, situations in which there are several types of events (multiple risks) and in which events may occur more than once (repeatable events) are presented. In the first birth example, it seems most appropriate to assume the time variable to be a continuous variable although it is, of course, measured discrete, for instance, in days, months, or years after a woman's 15th birthday.

Suppose T is a continuous random variable indicating the duration of nonoccurrence of the first birth. Let $f(t)$ be the probability density function of T, and $F(t)$ the distribution function of T. As always the following relationships exist between these two quantities,

$$f(t) = \lim_{\Delta t \to 0} \frac{P(t \leqslant T < t+\Delta t)}{\Delta t} = \frac{\partial F(t)}{\partial t}$$

$$F(t) = P(T \leqslant t) = \int_0^t f(u)\,d(u)$$

The survival probability or survival function, indicting the probability of nonoccurrence of an event until time t, is defined as

$$S(t) = 1 - F(t) = P(T \geqslant t) = \int_t^\infty f(u)\,d(u)$$

Another important concept is the hazard rate or hazard function, $h(t)$, expressing the instantaneous risk of experiencing an event at $T = t$, given that the event did not occur before t. The hazard rate is defined as

$$h(t) = \lim_{\Delta t \to 0} \frac{P(t \leqslant T < t+\Delta t \mid T \geqslant t)}{\Delta t} = \frac{f(t)}{S(t)}$$

in which $P(t \leqslant T < t+\Delta t \mid T \geqslant t)$ indicates the probability that the event will occur during $[t \leqslant T < t+\Delta t]$, given that the event did not occur before t. The hazard rate is equal to the unconditional instantaneous probability of having an event at $T = t$, $f(t)$, divided by the probability of not having an event before $T = t$, $S(t)$. It should be noted that the hazard

rate itself cannot be interpreted as a conditional probability. Although its value is always non-negative, it can take values greater than one. However, for small Δt, the quantity $h(t)\Delta t$ can be interpreted as the approximate conditional probability that the event will occur between t and $t+\Delta t$.

Above $h(t)$ was defined as a function of $f(t)$ and $S(t)$. It is also possible to express $S(t)$ and $f(t)$ completely in terms of $h(t)$, that is,

$$S(t) = \exp\left(-\int_0^t h(u)\,d(u)\right)$$

$$f(t) = h(t)\,S(t) = h(t)\exp\left(-\int_0^t h(u)\,d(u)\right)$$

This shows that the functions $f(t)$, $F(t)$, $S(t)$, and $h(t)$ give mathematically equivalent specifications of the distribution of T.

4. Log-linear Models for the Hazard rate

When working within a continuous-time framework, the most appropriate method for regressing the time variable T on a set of covariates is through the hazard rate. This makes it straightforward to assess the effects of time-varying covariates—including the time dependence itself and time-covariate interactions—and to deal with censored observations. Censoring is a form of missing data that is explained in more detail below.

Let $h(t|\boldsymbol{x}_i)$ be the hazard rate at $T=t$ for an individual with covariate vector $\boldsymbol{x}_i$. Since the hazard rate can take on values between 0 and infinity, most hazard models are based on a log transformation of the hazard rate, which yields a regression model of the form

$$\log h(t|\boldsymbol{x}_i) = \log h(t) + \sum_j \beta_j \chi_{ij} \qquad (1)$$

This hazard model is not only log-linear but also proportional. In proportional hazard models, the time-dependence is multiplicative (additive after taking logs) and independent of an individual's covariate values. Below it will be shown how to specify non-proportional log-linear hazard models by including time-covariate interactions.

The various types of continuous-time log-linear hazard models are defined by the functional form that is chosen for the time dependence, that is, for the term $\log h(t)$. In Cox's semi-parametric model, the time dependence is left unspecified (Cox 1972). Exponential models assume the hazard rate to be constant over time, while piecewise exponential model assume the hazard rate to be a step function of T, that is, constant within time periods. Other examples of parametric log-linear hazard models are Weibull, Gompertz and polynomial models.

As was demonstrated by several authors (Laird and Oliver 1981, Vermunt 1997, pp. 106–17), log-linear hazard models can also be defined as log-linear Poisson models, which are also known as log-rate models. Assume that we have—besides the event history information—two categorical covariates denoted by A and B. In addition, assume that the time axis is divided into a limited number of time-intervals in which the hazard rate is postulated to be constant. In the first birth example, this could be one-year intervals. The discretized time variable is denoted by Z. Let h_{abz} denote the constant hazard rate in the zth time interval for an individual with $A=a$ and $B=b$. To see the similarity with standard log-linear models, it should be noted that the hazard rate, sometimes referred to as occurrence-exposure rate, can also be defined as $h_{abz} = m_{abz}/E_{abz}$. Here, m_{abz} denotes the expected number of occurrences of the event of interest and E_{abz} the total exposure time in cell (a, b, z).

Using the notation of hierarchical log-linear models, the saturated log-linear model for the hazard rate h_{abz} can now be written as

$$\log h_{abz} = u + u_a^A + u_b^B + u_z^Z + u_{ab}^{AB} + u_{az}^{AZ} + u_{bz}^{BZ} + u_{abz}^{ABZ} \qquad (2)$$

in which the u terms are log-linear parameters which are constrained in the usual way, for instance, by means of ANOVA-like restrictions. Note that this is a non-proportional model because of the presence of time-covariate interactions. Restricted variants of model described in equation (2) can be obtained by omitting some of the higher-order interaction terms. For example,

$$\log h_{abz} = u + u_a^A + u_b^B + u_z^Z$$

yields a model that is similar to the proportional log-linear hazard model described in equation (1). In addition, different types of hazard models can be obtained by the specification of the time-dependence. Setting the u_z^Z terms equal to zero yields an exponential model. Unrestricted u_z^Z parameters yield a piecewise exponential model. Other parametric models can be approximated by defining the u_z^Z terms to be some function of Z. And finally, if there are as many time intervals as observed survival times and if the time dependence of the hazard rate is not restricted, one obtains a Cox regression model. Log-rate models can be estimated using standard programs for log-linear analysis using E_{abz} as a weight vector (Vermunt 1997, p. 112).

Unobserved heterogeneity or selectivity may bias the results obtained from the hazard models discussed

Table 1
Hazard rates illustrating the effect of unobserved heterogeneity

Time point	$A = 1$			$A = 2$			Ratio between $A = 2$ and $A = 1$
	$W = 1$	$W = 2$	observed	$W = 1$	$W = 2$	observed	
0	0.010	0.050	0.030	0.020	0.100	0.060	2.00
10	0.010	0.050	0.026	0.020	0.100	0.045	1.73
20	0.010	0.050	0.023	0.020	0.100	0.034	1.50
30	0.010	0.050	0.019	0.020	0.100	0.027	1.39

so far in various ways. The best-known implication is the negative bias of the time dependence. Other implications are that covariate effects may be biased (underestimated) and that one may find spurious time-covariate interactions.

We will illustrate the effects of unobserved heterogeneity with a small example. Suppose that the population under study consists of two subgroups formed by the two levels of an observed covariate A, where for an average individual with $A = 2$ the hazard rate is twice as high as for someone with $A = 1$. In addition, assume that within each of the levels of A there is (unobserved) heterogeneity in the sense that there are two subgroups $W = 1$ and $W = 2$, where $W = 2$ has a 5 times higher hazard rate than $W = 1$. Table 1 shows the assumed hazard rates for each of the possible A–W combinations at four time points. As can be seen, the true hazard rates do not change over time given A and W. The reported hazard rates in the columns labeled 'observed,' which were obtained by setting up a simple life table, show what happens if we do not observe W. First, it can be seen that both for $A = 1$ and $A = 2$ the observed hazard rates decline over time while the true rates were time constant. This illustrates the fact that unobserved heterogeneity biases the estimated time dependence in a negative direction. Second, while the ratio between the hazard rates for $A = 2$ and $A = 1$ equals the true value 2.00 at $t = 0$, it declines over time (see last column). Thus, when estimating a hazard model with these observed hazard rates, we will find a smaller effect of A than the true value of (log) 2.00. Third, in order to describe fully the pattern of observed hazard rates, we need to include a time-covariate interaction in the hazard model: the covariate effect changes (declines) over time or, equivalently, the (negative) time effect is smaller for $A = 1$ than for $A = 2$.

5. *Censoring*

A subject that always receives a great amount of attention in discussions on event history analysis is the problem of censoring. An observation is called censored if it is known that is did not experience the event of interest during some time, but it is not known when it experienced the event. In fact, censoring is a specific type of missing data. In the first-birth example, a censored case could be a woman which is 30 years of age at the time of interview (and has no follow-up interview) and does not have children. For such a woman, it is known that she did not have a child until age 30, but it is not known whether nor when she will have her first child. This is, actually, an example of what is called right censoring. Another type of censoring that is more difficult to deal with is left censoring. Left censoring means that we do not have information on the duration of nonoccurrence of the event before the start of the observation period.

As long as it can be assumed that the censoring mechanism is not related to the process under study, dealing with right censored observations in maximum likelihood estimation of the parameters of hazard models is straightforward. Let δ_i be a censoring indicator taking the value 0 if observation i is censored and 1 if it is not censored. The contribution of case i to the likelihood function that must be maximized when there are censored observations is

$$\begin{aligned}\mathscr{L}_i &= h(t_i|\boldsymbol{x}_i)^{\delta_i} S(t_i|\boldsymbol{x}_i)\\ &= h(t_i|\boldsymbol{x}_i)^{\delta_i} \exp\left(-\int_0^{t_i} h(u|\boldsymbol{x}_i)\,du\right)\end{aligned}$$

This likelihood function is, however, only valid if the censoring mechanism can be ignored for likelihood-based inference. The presence of unobserved heterogeneity that is shared by the process of interest and the censoring process will lead to a violation of the assumption that censoring is ignorable.

6. *Time-varying Covariates*

A strong point of hazard models is that one can use time-varying covariates. These are covariates that may change their value over time. Examples of interesting time-varying covariates in the first-birth example are a woman's marital and work status. It should be noted that, in fact, the time variable and interactions between time and time-constant covariates are time-varying covariates as well.

The saturated log-rate model described in equation (2), contains both time effects and time-covariate interaction terms. Inclusion of ordinary time-varying covariates does not change the structure of this hazard model. The only implication of, for instance, covariate B being time varying rather than time constant is that in the computation of the matrix with exposure times E_{abz} it has to taken into account that individuals can switch from one level of B to another.

The presence of unobserved heterogeneity may seriously bias the effects of time-varying covariates. More precisely, the effects of time-varying covariates may be partially spurious as a result of the presence of unobserved risk factors influencing both the covariate process and the dependent process. An example of an association that may be partially spurious is the association between a woman's labor participation and the first birth rate. In several studies, it has been found that women who are not employed have higher first birth rates than women who are employed. This association may, however, be partially the result of unobserved causes that work and fertility behavior have in common, such as certain gender role attitudes.

7. *Multiple Risks*

Thus far, only hazard rate models for situations in which there is only one destination state were considered. In many applications it may, however, prove necessary to distinguish between different types of events or risks. In the analysis of the first-union formation, for instance, it may be relevant to make a distinction between marriage and cohabitation. In the analysis of death rates, one may want to distinguish different causes of death. And in the analysis of the length of employment spells, it may be of interest to make a distinction between the events voluntary job change, involuntary job change, redundancy, and leaving the labor force.

The standard method for dealing with situations where—as a result of the fact that there is more than one possible destination state—individuals may experience different types of events is the use of a multiple-risk or competing-risk model. A multiple-risk variant of the hazard rate model described in equation (1) is

$$\log h_d(t|\boldsymbol{x}_i) = \log h_d(t) + \sum_j \beta_{jd}\chi_{ij}$$

Here, the index d indicates the destination state or the type of event. As can be seen, the only thing that changes compared with the single type of event situation is that we have a separate set of time and covariate effects for each type of event.

Again the presence of unobserved heterogeneity may distort the results obtained from the hazard model. More precisely, if the different types of events have shared unmeasured risk factors, the results for each of the types of events have shared unmeasured risks factors, the results for each of the types of events is only valid under the observed hazard rates for the other risks. In fact, the resulting dependence among risks is comparable to what in the field of discrete choice modeling is known as the violation of the assumption of independence of irrelevant alternatives.

8. *Repeatable Events and Other Types of Multivariate Event Histories*

Most events studied in social sciences are repeatable, and most event history data contains information on repeatable events for each individual. This is in contrast to biomedical research, where the event of greatest interest is death. Examples of repeatable events are job changes, having children, arrests, accidents, promotions, and residential moves.

Often events are not only repeatable but also of different types, that is, we have a multiple-state situation. When people can move through a sequence of states, events cannot only be characterized by their destination state, as in competing risks models, but they may also differ with respect to their origin state. An example is an individual's employment history: an individual can move through the states of employment, unemployment, and out of the labor force. In that case, six different kinds of transitions can be distinguished which differ with regard to their origin and destination states. Of course, all types of transitions can occur more than once. Other examples are people's union histories with the states living with parents, living alone, unmarried cohabitation, and married cohabitation, or people's residential histories with different regions as states.

Hazard models for analyzing data on repeatable events and multiple-state data are special cases of the general family of multivariate hazard rate models. Another application of these multivariate hazard models is the simultaneous analysis of different life-course events. For instance, it can be of interest to investigate the relationships between women's reproductive, relational, and employment careers, not only by means of the inclusion of time-varying covariates in the hazard model, but also by explicitly modeling their mutual interdependence.

Another application of multivariate hazard models is the analysis of dependent or clustered observations. Observations are clustered, or dependent, when there are observations from individuals belonging to the same group or when there are several similar observations per individual. Examples are the occupational careers of spouses, educational careers of brothers, child mortality of children in the same family, or in medical experiments, measures of the sense of sight of

both eyes or measures of the presence of cancer cells in different parts of the body. In fact, data on repeatable events can also be classified under this type of multivariate event history data, since in that case there is more than one observation of the same type for each observational unit as well.

The hazard rate model can easily be generalized to situations in which there are several origin and destination states and in which there may be more than one event per observational unit. The only thing that changes is that we need indices for the origin state (o), the destination state (d), and the rank number of the event (m). A log-linear hazard rate model for such a situation is

$$\log h_{od}^{m}(t|\boldsymbol{x}_i) = \log h_{od}^{m}(t) + \sum_j \beta_{jod}^{m} \chi_{ij}$$

The different types of multivariate event history data have in common that there are dependencies among the observed survival times. These dependencies may take several forms: the occurrence of one event may influence the occurrence of another event; events may be dependent as a result of common antecedents; and survival times may be correlated because they are the result of the same causal process, with the same antecedents and the same parameters determining the occurrence or nonoccurrence of an event. If these common risk factors are not observed, the assumption of statistical independence of observation is violated, which may seriously distort the results.

9. *Model-based Approaches to Unobserved Heterogeneity*

As described in the previous sections, unobserved heterogeneity may have different types of consequences in hazard modeling. The best-known phenomenon is the downwards bias of the duration dependence. In addition, it may bias covariate effects, time-covariate interactions, and effects of time-varying covariates. Other possible consequences are dependent censoring, dependent competing risks, and dependent observations. This section presents two types of methods that have been proposed for correcting for unobserved heterogeneity: random-effects and fixed-effects methods.

9.1 *Random-effects Approach*

The random-effects approach is based on the introduction of a time-constant latent covariate in the hazard model (Vaupel et al. 1979). This unobserved variable is assumed to have a multiplicative and proportional effect on the hazard rate, i.e.,

$$\log h(t|\boldsymbol{x}_i, \theta_i) = \log h(t) + \sum_j \beta_j \chi_{ij} + \log \theta_i$$

Here, θ_i denotes the value of the latent variable for subject i. In the parametric random-effects approach, the latent variable is postulated to have a particular distributional form. The amount of unobserved heterogeneity is determined by the size of the standard deviation of this distribution: The larger the standard deviation of θ_i or $\log\theta_i$, the more unobserved heterogeneity there is. Vaupel et al. (1979) proposed using a gamma distribution for θ_i, with a mean of 1 and a variance of $1/\gamma$, where γ is the unknown parameter to be estimated. Another option would be to assume $\log\theta_i$ to come from a normal distribution with mean zero and standard deviation σ.

Heckman and Singer (1982) demonstrated that the results obtained from continuous-time hazard models can be sensitive to the choice of the functional form of the distribution of the random effect. Therefore, they advocated using a nonparametric characterization of this distribution by means of a finite set of mass points whose number, locations, and weights are empirically determined. The nonparametric random-effects model proposed by Heckman and Singer is, actually, a latent class or finite mixture model. As in latent class analysis, the population is assumed to be composed of a finite number of exhaustive and mutually exclusive groups formed by the categories of an unobserved variable. Suppose W is a categorical latent variable with W^* categories, and w is a particular value of W. The model of Heckman and Singer can be formulated as follows:

$$\log h(t|\boldsymbol{x}_i, \theta_w) = \log h(t) + \sum_j \beta_j \chi_{ij} + \log \theta_w$$

Here, θ_w denotes the (multiplicative) effect on the hazard rate for latent class w. The contribution of the ith subject to the likelihood function in the case of a single non-repeatable event is

$$\mathscr{L}_i = \sum_{w=1}^{W^*} \pi_w h(t_i|\boldsymbol{x}_i, \theta_w)^{\delta_i} S(t_i|\boldsymbol{x}_i, \theta_w)$$

where π_w is the proportion of the population belonging to latent class w. In the terminology used by Heckman and Singer (1982), the number of latent classes (W^*), the latent proportions (π_w), and the effects of $W(\theta_w)$ are called the number of mass points, the weights, and the mass points locations, respectively.

The most important drawback of the parametric and nonparametric random-effects approaches to unobserved heterogeneity is that the latent variable is

assumed to be independent of the observed covariates. This is, in fact, in contradiction to the omitted variables argument that is often used to motivate the use of these types of mixture models. If one assumes that particular important variables are not included in the model, it is usually implausible to assume that they are completely unrelated to the observed factors. In other words, by assuming independence among unobserved and observed factors, the omitted variable bias, or selection bias, will generally remain (Chamberlain 1985, Yamaguchi 1986, 1991, p.132). To overcome the limitations of the standard random-effects approaches, Vermunt (1997) proposed a more general nonparametric latent variable approach to unobserved heterogeneity. It differs from Heckman and Singer's method in that different types of specifications can be used for the joint distribution of the observed covariates, the unobserved covariates, and the initial state. This makes it possible to specify hazard models in which the unobserved factors are related to the observed covariates and to the initial state.

9.2 Fixed-effects Approach

A second method for dealing with unobserved heterogeneity involves adding cluster-specific effects, or incidental parameters, to the model (Chamberlain 1985, Yamaguchi 1986). In fact, a categorical variable is included in the hazard model indicating to which cluster a particular observation belongs: observations belonging to the same cluster have the same value for this 'observed' variable while observations belonging to different clusters have different values. This approach to unobserved heterogeneity, which is called the fixed-effects approach, can only be applied with multivariate survival data, that is, when there is more than one observation for the largest part of the observational units. Note that actually the unobserved heterogeneity is transformed into a form of observed heterogeneity capturing the similarity among observations belonging to the same cluster.

The advantage of using fixed-effects methods to correct for unobserved heterogeneity is that they circumvent two objections against random-effects methods presented above: No functional form needs to be specified for the distribution of the unobserved heterogeneity and the unobserved heterogeneity is automatically related to both the initial state and the time-constant covariates.

The major limitation of the fixed-effects approach is that since each cluster has its own incidental parameter, no parameter estimates can be obtained for the effects of covariates having the same value for the different observations belonging to the same cluster: Only the effects of observation-specific or of time-varying covariates can be estimated. Another problem is that the incidental parameters cannot be estimated consistently, since by definition they are based on a limited number of observations regardless of the sample size. This inconsistency may be carried over to the other parameters if the parameters are estimated by means of maximum likelihood (Yamaguchi 1986).

Event-related/Evoked Potentials

The term event-related potential (ERP) refers to changes in the brain's electrical activity locked in time to an externally defined event. ERPs have been used since the early 1960s, when they were usually referred to as 'evoked potentials,' to investigate sensorimotor and cognitive function in healthy and clinical popu-

lations. This article outlines how ERPs are acquired, what is known about the origin of ERP signals in the brain, and the sorts of question to which the ERP method can be applied. A comprehensive introduction to these and related issues can be found in Rugg and Coles (1995).

1. *How are ERPs Obtained?*

ERPs are small in relation to features of the brain's electrical activity (the EEG) that are not time-locked to a specific event. Therefore it is necessary to employ processing techniques that can extract the ERP 'signal' from the 'noise' in which it is embedded. The most commonly employed technique is signal averaging, whereby a number of EEG segments, each time-locked to the same class of event, are averaged to give a waveform in which consistent features of the segments (the ERP) are retained while features that vary across segments are attenuated (see Fig. 1). Depending on the relative sizes of the ERP and the background activity (the 'signal-to-noise ratio'), the number of segments required for averaging might vary from as few as 10 to more than 1,000. It is important to note that the validity of the signal averaging procedure rests on the assumption that the ERP does not vary across segments to any significant extent. If this assumption is violated (e.g., because of habituation over successive segments or just poor time-locking to the eliciting event), the averaged waveform will not be representative of the time-locked activity elicited in the single segments from which it is derived.

As is shown in Fig. 1, the ERP is conventionally depicted as a plot of voltage against time, so that the ERP waveform represents fluctuations over time in the potential difference between a recording site on the scalp and some 'reference' site such as the earlobe or nosetip. These fluctuations represent the time-varying changes in neural activity that were triggered by the eliciting event. The depiction of ERPs in this fashion emphasizes the good time resolution that can be achieved with the method, and in the days when intrumentation limitations meant that ERPs could be

Figure 1
Idealized ERP waveform elicited by a brief auditory stimulus. The logarithmic time axis allows display of very early latency 'brainstem responses' (waves I-VI), 'midlatency' responses (No-Nb), 'vertex' potentials (P1-N2), and task-related endogenous components (Nd, N2, P300 and slow wave) (from Hillyard and Kutas 1983: with permission, from the *Annual Review of Psychology*, Volume 34 © 1983 by Annual Reviews. www.AnnualReviews.org)

Figure 2
Maps of the distribution over the scalp of the difference in voltage between ERPs elicited by correctly classified old and new pictures in a recognition memory test. The maps are shown for two time regions—300–500 ms and 700–900 ms—following the onset of the stimuli. They depict an idealized head as viewed from above. The black dots represent the locations from which recordings were made. The scalp distributions of the differences between old and new pictures differ markedly in the two time regions illustrated, indicating that the differences were generated by different neural populations

recorded from only a few sites at a time was sufficient to allow appreciation of the data. Technological advances mean that it is now commonplace to record from 100 or more electrodes simultaneously. The rich spatial information provided by such 'dense-array' recordings can best be appreciated by depicting data in the form of scalp 'maps' rather than as time-varying waveforms (see Fig. 2).

2. *Generation and Source Localization*

Because the electrical currents generated by single neurons are miniscule, scalp electrical fields must arise from neural populations in which the activity of the individual neurons is sufficiently synchronous to allow their currents to summate and be detectable at the scalp. It is generally believed that, under most circumstances, the duration of neuronal action potentials ('spikes') is too short to allow the currents associated with these potentials to summate in this manner. It is assumed therefore that most scalp electrical activity is generated by postsynaptic potentials, the duration of which is sufficient to allow summation even if their onset in different neurons is not perfectly synchronous.

Crucially, if activity in a neuronal population is to be detectable at the scalp, it must not only overlap in time, but also have certain spatial characteristics. Specifically, the neurons comprising the population must be arranged geometrically in a way that allows the currents in each neuron to flow in the same direction, so that the currents add to rather than cancel each other. Such a configuration is known as an 'open field' and generally involves the alignment of neurons in parallel. A good example of this sort of arrangement is given by the pyramidal cells of the neocortex, which are oriented at right angles to the cortical surface. Neurons in random or circular arrangements give rise to 'closed' fields, in which the currents generated by each neuron tend to cancel each other. Because the neurons in many brain structures have closed field configurations (for example, the basal ganglia), ERPs can never provide more than a partial record of the neural activity triggered by the event to which they are time-locked.

Although the principles underlying the generation of event-related scalp electrical fields are understood quite well, the localization within the brain of the regions responsible for a given field (the field's 'sources') is a formidably difficult problem. The difficulty arises because the shape of a field on the scalp does not predict the configuration of its underlying sources in any simple way, and there is no mathematical method for uncovering this relationship unambiguously (indeed, from a mathematical perspective the problem is 'ill-posed,' i.e., it does not have a unique solution). Because of this, in all but a handful of cases it has not been possible to localize the generators of ERP phenomena with any great accuracy. Unlike researchers using other neuroimaging methods, ERP researchers have therefore tended to describe their data not in terms of the activity or function of specific brain regions or systems, but with respect to features of the ERP waveforms themselves and their presumed psychological correlates.

3. *ERP Components and their Classification*

Although it is most natural to think of ERPs as representing brain activity which follows a given event (event-following potentials), ERPs can also be recorded during intervals preceding an event (event-preceding potentials). An example of event-preceding

potentials are those that precede a motor act ('motor' or 'readiness' potentials), providing valuable information about movement preparation and execution.

As can be seen from Fig. 1, an ERP waveform following a sensory event consists of a series of peaks and troughs, or 'deflections.' Early in the waveform, the timing ('latency') of these deflections shows relatively little variability across different individuals, and within an individual the size ('amplitude') and latency of the deflections are determined largely by the physical characteristics of the stimulus (characteristics such as intensity, duration, etc.). These early deflections—sometimes referred to as 'exogenous' potentials—reflect initial sensory processing of the eliciting event, and they are employed routinely in the clinical assessment of sensory function (Chiappa 1997). For example, subtle damage to the optic nerve can result in delay in the latency of exogenous visual ERPs.

As time since stimulus onset progresses, features of the ERP waveform are determined less by physical features of the stimulus and more by the psychological state of the subject and the nature of the processing accorded the stimulus. Indeed, from around 250–300 ms or so post-stimulus onset, psychological factors largely predominate, such that the same physical stimulus will elicit markedly different waveforms depending on such factors as its relative probability of occurrence, whether it signals the need to make a response, etc. Emphasizing their dependence on internal, psychological factors rather than external ones, late-onset ERP deflections are often referred to as 'endogenous' potentials.

The deflections observed in ERP waveforms are easy to measure and provide convenient descriptive labels; for example, 'P1' and 'N2' refer respectively to the first positive and second negative deflection in a waveform; 'N250' refers to a negative deflection peaking around 250 ms post-stimulus onset, etc. It is not the case, however, that each deflection represents the time course of a single source of neural activity within the brain. Because activity recorded at the scalp represents the sum of all the sources active at a given time, the peak of an ERP deflection need not reflect the moment when any one source is maximally active. For this reason a distinction is made between ERP deflections—the surface features of waveforms—and ERP components—contributions to the waveform arising from specific sources or source configurations, the spatial and temporal overlap of which yields the recorded waveform. An important part of ERP analysis involves the decomposition of recorded waveforms into their constituent components.

4. *Applications of ERPs*

As already mentioned, exogenous ERPs are widely used in the assessment of sensory function. Efforts have also been made to use endogenous components to assess cognitive function and its impairment in various clinical groups, albeit with only limited success as aids to clinical diagnosis. From the perspective of psychology and related disciplines, the ERP method is of interest largely to the extent that it can be used to further understanding of cognitive functions and their neural underpinnings. ERP findings can be informative in these respects for several reasons, only the most important of which are outlined here (see Rugg and Coles 1995). First, neural activity associated with stimulus processing can be measured with a temporal resolution in the millisecond range. Thus, the maximum time required by the nervous system to discriminate between different classes of stimulus (e.g., novel vs. familiar faces) can be determined directly, even when volunteers are not required to discriminate between or respond to the stimuli. Second, ERP waveforms can be formed 'off-line,' after experimental trials have been sorted into different conditions according to the subject's behavior. It is therefore easy to compare records of brain activity associated with different classes of response (e.g., remembered vs. forgotten items in a memory test). Finally, ERPs can be used to investigate whether different experimental conditions engage distinct cognitive operations. On the assumption that different patterns of neural activity imply the engagement of different cognitive operations, it follows that when two ERP scalp distributions differ (as in Fig. 2), it can be concluded that the experimental conditions associated with each distribution engaged at least partially separate cognitive operations. Thus, differences in the spatial characteristics of ERP fields can be used to make inferences at a psychological level, even if the location of the neural activity responsible for these differences is unknown.

These applications of the ERP method are illustrated below with respect to two central areas of psychological enquiry. For further information on these and other areas of psychology and cognitive neuroscience in which ERPs have made a contribution see Kutas and Dale (1997) and Rugg and Coles (1995).

5. *Selective Attention*

The question of whether human selective attention acts 'early' or 'late' during stimulus processing has proved difficult to resolve on the basis of behavioral evidence alone. ERP data clearly show however that when processing load is high, selective attention exerts an effect early on during processing. This conclusion derives from the finding that, in all sensory modalities investigated, attended stimuli elicit exogenous ERP components that are larger in amplitude than the components elicited by unattended stimuli. In the auditory modality, for example, attention has been reported to influence components occurring as early as 20 ms post-stimulus onset, which reflect the earliest cortical stages of auditory processing (Woldorff and

Hillyard 1991). Such findings have been interpreted as evidence that attention acts in part by selectively biasing stimulus processing before full perceptual analysis has occurred (Luck et al. 2000).

6. Language

Whereas the distinction between syntax and semantics is fundamental from a formal linguistic perspective, the question whether semantic and syntactic processes are distinct in terms of their underlying cognitive operations is the subject of debate. In 1981 it was shown that the terminal words of semantically 'anomalous' sentences (e.g., 'he took his coffee with cream and socks') elicited a negative-going ERP deflection (the 'N400' component) that was much enhanced relative to ERPs elicited by nonanomalous endings (e.g., 'it was his first day at work'; Kutas and Hillyard 1980). Subsequent work showed that this effect was present in the auditory modality also, and could be found for words at any position within a sentence. It was also shown that the amplitude of the N400 component depended on a word's semantic expectancy, rather than whether or not it was anomalous (e.g. check elicits a larger N400 than stamp following 'he mailed the letter without a check/stamp'). Later, it was demonstrated that syntactic anomalies (e.g., 'the broker persuaded to sell the stock' vs. 'the broker hoped to sell the stock') also elicit characteristic ERP deflections, but with quite different distributions over the scalp to the N400 and, for one such deflection (the 'P600' component or 'syntactic positive shift'), a difference in polarity (Osterhout and Holcomb 1992). These deflections also do not depend on anomaly *per se*; was in the 'garden-path' sentence 'the lawyer charged the defendant was lying' elicits an enhanced P600 relative to the same word in 'the lawyer charged that the defendant was lying,' presumably reflecting the need for the listener or reader to engage in 'syntactic repair' at this point in the sentence. These and related findings have been taken as evidence in support of the idea that the derivation of syntactic and semantic information during sentence comprehension depend on distinct neural and cognitive processes (Hagoort and Brown 1999).

7. Relation to Other Methods

The ERP method is only one of several methods permitting the noninvasive measurement of human brain activity. In particular, the method of functional magnetic resonance imaging (fMRI) has recently come to prominence as a powerful way to identify event-related neural correlates of sensorimotor and cognitive function (D'Esposito et al. 1999). Whereas fMRI has far superior spatial resolution to that possible with ERPs, the temporal resolution of fMRI is markedly inferior. Since an understanding of brain function requires that neural activity be located accurately in time as well as in space, ERPs are likely to continue to play an important role in cognitive neuroscience for some time to come. Indeed, the development of methods for the integration of ERP and fMRI data would represent a major step forward for functional imaging (McCarthy 1999).

Event Sequence Analysis: Methods

Event Sequence Analysis (SA) Methods are methods seeking patterns that recur across a number of sequences. They are applied to data on social sequences like occupational careers or life courses, as well as to

historical sequences such as might emerge in policy adoption or in the development of organizational structures and to cultural sequences like the various orders of elements in different versions of a widespread ritual or story. The most common techniques for seeking these patterns are standard sequence comparison algorithms widely available in biological software.

1. Sequence Analysis and its Origins

Sequence analytic methods are part of a general turn towards the use of exploratory techniques in social science. As such they stand with techniques like cluster analysis, multidimensional scaling, and factor analysis. All of these methods seek radical simplification of the data space in the hope that analyzable patterns can be found. They contrast with the many causal techniques that take high dimensionality of the data space for granted and analyze that space by seeking to find the impact of a set of 'independent' dimensions on one 'dependent' dimension of the data.

This turn to exploratory techniques has a number of sources. One of these has been the stockpiling of immense data sets analyzable in many diverse ways. Another has been the more or less exploratory use of causal methods enabled by commodification; where hundreds of regressions precede those actually reported, the idea of classical hypothesis testing becomes questionable. Exploratory analytic techniques have generally been more common in applied social science rather than in academic work, having their widest use in market research. Within the academy, they have seen wider use in psychology than in any other social or behavioral science. While not unknown in political science and sociology (see, e.g., the various works of E. O. Laumann, such as Laumann and Knoke 1987), they are virtually absent from ceconomics.

The turn to sequence analysis in particular, however, proceeded from a critique of causal conceptions articulated by Abbott (1983, 1988, 1997) and Abell (1987). Both writers criticized what they called the 'variables' tradition for assuming that the social world is best imagined in terms of independent units of analysis whose properties 'cause' one another rather than in terms of chains of actions and events. Abell's argument was the more abstract, being rooted in a theory of social action based on rational choice. Abbott's was more empirical, being driven by the problem of comparing histories across social units. Both writers sought methods that would identify and compare similar chains of events across varieties of social sequence data.

Sequence analytic strategies vary in the amount of narrative detail they retain. Essentially, the more narrative detail retained the less powerful the modes of generalization or pattern search available. Strongest in retaining detail is David Heise's (1989) event structure analysis (ESA), which is essentially an interactive program for establishing the essential narrative dependencies in a complex story. The analyst inputs events and answers questions posed by the program about which events depend on which others and how. The program then produces a minimal representation of these dependencies. While it is very useful for establishing rigorous narrative patterns, ESA has not seen widespread use as a technique for generalizing about sequence patterns (for an example, see Griffin 1993).

Abell's (1993) method for narrative analysis retains less empirical detail. It begins with a 'narrative table.' The table is essentially a matrix of actors across actions, implicitly like the Heise pattern, but ignoring the specific content of events to focus on the network 'shape' of the connections between events. Narratives are similar if they can be reduced homomorphically to the same network structure. Abell's method has not seen substantial use, perhaps because his notion of similar narrative structure is not seen by empirical analysts as of immediate utility, despite its theoretical elegance. (But see the comments by various writers on Abell's techniques in *Journal of Mathematical Sociology* **18**, Numbers 2 and 3.)

Abbott's approach simplifies sequence data far more than do those of Abell or Heise, insisting on unilinear sequences of simple events. These sequences are then compared using the widely available pattern-matching algorithms that have emerged in computer science and biology since the 1970s (for a review, see Abbott and Tsay 2000). As might be expected given its simplicity, Abbott's method has seen the widest use of SA methods. It is variously referred to as sequence analysis, optimal matching analysis, or optimal alignment, the latter two being names for the standard algorithms used to measure resemblance between sequences.

Abbott's method (hereafter abbreviated OM for its most common name, optimal matching) presupposes a set of 'sequence data,' that is, a set of strings (sequences), each one of which is a vector of elements representing a succession of events in some discrete order. In career data these might be sequences of jobs held in each month over some period. In cultural analysis, they might be orders of gestures in rituals. Events can recur or return an indefinite number of times, and there is no necessary constraint of equal length on the sequences.

Simply described, Abbott's method consists in using dynamic programming algorithms to define distances between all possible pairs of sequences in a dataset. These distances are then analyzed by clustering or scaling to produce some typology of sequence types. This typology may be used as a simple description or as a dependent or independent variable in more standard causal techniques. Thus stated, Abbott's formulation of sequence analysis for the social sciences is equivalent to what is known in computer science as

the multiple string alignment problem, on which there is an extensive literature (see Gusfield 1997, Chap. 14).

Algorithms for multiple string alignment are typically based on simple algebra establishing 'Levenshtein distance' between two strings, the minimum number of edit operations (insertions, deletions, replacements) necessary to transform one string into the other. Although in some applications more complex operations have been investigated (see papers in Sankoff and Kruskal 1983), the string comparison literature has focused on the simplest three operations.

Finding the minimal edit distance between two sequences is a matter of inspection unless varying weights are placed on varying operations. Typical weighting schemes involve a fixed insertion and deletion weight coupled with replacement weights that vary in terms of what replaces what. Under such weighting schemes, the minimal edit distance problem must be solved by a simple dynamic recursion usually attributed to the classic paper of Needleman and Wunsch (1970).

Sequence analysts may also be interested in the question of whether a set of sequence data has some common subpattern, i.e., whether there is a characteristic subsequence that may appear in many or most sequences. This problem, known technically as the multiple local alignment problem, has been solved by a Gibbs Sampling algorithm due to Lawrence et al. (1993). Abbott has applied it to the analysis of rhetorical subsequences in sociological articles (Abbott and Barman 1997).

2. *Methodological Issues*

Two kinds of methodological issues have arisen in the area of SA methods. In the main these concern OM methods, as these are the most widely applied. The first such issues are those proper to the method itself, the second those concerning its utility. Like all methods, OM has its own internal assumptions and difficulties. Issues of data coding have vexed many users, although there is some indication that the methods, like most exploratory methods, are less vulnerable to the vagaries of coding than methods taking the data as given. One coding issue in particular has seemed worrisome, that of coding the underlying temporality. Some have used regular time intervals; others have collapsed continuous episodes. Another important issue has been the setting of weights of replacement and insertion/deletion. A wide variety of schemes have been used, but relatively few analysts have studied the impact of varying schemes. It is clear that all these areas need more experimentation than has presently been done. This is also true in terms of validation. Most typologies and clusterings in the OM literature have been accepted as is, without further validation. A few papers have used Monte Carlo validation methods.

The other major issues with OM methods in particular, as with SA methods more generally, concerns their utility. There are two versions of this concern, one small-scale, the other more general. The small-scale issue involves what SA methods can really add to event history or other methods investigating hazard rates for particular kinds of events. These are the standard 'causal' methodologies that are applied to sequence data. In areas where such methods are well-developed (examination of careers, labor force involvement, and marital status), SA methods seem to standard analysts to have little to add. In other areas, however, particularly in the analysis of sequential cultural structures like stories or rituals, event history methods themselves have no utility. It is not yet clear whether SA methods can provide standard-method career analysts with results that will surprise them. (Like any paradigm, event history methods to some extent enforce criteria for results that favor their own types of results.) All the same, the eventual success of SA methods will depend on finding regularities that event history methods cannot find. A clear discussion (and example) of such regularities appears in Stovel et al. (1996).

The more general question about SA's utility seems to have a clearer answer. There is little question that the broad project of employing pattern-matching techniques in social science data is a sound one. Partisans of SA methods entered the area largely to carry out a theoretical agenda that began as an attack on standard methodologies. But in turning to the computer science and biological literature, they found one of the most rapidly advancing areas of modern scientific methodology. Seeking patterns directly, rather than through hypothesized models, is not only good science, but also may be one of the only means of addressing the monumental data sets of the future.

3. *Future Developments*

To date, most applications of SA have involved a fairly limited substantive range. The most common application has been to career data. Some have worked with particular job histories, others with broader occupational classes. Still others have combined family data into these patterns. A number have worked with the 'careers' of larger social organizations—professions, counties, and nations. Still other applications have involved patterns of activity—at travel agencies, libraries, decision-making groups, and the like. A final group of studies has considered cultural artifacts—stories, dances, academic articles and so on. As these examples show, the method has been typically applied where standardized patterns are strongly expected.

Most early SA was done using fairly simple computer packages adapted for the purpose. At the beginning of the twenty-first century standard bio-

logical packages are being adapted for social use (e.g., CLUSTAL by scholars at the University of Strasbourg). Applications of SA can be expected to grow more common once the actual algorithm (not just the weighting scheme) can be tailored to the type of sequence regularity expected in the data.

The extraordinary flowering of pattern-matching methods in biology and computer science will undoubtedly lead to greater application of these methods within social analysis. They are already widely used in market research, of course, and therefore constitute a central part of what is by far the most extensive and comprehensive form of social scientific analysis at present. To be sure, the causal paradigm against which SA methods were developed remains strong within the empirical social sciences. But in the past, widespread availability of new methods has led to wholesale adoption even in the face of earlier paradigms. Indeed, the present causal methods spread precisely in this way. Given the rise of pattern-matching as a general strategy of scientific inquiry, SA and related methods will almost certainly spread. They will also constitute the entering wedge of a much broader set of descriptive approaches to social reality that can be expected to transform social inquiry in the next decades.

Everyday Life, Anthropology of

1. The Study of Everyday Life

From the 1960s and onward the concept of 'the study of everyday life' became an increasingly popular notion in many social sciences, such as anthropology, history, and sociology, as well as in the expanding field of cultural studies.

It has come to signal a special interest in the commonplace and the seemingly trivial routines and activities of daily life as well as a focus on 'ordinary people' as creative actors rather than passive consumers or objects of domination. The different ways in which this seemingly simple concept has been put to work illustrate changing concerns in social and cultural research, as well as conflicts between different research paradigms. Like few other similar concepts, the study of everyday life has been used not only as a research perspective or analytical tool but as a research ideology. The study of everyday life often developed as an alternative to or critique of mainstream traditions.

The use of the concept as an alternative approach means that it is constantly being constructed in opposition to something else. It can be organized as the study of the life and thoughts of ordinary or common people against that of elites, intellectuals, or experts. It can be defined as the routines, habits, and phenomena which tend to be neglected because their 'everydayness' makes them invisible or self-evident, unlike colorful rituals, celebrations, or other activities with high visibility or prestige. Here it is 'the everyday' as contrasted to 'the Sunday best' in social life, working with polarities like mundane/sacred, informal/formal, repetitive/unique, trivial/special. Everyday life can further be seen as the arena of expressions and meanings threatened by invasion from 'above,' by institutions like the state, the market or just 'the system.' This perspective favors a view of everyday life as resistance against domination. The focus on resistance is often linked to a view of everyday life as a site of cultural creativity. Finally, 'the study of everyday life' often defines a research orientation rather than an empirical field. It is then seen as a certain style of doing research, usually with a focus on qualitative and ethnographic methods—exploring the hidden worlds of daily life. The argument is often that by focusing on seemingly banal phenomena new and sometimes surprising analytical

insights into major social or cultural issues may be produced.

The study of everyday life has emerged as an arena of intense cross-disciplinary dialogues, but it is also an interest which also has developed in a constant interchange with new public and political ideas about the importance of everyday life (see Gullestad 1991) (see *Common Sense, Anthropology of*).

2. The Making of a Concept

The development of everyday life as a research topic is thus a complex one. It has entered the social sciences along many paths and in this process been charged with very different theoretical and ideological meanings. There are two nineteenth-century traditions which can be seen as starting points for the twentieth-century interest in the study of everyday life.

First, the works of those cultural historians, who in the late nineteenth century turned to the everyday of 'ordinary people' to create an alternative to the classic history of 'kings and elites.' Second, the interest among early social researchers and reformers exploring the lives of urban poor or rural peasants, starting with Henry Mayhew's classic work *London Labor and the London Poor* of 1861.

2.1 Sociological Approaches

It was this latter interest in questions of social welfare that influenced the interwar ethnographic studies of the so-called Chicago School of American sociology. An early example is Nels Anderson's book *The Hobo: The Sociology of Homeless Men* of 1923.

This interest in urban everyday life of the Chicago School was developed further by the new generations of postwar American sociologists. Behind the new label 'The Sociology of Everyday Life' very different theoretical traditions and research perspectives were found. One was the symbolic interactionism of Erving Goffman's (1959) pioneering work *The Presentation of Self in Everyday Life* with its qualitative, ethnographical approach to the seemingly trivial or invisible routines of 'the everyday,' as it surfaced in patterns of social interaction. For early phenomenological contributions to this sociology of everyday life see, for example, Schutz (1973) and Douglas (1971). The third new approach was ethno-methodology (see Garfinkel 1984), mainly devoted to understanding the construction of common-sense knowledge in everyday life. Today, the sociology of everyday life usually stands for a qualitative and ethnographic approach (see Glassner and Hertz 1999).

In France, the sociology of the everyday developed along very different lines. Here the studies of popular mentalities in the Annales School of social history and especially the works of Fernand Braudel created an early analytical interest in the role of everyday life for understanding society. The sociologist and rather unorthodox Marxist Henri Lefevbre started to explore the concept of the everyday already in the interwar period and published a number of books on the topic between 1947 and 1991 (see, e.g., Lefebvre 1971). His interest in everyday life was connected with the rapid modernization France underwent especially after the Second World War with the creation of a new consumer based and standardized everyday life. He used the term 'everydayness' (*le quotidien*) to describe what he saw as the banality and conformity of modern everyday life and the ways in which it was colonized by modern capitalism. But Lefebvre's approach was not only centered around questions of alienation and domination. His treatment of the problems of 'everydayness' also stressed the ways in which social scientists underestimated the role of the everyday, not only as a site of domination but also as an arena with potentials for transcendence and change—the peak experiences or special moments embedded in it (see Shields 1999).

Lefebvre's discussions of everyday life had a strong philosophical profile, which may be one of the reasons his work did not come to inspire empirical studies in the same way as the work of another French sociologist, Michel de Certeau. His book (1984) has been very influential in shaping the approaches to the study of everyday life in many disciplines during the 1980s and 1990s. Lefebvre and de Certeau both shared an interest in the uses of space in everyday life, but the similarities end there. Unlike Lefebvre, de Certeau focused on everyday life as an arena of cultural creativity and resistance, and above all on consumption as creative cultural production.

2.2 Anthropological Approaches

In anthropology the actual concept 'study of everyday life' was not at first used very frequently, in spite of the fact that anthropology often was seen as 'the science of the everyday' with its ethnographic and qualitative explorations of life in different settings over the world. One reason for the lack of an explicit use of the concept of everyday life was that it was seen as a cultural category belonging to the modern Western world. In non-Western societies this polarity between the everyday and its counterparts, however defined, did not seem very relevant. In the broad anthropological approach to the study of culture there was no need for a subcategory labeled everyday culture.

In many ways the interdisciplinary interest in studies of everyday life among historians and sociologists from the 1960s and onward meant an anthropologization of both approaches and theoretical frameworks. It was not only the ethnographic methods and the metaphors of 'discovering' and 'exploring' everyday life as a hidden but exotic culture which accounted for this anthropologization. The anthropological connection also had to do with studies of everyday life

emphasizing a cultural perspective on society. It was in the habits, rituals, routines, and traditions of daily life that 'culture' was embedded, as invisible to the actors as 'water to the fish,' to quote a popular metaphor from the 1970s.

A much more explicit use of the category of the everyday was found in the anthropological branch of European ethnology, which from the 1960s and onward redefined itself as a discipline in which the study of everyday life in European settings, past and present, was central. This transformation may serve as an example of how the concept came to be given strong symbolic and ideological charges (see Frykman and Löfgren 1996).

As European ethnologists in the 1960s oriented their research towards modern industrial society rather than vanishing peasant traditions the basic concept of folk culture was exchanged for the study of the everyday and 'the ordinary people.' These new concepts not only signaled a break with earlier generations but also worked as a boundary marker against neighboring disciplines. Ethnologists studied everyday life with a qualitative perspective unlike sociologists and historians, the concept of everyday life was used to show that the ethnological interest in society was not concerned with formal institutions and macrostructures. In reality the concept was thus not about the contrast between everyday and non-everyday phenomena, but a way of stressing a research interest focusing on neglected groups, activities, and spheres.

3. *Everyday Life and Cultural Creativity*

Another research tradition in which the notion of everyday life became very important was the emerging field of Cultural Studies. As in European ethnology this interest in everyday life during the 1980s and 1990s was linked closely to the new concept of cultural creativity.

Just as the notion of everyday life, the concept of creativity functioned as a counter argument in cultural research. Groups and settings, which at first glance seemed characterized by passivity, simply reproducing dominant patterns, were in the new studies coming out as culture builders and bricoleurs: busy reworking, elaborating, and thickening their everyday lives with new meanings and routines. This approach is very striking in de Certeau's work as well as in much of the studies made by the so called Birmingham School of Cultural Studies. A good example is Willis' (1990) book *Common Culture: Symbolic Work at Play in the Everyday Cultures of the Young*. Here everyday creativity becomes not only a counter argument against the presupposition that creativity is an elite resource, a cultural capital of the gifted, of artists, writers, intellectuals, etc, but also against the notion that modern mass consumption is a passifying, homogenizing force in people's lives.

When consumption was redefined as 'cultural production' or 'symbolic production,' the creativity of everyday life moved in to occupy a central position in this production process. This emphasis on cultural creativity as resistance must be seen as a reaction against an earlier discourse on the seduction of mindless consumers: locked up in the iron cage held together by market forces. Creativity became, in some ways, the weapon of the weak—a positive strategy of resistance. More rarely the concept was used to describe strategies of dominance and oppression: other terms were used for the creative and imaginative ways of control and manipulation.

The pairing of cultural creativity and everyday life can thus be seen as an attempt to redress the balance, to develop a more actor-oriented approach in studies of mass consumption. In this process, however, the 'when, where, how, why, and who' of cultural creativity in everyday life was narrowed down and produced certain paved roads: a tendency to over-research some aspects and arenas and overlook others (see Löfgren 1997).

This slanting of the two concepts was not a very conscious process. It started with the focus on consumption as creativity, a creativity much focused on symbolic production and expressive forms in what Featherstone (1991) has called the aesthetization of everyday life. This very selective emphasis was made more narrow by a marked concentration to specific social settings, above all youth cultures with their constant experimentation with identities and reworking of mass media and mass consumption styles, images and commodities.

With a selective focus like this cultural creativity became a very positive concept. It was seen as enrichening, elaborating, 'thickening' everyday life, a process through which people make their daily existence colorful, unique, specific, distinct' and above all positive. The perspective usually was reserved for those defined as the underdogs of the modern world: consumers, workers, women, teenagers, colonial, and postcolonial subjects, and this is where the concept is linked closely to ideas of counter-hegemony, to the tactics of resistance in the world of mass consumption, or in postcolonial processes of globalization.

4. *Problems and Potentials*

Just like everyday life creativity became a concept mainly for the age of late modernity. The academic interest in the two concepts mirror a public and political concern too—especially in North European and North American settings—which had its roots in the counter-cultures of the 1960s and 1970s and the interests in alternative life-styles as well as the democratization of cultural expression. During this period the idea of the importance of everyday life became a powerful political symbol, condensing and unifying a

number of sometimes conflicting values (see Gullestad 1991). Everyday life was 'where the action was,' the location of 'real or authentic life.' By studying and engaging this arena silent groups and interests could be given a voice.

Such political and popular interests influenced academic research. Some activities and people easily came to be seen as more everyday than others. Another danger of this perspective was that everyday life was too easily seen as something 'down there,' in a way that seldom reflected over the problem of what the opposite of the everyday was supposed to be. It was forgotten that everyday life existed not only in retirement homes or on the streets but also in the corridors of power, that there were everyday practices not only in immigrant suburbs but also in scholarly research projects. Researchers who sometimes said that they wanted to 'get out into everyday reality' missed the point that what is interesting about the everyday is that it is ever-present.

Taking such ambiguities and possible ideological overtones into account, research interest in the study of the everyday has on the whole been important both in revitalizing and redirecting scholarly attention to the role of the seemingly trivial activities and ideas embedded in the commonplace. During the last decades of the twentieth century, the study of everyday life has been constituted as a very productive cross-disciplinary field, developing innovative research strategies for destabilizing or problematizing the taken-for-grantedness of much daily life.

The study of the everyday has also been a strategy to avoid paved road in research and develop back-door entrances to major issues. Two examples may illustrate such strategies. The first is taken from the French sociologist Kaufmann's ethnographies of daily life, his study of the conflicting values of modern marriages analyzed through the routines of doing the laundry in a sample of French families (Kaufmann 1998). Through extensive interviews with wives and husbands about their laundry habits Kaufmann throws new light on the constant negotiations typical of modern marriages, negotiations about divisions of labor, definitions of love and individual space, as well as changing perceptions of the moral economy of the family.

Similar examples of such a use of back-door entrances to major issues can be found in those studies of nationalism, which do not take ideology or official rhetoric of major institutions as their starting point, but want to understand the power of 'the national' through the modes in which it is anchored and materialized in everyday life. Such studies, for example, Billig (1995), illustrate the powerful ways in which the nation–state has been made visible and tangible in a wealth of everyday situations and settings, how citizens have been touched by the state.

Studies like these work as a reminder that the seemingly insignificant may be a good starting point for exploring the workings of society. Studies of everyday life have produced techniques and methods for understanding how a lot of cultural energy may be condensed or crystallized in a trivial situation, an unperceived object or a prosaic routine. They have also led to a much greater reflexivity about the manners in which the study of the everyday is conditioned by the researcher's own embeddedness in their own everyday practices.

Evidentials in Linguistics

The term 'evidentials,' introduced originally in descriptions of languages where suffixes express the source of subjective knowledge—as by hearsay, or by

dream—was extended progressively to a repertoire of grammatical devices coding different kinds of evidence on which statements are based: (a) markers indicating the source of the speaker's information or knowledge, and (b) epistemic markers coding the speaker's attitude toward knowledge. In this broad sense, evidentials qualify the source in different ways (hearsay, inference, appearance) and specify the truth value of an utterance (Chafe and Nichols 1986). Expanding the notion of epistemic modality to the status of the speaker's knowledge (Palmer 1986, p. 51), evidentials cover most of what linguists treat now under the notion of evidentiality: a strict grammatical distinction between direct (typically 'unmarked') and indirect evidence, the latter being based on verbal report and inference (Willett 1988, p. 57). However, this broader conception of evidentiality is not without problems.

All languages can express the speaker's (or the writer's) various modes of access to information, as well as the degree of the speaker's responsibility for that information. In most of the Indo-European languages, information about the source of the conveyed content is not grammaticized, but may be provided by various optional devices, either syntactic ('They say that'…, 'I heard that'…) or lexical (adverbs: 'allegedly,' 'reportedly'…; or particles such as Bulgarian *kaj*, *už* …). Many languages do, however, encode in their grammars specific forms for expressing direct experience, reportedness, hearsay, inference, etc. For instance, some Balkan and Middle Eastern languages provide paradigms (mediative forms derived from the perfect), which refer to the information source or to the speaker's attitude toward the information, without specifying explicitly its source or commenting on its truth. These forms are opposed to the indicative forms, which are neutral with respect to the source. In these languages, the speaker's choice of the form is subordinate to the register (colloquial dialogue, historical narrative, distantiated narrative, etc.), so that the specific interpretation of the information mediated through report or inference depends on the register (Guentchéva 1996b).

In other languages the speaker must specify the way in which the information was acquired, by choosing a grammatical marker indicating whether the information is based on direct experience, or on reports or inference (something seen, told, heard, inferred, including dreams, tales, and myths). In Tibetan (Tournadre 1996), special markers serve to indicate that the situation has been seen (*-song*), is common knowledge or has been heard from someone else (*-pare'*), or is inferred (*-sha'*):

(1) mätrokungkar-la sāyom-ki'
Metrokungkar-LOC earthquake-ERG
khābgpa Mangpo
house many
Lo-*'song*/*-pare'*/*-sha'*
destroy-AUX
'In Metrokungkar, the earthquake destroyed many houses'

Moreover, the hearsay morpheme *-sa* may combine with any of these verb forms, to indicate the source of the speaker's informant's information. The system is even more complex, since these markers interact closely with person and with the semantics of lexical verbs.

The three major issues are: (a) are there pure evidential systems? (b) what is the core meaning of evidentiality? and (c) what is the relation of evidentiality to modality?

Tuyuca (Brazil and Columbia) is often presented as a 'classical evidential system.' If a Tuyuca speaker wishes to say 'he played soccer,' he must choose an appropriate suffix (Barnes 1984, p. 256):

(2a) díiga apé-**wi** (I saw him play)
(2b) díiga apé-**ti** (I heard the game and him, but I didn't see it or him)
(2c) díiga apé-**yi** (I have seen evidence that he played: his distinctive shoe print)
(2d) díiga apé-**yigi** (I obtained the information from someone else)
(2e) díiga apé-**hĩyi** (It is reasonable to assume that he did)

At first sight, this system appears to be based on the contrast between information obtained through direct sensory experience (visual in (2a) and nonvisual in (2b)), and information obtained through indirect experience (apparent, inferred in (2c), secondhand report in (2d)). The assumed evidential in (2e) seems to hover on the boundary between direct and indirect evidence, being used only when no information about the state or event is being or has been received. Furthermore, this analysis does not take into account the fact that the visual *-wi* of (2a) can co-occur with the 'resultative' morpheme *-ri*: *wáarigi nū-wi*. While this construction may be translated as 'he went,' the literal gloss is 'he was here earlier, and later I couldn't find him.' This is very similar to the inferential meaning of the perfect in Western languages. Clearly, this kind of inference should be differentiated from that in (2c).

Wintu provides an instructive example of another kind. According to Schlichter (1986, p. 54), Wintu has an evidential deictic system establishing a strict grammatical distinction between a direct 'visual experience' (unmarked) and an indirect experience that is 'an alternative to the temporal orientation of "Western" civilization.' It has four evidentials:

(3a) heket wira waca:-bi-**nt**^{h}**e**·-*m*
someone come cry-Imperfective-NONVISUAL SENSORIAL-DUB = 3 person subject
'Someone is coming crying (I hear)'

(3b) Č'epkal neɪ ba·-bi-**nt**^{h}i-da
bad we eat-Imperfective-SENSE-we
'We've been eating bad things (I sense)'

(4) Minel kir-**ke**·-m die COMPLETIVE
ASP-HEARSAY–DUB = 3 person subject
'He has died. (I'm told)'

(5) Ničaj ewin suke-**re**·
nephew here stand-INFERENTIAL
'My nephew must have been here (see tracks)'
(6) *?lmtop· nuqu·-·el*
berries ripe-EXPECTATIONAL
'The berries must be ripe (it's that time of year)'

The non-visual *-nt^{h}er* in (3), deriving from a passive form of the perception verb *mut-* 'hear, feel, sense, perceive,' involves a fact known to the speaker through a sense other than vision, or by any kind of intellectual experience or 'sixth sense.' It interacts closely with person, agentivity, and aspect. Occurring most often in third person, as in (3a), it only expresses the speaker's perception of the situation; but when occurring in first person (the subject marker *-da* is required), it involves the speaker's experiential role, as in (3b). Furthermore, it is always in complementary distribution with the derivational suffix *-a*, which indicates that 'the grammatical subject is a voluntary participant or agent of the situation.' It seems also to have developed a surprisal or 'mirative' meaning. The suffixes *-ke·* and *-re·* are true evidentials, indicating, respectively, information known through hearsay (4), and information based on inference (5). Finally, the suffix *-ʔel* in (6) is usually used to specify the speaker's 'experience with similar situations, regular patterns, or repeated circumstances common in human life.' It thus has an 'experiential' meaning, though it can also function as a hearsay marker in myths.

The comparison between Tuyuca and Wintu shows that their evidential systems do not cover the same semantic space. It demonstrates clearly that the languages grammaticize different distinctions, and that the diverse processes in the grammatical categorization of each language are based on different conceptualizations.

Commenting on the search for a core meaning, Anderson (1986, p. 274) points out that not all forms that have been called 'evidential' share a common set of 'evidential functions.' He proposes four parameters to identify a true evidential: (a) it shows 'the kind of justification for a factual claim which is available to the person making that claim', (b) it is not itself the main predication, but rather 'a specification added to a factual claim about something else', (c) the indication of evidence is its primary meaning, not just a pragmatic implication, and (d) it never occurs as, a derivational morpheme nor as an element in a compound. Anderson's model and other recent cross-linguistic analyses show that the basic principle governing the unity of evidentiality in a particular language and across languages is the widespread occurrence of mediated information. Evidentiality is the grammatical manifestation of a two-dimensional operation binding simultaneously the event's own spatial and temporal coordinates (event's time reference) and the speaker's spatial and temporal reference (speech time reference). This is not to say that the two time references co-occur, but that the binding of the two reflect a scalar mapping of temporal relations which allows the speaker to express different degrees of disengagement with respect to the content of the utterance (Déscles and Guentchéva 2000).

From a typological point of view, the semantic space of evidentiality is articulated according to two fundamental meanings: inferential and reportive (including an unspecified third person, hearsay, rumor, common knowledge, tales, and myths). Cross-linguistic data suggest that attested evidential systems are based mainly on a binary opposition which distinguishes mediated (and morphologically overt expression) from nonmediated information (most often carried by the non-overt member of the morphological opposition). When a language has only one evidential marker, its main function is the reportive one. If the one marker covers both reportive and inferring information, its interpretation is left to the context. When a language has two markers, they may distinguish mediated and nonmediated information (Turkish, for instance), or reportive and inferring information.

Reportives are found in a wide variety of languages. In some, a true reportive evidential is derived from a verb of saying and is used in dialogue as well as in tales and myths. In Makah (Jacobsen 1986, p. 17), the reconstructed passive form *-wa:t* of the verb *wa·* 'say' indicates hearsay and this also occurs in the narration of tales and myths:

(7a) *xu·bitdib$^{?}$**u***
'He was snoring'
(7b) *xu·bitdibit**wa·d***
'He was snoring (I was told)'

Clearly, (7b) is a mediated message. The denoted situation is part of the original utterance attributed to someone other than the speaker; i.e., it combines the term reference of the original utterance with the speaker's time reference. This is not to say that *wa:**t*** always implies an antecedent speech act of another speaker; it may merely be a mental construct of overhearing, common knowledge, tales, etc.

Although the relation between hearsay and indirect discourse is very close, they are independent. Indirect discourse usually involves overt expression of *verba dicendi*, and deictic transposition which 'shifts' person, tense, and mood. Alternatively, it may be a special mophosyntactic device, as in Maricopa (Gordon 1986, p. 86). Cliticized to the invariant form verb *'ish* or *ish* 'say,' *-'a* in (8a) conveys heard information in an independent clause, while in (8b), *-k* introduces 'a complement whose verb is not marked with switch-reference suffixes' and indirect discourse interpretation:

(8a) *Bonnie-sh chuy-k-'ish-'a*
Bonnie-Sj marry-**k**-say + sh-hearsay
'(They said, I hear tell) Bonnie got married'
(8b) *Bonnie-sh chuy-k uu'ish-k*
Bonnie-Sj marry-**k** say + Pl-Asp
'They say Bonnie got married'

As noted earlier, in some languages, the overt inferential markers arise from perfects, while in others they arise from perception verbs. In the latter case, the message does not focus on the source of the evidence but, rather, on the fact that the evidence is not reported verbally. Occurring in the utterance, an inferential evidential indicates that the factual content of the message is mediated by sensory perception, but also by experience or intuition. Clearly, the speaker may construct an inferential reasoning about a supposedly produced event.

Wintu provides two grammatically different inferential markers which reflect inferential reasoning: *-re* in (5) and *-ʔel* in (6). With *-re* the speaker indicates that an earlier plausible event is inferred from traces in evidence. The grammar thus encodes an abductive reasoning, which involves (Peirce 1974, Vol. II, p. 636; Vol. V, p. 171): (a) a law allowing an explanatory inference of hypothesis based on observed facts, and (b) the observed facts that are traces sufficient to relate to the hypothesis, which is merely taken to be plausible. With *-ʔel* the speaker indicates that it is inferred from experience 'the existence of phenomena such as we have observed in cases which are similar' (Peirce 1974, Vol. II, p. 636); the grammar encodes an inductive reasoning.

The (ad)mirative meaning of evidential constructions (expressing surprise or irony) is an extension of the reportive or the inferential. It arises when the speaker confronts an unexpected discovery and expresses the contrast between the expected and discovered situation ('I didn't know that S (but now I do)').

While evidentiality has often been identified with epistemic modality, analyses of data from different languages show that neither the concept of 'truth' nor the strength of a speaker's commitment to his or her statement's truth value fully accounts for evidentials and evidentiality. The translation of evidential constructions with modals (English 'must,' French *devoir*) in European languages is not always an adequate one (Chvany 1999, p. 437). Moreover, in some languages modal verbs appear in mediative forms.

Among recent attempts to assign a uniform treatment of evidentiality, an account in terms of a dual time-reference (to speech time and event time) appears to be the most promising and relatively straightforward. Interpretation may, however, vary according to gender or stylistic register. The speaker's disclaimer of responsibility is organized along a continuum of degrees of disengagement with respect to the content of the utterance.

Evolution and Language: Overview

The complex relationship between evolution as a general theory and language is discussed here from two points of view. The first concerns the isomorphism of the basic structure of evolutionary theory in biology and linguistics. The many languages in the world fall into coherent groups of successively deeper level and wider membership, e.g., the Romance languages and the Germanic languages at a more superficial level are both themselves subgroups of the wider Indo-European language family. Similarly in biology groupings

like the orders of primate, the Felidae (catlike animals), and others are subgroups of the larger class of mammals. The existence of such hierarchies in both fields is accounted for by a similar dynamic process of change and differentiation through time. The second major topic is the unique and basic role of language in the evolution of communication.

1. *The Parallel between Biological and Linguistic Evolution*

The essential resemblance, or homology of structure, between biology and linguistics is based on the equating of languages to species and dialects to varieties. In both fields somewhat similar criteria are employed to distinguish these levels and in both cases they have a penumbra of vagueness. In biology membership in the same species is defined by the possibility of fertile interbreeding. In linguistics, a language is defined by the test of mutual intelligibility. The vagueness in both cases derives from the fact that we are striving to capture by definitions the distinctions of two levels, species and variety, language and dialect, when in fact in both cases we are dealing with a dynamic process. The variety of today is the species of tomorrow and the dialect of today is the language of tomorrow.

1.1 *Transformationism Versus Creationism*

The transformational meaning of evolution arises from the considerations involved in any class of phenomena in which the investigator is confronted by the existence of a variety of kinds or species. In such instances there are two fundamentally different types of theory to account for the existence of distinct kinds. According to the creationist view the distinctness of species is explained as issuing from distinctive creative acts. Species can be created or destroyed but they cannot give rise to other and new species since this would change their essential characteristics. When confronted with fossil evidence that the species of different geological epochs were, in general, similar although distinct, the creationist necessarily denied that any lines of development connected them. The theory thus adopted was called 'catastrophism,' namely that by a succession of cataclysms earlier species had been destroyed and were replaced by more recent ones through new creative acts.

The evolutionary theory of transformation of species on the contrary maintained that there are no fixed bounds to variation. Therefore earlier species give rise to later ones by the process of developmental evolutionary change. The fact that in life forms species fall into coherent larger groupings, the genera, and that groups of genera then form distinct families and so on in an ordered hierarchy receives a distinctive transformationist explanation.

According to transformationist theory, those species that belong to the same genus are the differentiated descendants of a single ancestral species, their resemblance being explained by common descent. The resemblances among genera that belong to the same family are explained in turn by the theory that the species ancestral to each genus are descendants of a still earlier form ancestral to the whole family, and similarly with larger and taxonomically higher groupings. Fossil forms are then either ancestors of existing groupings or additional lines of descent that have become extinct without leaving descendants.

The model of evolution that emerges is that of a branching tree. The varieties of today are like twigs that, as they sprout, become the species of tomorrow. The theory of evolution as transformation applies both to linguistic and biological evolution. This resemblance was noted by Darwin himself in *The Descent of Man* (1871, p. 40) and had indeed been noted earlier by Lyell (1863), the founder of modern geology. As Darwin states: 'the formation of different languages and of distinct species and that both have been developed through a gradual process is curiously parallel.'

In linguistics the creationist view is represented by the Biblical account of the Tower of Babel, according to which all language differences were created at the same time by the confusion of tongues. By not noting that languages fall into coherent groups like the Germanic languages etc., and that these in turn function as units within higher level units in an ordered hierarchy, the Biblical account which reigned supreme until nearly the end of the eighteenth century was inferior to its creationist counterpart in Linnaean biology, which did note the coherence in biological classification but simply ascribed this coherence to a divine plan to produce such groupings.

Perhaps because the Babel theory more egregiously failed to account for such groupings, the creationist account was superseded earlier in linguistics than biology. The event that marks most clearly the triumph of transformationism over creationism in linguistics was the recognition that the resemblance among the languages we now call Indo-European is to be explained as a result of common inheritance with differential changes from an extinct ancestral form of speech which in later terminology was called Proto-Indo-European. The acceptance of this theory is usually but somewhat arbitrarily dated from a statement of Sir William James, an eminent British official in India, in 1786. In fact, in regard to the Finno-Ugric languages this explanation had been advanced and accepted some years earlier. Thus the recognition of transformation in linguistics substantially antedates its acceptance in biology.

Probably the chief factors in the relatively earlier acceptance of this type of explanation in linguistics as

compared to biology is the vastly more rapid rate of change in language. The commonsense objection that actual changes in species had never been observed in historic times and that, to all appearances, they were fixed appears to have been the most powerful factor in the rejection of transformationism by biologists in the period preceding Darwin. Darwin in turn appealed to languages as an exemplification of the reality of the process of transformation he proposed in regard to life forms (cf. Alter 1999).

Language within the realm of individual experience and unaided by records from an earlier period seems fixed on the whole, but not to the same degree. Older people can recall vocabulary items that were current in their youth but are now no longer heard.

These changes, apparently small within the lifetime of a single person, display powerful cumulative effects in periods of time within the scope of human records. Thus Anglo-Saxon (Old English) exhibits differences from modern English over a period of about 1,200 years, comparable to that between English and German at the present time. If Anglo-Saxon and modern English were spoken contemporaneously they would undoubtedly rank as separate languages. It was possible then to note in this historically well-documented instance the change of one language into another. Moreover there are earlier records of German also in the form of Old High German and Old Low German. These languages are both far more similar to Anglo-Saxon than modern English is to contemporary German. Thus one could actually observe a convergence as one went back in time, the mirror image as it were of the hypothetical divergence in time from a single common ancestor.

In general, languages ancestral to existing groups of genetically related languages, which would correspond to fossils in biology, take us back to periods before the existence of written records. However, in the well-known instance of Latin, there are abundant records of a language which through a series of locally different variants has given rise to the existing diversity of Romance local dialects and standard languages. In view of these well-known facts, it was not too audacious a step to assume that in similar fashion an ancestral language had once existed bearing the relation to the existing branches of Indo-European that Latin does to Romance speech forms. It thus becomes a mere historical accident that Latin survived in written form, whereas Proto-Indo-European, which was spoken before the existence of writing, could not be known through such evidence.

The transmission of physical characteristics by the genetic mechanism corresponds to the transmission of language by learning from one generation to the next. In both cases variations arise, some of which are perpetuated. In both instances geographical isolation whether complete or imperfect is the usual factor in the perpetuation of different variants, although linguistic isolation of social groups in the same territory also occurs. Difficulties of determining where a variety ends and species begins, difficulties that were important factors in Darwin's disillusionment with creationist theory, resemble the linguistic difficulty in defining language as against dialect. Ultimately these variant descendants become sufficiently distinct as to be indisputably ranked as separate languages or species.

The status of transformationalist explanations of linguistic similarities was further enhanced by the largely successful reconstruction of Proto-Indo-European where, as is usually the case, the ancestral language was not known from written records. This enterprise received a great impetus through the discovery that in certain respects, especially the sound system, changes were not haphazard but rather showed a surprising degree of regularity.

The enterprise of reconstructing Proto-Indo-European and the laying of the foundations of the comparative method that underlies it was essentially carried out by the so-called Neogrammarian School of the 1870s and the 1880s.

1.2 Cladistics in Linguistics and Biology

In the course of laying out more explicit methods of historical comparison and reconstruction the Neogrammarian School developed the notion that only those changes which were innovations, not those which were retentions, were relevant in classification. The period in which what marked one subgroup as a development distinct from that of another was defined by the different set of changes that each was undergoing from a common original. Retentions were simply inherited features that persisted from the common period.

This was indeed the very point made by Willi Hennig (1966) the founder of cladistics in modern biology, some 70 years later. However, in linguistics as in biology, it is not easy in many instances to distinguish innovations from retentions. For example, for a long period it was held that the Italic and Celtic branches of Indo-European shared an important innovation that helped to define a separate Italo-Celtic branch of Indo-European, namely the formation of a passive voice in -r. However, when Tokharian in Chinese Turkestan was discovered from documents as a new branch of Indo-European in the 1930s, it was found to have a passive in -r but hardly anything that would otherwise affiliate it with Italic or Celtic.

1.3 Analogy and Homology in Linguistic and Biological Evolution

Just as transformationism is a dynamic interpretation in time of the hierarchy based on differences and

shared similarities in languages, so the creationist view of fixed species is implied in the use of properties for classification with typological rather than genetic relevance. Once again there is a parallelism between biology and linguistics. In the terminology of biology, we wish to distinguish between homologies that are similarities which are the outcome of common descent, and analogies that result from convergence usually through similarity of function and are irrelevant to historical classification.

In language it is possible to define two kinds of criteria that define the difference between homologies and analogies. The former are those that involve sound and meaning simultaneously, while the latter concern sound in abstraction from meaning or meaning in abstraction from sound. Thus the resemblance between English *nose* and German *Nase* involves both sound and meaning. If supported by a reasonably large number of other resemblances of the same kind, these forms are then said to be 'cognates,' i.e., related. Such cognates are the basis for drawing the conclusion of a common origin of English and German.

An example of resemblances of sound without meaning is the existence of tonal systems, i.e., systems in which pitch difference distinguishes semantically different meaningful elements if we simply take these systems as such abstracting the sounds from the meanings of the words being compared. An example of meaning without sound is the existence of sex gender in two different languages where we disregard the sounds by which the differences between masculine and feminine are expressed.

The latter criteria, sound without meaning and meaning without sound are called typological by linguists; these criteria define types of languages e.g., tonal vs. non-tonal, gender vs. non-gender. The use of typological criteria for genetic linguistic classification requires the assumption that certain features like the essential as opposed to the accidental features of the creationists are fixed and define the species; or in this instance the language family. Thus if we state that tonalism is a requirement for membership in a particular linguistic stock we are assuming that a tonal language can never become a non-tonal language. If this were true monogenesis would be refuted. We would initially have two or more languages, each of which would have tonality or non-tonality as an essential attribute and would be incapable of either acquiring tonality where it was lacking or losing it where it was present. This is the analogue of the notion of fixed species.

Once it is realized that a classification based on gender or non-gender is similar in principle to a biological classification into flying and non-flying animals, we see that a Semitic language which ceases to have triconsonantal roots does not cease to be a Semitic language by descent, any more than a bat ceased to be a mammal when it acquired the property of flight.

1.4 Differences between Linguistic and Biological Evolution

Thus far the discussion has stressed the basic parallel between linguistics and biological evolution. However, there are significant differences, mostly in the contrast between genetic and social transmission. There is not only lineal transmission of languages to one's biological offspring but also lateral transmission in that speakers are capable of bilingual, or indeed multilingual behavior. Thus a child may acquire a language that is not the native language of its parents. Moreover, unlike the genome which is fixed at birth, speakers may borrow words and grammatical forms which are part of the inherited language of another group of speakers with whom they have come in contact, and which may in turn be transmitted to their own offspring as part of their native language acquired from their parents. The closest analogue to this in biological evolution is hybridization. In the animal kingdom hybrids are usually infertile but in the plant kingdom this is not invariably so.

1.5 Language, Natural Selection, and the Notion of Progress in Language

The theory of evolution in its Darwinian form not only espoused transformationist as against the creationist notion of fixed species, but also suggested as its main mechanism natural selection in order to provide a plausible account of the transformation of species. The concept of the transformation of species was, of course, not new. Lamarck, for one, had already espoused it at least 50 years before Darwin.

Now as Darwin states repeatedly, the descendants of a particular life form are, through the agency of natural selection, likely to be more efficient though this of course is relative to a particular environment. There is, however, still implicit in the notion of natural selection the theory of long-term advance in the series of life forms.

It is true, moreover, that the paleontological evidence as we go back in time becomes increasingly confined to forms of relatively simple and undifferentiated structure and of a more limited range of adaption to the environment. It was precisely one of the recommendations of the theory of natural selection that it helped to make this temporal advance intelligible.

This aspect of evolutionary theory has also been applied to language. The new linguistic forms that arise continually in any linguistic community may then be likened to variations, only the fittest of which survive and become incorporated in the language. Lyell (1863) in his elaborate comparison of language to biological species, noted also that the spread of specific languages over wide areas resembles the

biological processes of adaptive radiation and the extinction of species. Natural selection as applied to language would then involve an intralinguistic struggle for survival among forms within the language and an interlinguistic struggle among languages in which some spread and produce descendants while others perish.

Regarding the intralinguistic struggle it appears that many changes are functionally indifferent, and that while certain changes make for greater efficiency there are certain outcomes of normal processes of change, such as grammatical irregularities and semantic ambiguities, which are functionally negative. Taking linguistic change as a whole there seems to be no discernible movement towards greater efficiency such as might be expected if in fact there were a continuous struggle in which superior linguistic innovations won out as a general rule.

Similarly it can be seen that one language succeeds another not because it is more advanced as a language, but for extralinguistic reasons of the military, economic, or cultural superiority of its speakers. This is not to say that there are not important differences between languages that have been the object of literary cultivation and those that have not, and those that possess an extensive technical vocabulary and those which do not. However, such differences are but reflections of non-linguistic differences. They affect nothing basic in the language itself. Any language is capable of literary expression or technical expansion if non-linguistic circumstances encourage or require it.

The question that has just been discussed relates to another way in which languages of the present do not conform to one of the basic aspects of evolutionary theory in biology. A theory which regarded all species as interconnected, but which posited some mammalian form as the primitive ancestral type for all life whence descended in one line all the other vertebrates and in another the ancestor of all non-vertebrate phyla, and in which plants and Protozoa first appeared in the most recent period, would be a strange evolutionary theory. In addition to the notion of transformation of species that of progress or advance of some kind is inherent in the notion of natural selection. In general we are dealing with the increase in the range and variety of adjustment to the environment. Among the developments that may be considered advances there are, on the perceptual side the ability to respond to finer differences in stimuli, to stimuli from a greater distance, and to new ranges of stimuli, e.g., a new sense. On the motor, or effector side there are the ability to live in a greater range of temperature or moisture, speed of movement, and the ability to make finer manipulatory adjustments to objects in the environment. In the interface between perception and response come the coordination of responses to stimuli such as the development of a central nervous system, of social cooperation and intelligence in general, and finally speech itself.

This gives us many facets of comparison and we cannot simply arrange all species on a linear scale of more advanced and less advanced. It is clear that time, indeed vast periods of time are required for the development of more advanced species in the sense just sketched. This is borne out in general by the paleontological record which shows that on the whole more advanced species appear later than less advanced although the less advanced persist as viable adaptions.

In the nineteenth century and the earlier part of the twentieth century the belief persisted that languages could in a similar way be arranged from least to more advanced. This was generally expressed by the notion of successive types. The most prominent and persistent of these schemes was the threefold division into isolating, agglutination, and inflective. The earliest and most rudimentary type was the isolating in which, ideally, each word was completely simple and could not be divided into parts as do many words in English, e.g., truth-ful-ly. In the agglutinative stage formerly isolated meaningful units were merely glued together mechanically without any modification of their parts. In the final stage, inflection, there were modification and adaptations of the parts of a word so that the word was a complex organic structure.

Generally only Indo-European was considered to embody the highest stage. The ethnocentrism of this scale is obvious and there were such anomalies as the fact that the closest language to an ideal isolating one was Chinese with its ancient literature and civilization. Further, certain American Indian languages turned out to have a more complex word structure than Indo-European. Moreover in historic times Indo-European languages seemed to be losing their complex inflectional structure and to approach more and more an isolating type, a retrograde movement from the viewpoint of this theory. These considerations led ultimately to its abandonment.

As a further criticism it may be noted that only one very limited aspect of languages was being considered, namely how words were formed from smaller meaningful units, the aspect of language called morphology. In fact it is not clear in what ways an isolating structure is any way less adapted to the functions of language than an agglutinative or inflective. It can also be seen that in this now abandoned traditional treatment the subject of evolution is almost solely in the context of simplicity evolving into complexity and limited to the morphological structure of words. The significance of simplicity versus complexity has certainly been overrated. Irregular alternations, a supposedly glorious property of the inflectional type, have no evolutionary superiority. Irregular alternations are, by definition, functionless. The variation between 'go' and 'wen-' is useless since the difference in meaning between present and past is already adequately expressed by the '-t' of the past in 'wen-t.' A past 'go-ed' would perform the same work and without the burden of learning this irregularity–a real, if hardly noticed,

difficulty for the native speaker and a more conspicuous one for an individual who learns English as a second language. That this is a point of inefficiency is witnessed by the universal tendency towards analogic change, that is, the imposition of regularity. This is hindered by sheer frequency of use that tends to perpetuate irregularities in the most frequent words as in the inflection of 'to be' and the irregular plurals 'feet,' 'teeth,' etc.

While the analogic process mentioned above tends toward regularity, universal processes of linguistic change produce new irregularities. The irregular plurals 'feet,' 'teeth,' 'mice,' etc., came into existence from earlier regular forms. In Anglo-Saxon we had *fot* 'foot' and *fot-i* 'feet.' The first vowel of the plural was fronted by the influence of the plural '-i' expressed by a front vowel ('i' as in 'pit') producing a vowel in the first syllable similar to 'ö' of present day German, i.e., *föti*. This vowel was unusual in English and the rounding was redundant, as the plural was already expressed by the '-i' since the singular was *fot*. Possibly in consequence of this the front rounded vowel was unrounded and the final vowel dropped. Thus we finally had singular *fot*, plural *fet* giving modern English 'foot/feet' which generations of children venturing on an analogical plural 'foots' have been unable to dislodge.

Recapitulating in terms of the earlier consideration of evolutionary advance, it becomes clear that it is not complexity as such which is more advanced than simplicity but any change in efficiency relative to a function to be performed. The traditional criterion for simplicity in the way words are put together from smaller meaningful parts (morphology) is here of minor significance. Similarly in biology a hoof is more efficient than toes in relation to locomotion but a hoof is simpler in form than toes. In other instances we have growth of complexity as functionally relevant, e.g., in the differentiation of teeth in relation to grinding (molars), cutting (incisors), etc.

2. *Language and Communication*

The basic function of language is communication. This implies that language should be considered in the more inclusive framework of the evolution of communication. To discuss the evolution of language by considering language in isolation from communication in general is like discussing the evolution of the bow without regard to its relation to other weapons.

2.1 *The Three Stages of Language Evolution*

The evolution of language from the viewpoint of communication can be divided into three stages: pre-language, language proper, and post-language. Although this is the chronological order of their first appearance, each continues to exist after the initiation of the next stage.

2.2 *The Age and Definition of Language Proper*

The most commonly held view is that true language first developed in our own species *homo sapiens sapiens* ca. 50,000 years BP. No doubt non-language communication existed previously as it does in many species both in the genus *homo* and outside of it. There is no satisfactory account, conjectural as it must be, of steps leading from pre-linguistic communication to language proper. For many the problem of the origin of language is the development of such an account.

We can however consider what distinguishes language proper from non-language, which we may call pre-language in this context. This sets up the requirements of what must come into existence before we can talk of language as distinct from pre-language. The two major requirements are duality of patterning and an infinity of possible sentences. The term duality, (first used by Hockett 1958), refers to the existence of two levels in language. The first is the level of sound units (phonemes) which are relatively limited in number, roughly 10 to 70, and which are in themselves and in isolation meaningless. In combination they form meaningful units of various levels from the smallest, the morpheme e.g., 'hand,' 'the,' 'streng-' as in 'strength' through words, simple or complex morphemically 'hand,' 'the,' 'streng-th' and phrases, up to the sentence level. The sentence is a unit that can occur in isolation to express a coherent thought, e.g., *you* 'forgot to put out the cat.' This analyzability of complex sequences of sound to produce sentences as expressions of coherent thought can be called grammaticality, and the rules when codified form what is called grammar. As a second major property that distinguishes true language from pre-language there is the infinitude of grammatically well-formed sentences that can be formed in conformity to the rules of grammar. There is no finite length for a possible sentence.

Pre-language is then not true language because it lacks these properties of duality and infinity. Pre-language continues to function in human societies as gesture and expressive cries although the latter are often conventionalized, e.g., 'ouch!' The advantage brought by grammatical rules which organize the finite set of distinctive sounds or phonemes is not only a vast increase in the number of lexical elements constituting the vocabulary but the possibility of combining in sentences categories not found together in reality, e.g., lies, hypotheses, and past or future states of affairs.

It seems unlikely that genuine language developed from gestural elements. In addition to the values inherent in a grammatical organization on the dual level of phonemes and morphemes, certain advantages

of the sound medium will help explain why the first true language is spoken language. The use of vocal organs, an overlaid function, did not require the development of a new organ through the slow mechanism of genetic change. The voice is always available, involves little exertion, and does not interfere with other activities except, to a minor degree, eating. Above all, it allows the hand to be utilized. Moreover it can be used by day or night and is perceptible in all directions.

The development of brain lateralization and an increase in complexity and intelligence in the brain are also a major concomitant. Probably this should be viewed as reciprocal. The development of the brain made language possible but the development of the brain itself was to a great extent the result of the use of language.

2.3 Post-language

Despite all of its advantages language in its physical aspect lacks permanence and range. The first advance in what we may call post-language is the invention of writing ca. 10,000 BP in the Middle East. It gives permanence to speech and overcomes distance by the sending of written missives. Relatively recent inventions such as telegraphy, radio, and the computer all give greater range and the possibility of channelized and hence more private communication. All that these developments have in common is that they are isomorphic with spoken language at the sentence level and often at lower levels such as the word or the morpheme. By this is meant that there are rules of one-to-one correspondence between entire sentences in spoken language and some sequence of written or other symbols without necessary one-to-one correspondence on the lowest level of basic phonologic elements (phonemes). Because of the isomorphism on the sentence level of all these systems with spoken language, any inefficiencies that adhere to the semantic and grammatical systems of spoken language are unaffected.

In its semantic aspect certain disadvantages rise from its method of definition of semantic units. This is because the meaning is learned normally not by definition but in context and implicitly rather than explicitly. The two main properties of meaning in natural languages that arise are ambiguity and vagueness. By ambiguity is meant the existence of alternative and different meaning, i.e., homonymy. Vagueness is the lack of definite boundaries to the set of cases in which a term applies. Imagine that the speakers of English are confronted with a man without a single hair on his head. They will presumably agree that he is bald. Now take a man with a full head of hair and remove the hairs one by one. There will be lack of agreement as to the point at which the statement that he is bald is true and, no doubt, an interval within which some or all speakers will be uncertain. We might agree to define the man as bald if he has fewer than a certain number of active hair follicles. In everyday discourse many terms have an ambiguous set of meanings each of which is vague. Actually much ambiguity is harmless. For example the use of the term 'case' both in grammar and law will presumably mislead no one and such instances are even a conservation of vocabulary resources. Vagueness can in principle be eliminated by an agreement on boundaries. However the absence of boundaries corresponds to our own lack of precise knowledge. Do we wish to count active hair follicles every time that we are about to employ the word 'bald'?

Far more insidious are the closely similar but distinct meanings of such words as 'function' in the social and biological sciences. The needs of philosophical and scientific discourse cannot always in the long run be satisfied by the traditional implicit definitions. The first step in departing from the traditional use of terms is the use of definitions by postulation but employing the semantic and grammatical structure of natural language. The physicist defines 'force' in the professional discourse of physicists. Sometimes, however, such half-measures prove inadequate and, as in the case of mathematics and formal logic, an entire system with its own syntactic rules and symbolization of terms is created by postulation.

The development in technologically advanced societies of such formalized systems that overcome in good part the ambiguity and vagueness of meaning and the morphological irregularities of natural language does not mean the supersession of language. It may rather be interpreted within the overall context of the evolution of communication, as part of the process by which each kind of communication becomes more efficiently served by an instrument that more adequately fulfills some specific function. The constant availability and flexibility of language in expanding to cover new needs suggests that it will not be replaced in person-to-person interaction in the foreseeable future, if ever.

2.4 Ordinary Language as the Ultimate Level of Explanation

Language plays a unique role among means of communication that aside from all other considerations assures its future. If we wish to explain a symbol we must do it in some sign system. If the term is still not understood it must be explained in some lower-level system, and so on. But at some point this process must reach an end. Such a system provides the level of ultimate explanation. Language serves this function, hence its generality as compared with the limited subject matter of other signs. For example one explains the symbolic use by the Navajo of 'red' as referring to 'north' by means of a word for 'north' in Navajo or

some other language and it is then assumed to be understood.

Ontogenetically, too, such systems or post-language symbols (e.g., traffic lights) are learned after language and by the use of language, but never vice versa. We would not entrust a pre-language infant with crossing the street alone. Humankind is a symbolic animal who constantly devises new post-language signs. For example, without explicit argument or legal enactment there arose in the United States in the 1990s the convention of a black rim for glass pots containing ordinary coffee and an orange-tannish hue for decaffeinated coffee where publicly served.

2.5 The Evolution of Societal Specialization in Communication

In general, the greater the economic productivity and density of population, the less likely that speech communities will differentiate into linguistically distinct local variants. Further, the felt needs of wider communication will result in the development of standard languages and lingua francas. Such developments may be accelerated by the concentration of political power that will expand the role of some particular form for convenience in administrative use and/or to enhance solidarity by the common use of some preferred speech form. Such developments generally lead to widespread bilingualism or multilingualism in which each language fulfills some specific function.

Greater societal differentiation is reflected in, and has as one of its important aspects, changes in the social aspects of communication. In folk societies the majority of individuals are roughly of equal status in regard to communication. In industrialized societies specialized senders such as journalists, broadcasters, and authors of books send to far more people than those from whom they receive communications. No doubt the Internet is a further stage in this process, increasing the density of communication and the proportion of persons who both send and receive multiple communications.

It can be seen then that it is not so much language that has evolved after its initial invention as communication in general. Within this process, ordinary spoken language has a central and unique position as the source of post-language developments and as the ultimate level of explanation. In this broad sense there is a correlation between the evolution of communication and the evolution of culture. Language, evolves by begetting that which is not language, but transcends it even while ultimately being dependent on it and having language as its source.

Evolution: Diffusion of Innovations

This article discusses the model of the diffusion of innovations and describe this model's key variables. First, however, a brief history of diffusion research is presented. The paradigm for diffusion research can be traced to the rural sociology research tradition, which began in the 1940s. Rural sociology is a subfield of sociology that focuses on the social problems of rural life. One rural sociology study in particular influenced the methodology, theoretical framework, and interpretations of later students in the rural sociology tradition, and in other diffusion research traditions. Ryan and Gross (1943) investigated the diffusion of hybrid seed corn among Iowa farmers. Hybrid seed, the result of agricultural research, was made available to Iowa farmers in 1928. The hybrid vigor of the new seed increased corn yields on Iowa farms, hybrid corn varieties withstood drought more effectively than the open-pollinated seed they replaced, and hybrid corn

was better suited to harvesting by mechanical corn pickers. By 1941, about 13 years after its first release, the innovation was adopted by almost 100 percent of Iowa farmers. Ryan and Gross studied the relatively rapid diffusion of hybrid corn in order to obtain lessons learned that might be applied to the diffusion of other farm innovations. However, the intellectual influence of the hybrid corn study reached far beyond the study of agricultural innovations, and outside of the rural sociology tradition of diffusion research. Since the 1960s, the diffusion model has been applied in a wide variety of disciplines such as education, public health, communication, marketing, geography, sociology, and economics (Pelto 1973, Rosen 2000, Van den Ven et al. 1989, Zaltman et al. 1973). Diffusion studies in these various disciplines have ranged from the rapid diffusion of the Internet to the nondiffusion of the Dvorak keyboard (in typewriters and computers). The innovations that have been studied in diffusion research have mainly been technological innovations.

Diffusion is the process by which (a) an innovation (b) is communicated through certain channels (c) over time (d) among the members of a social system (Rogers 1995). Diffusion is a special type of communication concerned with the spread of messages that are perceived as new ideas, and necessarily represents a high degree of uncertainty to the individual. The four main elements in the diffusion of new ideas are (a) the innovation, (b) communication channels, (c) time, and (d) the social system.

1. *The Innovation*

An innovation is an idea, practice, or object that is perceived as new by an individual or other unit of adoption. The characteristics of an innovation, as perceived by the members of a social system, determine its rate of adoption. Some innovations diffuse relatively slower, and other innovations diffuse faster. Why do certain innovations spread more quickly than others? The characteristics which determine an innovation's rate of adoption are: (a) relative advantage, (b) compatibility, (c) complexity, (d) trialability, and (e) observability.

1.1 *Relative Advantage*

This is the degree to which an innovation is perceived as better than the idea it supersedes. The degree of relative advantage may be measured in economic terms, but social prestige, convenience, and satisfaction are also important factors. It does not matter so much if an innovation has a great deal of objective advantage. What does matter is whether an individual perceives the innovation as advantageous. The greater the perceived relative advantage of an innovation, the more rapid its rate of adoption will be.

1.2 *Compatibility*

This is the degree to which an innovation is perceived as being consistent with the existing values, past experiences, and needs of potential adopters. An idea that is incompatible with the values and norms of a social system will not be adopted as rapidly as an innovation that is compatible. The adoption of an incompatible innovation often requires the prior adoption of a new value system, which is a relatively slow process.

1.3 *Complexity*

This is the degree to which an innovation is perceived as difficult to understand and use. Some innovations are readily understood by most members of a social system; others are more complicated and will be adopted more slowly. New ideas that are simpler to understand are adopted more rapidly than innovations that require the adopter to develop new skills and understandings.

1.4 *Trialability*

This is the degree to which an innovation may be experimented with on a limited basis. New ideas that can be tried on the installment plan generally will be adopted more quickly than innovations that are not divisible. An innovation that is trialable represents less uncertainty to the individual who is considering it for adoption, who can learn by doing.

1.5 *Observability*

This is the degree to which the results of an innovation are visible to others. The easier it is for individuals to see the results of an innovation, the more likely they are to adopt it. Such visibility stimulates peer discussion of a new idea, as friends and neighbors of an adopter often request innovation-evaluation information about it.

2. *Communication Channels*

The second main element in the diffusion of new ideas is the communication channel. Communication is the process by which participants create and share in-

formation with one another in order to reach a mutual understanding. A communication channel is the means by which messages get from one individual to another. Mass media channels are more effective in creating knowledge of innovations, whereas interpersonal channels are more effective in forming and changing attitudes toward a new idea, and thus in influencing the decision to adopt or reject a new idea. Most individuals evaluate an innovation, not on the basis of scientific research by experts, but through the subjective evaluations of near-peers who have adopted the innovation. So the process is essentially social in nature, being driven by individuals talking to others about the new idea, as they give meaning to the innovation.

3. *Time*

The third main element in the diffusion of new ideas is time. The time dimension is involved in diffusion in three ways.

3.1 *Innovation-decision Process*

First, time is involved in the innovation-decision process. The innovation-decision process is the mental process through which an individual (or other decision-making unit) passes from first knowledge of an innovation to forming an attitude toward the innovation, to a decision to adopt or reject, to implementation of the new idea, and to confirmation of this decision. An individual seeks information at various stages in the innovation-decision process in order to decrease uncertainty about an innovation's expected consequences.

3.2 *Innovativeness*

The second way in which time is involved in diffusion is in the innovativeness of an individual or other unit of adoption. Innovativeness is the degree to which an individual or other unit of adoption is relatively earlier in adopting new ideas than other members of a social system. There are five adopter categories, or classifications of the members of a social system on the basis on their innovativeness: (a) innovators, (b) early adopters, (c) early majority, (d) late majority, and (e) laggards.

3.2.1 Innovators. These are the first 2.5 percent of the individuals in a system to adopt an innovation. Venturesomeness is almost an obsession with innovators. This interest in new ideas leads them out of a local circle of peer networks and into more cosmopolite social relationships. Communication patterns and friendships among a clique of innovators are common, even though the geographical distance between the innovators may be considerable. Being an innovator has several prerequisites. Control of substantial financial resources is helpful to absorb the possible loss from an unprofitable innovation. The ability to understand and apply complex technical knowledge is also needed. The innovator must be able to cope with a high degree of uncertainty about an innovation at the time of adoption. While an innovator may not be respected by the other members of a social system, the innovator plays an important role in the diffusion process: that of launching the new idea in the system by importing the innovation from outside of the system's boundaries. Thus, the innovator plays a gatekeeping role in the flow of new ideas into a system.

3.2.2 Early adopters. These are the next 13.5 percent of the individuals in a system to adopt an innovation. Early adopters are a more integrated part of the local system than are innovators. Whereas innovators are cosmopolites, early adopters are localites. This adopter category, more than any other, has the greatest degree of opinion leadership in most systems. Potential adopters look to early adopters for advice and information about the innovation. This adopter category is generally sought by change agents as a local missionary for speeding the diffusion process. Because early adopters are not too far ahead of the average individual in innovativeness, they serve as a role-model for many other members of a social system. The early adopter is respected by his or her peers, and is the embodiment of successful, discrete use of new ideas. The early adopter knows that to continue to earn this esteem of colleagues and to maintain a central position in the communication networks of the system, they must make judicious innovation-decisions. The early adopter decreases uncertainty about a new idea by adopting it, and then conveying a subjective evaluation of the innovation to near-peers through interpersonal networks.

3.2.3 Early majority. This is the next 34 percent of the individuals in a system to adopt an innovation. The early majority adopt new ideas just before the average member of a system. The early majority interact frequently with their peers, but seldom hold positions of opinion leadership in a system. The early majority's unique position between the very early and the relatively late to adopt makes them an important link in the diffusion process. They provide interconnectedness in the system's interpersonal networks. The early majority are one of the two most numerous adopter categories, making up one-third of the members of a system. The early majority may deliberate for some time before completely adopting

a new idea. 'Be not the first by which the new is tried, nor the last to lay the old aside,' fits the thinking of the early majority. They follow with deliberate willingness in innovations, but seldom lead.

3.2.4 Late majority. This is the next 34 percent of the individuals in a system to adopt an innovation. The late majority adopt new ideas just after the average member of a system. Like the early majority, the late majority make up one-third of the members of a system. Adoption may be the result of increasing network pressures from peers. Innovations are approached with a skeptical and cautious air, and the late majority do not adopt until most others in their system have done so. The weight of system norms must definitely favor an innovation before the late majority are convinced. The pressure of peers is necessary to motivate adoption. Their relatively scarce resources mean that most of the uncertainty about a new idea must be removed before the late majority feel that it is safe to adopt.

3.2.5 Laggards. These are the last 16 percent of the individuals in a system to adopt an innovation. They possess almost no opinion leadership. Laggards are the most localite in their outlook of all adopter categories; many are near isolates in the social networks of their system. The point of reference for the laggard is the past. Decisions are often made in terms of what has been done previously. Laggards tend to be suspicious of innovations and change agents. Resistance to innovations on the part of laggards may be entirely rational from the laggard's viewpoint, as their resources are limited and they must be certain that a new idea will not fail before they can adopt.

3.3 Rate of Adoption

The third dimension in which time is involved in diffusion is in rate of adoption. The rate of adoption is the relative speed with which an innovation is adopted by members of a social system. The rate of adoption usually is measured as the number of members of the system that adopt the innovation in a given time period. As shown previously, an innovation's rate of adoption is influenced by the five perceived attributes of an innovation.

4. The Social System

The fourth main element in the diffusion of new ideas is the social system. A social system is defined as a set of interrelated units that are engaged in joint problem-solving to accomplish a common goal. The members or units of a social system may be individuals, informal groups, organizations, and/or subsystems. The social system constitutes a boundary within which an innovation diffuses. How the system's social structure affects diffusion has been studied. A second area of research involved how norms affect diffusion. Norms are the established behavior patterns for the members of a social system. A third area of research has had to do with opinion leadership, the degree to which an individual is able to influence informally other individuals' attitudes or overt behavior in a desired way with relative frequency. A change agent is an individual who attempts to influence clients' innovation-decisions' in a direction that is deemed desirable by a change agency.

A fourth type of research involves the types of innovation-decisions (whether individual adoption decisions or organizational decisions, and whether they are made by an authority or by consensus). Another type of research, conducted mainly by anthropologists, analyzed the consequences of innovation.

A crucial concept in understanding the nature of the diffusion process is the critical mass, which occurs at the point at which enough individuals have adopted an innovation that the innovation's further rate of adoption becomes self-sustaining. The concept of the critical mass implies that outreach activities should be concentrated on getting the use of the innovation to the point of critical mass. These efforts should be focused on the early adopters, the 13.5 percent of the individuals in the system to adopt an innovation after the innovators have introduced the new idea into the system. Early adopters are often opinion leaders, and serve as role-models for many other members of the social system. Early adopters are instrumental in getting an innovation to the point of critical mass, and hence, in the successful diffusion of an innovation.

5. Opinion Leaders

The two-step flow model of mass communication suggests that communication messages flow from a source, via mass media channels, to opinion leaders, who in turn pass them on to followers (Rogers 1995). This two-step flow model of mass communication can be utilized to diffuse an innovation. The model focuses attention on the inter-media interface between mass media channels and interpersonal communication channels. Mass media channels are primarily creators of awareness-knowledge of innovations, while interpersonal networks are more important in persuading individuals to adopt or reject innovations.

The two-step flow model highlights the importance of opinion leaders in diffusing innovations, and especially in reaching the critical mass. Opinion leaders informally influence other individuals' attitudes or

overt behavior in a desired way with relative frequency, so they are critical to the successful diffusion of innovations.

6. New Communication Technologies

We live in the age of a communication revolution. New and developing communication technologies, and, ultimately, equipment and systems, are influencing the communication industry and American society greatly. Take the Internet, for example. The Internet is a network of interconnected computer systems. By using the Internet as a data highway, an individual can communicate with colleagues and friends at great distance very cheaply, and gain direct access to information in other computer systems. Therefore, diffusion of the Internet has been exceedingly rapid. From 1990 to 2001, the number of individuals adopting the Internet in North America rose from approximately 5 million to 200 million. A huge percentage of the population is interconnected via the Internet. The critical mass in the diffusion of the Internet occurred in about 1989 or 1990, after 20 years of very slow increase in the rate of adoption of computer networks.

Most schools and local libraries are connected to the Internet, and can provide Internet access to individuals who otherwise might not own, or have access to, a computer. The potential for using computer-mediated communication for outreach activities is enormous, and the nature of the diffusion process may be speeding up and becoming less spatially restricted.

Evolution, History of

The term 'evolution' is widely used to denote the development through time of societies, cultures, and more especially of living species. It is often contrasted with the view that these entities were divinely created as we see them today, and is routinely (but increasingly controversially) associated with the idea of progress. This article outlines the various models of evolution which have been suggested to account for the development of life and of social organization, and then shows how the theories were formulated and popularized. Particular attention is paid to the work of Charles Darwin, whose theory of biological evolution by natural selection is seen as the most influential expression of the basic idea of natural development.

1. Models of Evolution

The term 'evolution' is derived from the Latin *evolutio*, denoting the unrolling of a scroll. In the eighteenth century it was applied to the growth of the embryo, then often described as the mere expansion of a preformed miniature. This application was retained up to the nineteenth century, by which time it was clear that the development of the embryo consisted of the progressive appearance of more complex structures. The philosopher Herbert Spencer generalized the term by applying it to any process of natural progressive development, thereby creating the still-common belief that all evolution must be progressive. In particular, Spencer applied the term to the development of societies and of life on earth.

Charles Darwin did not often use the term when describing his theory of the origin of species, but by the end of the nineteenth century this had become the most common version of 'evolution.' But Darwin's theory did not imply an inevitable progression toward complexity, and much controversy has surrounded the association between evolution and progress. Darwin's theory of natural selection now dominates biology and is being extended to many other domains, but it is but one of a number of mechanisms which have been suggested to explain evolution, each of which has its own associated implications.

1.1 The Ladder of Progress

Perhaps the most popular model of evolution, and one which reveals the link with embryology, is of a linear hierarchy of stages of development from inception to maturity. Such a model simply assumes that all change is progressive and that there is only one direction of development. When applied to societies or species, the model can be adapted by supposing that many lines of

development each ascend the same hierarchy but at different rates, so that the slow developers illustrate the ancestral stages already passed through by those at the top of the scale.

1.2 Evolutionary Trees

Although the ladder model is still popularly applied to the evolution of life on earth, and was once accepted in the social sciences, biologists and sociologists now realize that there is no single goal toward which evolution is developing—neither the human race nor Western civilization can be treated as the most mature phase of development. Evolution is better represented as a tree or bush with many branches, each of which is constantly subdividing. The end product of one branch cannot be seen as the goal toward which all the others are ascending, and it is impossible for the end product of one branch to illustrate exactly the ancestral form of another branch. The living apes are not immature humans, because even if the common ancestor from which humans and apes have evolved would be classified as an ape, it would no longer be identical to any of the living ape species. If there is progress on the branching-tree model, it has to be defined in more sophisticated terms so that there are many different ways to become more complex.

Darwin argued that branching evolution explains how we are able to classify species into groups within groups (species, genera, families, etc.). Two species descended from a common ancestor will still share many characters derived from that ancestor, and will share some characters with even more distant relatives. Darwin and his modern followers assume that each new character is developed only once, so all species exhibiting the character are descended from a common ancestor which also had the character. This assumption will be invalidated if there are cases where two lines of evolution evolve the same character independently (convergence or homoplasy). It will also be invalidated if there are even small-scale examples of ladder-like evolution where several branches are constrained to evolve along the same pattern of development (parallelism).

1.3 Adaptation

The branching model had already been applied to the evolution of languages before Darwin and his followers used it to transform biology. Darwin's key insight was that there was no natural mechanism that could force evolution along a single predetermined path. Evolution is driven not by progress but by the necessity for each species to adapt to its environment in an ever-changing world. Branching occurs because a single population can sometimes become divided by a geographical barrier, after which each isolated population will develop independently in response to the different adaptive pressures it encounters. Progress to a more complex structure is at best a by-product of adaptation and is never inevitable in any one branch; indeed, many species are the products of degenerative evolution. In the animal kingdom, two branches of evolution can seldom if ever rejoin via hybridization (although this does happen in plants). Here, there is a clear contrast with social and linguistic evolution, where mergings and borrowings are frequent.

1.4 Darwinism and Lamarckism

Two mechanisms of adaptive evolution have been suggested: natural selection (Darwinism) and the inheritance of acquired characters (Lamarckism). Darwin assumed that the species consists of a population of organisms which exhibit some degree of individual variation and that these variations are inherited—we now explain them as genetic differences produced by mutations. He argued that if the population is exposed to a new environment, some variants will by chance be able to cope better with the new conditions; they will survive and reproduce, transmitting their favorable characters to the next generation. Any that are less fitted to the environment will be unlikely to breed and may even die, so their characters are eliminated from the population. Over many generations this process of natural selection (Spencer called it the 'survival of the fittest') will change the species to adapt it to the environment.

Some time before Darwin, J. B. Lamarck proposed that the inheritance of characters acquired during an organism's lifetime could accumulate to give adaptive transmutation. An acquired character is produced by the organism's behavior, which in the wild is usually a response to the environment. Thus, the ancestral giraffes, striving to reach the leaves of trees as an alternative source of food, were able to lengthen their necks, just as a weightlifter can acquire better-developed muscles. If such characters are inherited, the next generation of giraffes would be born with longer necks and would then stretch them further. This mechanism was once popular in biology, and corresponds quite closely to how humans transmit new ideas to their descendants. But where teaching and learning provides a natural mechanism for ideas to be transmitted, modern genetics has shown that there is no way in which acquired biological characters can be inherited. Lamarckism has been banished from biology: The giraffe got its long neck because those who by chance inherited the genes producing that character reproduced faster than those who carried the genes for shorter necks. The genetic differences are the product of mutations which are random as far as the requirement of the species are concerned.

1.5 Nonadaptive Evolution

There are also several mechanism of biological evolution which suppose that not all developments are

adaptive. The possibility that saltations (evolutionary jumps or macromutations) might found new populations was once taken seriously even by geneticists. The theory of orthogenesis supposed that the species was somehow programmed to vary continuously in a particular direction, forcing groups of species to evolve in parallel. Such ideas are now largely discounted in biology, although the possibility that there might be constraints on the range of possible variation is taken more seriously. In the social sciences, the question of whether all cultural and social differences serve a practical purpose has been much debated.

2. *Pre-Darwinian Evolutionism*

Darwin's was not the first theory of evolution, although the publication of his *Origin of Species* in 1859 triggered the conversion of most scientists to evolutionism. Several earlier versions of the idea were proposed, and although rejected by conservative thinkers and most scientists, they did much to prepare the way for the reception of Darwinism.

2.1 *Creation and Design*

The early Church Fathers did not take the Genesis story of creation in the Bible literally, and it was the Protestant theologians of the seventeenth century who established the world view which survives in modern 'young earth' creationism. Archbishop James Ussher published his much-ridiculed calculation that the earth was created in 4004 BC. In such a climate of opinion a form of natural theology flourished in which it could be argued that God had designed and created all of the modern species just as we see them today, each with the structures and instincts appropriate for its intended habitat. John Ray and many other naturalists stressed the adaptation of species to their environment, and argued that similarities could be used to classify species because they expressed the rational order of God's plan of creation—a view adopted by Carolus Linnaeus, who founded the modern system of biological classification (Greene 1959). Others exploited the ancient concept of the 'chain of being,' in which the plan of creation was a linear hierarchy with the human species at the top of the animal series. This was promoted without any sense of a progression through time, although the influence of the chain was retained in some of the early theories of progressive evolution.

2.2 *Evolution in the Enlightenment*

The more radical thinkers of the eighteenth-century Enlightenment recognized that the Earth was much older than Ussher's estimate, and that the planet had changed considerably in the course of its history. Some explored the possibility that life had been produced by spontaneous generation from nonliving matter, and began to doubt that species remained unchanged through time. The French naturalist Georges Leclerc, Comte de Buffon, was especially influential in this respect, as were the materialist philosophers Denis Diderot and the Baron d'Holbach (Roger 1998).

Toward the end of the eighteenth century, Erasmus Darwin (grandfather of Charles) published a theory of transmutation in his *Zoonomia*, arguing that all living things were derived from a simple origin and had become more complex through their striving to adapt to the environment. These views were echoed in a more sophisticated form in J. B. Lamarck's *Zoological Philosophy* of 1809. Lamarck accepted that there was a basic progressive force driving living things to ascend the chain of being over many generations, but he accepted that no linear pattern is visible in the present animal and plant kingdoms, explaining the divergence as a consequence of life's constant need to adapt to an ever-changing environment. He invoked the inheritance of acquired characters (described above) to explain this process, and his name has been associated with that mechanism ever since (Corsi 1988).

2.3 *The Fossil Record*

Historians used to think that Lamarck was marginalized by his great rival, Georges Cuvier, who pioneered the study of fossil bones to reconstruct the history of life. Cuvier showed that there was a succession of populations in the course of the earth's history, but insisted that species disappear abruptly from the record through the action of geological catastrophes. He rejected transmutation, but did not openly endorse the idea of divine creation—although the theory of a succession of creations was popularized by Cuvier's British followers, including William Buckland. Although they had extended the Earth's history, Cuvier and Buckland were convinced that the human race was a recent creation. Their work thus endorsed a view of human history in which there was no time for social evolution, many scholars still believing that language and the arts of civilization were taught to the earliest humans by their Creator.

Later historical work has shown that although the theory of successive creations was endorsed by the scientific establishment, more radical thinkers were attracted to Lamarck's theory (Desmond 1989). Darwin, who developed his theory in the 1830s, concealed it for fear of being associated with this radical movement. The situation changed significantly following the anonymous publication of Robert Chambers' *Vestiges of the Natural History of Creation* in 1844. Chambers argued that an ideology of progress was just what the middle class needed to support its demands for reform, and provided a scientific foun-

dation for this ideology based on the idea of progressive evolution. Although he presented evolution as the unfolding of a divine plan, his book's open recognition that humans are transformed animals, and that the mind is a product of the expansion of the brain caused an outcry from conservative thinkers. Over the following decade, however, *Vestiges* popularized the idea of progressive evolution, creating a space in which Darwin's more scientific theory could have an impact.

3. The Development of Darwin's Theory

Charles Darwin was converted to evolutionism by his discoveries on the voyage of HMS *Beagle* (1831–6) and returned to England determined to understand how the process worked. He soon discovered the mechanism of natural selection, and continued to work on the various aspects of his theory in relative secrecy. Much controversy has surrounded Darwin's discovery, because in addition to the many scientific factors influencing his thinking, he acknowledged the impact of Thomas Malthus' principle of population, a product of the ideology of *laissez-faire* economics.

3.1 Scientific Influences

While studying at Cambridge, Darwin was attracted to William Paley's *Natural Theology* of 1802, which restated the argument that species are adapted to their environment through the wisdom and benevolence of the Creator. On the voyage of the *Beagle*, his observations of South American geology converted him to Charles Lyell's uniformitarian position, which accounted for all geological change in terms of the action of observable forces over vast periods of time. Biogeographical studies, especially those of the birds of the Galapagos Islands, forced him to rethink the idea of Divine Creation, because he saw that individual islands had each acquired a distinct species of immigrant families, such as the finches. On his return to England he soon accepted a complete evolutionary philosophy and began to search for a mechanism (Browne 1995).

Darwin saw that evolution must be a branching process and that the ultimate cause was the adaptation of isolated populations to different environments. He studied animal breeding and realized that breeders produce new varieties by selecting out individual animals with the required character and breeding only from these. Artificial selection draws on the natural and largely random variability of the population and allows only individuals with a selected character to breed, thereby enhancing that character in future generations. Darwin was soon looking for a natural equivalent of this process.

3.2 Malthus and Population

A vital step in Darwin's thinking came when he read Malthus' *Essay on Population*, which argued that populations breed so rapidly that they outstrip their food supply. Drawing on hints in Malthus, Darwin realized that population pressure must generate a struggle for existence in which many individuals die. He was now able to argue that any better-adapted variant would be more successful in the struggle and would be more likely to survive and reproduce, while poorly adapted variants would die, thus establishing the theory of natural selection described in Sect. 1.4. This gave Darwin the basis on which to erect a comprehensive account of evolution. The role played by Malthus' ideologically loaded principle has, however, led to frequent charges that Darwin's theory is itself a projection of *laissez-faire* values on to nature, with the consequence that the theory would be used to justify the competitive ethos of Victorian capitalism (Young 1985). Much controversy also surrounds the degree of Darwin's commitment to the idea of progress. Although the selection theory undermines the ladder model of progress, historians now accept that Darwin's thinking was influenced by the assumption that competition is the driving force of a more general form of progress. However, it is clear that Darwin's commitment to branching evolution went far beyond the conventional social values later linked to his theory, while his application of the population principle undermined Malthus' own ideology, which was an attempt to discredit the optimism of social progressionists.

Darwin let only a few close contacts know of his theory, while continuing to work on exploring its scientific implications. He came to appreciate that, even in a stable environment, specialization would allow natural selection to continue the process of divergence by which species separate from close relatives. Eventually, he began to write up his ideas for publication, but was interrupted in 1858 by the arrival of a paper by Alfred Russel Wallace describing a similar (although not identical) theory. The joint Darwin–Wallace papers were published in that year, while Darwin rushed to complete the *Origin of Species*.

4. Darwinism in Biology

The *Origin of Species* sparked an intense debate which soon led to the conversion of most scientists and educated people to evolutionism (Hull 1973). Despite initial opposition by conservative thinkers, the belief that the human race was the outcome of a progressive trend built into nature was accepted. In science, too, creationism was replaced by the expectation that all living species are the products of natural processes, and here, too, there was a widespread assumption that such processes guaranteed progress, even if super-

imposed on a branching model of development. The success of Darwinism needs to be assessed with care because the popularity of this developmental model of evolution meant that the more radical implications of Darwin's thinking were evaded (Bowler 1988). Far from welcoming the theory of natural selection, most nineteenth-century scientists, including some of Darwin's leading supporters, were lukewarm about it. Opposition grew toward the end of the century, with many alternative mechanisms of evolution being tried out.

4.1 The History of Life

Much of the first generation of evolutionists' efforts focused on reconstructing the course of the history of life on earth from anatomical, embryological, biogeographical, and fossil evidence (Bowler 1996). Darwin himself treated this project with caution, but under the influence of the German biologist Ernst Haeckel, a whole generation of evolutionists strove to complete it. They had some successes, but the problems were much greater than they had anticipated and the project was sidelined by new developments in biology at the beginning of the twentieth century. Darwin had stressed the imperfection of the fossil record, but in a few important areas new discoveries helped to show how the major steps in evolution had taken place. Elsewhere, anatomical and embryological evidence was used to reconstruct evolutionary relationships, on the assumption that new characters were developed only once. In embryology, Darwin's assumption that early stages of development would illustrate affinities was overtaken by Haeckel's recapitulation theory, according to which earlier stages could actually illustrate ancestral adult forms. This way of thinking was a product of the progressionist way of thought, presupposing a privileged line of development toward maturity. Only in biogeography did it become clear that evolution was a highly irregular process, depending on the hazards of migration in a world where geological forces were constantly remolding the topography.

4.2 Natural Selection and the Alternatives

Historians have focused on the debates over natural selection, but this is more a product of our modern preoccupation with that mechanism than of its significance in late-nineteenth-century biology. One much-discussed theme centers on Darwin's concept of heredity, which was quite unlike the model of unit-character inheritance promoted by Mendelian genetics. It has even been argued that, without the concept of nonblending unit characters, natural selection was fatally flawed. It is true that Darwin was much concerned by Fleeming Jenkins' 1867 review which argued that if male and female parental characters blend in the offspring, the advantages of a well-favored 'sport' or mutation would be diluted rapidly. But as A. R. Wallace pointed out, this objection is irrelevant if there is a continuous range of variation in the population, which is the case for most characters (Gayon 1998).

In fact, many of the objections to natural selection were intended only to show that evolution must be a more purposeful process than any mechanism based on random variation would allow. One major alternative which now became popular was the Lamarckian theory of the inheritance of acquired characters, in which the animals' own behavior directs their variation. Some objections to natural selection were aimed at the whole idea of adaptive evolution and were intended to show that some internally driven force directed the organisms' variation. The theory of orthogenesis supposed that variation generated linear evolutionary trends, while the theory of saltations assumed that macromutations could somehow found new breeding populations (Bowler 1983).

5. Human Origins and Social Evolution

Many religious thinkers objected to the idea that the human soul was the product of evolution from an animal ancestry. Much of this initial opposition was overcome by stressing the purposeful nature of evolution, allowing the appearance of humanity to be presented as the culmination of a divine plan (Moore 1979). Darwin's theory of evolution threatened this assumption, and in his *Descent of Man* of 1871 he argued that humans had evolved from African apes which had stood upright as an adaptation to a new lifestyle on the open plains. Most late-nineteenth-century accounts of human evolution, however, stressed the expansion of the brain as the main driving force of the process. At the same time, the idea of progressive evolution was applied to the history of human cultures and societies. Some evolutionists, including Spencer, stressed competition as the driving force of progress, leading to the charge that they were promoting a 'social Darwinism' designed to legitimize capitalist values. While Darwin's theory was certainly associated with this movement, it was by no means the only scientific justification offered.

5.1 Cultural Evolutionism

Coincidentally with the Darwinian revolution, archaeologists undermined the belief that the human race was a recent creation, and exposed a vast period of prehistory in which our ancestors had used only stone tools. It was this initiative rather than any influence from Darwinism which led anthropologists such as

Edward B. Tylor to equate modern 'savages' (i.e., people with relatively unsophisticated technology) with the ancestral stages through which civilized humans had passed in prehistoric times on their march toward a more mature culture. Cultural evolutionism was a product of the nineteenth-century developmental viewpoint, based on the ladder model of progress (Bowler 1989a). Tylor himself did not accept that humans had evolved from apes, but other cultural evolutionists, especially John Lubbock, linked the two modes of evolution and argued that 'savages' were biologically as well as culturally primitive—living examples of the earlier stages in human biological and mental evolution. Herbert Spencer's model of social evolution, while stressing ostensibly the divergent nature of evolution, still presented 'lower' races as surviving primitives incapable of matching the mental powers of the Anglo-Saxons.

5.2 *Social Darwinism*

Spencer is most often remembered, however, as the social philosopher who linked the idea of progress to the ideology of free-enterprise individualism. As an exponent of *laissez-faire*, and the coiner of the term 'survival of the fittest,' it has been easy for critics to portray Spencer's enthusiasm for struggle as the motor of progress as a direct application of the Darwinian selection theory to society, hence the image of him as the founder of 'social Darwinism.' Spencer worried about the elimination of the unfit, but in biology he defended Lamarckism, and his enthusiasm for struggle came more from a conviction that competition would stimulate individual self-improvement (which in a Lamarckian scheme could be passed on to future generations). Darwin's theory is thus only one of the scientific factors which stimulated the ideology of 'progress through struggle'—remembered preferentially because natural selection has now become the only mechanism by which that metaphor can be put into practice in biology (Bannister 1979). In the later nineteenth century, there was more emphasis on struggle between nations and races, which bypasses the central feature of natural selection within populations.

6. *Modern Darwinism*

By the end of the nineteenth century, the attempt to reconstruct the course of biological and social evolution had run out of steam. The social sciences abandoned the evolutionary model and any suggestion that human behavior is predetermined by biological factors. Biologists began to study the actual processes of heredity and variation, leading to the emergence of Mendelian genetics. The geneticists destroyed Lamarckism, and although at first hostile to the selection theory, they were eventually convinced that genetic mutation was the source of the random variation that is the raw material of natural selection. By the mid-twentieth century, the 'Modern Synthesis' of Darwinism and genetics had come to dominate biology but remained controversial elsewhere.

6.1 *The Modern Darwinian Synthesis*

In the last decade of the nineteenth century, the statistician Karl Pearson developed a mathematical model of natural selection acting on the variations in a wild population (Gayon 1998). But many biologists were now exploring the idea that new species were produced by saltations or macromutations, and it was partly from this tradition that the 'rediscovery' of Gregor Mendel's laws of particulate inheritance emerged. Ignored since the 1860s, these laws postulated the existence of unit characters transmitted unchanged from one generation to the next. In 1900, Mendel's laws were proclaimed as the basis for a new science of heredity, which William Bateson soon called 'genetics.' But Pearson was already hostile to Bateson's saltationism, while Bateson rejected Pearson's commitment to continuity and adaptation. Genetics was thus perceived as a new alternative to Darwinism, although it destroyed the credibility of Lamarckism by suggesting that there is no plausible way in which acquired characters can affect the gene (Bowler 1989b).

T. H. Morgan's studies of genetic mutations showed that most macromutations are fatal, while small mutations simply add to the genetic variation in the population. Soon, Morgan conceded that natural selection would affect the reproductive success of the various genes. In the 1920s and 1930s, R. A. Fisher, J. B. S. Haldane, and Sewall Wright brought together the statistical study of populations with the new genetics to create a science of population genetics based on the genetical theory of natural selection (Provine 1971, Mayr 1982). Naturalists such as Julian Huxley and Ernst Mayr now recognized that the adaptation of local populations to their environment was the most likely explanation of how species originate. The new selection theory was integrated with these wider developments to create what Huxley called the 'Modern Synthesis.'

6.2 *Later Developments*

The Darwinian synthesis has dominated biology since the mid-twentieth century, although there have been numerous developments within it and some efforts to limit its applicability. Some modern thinkers now argue that the concept of natural selection can be applied to almost all areas where change is observed, sweeping away the whole idea of a universe which is

the product of divine purpose. Most controversial are efforts to apply selection to human beings, especially in the area of social behavior. The science of sociobiology has been successful in explaining the social behavior of animals in terms of genetics and reproductive success, via the concept of the 'selfish gene.' But E. O. Wilson's efforts to apply sociobiology to human behavior by suggesting that we are driven by instincts implanted by natural selection have been greeted with much suspicion by social scientists, and have also been dismissed as a revived 'social Darwinism' by the political left (Segerstrale 2000).

Evolution, Natural and Social: Philosophical Aspects

In its most minimal sense, *evolution* simply means gradual change by some natural process. In this sense, belief that species of plants and animals have evolved is at least as old as Aristotle's contrary belief in the fixity of the species. The theory of evolution acquires more content as the nature of the natural process involved is specified.

Charles Darwin (1859) provided the broad outlines of the modern theory. There are traits that are inherited. There is some process that produces natural variation in these traits. The traits may affect the ability of the organism to reproduce, and thus the average number of individuals bearing the traits in the next generation. Therefore, those traits that enhance reproductive success increase in frequency in the population, and those that lead to reproductive success below the average decrease in frequency. The three essential factors in Darwin's account are (a) natural variation, (b) differential reproduction, and (c) inheritance. The questions of the existence, extent, and nature of these factors are empirical scientific questions.

Could these processes, as they naturally occur, account for large changes over time? Darwin argued that they could by calling attention to the large changes that had come about from the selective breeding of plants and animals. Selective breeding is just a particularly severe form of differential reproduction, imposed by the breeder. Darwin emphasized this argument by calling his theory a theory of Natural Selection:

> I have called this principle, by which each slight variation, if useful, is preserved, by the term Natural Selection, in order to mark its relation to man's power of selection. But the expression often used by Mr. Herbert Spencer, of the Survival

> of the Fittest, is more accurate, and is sometimes equally convenient. We have seen that man by selection can certainly produce great results, and can adapt organic beings to his own uses, through the accumulation of slight but useful variations, given to him by the hand of Nature. But Natural Selection, as we shall hereafter see, is a power incessantly ready for action, and is as immeasurably superior to man's feeble efforts, as the works of Nature are to those of Art. (Darwin 1859 *Origin of the Species*, 6th edn., Chap. III)

The status of Spencer's description has been a matter of controversy. On superficial reflection on the slogan, *survival of the fittest*, more than one commentator has asked: 'If fitness is fitness to survive, is not the theory of survival of the fittest simply a tautology?' At this point we can give a preliminary examination of this idea in a highly idealized setting. Let us take *Darwinian fitness* just to mean expected number of offspring. Let us suppose that the population is effectively infinite, so that the expected number of offspring for a type can be taken to equal the average number of offspring. Let us suppose that reproduction is asexual and transmission of a type is perfect. If we had one generation every time unit, these assumptions specify a dynamics of population proportions called the discrete time *replicator dynamics*. Taking generations close together, or taking overlapping generations, it is possible to idealize to a system of differential equations which represent the continuous time *replicator dynamics* (Taylor and Jonker 1978, Hofbauer and Sigmund 1988). This is an idealized model of differential reproduction. In this idealized model, we can ask whether it can be proved that the fittest type will go to fixation in the population.

To get any kind of affirmative answer, we must make more assumptions. Suppose that the fitness of a type is fixed. It does not depend on the frequency of types in the population. The environment is considered constant. Suppose that all the types of interest are initially present in the population and that one of them has the greatest Darwinian fitness. Then it is possible to prove that the dynamics will converge to a state of fixation of the fittest strategy, a state where its proportion of the population is 100 percent. Convergence means just that the population gets arbitrarily close to fixation in an arbitrarily long time. In this sense, survival of the fittest can be mathematically demonstrated. In this sense it is a tautology.

But the demonstration depends not only on the conception of Darwinian fitness, but also essentially on a battery of idealizations and assumptions. If the Darwinian fitness of a type is not fixed, but dependent on the frequency of other types in the population, then—even with all the other idealizations in place—the dynamics may not converge to any state at all. (It may cycle or even exhibit chaotic behavior.) If there is a fitter type not present in the population, then differential reproduction provides no way for it to get in. The model can be modified in various ways to allow for mutation, which may put the type in question into the population, but then the theorem is no longer true. If the population is finite, then only probabilistic conclusions can be reached. These depend on factors other than simply Darwinian fitness, such as the distribution number of progeny for a type and the size of the population. Moreover, in a finite population mutation cannot keep every possible type in play, but rather must be modeled as a chance process that introduces some new types from a very large space of possible types. With the slightest move towards realism the tautology goes away.

In the first half of the twentieth century, Darwinian theory was enriched by Mendelian genetics. Gregor Mendel, an Augustinian monk, had discovered basic principles of genetics by a series of experiments in plant breeding carried out in the garden of the monastery (Mendel 1866). Mendel first bred pure strains of peas that differed in seven selected traits, for instance, green vs. yellow seeds. He crossed these, self-fertilized the hybrids, and studied the frequency of the traits in the hybrids. He found a ratio of 3:1, from which he concluded that each individual carries two genetic units for the trait, one from each parent, chosen at random from the parent's two genetic units. (This is haploid reproduction.) Thus from hybrid parents, carrying color genes $\langle gy \rangle$ we would expect to get homozygotes $\langle gg \rangle$ and $\langle yy \rangle$ one-quarter of the time each and heterozygotes $\langle gy \rangle$ one-half of the time. This 1:2:1 ratio then explains the observed 1:3 ratio on the hypothesis that one of the possibilities is *dominant*, so that this possibility is expressed by the heterozygotes as well as by the appropriate homozygote. Mendel opened the door to genetic models of inheritance.

Mendelian genetics introduces a new source of variation in such sexually reproducing haploid species. Recombination of genes creates rapid variation. But the variation created has its limits. Can recombination of fixed genetic units account for the origin of new species and the whole sweep of Darwinian evolution? Darwinians thought not, and at the beginning of the twentieth century Darwinism and Mendelism were enemies. Only when mutation is included in the picture, so that more fundamental sorts of variation are possible on a longer timescale, is it evident that Mendelism and Darwinism can be thought of as reinforcing each other. This 'modern synthesis' of evolution and genetics was created in the first half of the twentieth century (Fisher 1930, Haldane 1932, Dobzhanski 1937, Wright 1968, 1969, 1977, 1978).

Mendelian genetics also enriches the account of differential reproduction. We now need to consider reproduction at more than one level. Individuals reproduce but so do genes. Fitness on one level is connected to that on the other, but in a way that can be complicated. The most obvious case is one in which expression of genes works in such a way that an individual who is a heterozygote is then fitter than either of the homozygotes. A famous example is that of sickle

cell anemia. The two possibilities of the gene are sickle, s, or not, n. Heterozygotes, ⟨s,n⟩ are protected against malaria; ⟨n,n⟩ are not, and ⟨s,s⟩ die from sickle cell anemia. But heterozygotes cannot take over the population, because of the mechanics of genetic reproduction. Here, frequency-dependent selection re-emerges at the level of the gene.

Mendelian genetics is a mathematical model (or a set of mathematical models). In 1953 Watson and Crick opened the door to understanding the physical basis of genetics at the molecular level. The dynamics of genetic replication, recombination, mutation, and expression can and are being studied at this level. Already the study of molecular genetics has provided many surprises such as the action of retroviruses that can transcribe their own information into the DNA of the host cell, the fact that bacteria can exchange genetic information, and the existence of plasmids—rings of DNA in bacteria that exist and replicate independently of the bacterial chromosome. With the theory of largely adaptively neutral mutations (Kimura 1968, 1983), molecular genetics has also provided the basis of a molecular evolutionary clock which can be used to reconstruct evolutionary history.

The history of the theory of biological evolution has been—and will continue to be—a story of the gradual amplification of Darwin's insights by empirical research. The three essential factors in Darwin's account—natural variation, differential reproduction, and inheritance—remain at the center of the theory, but in a form that Darwin could not have imagined.

By social evolution, we mean not the evolution of sociality, which may be one aspect of biological evolution, but rather a social process in some way analogous to the process of biological evolution. But what is the analogy to fix upon? Different thinkers have had different aspects of biological evolution in mind (and sometimes, different conceptions of the nature of the biological process). In its most minimal sense, social and cultural evolution can just be thought of as social and cultural change. So interpreted, the theory of social evolution would be such a truism as to lack all interest. Are there deeper and more informative analogies that are worth exploring?

Some thinkers have thought of ideas that can spread through, or disappear from, a population as analogous to genes (Campbell 1965, Cavalli-Sforza and Feldman 1981, Lumsden and Wilson 1981, Boyd and Richerson 1985). These *memes* (Dawkins 1976) can recombine in various ways. (A comprehensive discussion of this topic would have to range from nineteenth century associationalist psychology to modern genetic programming.) They can replicate themselves as they spread from mind to mind. They can be thought of as having a sort of Darwinian fitness in terms of the replicator process.

Others have focused on adaptive dynamics as the appropriate analogy. Darwinian evolutionary models fall, more or less, within a broad class of adaptive models which also includes various kinds of learning models. In psychological theories of reinforcement learning, if it assumed that there is some 'reward' that is reinforcing, and the theory models the dynamics of behavior under various learning schedules. (The determination of what sort of thing is reinforcing is empirical, but extrinsic to the theory.)

We might then model various dynamical processes of social learning or adaptation instead of trying to model social evolution so as to have a close resemblance to biological evolution.

One common way for individuals to adapt in a social setting is to imitate others whom they observe to be successful according to some generally shared criterion of success. It is a remarkable fact that the replicator dynamics, introduced by Taylor and Jonker (1978) as a mathematical model of differential reproduction, has been derived from a number of different models of learning by imitation in a large population (Binmore et al. 1995, Björnerstedt and Weibull 1996, Schlag 1998). The replicator dynamics also has deep connections with classical psychological models of positive reinforcement learning (Borgers and Sarin 1997).

The replicator dynamics is a member of the broader class of adaptive dynamics according to which all behaviors with greater than average success increase their population proportion, which is a subset of the still broader class according to which the most successful behavior increases its population proportion. These broader classes of adaptive dynamics may also come into play in theories of social evolution (Weibull 1995, Samuelson 1997).

Populations may not be large, and encounters may not be random but rather structured. Learning by imitation in such settings may lead to different results than it would lead to in large random mixing populations, just as biological evolution may be affected by population structure and population size (Hamilton 1964, Axelrod and Hamilton 1981, Frank 1998, Sober and Wilson 1998, Epstein 1998, Lindgren and Nordahl 1994, Nowak and May 1993, Grim 1996, Pollack 1989, Anderlini and Ianni 1997). It is of particular interest that population structure can favor evolution or learning of cooperative behavior in interactions where it would not survive in large random mixing populations.

Classical reinforcement learning is the kind of learning that demands the least thought. A more sophisticated learner might use some kind of inductive reasoning to form beliefs about the aspects of the environment that, together with her actions, influence payoffs and then act optimally according to these beliefs. If the relevant aspects of the environment include the actions to be taken by other agents, then the reasoning involved may be complicated, depending on the strategic sophistication of the agents and the character of the payoffs. (I am trying to predict what she will do. Is she trying to predict what I will do? If so

what will she predict and what will she do and what is my best response? But might she be imagining that I am thinking this way? And so forth.)

Here there is a whole spectrum of learning models, whose appropriateness depends on the inductive and strategic sophistication of the agents being modeled (Fudenberg and Levine 1998).

If small probabilistic perturbations are added to deterministic dynamics of learning or evolution, then a new kind of equilibrium concept is appropriate, that of a *stochastically stable* equilibrium. In some cases, nature of the underlying deterministic dynamics does not matter, and the stochastically stable equilibrium is determined by the payoff structure (Foster and Young 1990, Kandori et al. 1993). A small population with local interaction may reach stochastically stable equilibrium much faster than a large population with random interactions (Ellison 1993).

The stage of development of the theory of social evolution is comparable to the earlier stages of the theory of biological evolution. There is no analog of molecular biology in view for social evolution. Rather, there are various mathematical models of learning that can be put to empirical test in special domains of application (Suppes and Atkinson 1960, Cavalli-Sforza et al. 1982, Hewlett and Cavalli-Sforza 1986, Roth and Erev 1995, van Huyck et al. 1995, Friedman 1996, Camerer and Ho 1998, 1999).

The processes of biological evolution and social evolution can interact (Cavalli-Sforza and Feldman 1981, Boyd and Richerson 1985, Crawford 1989). The biological evolution of humans as a social species sets the stage upon which social evolution is carried out. Social structure can feed back to biological evolution by imposing or modifying selective pressures. Basic cultural norms, for instance, the prevailing system of agriculture in a society, can be influenced by the biological evolution of other species. As both Darwin and Mendel observed, they can impose selective pressures on domesticated plants and animals. When cultural changes allow humans to survive in new or modified environments, selective pressures on humans themselves can be modified, as emphasized by Baldwin (1902). As humans continue to transform the planet, the biological effects of human cultural evolution become more and more extensive.

B. Skyrms

Evolution of Cognition: An Adaptationist Perspective

Human and animal cognition is complex and functionally organized. The theory that best accounts for the existence of organized, functional complexity in the design of living things is Darwin's theory of evolution by natural selection. Because developmental processes have reproductive consequences for organisms, cognitive development is also a target of natural selection, leading to the evolution of adaptive developmental trajectories. Hence, developmental and evolutionary accounts of cognition are complementary and not mutually exclusive. The adaptive organization of cognition should be studied from a functional, ecological perspective, taking the species' natural history into account, and using a variety of methods, including laboratory studies of cognition, neuropsychological dissociations, developmental studies, and phylogenetic/comparative research.

1. The Functional Complexity of the Brain and its Processes

One of the characteristic features of living things is their complex, functionally organized structure—living things appear to be designed to solve the problems confronting them in ways that are often ingenious, elegant, and economical. Humans are no different. Indeed, the human brain is probably the paramount example of a complex, functionally organized structure in the biological world. Viewed macroscopically, there is nothing particularly remarkable about the human brain. A little more than a liter in volume, it simply looks like a wrinkled mass of tissue. However, the brain, as is now generally recognized, is a cognitive organ. It represents, stores, and processes information, and it is in the information processing abilities of the brain that its functional complexity resides. But how did the cognitive architecture of the brain arise?

One of the great puzzles of biological life is the origin of the kind of complex, functional organization that the brain so clearly illustrates. According to the laws of physics, organized systems should tend toward disorder; but biological systems are not only highly ordered, they seem to increase in complexity with time (Dawkins 1986). Ordered structures can persist, however, if they reproduce themselves faster than they fall apart. By reproducing themselves, biological entities initiate a process—evolution through natural selection—that Darwin recognized could account for ever increasing refinement of complex, functional organization. Features of an organism's design that confer an advantage in acquiring resources for reproduction will enhance their own spread through differential reproduction. The slow accretion of such incremental improvements in the design of organisms can eventually result in the evolution of the ingenious, elegant and economical structures (called adaptations) that are so common in living things.

Because organisms in all their complexity develop from single cells, some might argue that the complex

functional organization of the brain requires a developmental explanation, rather than an evolutionary one. However, the development of the brain and learning are exceedingly complicated processes, just as much in need of an evolutionary explanation as the final product, adult cognition. Development can evolve, precisely because it is repeated from generation to generation with variation in developmental trajectories, where some lead to fitness-enhancing improvements and some to less fit products. Natural selection will act on these developmental trajectories to produce ever more adaptive ones.

Moreover, an evolutionary view of cognitive development leads one to expect the same economy and efficiency of design in developmental mechanisms (Elman et al. 1996). From an evolutionary point of view, what is important is whether an adaptation develops reliably, that is, whether the trait is reproduced reliably, in the sorts of environment typical of the species. If this can be accomplished by exploiting the information structure of the environment, then there is reason to believe that natural selection would favor the use of such information (see *Modularity versus Interactive Processing, Psychology of*). Evolution through natural selection is not synonymous with the 'genetic coding' of functional architecture. Darwin, after all, was able to formulate his theory of natural selection without any knowledge of genetic coding.

A corollary of this view is that what often appears to be cognitive 'flexibility' can, in fact, be the result of selection for developmental efficiency. Evolved mechanisms may be designed to tolerate some kinds of variation in developmental inputs, particularly variation that is not functionally relevant to the adaptive problem the mechanism solves. Consider language, for example. Modern English, Japanese, and Quechua are all evolutionarily novel inputs to the mechanisms for acquiring and processing language, yet each of these modern languages solves the problem of communication effectively, for which language abilities were presumably selected. Hence, viewed from one perspective, the developmental mechanisms are flexible in being able to accommodate a wide range of novel inputs, but viewed from another angle, they have functional design constraints that all modern languages satisfy. From an adaptationist point of view, what is important is that adults develop reliably functional competence in linguistic communication (see *Language Acquisition*).

Rather than offering mutually exclusive accounts mental structure, development and evolution complement each other. Development provides a proximate explanation for how mental complexity is constructed during the course of a lifetime, while evolution through natural selection explains why such complex developmental processes arose over evolutionary time. Recently, there has been considerable interest in how complexity can emerge through interactions of various kinds between evolutionary and developmental processes. Such emergent phenomena admit of various kinds of explanation. Some theorists prefer to locate the explanation for emergent complexity in the local interactions that produce it. However, it is unclear whether complexity that arises in the absence of natural selection is organized functionally in a way that provides an adaptive fit between the organism and its environment. For this reason, many theorists prefer to focus on natural selection as the cause of functionally organized complexity. Adaptations are not merely complex traits, but are also organized functionally. This functional organization is observed at various levels of biological organization: biochemical, physiological, anatomical, and cognitive, with developmental mediation playing a greater role at higher levels of organization.

Regardless of the level of organization that is involved, what matters is that a trait in some way enhances its own reproduction. In the course of competing for resources, such as food, shelter, and mates, the individual is faced with many different challenges that vary with the ecological and social environments encountered. It is by virtue of its ability to solve such adaptive problems that an adaptation furthers its own reproduction, and hence is said to have the function of solving that problem (Williams 1966). Mobile species, in particular, are highly dependent upon cognitive adaptations that can interpret and integrate information in order to respond adaptively to a heterogeneous environment. The animal kingdom is filled with many striking examples of cognitive adaptation, such as the ability of Clark's nutcrackers (*Nucifraga columbiana*) and other food-caching birds to recall the location of thousands of widely scattered food stores after a delay of several months (Gallistel 1990, pp. 155–8; see also *Animal Cognition*).

2. *Consequences of Cognitive Evolution*

The evolutionary account of adaptation has three important consequences for cognitive functioning. The first is that traits must be evaluated from a practical, ecological perspective (see *Decision Making (Naturalistic), Psychology of*). Traits with no impact on an organism's reproductive success cannot evolve through natural selection. From an evolutionary point of view, one would only expect cognitive adaptations for the sorts of problem that could conceivably have an impact on reproductive success. Typically, this will mean traits that have a real impact on the organism's interactions with the physical, biological, and social world upon which successful reproduction ultimately depends. Natural selection, therefore, gives rise to practical cognitive mechanisms that can solve the real world problems confronting the organism. While the ability to solve evolutionarily novel tasks may indeed be beneficial, it is important to keep in mind that

performance on artificial tasks, such as laboratory tasks often used in cognitive psychology, may depend on the degree to which these tasks reflect aspects of adaptive problems faced by organisms during their evolutionary history.

The second important consequence is that, in order to understand the adaptive organization of cognition, one needs to consider the past history of the species. Evolution is a slow, historical process. Complex adaptations take many generations to evolve, so the evolved design of an organism will reflect the sorts of problem that confronted ancestral members of the species and not necessarily the problems confronting the species currently. Hence, it is often useful to make a distinction between the proper and actual function of a cognitive adaptation (Millikan 1984). The proper function of an adaptation is the function that it served in ancestral environments, by virtue of which it persisted and proliferated over successive generations. The actual function of an adaptation is the use that it serves currently in a particular individual. The actual function of a mechanism may or may not correspond to its proper function. Consider object segregation in vision. The properties of light have changed very little, if at all, since the mechanisms of object segregation began to evolve in ancestral vertebrates. Hence, there is every reason to believe that object segregation in modern humans functions much as it always has: the proper and actual functions of the mechanisms are identical. Compare the situation with language (see *Language Acquisition*). The best available evidence suggests that languages evolved as a spoken form of communication (Pinker 1994). Written language, on the other hand, shows evidence of being a relatively recent cultural invention with an origin dating to only a few thousand years ago. Reading and writing employ some of the same cognitive processes as spoken language, but this does not make reading and writing part of the proper function of these mechanisms. Reading, writing, and speech are all part of the actual function of linguistic processes, while speech alone constitutes the proper function of the mechanism. The distinction between proper and actual functions is important to bear in mind, because the structure of an evolved mechanism is best explained by its proper function, not its actual function, and mechanisms which may appear to be maladaptive in present environments might not have been so in past ones.

The third important consequence is that cognitive adaptations are exhibited universally among individuals with an identical history of selection. Although individual variation is crucial for the evolutionary process, natural selection systematically sifts through this variation, retaining those variants that are relatively beneficial and displacing those variants that are less adapted to their environment. Eventually all variation with reproductive consequences is eliminated from the species, leading to universal, species-typical cognitive adaptations, and a residue of variation with no systematic reproductive consequences. Hence, there are three basic products of the evolutionary process that are expressed in the individual: adaptations, by-products, and random effects (Buss et al. 1998). Adaptations are complex, functionally organized structures that evolved as the accumulated product of natural selection acting on variants solving a specific problem (see). Adaptations often appear as though they were designed to solve specific problems, and are therefore said to show evidence of special design (Williams 1966). By-products are incidental features of adaptations that played no role in an adaptation's selective history. Because they derive their structure from adaptations, by-products may also appear complex and functionally organized. Random effects are random features of an organism with no functional organization, no history of systematic selection, and tending to show individual differences in their expression.

3. *Methods and Evidence in the Study of Cognitive Evolution*

The hallmark of adaptation by natural selection is functional specialization, or special design. In general, the principles of adaptive design are similar to the principles of good engineering: efficiency, precision, reliability, and so on. Just as the features of a well-engineered machine can be distinguished from the products of chance, so can the features of evolved adaptations (Williams 1966). To demonstrate the existence of an adaptation it is necessary to demonstrate design for a specific adaptive function, but not just complex organization *per se*, because it is important to distinguish adaptations from by-products. Some of the sources of evidence for special design are the following.

3.1 *Laboratory Studies of Cognition*

It is useful to study an organism in its natural environment in order to understand the adaptive problems that it faces and the selection pressures operating on it. In this respect, observational studies are very important, but they have their limitations when it comes to elucidating the nature of the psychological mechanisms underlying observable behavior. For this purpose, controlled laboratory studies using methods from cognitive psychology are ideal (see *Inferences, Psychology of*). For example, in order to test the proposal that human resource acquisition is sensitive to variability in returns, as predicted by evolutionary theories of foraging behavior (Stephens 1981). Rode et al. (1999) employed a standard procedure used by cognitive psychologists studying people's decision making. They offered people a choice between two gambles with the same expected return, but with more or less variability in returns. By introducing a minimal requirement that people had to

satisfy in order to win any money, Rode et al. (1999) were able to manipulate whether people selected the more or less variable option in a manner predicted by Stephens' (1981) risk sensitive foraging theory, but not by standard models of human decision-making. These laboratory studies complement nicely the observational field studies performed by human behavioral ecologists studying traditional foraging peoples (e.g., Smith and Winterhalder 1992).

3.2 Neuropsychological Dissociations

If the mind of an organism is composed of different, functionally specific adaptations, then these adaptations should, in principle, be dissociable: a particular competence may be disabled, either temporarily or permanently, while others are left largely intact. Such dissociations can be an important source of evidence for special design, because while it can be difficult for the observer to identify distinct cognitive abilities in the behavior of normally functioning individuals, the absence of a specific competence can bring its nature and boundaries into strong relief, against a backdrop of intact skills. Many such dissociations have been identified in humans, and the study of patients with particular kinds of neurological impairment has been a valuable source of data for testing hypotheses about the functional building blocks of the mind. For example, the study of autism, in which social cognition is impaired relative to nonsocial competences, has provided evidence for the existence of a variety of cognitive mechanisms whose hypothesized evolved function is to interpret and predict the behavior of others (Baron-Cohen 1995; see *Theory of Mind*).

3.3 Developmental Studies

One reason among many for studying cognitive development is that potentially it can illuminate the functional components that underlie adult competences. Many such competences, although they appear to function seamlessly in adults, are in fact composed of separate components whose individual operation can be observed more readily in children. For example, many mammalian species orient spatially using the large-scale structure of the environment (Gallistel 1990; see *Animal Cognition*). Adult humans use many spatial cues to orient themselves during navigation, obscuring the separate subcomponents of this competence. However, this core mammalian competence is observed more readily in young children (Hermer and Spelke 1994; see *Infant Development: Physical and Social Cognition*).

3.4 Phylogenetic/Comparative Approaches

Even if one's interest is in human cognition, there are still valuable insights to be gained from the study of nonhuman species. Such studies provide yet another way of isolating the adaptive components of cognition. For example, it has been claimed that the human adult number competence—specifically, the ability to count and perform other manipulations with numbers—is derived from a core number competence, observable in infants (Carey and Spelke 1994 see). However, such a core competence has also been found in Rhesus monkeys (*Macaca mulatta*) (Hauser et al. 1996), suggesting that the competence seen in human adults has other components as well.

4. Conclusion: Evolutionary Theory as Computational Theorizing

In his classic book on vision, Marr (1982) stressed the importance of beginning investigations of complex systems with a computational theory—a task analysis of the problem to be solved (see *Vision, Psychology of*): What are the available inputs? What are the desired outputs? What are the constraints on the system? The answers to these questions serve as an important guide when formulating hypotheses about the cognitive mechanisms that actually solve the task. Although Marr's theory has been highly influential in vision research where there is some intuitive appreciation of the functions of mechanisms in the visual system, his theory has not been applied as readily in other areas of psychology. The merging of Marr's approach with insights from evolutionary theory offers promise for many areas of psychology outside perception. Evolutionary biology is a rich source of task analyses for a variety of adaptive problems that require cognitive solutions, in many practical domains. Moreover, cognitive psychology is a rich source of theoretical constructs for describing the psychological mechanisms that can solve such problems. Hence, evolutionary theorizing and cognitive psychology are well suited to play complementary roles in the study of the mind's design.

Evolution: Optimization

A claim for 'optimization' has one meaning to the various kinds of scientists who study evolution. It is a claim that a trait has evolved or is evolving 'optimal' characteristics that enable it to perform better than counterparts with different characteristics. A biologist studying, say, the body size of a species might claim it to be the body size that results in a higher number of offspring than that produced by any other plausible body size. An economist studying, say, the pattern of resource use in a given company might claim it to be the pattern that maximizes the company's market share. What unifies these examples is that there is an implied process of selection among competing entities, with the competitor who performs better at a given task receiving a greater reward.

The focus here is on optimization in biological evolution; further information on the other contexts in which optimization may be important can be found in Schoemaker (1991) and references therein.

1. *The Term 'Optimization'*

When a biologist makes a claim about optimization (e.g., Tyler and Gilliam 1995), it is most often a claim about natural selection among individuals within populations; such a claim generally (but not necessarily) excludes selection at the level of the population or species. More controversially, it usually excludes 'random' or nondirectional forces, such as genetic drift (random sampling of gametes and individuals in populations), from having any significant affect on the trait's evolution.

A claim about optimization also always has an explicit or implicit assumption about trait inheritance, a common one being that the trait values of parents and offspring are identical or nearly so. This, along with the reproductive advantage of an optimal trait, implies that the trait will become fixed in the population, all other things being equal.

2. *The Controversy Over 'Optimization'*

What *does not* engender controversy among evolutionary biologists is the overall theoretical conception of the process of optimization. Most evolutionary biologists agree that one can make predictions of optima for traits and that natural selection could plausibly act to cause evolution in the direction of these optima. In addition, most of these biologists agree that at least some aspects of the process of optimization occur in nature (see Travis 1989 for more details).

What *does* engender controversy can be better understood by describing the two most important contexts in which optimization is invoked.

2.1 *Continuously-distributed Traits and 'Optimization'*

The first context involves traits having a more-or-less continuous distribution, usually with one central peak. Many traits have such a distribution; often it is statistically indistinguishable from a normal distribution. So, for example, Van Valen and Mellin (1967) showed in their study of human babies in New York City that birth weight has such a bell-shaped distribution. Optimizing selection is invoked in such examples to explain the peaked character of the trait distribution, the hypothesis being that a central trait value performs better than any other trait value. In their study, Van Valen and Mellin showed that the probability of perinatal death is minimal at a central weight (about 3.6 kg for males and about 3.8 kg for females). Ostensibly, this is because more deviant weights are associated with specific physiological deficits that are congenitally or environmentally based, their consequence being a higher risk of death. Subsequent work has revealed that the length of the gestation period also affects the probability of perinatal death (see Schluter and Nychka 1994.)

What then explains the presence of the continuous trait distribution? After all, if there is one best birth weight, why isn't there at most a small range of birth weights around this best weight? More generally, why do any traits undergoing trait optimization have continuous trait distributions? It is in answering this question that controversy has arisen; there are at least

three different claims as to why such distributions occur.

The first claim is that the genetic 'details' of trait determination impede the action of optimizing natural selection. What this means is that the nature of trait determination and the Mendelian 'breakdown' of the trait when reproduction occurs act together to generate a continuous trait distribution in the next generation. So, for example, imagine that natural selection is such that only individuals with the optimal trait live to the start of reproduction, the result being that there is only one type of trait remaining in the population at that time. If one assumes that the optimal trait does not breed true and is, say, the result of an individual being a heterozygote at all or most of the loci affecting the trait, then newborn offspring will manifest a continuous trait distribution. This is a necessary consequence of the normal segregation of alleles during gamete production and the subsequent union of gametes to form the offspring of the next generation.

The underlying presumption of this claim about genetic details is that they are an unchangeable impediment to the action of natural selection even when the intensity of selection is strong. This could happen even if the optimal trait is not associated with being a heterozygote at many loci. One possible (but not necessary) consequence is that a stable amount of genetic variation can be maintained in a population, as a result of the balance between optimizing natural selection, which will tend to eliminate genetic variation, and the genetic details of the trait (including mutation), which can act to preserve or increase it. Such a balance has been invoked as an explanation for the high levels of genetic variation seen for some traits in some populations (see Lande 1988 and Turelli 1988 for further discussion.)

The second claim as to why continuous trait distributions occur is that natural selection is not and never will be strong enough or constant enough to eliminate or nearly eliminate nonoptimal traits from the population. However, the presumption here is that this would occur if selection were stronger; genetic details would not get in the way.

The third claim is that it is just a matter of time until the continuous distribution disappears and an optimal or near-optimal trait predominates in the population, the notion being that the current data reveal only an intermediate state of a long process. From this viewpoint, natural selection is powerful and sustained enough to cause trait optima to evolve and genetic details will not ultimately prevent this from happening, as the process of mutation will ultimately provide the appropriate kind of genetic variation to allow an optimal trait to become fixed. So, for example, a mutation that when homozygous produces an optimal trait might arise in a population in which the trait has been manifested only by heterozygotes. The true-breeding optimal trait may increase in frequency and displace the heterozygotes (see Hammerstein 1996 and Eshel and Feldman 2001 for further discussion of the dynamics and outcome of this kind of long-term evolution.)

2.2 *Fixed Traits and 'Optimization'*

The second context in which optimizing selection is invoked concerns traits that are constant in a given species. For example, functional anatomists speak of *the* horse's foot as having evolved for the task of running on uneven ground at high speed (e.g., see Hildebrand 1985) and behavioral ecologists speak of *the* dance language of honey bees (e.g., see Wilson 1971). In such instances, the trait is regarded as having a single state, which is often taken to be the result of past optimization; in other words, the trait is the way it is because it performs better than all reasonable alternatives and this superior performance has resulted in the past elimination of alternative forms of the trait. The underlying attitude is very often that optimality 'must be,' given the importance of the trait to the organism. From this viewpoint, the potential for understanding how the trait is optimal is limited only by the industry and ingenuity of the investigator (cf., Cain 1989). Such an 'adaptationist' approach is reasonable enough in theory although it is easy to see the potential for circularity in practice because discrepancies between the predictions of a model used to describe the optimal trait and the data can always be attributed to an incomplete or flawed model.

2.3 *Types of Optimality Models*

All optimality models make a prediction about the trait of *an* individual. Beyond this common aspect, there is as much variety in the features of optimality models as there is in the traits studied. However, one can recognize two general classes of such models. The first class concerns traits for which one can determine the performance of a trait by reference only to the functioning of the trait itself. Traits still affect one another in that an optimal trait will outperform all others and thereby cause their selective elimination from the population. But the performance of any trait is the same in isolation as it is in a population. There are many optimality models of this kind in every area of evolutionary biology. For example, when constructing an optimality model of the shape of a horse's foot, a functional anatomist will likely regard the performance of the foot as independent of the performance of any other individual's foot in the population. Similarly, an ecologist might assume that the evolutionary consequence of a given number of offspring produced by an individual is independent of the numbers produced by other individuals.

In contrast, the second class of optimality model involves traits whose performance is inherently related to the performance of other individuals because it is dependent on the frequency or density of various traits in the population. Such dependency arises naturally for many traits, especially for those relating to the sexual production of offspring. A classic example is the evolution of the sex ratio, the relative ratio of males and females in the population. The evolutionary fate of a female producing, say, all or nearly all daughters depends very much on whether all of the other females in the population do this as well, as opposed to producing, say, equal numbers of daughters and sons. In the former instance, the population could go extinct; in the latter instance, even a female producing only daughters may survive. If the tendency to produce given numbers of males and females is autosomally inherited and sons and daughters are equally costly in terms of energy, one can show that a female-biased sex ratio will be optimal if the population is subdivided and females tend to migrate more than males (Hamilton 1967). However, in an infinite randomly-mating population such a sex ratio is not optimal; instead, a female producing equal numbers of daughters and sons will be optimal as long as equal numbers of males and females are not produced by the population as a whole. Finally, when equal numbers are produced, there is no optimal sex ratio; all sex ratios are evolutionarily equivalent. This variety of outcomes is typical for interactive traits.

Traits like the sex ratio are often analyzed with a model in which one determines the trait which when common prevents the invasion of rare mutants into the population. Such a trait is taken to be optimal in the sense that individuals possessing it outperform all other traits when the population has this configuration (this does not necessarily imply that the trait has an advantage for all other configurations.) This evolutionarily stable strategy (ESS) approach has received considerable attention since about 1980, with extensive elaboration of the theory in formal game-theoretic terms and extensive application of models to the data (see Charnov 1982, Maynard Smith 1982, and especially Hines 1987 for examples and further details.)

For other traits there is no necessary choice about what type of optimality model to use and the choice depends upon the investigator's prior assumptions about whether and how individuals interact with one another.

3. *Optimization and the Debate about the Adaptationists' Claim*

To proponents of the adaptationist approach, such as Parker and Maynard Smith (1990), the danger of circularity in claims of optimality is real but of little concern if one is careful and rigorous when deriving the model and if one is scrupulous when testing it. To opponents of this approach, such as Gould and Lewontin (1979), it is inherently flawed because the hypothesis of optimality is never challenged or tested, as a failed optimality model is simply replaced with another optimality model. One alternative they suggest is to formulate predictions from nonadaptive or nonoptimal hypotheses, which can compete with the predictions of the optimality model. For example, one might claim that a trait has not evolved in response to the present environment, but instead evolved in a past environment; a plausible ancestral trait would then be used as a predictor of the trait and its predictive performance would be compared with that of an optimality model. Adherents of this 'pluralist' approach often claim that if the predictions of one or more of these nonoptimal competing hypotheses explain the data as well as the optimality model does, the former should be given precedence as an explanation for the trait (cf. Lewin 1980).

There are substantive differences between these viewpoints and as a result, proponents and opponents of the adaptationist approach have traded claims and counterclaims for decades; this is a central debate in evolutionary biology (see Orzack and Sober 1994, 2001). Adaptationists generally regard natural selection to be the only important influence on trait evolution, while pluralists regard natural selection to be just one of several such influences, the others being genetic drift, constraints engendered by genetic details, and phylogenetic inertia (the carryover of traits from a species' ancestors; see Harvey and Pagel 1991 for further details). In an important sense, however, adaptationist and pluralist claims about trait evolution have a common feature—both start with a *premise* as to the truth or falsity of the adaptationist approach. To adaptationists, the near-certainty of optimality follows necessarily from what they view as the basic and unquestionable Darwinian dynamic of variation and selection; to pluralists, the near-certainty of nonoptimality follows necessarily from what they view as the inherent genetic and developmental complexity of the organism.

One alternative to the reliance on either of these premises is to assess the validity of the adaptationist approach via an ensemble test in which the successes and failures of specific optimality models at predicting trait values and explaining trait variation are tallied (see Orzack and Sober 1994 for further details.) One might regard the adaptationist claim to be true if, say, 90 percent of traits examined could be adequately explained by an optimality model. This ensemble test faces difficult but not insurmountable problems that relate to how traits and models are chosen to be part of the ensemble. Nonetheless, such a test has several virtues, an important one being that the truth or falsity of the adaptationist approach is not a premise; instead, either possibility is a potential *conclusion* of the ensemble test. To this extent, a central debate in evolutionary biology could be resolved on the basis of

data, instead of being left unresolved because of the contradictory premises investigators use as a basis for their analyses.

Evolution: Self-organization Theory

Self-organization theory holds that the distinctive characteristics of living systems require explanation in terms of life's emergent properties at different levels of organization. The properties of living systems cannot be understood simply in terms of the Darwinian processes of change in genotypes, associated modification in the fitness of phenotypes, and selective pressures from changing environments. They require explanation in terms of organizing principles expressed at different levels of biological organization, from cells through whole organisms to communities and ecosystems.

1. Historical Background

Self-organization theory is based on the evidence that living systems express distinctive types of intrinsic dynamic order. In the eighteenth century the founder of modern biology, Carolus Linnaeus, regarded his taxonomy as a prolegomenon to a general theory of biology based on the Enlightenment principle which observed that regularities of structure in nature can be explained by underlying generative laws of form. This same idea informed the comparative morphological studies of Goethe, Cuvier, St. Hilaire, Reichert, and Owen in the eighteenth and nineteenth centuries, despite differences of emphasis among them.

A revolution in biological thought occurred when Darwin replaced intrinsic principles of order in organisms by historical and functional contingencies. For Darwin, constraints on morphology came from descent, specifically descent from ancestors whose morphologies were the result of adaptation to particular habitats, realized through the selection of fitter hereditary variants (Mayr 1988).

Within embryology the problem of biological form remained: how does the morphology of the adult organism emerge through growth and transformation

of the egg? During the twentieth century this problem was transformed by the rise of genetics into a new question: what are the changes in gene activity that underlie morphological change in developing organisms? In evolutionary studies a crucial question became, what are the changes in genes that underlie the evolution of different species? Developmental and evolutionary genetics are now converging to provide detailed answers to these questions.

What remains problematic is explaining relationships across levels of biological organization, from patterns of gene activity, to phenotypes (morphology and behavior), to community organization, and to higher-level dynamics such as patterns of species extinctions. The difficulty is that there is a hierarchy of organizational levels. Collapsing these levels down to genes and their products does not provide explanations of the different structures of cells, tissues, organs, and organisms that emerge during development and in the course of evolution. It is here that principles of self-organization in biology have re-emerged in a somewhat different guise from more classical conceptions, sharpening the issues defined earlier and working systematically at different levels of biological order.

The unifying term for this field of study is the sciences of complexity (Cowan et al. 1994). The field focuses on the emergent properties of complex systems during the course of development and evolution (Solé and Goodwin 2000). One of the descriptive terms for these emergent properties is 'order for free' (Kauffman 1995), meaning that the order arises spontaneously, can occur at any level, and is not a result of natural selection. In fact, natural selection can do no more than stabilize emergent order if it is adaptive, a principle of evolutionary theory which is sometimes forgotten. This new perspective offers the possibility of integrating the historical and functional explanatory framework of neo-Darwinism with the 'intrinsic principles' approach of nonlinear dynamics, the heart of the sciences of complexity. The theory of self-organization now provides the possibility of recasting evolutionary principles in consistently dynamic terms, resolving the tensions that have existed between development and evolution, ontogeny and phylogeny.

2. *Development, Behavior, and Life-cycles*

Developing organisms can be understood as self-organizing systems whose morphology emerges from the dynamics of 'morphogenetic fields.' These fields are defined by the coordinated properties of cells and their interactions via signaling molecules, the extracellular matrix, adhesion molecules, cell movement, and so on. The particular patterns that emerge are often not obvious at all from the properties of individual cells and require higher-level concepts to be understood.

This principle can be illustrated by the classic example of the cellular slime mold, *Dictyostelium discoideum*, whose vegetative phase consists of single amoebae that live on bacteria in damp, rotting vegetation, growing and dividing independently of one another. Under conditions of starvation and dessication their metabolism and behavior change so that they begin to interact through pulsatile signals of a metabolite (cyclic adenosine monophosphate) that is released periodically by individual cells and diffuses between them. A cell receiving such a signal emits a pulse itself and moves toward its source, producing dynamic patterns of movement that result in the aggregation of thousands of cells. During this process of aggregation, spiral waves of moving cells are observed. The pattern cannot be explained in terms of individual cell behavior; it requires the higher-level concept of an 'excitable medium' which serves as a morphogenetic field for the slime mold (Goodwin 1994).

Initially uniform patterns of aggregating cells break up into streams, another purely dynamic process resulting from an intrinsic instability that breaks the symmetry of the initial aggregate (Höfer et al. 1995). The cells form a shapeless mound of several thousand similar cells around the cell or cells that initiated the signaling process.

Vasiev et al. (1997), who have modeled this whole developmental sequence in the slime mold, point out that 'this complicated process could take place without the necessity for transcription of new genes. In real life, however, it is known that many different genes are transcribed during aggregation and mound formation.' For instance, after stream formation, molecules are produced which make cells sticky, reinforcing and stabilizing this pattern. The mound then self-organizes into an elongated shape called a slug, a few millimeters in length. The slug assembles under the influence of continuous periodic signals that come from the same region of cells, which becomes the leading end of the migrating slug. The migration of the slug is a coherent movement of the whole mass of several thousand cells—in other words, the coordinated dynamics of an excitable medium involving three-dimensional waves of activity that propagate through the slug from anterior to posterior (Bretschneider et al. 1999).

During migration of the slug, two types of cell differentiate, involving differential gene activities: the front one-third of the cells of the slug develop stalk characteristics while the posterior two-thirds become the spores. Differential gene activity is a major feature of this process. The slug stops migrating and organizes itself into a fruiting body consisting of a stalk supporting a spherical mass of spores a few millimeters above the surface. When conditions become moist again, resulting in bacterial growth, the spores are released and amoebae emerge to start the life cycle again, growing on the bacteria.

This example illustrates the point that to understand

a species' life cycle it is necessary to understand the dynamics of self-organizing patterns as well as the role of gene activity, which can both initiate and stabilize the morphogenetic changes characteristic of the species. During evolution, changing patterns of gene activity will occasionally produce coherent changes of morphology and behavior, which will persist if they are adaptive. What is becoming clear is that gene activity can stabilize, consolidate, or initiate developmental events, but these processes can only be understood in terms of the self-organizing, coherent dynamics of whole life cycles.

3. *Patterns of Behavior in Social Insects*

Entomologists have recognized for many years that communities of insects display high levels of coherent order in their activities and social organization (Hölldobler and Wilson 1990). However, these usually cannot be understood simply by observing the behavior and interactions of individuals. For example, several species of ant exhibit a rhythmic pattern of activity–inactivity in the brood chamber, where the workers are tending the queen and the brood, whereas individual ants have no tendency to show such rhythmic behavior. On the contrary, their activity patterns in isolation or at low density have been characterized as chaotic, in the technical sense of the term (Cole 1991). Another example comes from termite colonies, which construct very complex nests with coherently organized passageways, vaults, and ceilings. However, observation of activity in termite 'construction gangs' reveals a pattern of behavior that is anything but coherent. Individuals move about, join groups working on different building sites scattered about the construction area, stop suddenly for several minutes, and then scatter randomly to new sites. In these cases, how does coherent order arise from such disorder?

Once again, explanations of pattern require an analysis that goes beyond genes, individual behavior, and natural selection, to models that introduce a new level of complexity in the dynamics of the group. Rhythmic behavior of workers in brood chambers can be shown to arise from chaotic behavior of individuals as a result of stimulatory interactions between ants when they exceed a critical density, as usually occurs in brood chambers (Solé et al. 1993). Furthermore, the range of parameters (e.g., sensitivity of ants to one another and density) that result in rhythmic activity is large, so that this behavior pattern is robust to significant genetic and environmental disturbance, as stable evolutionary characters must be. Similarly, it has been shown (O'Toole et al. 1999) that the coherent architectural results of apparently disorganized termite behavior arise from a dynamic process called 'self-organized criticality' (Bak 1988). The attraction of termites to occupied building sites, the sudden immobility at high density (but variable size) of construction gangs, and subsequent scattering to new sites form the basis of a process ensuring that all sites grow at roughly the same rate. With such synchrony the nest components fit together coherently to give organized architectural constructions. Again, this dynamic is stable to parameter perturbation. 'Order for free' must be robust if it is to persist in evolution.

4. *Emergent Properties of Ecosystems and the Biosphere*

A crucial issue in the study of natural ecosystems concerns the relationship between complexity and stability: are complex ecosystems more or less stable than simple ones? Complexity may be defined, following May (1973), using the notion of 'degree of connectedness': ecosystems whose species are richly interconnected are more complex than sparsely connected ones. May's theoretical study, using conventional population dynamics to model ecosystems and using linear stability analysis, showed that there is a fairly sharp transition between two states. Below a critical degree of complexity (connectivity) ecosystems are stable; above, they are unstable. Detailed analysis of field studies by Keitt and Marquet (1996) showed that there is an interesting inverse relationship between number of species in an ecosystem and their connectivity, supporting May's conclusion and suggesting an underlying dynamic order. Furthermore, these investigators examined the frequencies of species extinction events of different sizes in ecosystems that were getting more complex as a result of the introduction and establishment of new, exotic species. Their results revealed a regular 'power law relationship' that is suggestive of an organized dynamic.

A study by Ellner and Turchin (1995) took stability analysis a step further in identifying a special emergent property of ecosystems. They examined an extensive set of ecological time series within an ecosystem and concluded that they showed chaotic dynamics. Their conclusion supported a conjecture from purely theoretical studies of co-evolving systems, that interacting populations co-evolve 'at the edge of chaos' (Wolfram 1986). Langton (1990) then noticed that there are sets of interaction rules that result in highly ordered patterns of stable behavior and others that result in extremely complex activities without any repetitive order ('chaos'). The rules can be ordered logically and it turns out that in between the ordered and the chaotic regimes there is a realm of complexity whose behavior suggested a potential for 'emergent computation' (Langton 1990). Langton suggested that real biological evolution might occur in such a domain of complex dynamics, the edge of chaos, where new order can arise as evolving populations move from order to chaos and on into new order.

Langton's provocative conjecture has spawned a number of more sophisticated computer models of co-

evolving populations, among them one by Kauffman and Johnsen (1991). What this model simulates is a dynamic pattern of species extinction sizes of the type described by Pimm (1984) and the time series behavior examined by Ellner and Turchin (1995). A more accurate fit to the data has been obtained by Kauffman (1995) using an extended version of the original model.

A further development of self-organization theory arises from a study of extinction statistics obtained from the fossil record. Solé et al. (1997) showed that extinction has the property of 'self-similarity,' a power-law governing the relationship between probability of extinction and size of extinction event (small extinctions are common and large ones are rare). A model of ecosystem dynamics that fits these observations has been constructed (Solé et al. 1996, 1998), suggesting a clear distinction between the dynamics of microevolution (adaptive modifications of species) and macroevolution (patterns of extinction events). Competitive interactions between species and adaptive processes clearly occur in evolution, but they do not explain the large-scale pattern of evolutionary change (extinction sizes and probabilities). The latter arises from the collective dynamics of ecological networks as an emergent property that is not reducible to the competitive interactions and adaptive modifications of species. Micro- and macroevolution are then distinct, requiring different explanations.

Finally, unexpected regularities are observed at the level of the whole biosphere in variables such as the oxygen and carbon dioxide content of the atmosphere, the mean surface temperature of the earth, and the concentrations of various ions (calcium, sodium, potassium, chloride, phosphate, sulfate, etc.) in the oceans. Purely geophysical processes are unable to account for the stability of these quantities over geological time periods (millions of years) and the evidence now favors the intimate involvement of biological processes as crucial contributors to global biosphere dynamics. This radical shift of focus for evolutionary thinking comes from the work of James Lovelock (1979, 1991) and the study of microbial communities by Lynn Margulis (1987), who together gave birth to the Gaia Hypothesis. A whole new class of models is under development to account for the capacity of the living earth to regulate variables crucial for life by processes that give rise to emergent stability properties (Harding 1999, Lenton and Watson 2000).

Evolutionary Approaches in Archaeology

Since the 1970s, archaeologists in the US and the UK have sought to understand the material record of human existence in terms explicitly drawn from Darwinian evolutionary theory. All such approaches begin from the assumption that human behavior, like other aspects of the human phenotype, is shaped by variation generation (i.e., mutation if the focus is on biologically inherited traits), selection, and random processes (e.g., drift, founder effect). Beyond this basic area of agreement, views diverge considerably on how evolutionary processes shape the archaeological record and how archaeological methods should be tailored to facilitate their study. In some respects, the debates about evolution in archaeology parallel those in evolutionary biology.

1. *Evolution*

'Cultural evolution' is often used by archaeologists to refer to a progressive historical trend, with progress defined in ethnocentric terms, such as greater social and political complexity. Anthropologists of the mid-twentieth century, including Leslie White and Julian Steward, brought such progressive evolutionism into the anthropological mainstream, and the 'New Archaeology' of the 1960s and 1970s was influenced by these efforts. Dunnell (1980) has argued, however, that 'cultural evolution' of the progressive variety, which can be traced back to the nineteenth-century writings of Spencer, Tylor, and Morgan, has little in common with scientific evolution, which was developed within biology following publication of Darwin's *Origin of Species* in 1859. According to Dunnell (1980, p. 44), 'cultural evolution' is not scientific because it provides no mechanisms to explain history, instead positing plausible empirical generalizations that summarize certain ethnographic observations recorded during European expansion across the globe.

Dunnell (1982) and others (Lyman and O'Brien 1997, Schennan 1991) find antecedents of a scientific evolutionary archaeology not in 'cultural evolution' of the progressive variety but rather in culture historical studies of the early through mid-twentieth century. What culture history had going for it that cultural evolution did not was a 'decidedly materialist feel' (Lyman and O'Brien 1997, p. 43). 'Materialism,' which is used in this context as a synonym for 'population thinking' (Mayr 1959), is the view that historical change arises out of individual variation. This was Darwin's great insight (Lewontin 1974). Before Darwin, explanations of change were bound by an essentialist worldview. With habits of thought derived ultimately from Aristotelian essentialism, early evolutionists could only conceive of change as taking place when things are transformed into other things through individual striving or the unfolding of potentials inherent in the individual's underlying essence. Caterpillars are transformed into butterflies; monarchies are transformed into parliamentary democracies. Darwin freed evolution from the bounds of essentialism when he argued that 'descent with modification' could arise as a purely mechanistic consequence of variants being reproduced and dropping out of populations at different rates. Inasmuch as they purport to be Darwinian, all of the evolutionary approaches summarized below adhere at least implicitly to this fundamental understanding of the mechanism that produces change through history.

2. *Evolutionary Approaches in Archaeology*

Taking inspiration from Darwin's phrase 'descent with modification,' Durham (1992) distinguishes between cultural evolutionary studies focusing on descent and those focusing on modification. Out of favor during the heyday of the 'New Archaeology,' studies of cultural descent were revived during the 1980s in works such as Renfrew's (1987) study of Indo-European origins, Kirch and Green's (1987) study of cultural phylogeny in Polynesia, and Flannery and Marcus's (1983) study of Zapotec prehistory. Other historical sciences, such as historical linguistics and biological anthropology contribute along with archaeology toward the common goal of reconstructing cultural phylogenies.

When biological, linguistic, and material similarities are summarized in the form of a cultural phylogeny, an underlying assumption is that the pattern was created by the mechanisms outlined by Darwin (which Durham (1992) subsumes under 'modification'). But how would Darwinian mechanisms work to generate the material remains that make up the archaeological record? The ways that archaeologists have answered

this question can be conveniently grouped under five headings, which provide a framework for the following survey of evolutionary approaches in archaeology.

2.1 Evolutionary Archaeology

The approach instigated by Dunnell (e.g., 1978, 1980) is often called evolutionary archaeology (EA) by both its proponents and its critics (e.g., Boone and Smith 1998). Evolutionary archaeologists contend that culture constitutes an inheritance system that parallels genetic inheritance. Moreover, culturally transmitted traits, like genetic traits, may affect an organism's probability of survival and reproduction, which leads to frequency change over time in cultural traits just as it does for genetic traits. The complete human phenotype is encoded by both genetic and cultural instructions, and artifacts and other cultural manifestations therefore owe their existence and diversity to the same evolutionary processes (selection and drift) that create biological diversity (e.g., Dunnell 1989). Humans perceive and solve problems, but the importance of these intentional efforts is that they generate variation, which then becomes available for selection (Rindos 1989).

David Rindos' (1984) work on the origins of agriculture incorporated many aspects of the EA approach first articulated by Dunnell (1980). Rindos viewed the emergence of domesticates as a Darwinian evolutionary process in which selective pressures shaped genetic evolution of the plants at the same time they were shaping cultural characteristics in coevolving human populations. Rindos argued that the same coevolutionary processes govern the mutualistic relationships between humans and their domesticated plants as those which govern other animal-plant relationships, such as that between ants and acacia trees that they harvest for food. A distinctive (though perhaps not unique) feature of the human-plant coevolutionary relationship is that two distinct modes of inheritance, one cultural and one genetic, are responsible for transmission of the human behavioral traits that are being shaped by selection. Nonetheless, Rindos subsumed frequency change in both genetic and cultural traits within the same set of coevolutionary models. Hart (1999) has recently applied and extended Rindos' framework in a study of the evidence for maize agriculture in the Eastern Woodlands.

Theoretical works in the EA tradition have elaborated themes originally introduced by Dunnell, such as the style-function dichotomy. According to Dunnell (1978), functional traits can be understood in an evolutionary context to be those traits that are fixed by selection (i.e., they have positive fitness values), whereas stylistic traits are those for which frequency change can be attributed to drift. Dunnell contends that archaeological frequency seriation requires neutral traits, and this has been borne out by mathematical models and simulation (Neiman 1995, Lipo et al. 1997). Results of this research have been used to develop a series of inferences regarding intergroup interaction in the Woodland period Midwest (Neiman 1995) and lower Mississippi Valley (Lipo et al. 1997).

Left unanswered in Dunnell's original works is the question of whether biological reproductive success is necessary for a cultural trait to exhibit positive fitness and thus be favored by selection. Leonard and Jones (1987) introduce the term 'replicative success' to refer to any trait that increases in frequency relative to alternative traits, but they maintain that cultural traits that do not affect biological reproductive success cannot be termed functional (i.e., subject to selection). Barton and Clark (1997, pp. 12–13) summarize the conflicting positions of evolutionary archaeologists on this issue.

A theoretical issue dealt with at greater length in EA (e.g., O'Brien and Holland 1990, Neff and Larson 1997) is the supposed circularity of 'fitness' when more fit individuals are identified as such only because they enjoy greater success at passing on genetic or cultural information. As in evolutionary biology, the 'propensity definition' of fitness backed up by engineering analysis of artifact design are seen as means to circumvent this circularity (O'Brien and Holland 1990). These arguments lead to one of the major methodological prescriptions of EA, namely that investigation of evolutionary history should focus on concrete phenomena (artifacts at various scales) and proceed by advancing and testing hypotheses about the forces that shaped observed artifact design. A focus on concrete phenomena, such as artifacts, is also suggested by Dunnell's (1980) discussion of empirical sufficiency.

Substantive applications within EA, not surprisingly, have tended to emphasize the explanation of variation at the level of the artifact. Examples are found in a volume edited by Teltser (1995), where the case studies include one on ceramic source-usage variation through time, one on the design of agricultural fields, one on artifactual change following the arrival of Europeans in the New World, and one on ceremonial architecture in Polynesia. In these studies, the history of artifact design changes is explained by reference to constraints and opportunities posed by the environment. The models of neutral trait distributions developed by Neiman (1995) and Lipo et al. (1997) have also emphasized variation at the level of the artifact.

2.2 Evolutionary Ecology

The evolutionary ecology (EE) approach to the analysis of archaeological remains emerged in the early 1970s (citations in Broughton and O'Connell 1999).

Archaeologists identifying themselves with this approach (e.g., Boone and Smith 1998) stress the fact that human organisms have been designed by past selection of genetic variation to seek fitness-enhancing ways of responding to environmental conditions. Thus, cultural change and diversity are explained primarily by phenotypic adjustment to variable opportunities and constraints posed by the environment. More specifically, 'adaptive phenotypic variation involves the interaction between genetically or culturally evolved cognitive mechanisms and variable environmental conditions' (Boone and Smith 1998, p. S144). To take a now paradigmatic example, snowmobiles replaced snowshoes among the Cree in less than one human generation, a change that evolutionary ecologists explain by reference to Cree calculation of energy return rates under various transportation options and subsequent decisions to adopt the most efficient one.

The premise that humans have been designed by natural selection to seek fitness-enhancing behaviors warrants the use of optimization models, which is a key defining feature of the EE approach to archaeology. That is, given a set of alternative behavioral strategies, evolutionary ecologists assume that humans will follow the strategy that tends to maximize biological fitness in a given environment. Broughton and O'Connell (1999) point out that this underlying premise leads most naturally in archaeology to an emphasis on subsistence and settlement. For instance, usage of prey species, about which the optimal foraging models of EE make clear predictions, can be inferred more or less directly from archaeological data. Winterhalder and Goland (1997) have used the prey-choice framework to explore how different plants, including eventual domesticates, might have been brought into the diet of hunter-gatherers. This account converges with and complements the EA account of agricultural origins offered by Rindos (1984). In some cases, predictions about prey choice can also be extended to predictions about change in tools used to obtain various prey species, thus extending the applicability of EE into the realm of technology (Broughton and O'Connell 1999). Winterhalder (1997) shows how optimization models of evolutionary ecology apply to another key area of archaeological interest, exchange.

Although the inference of behavior from archaeological remains is quite direct when the focus is on subsistence, EE models, by definition, are always stated in behavioral terms, and this means that methods for reconstructing behavior from archaeological remains are crucial components of the EE program. EE proponents recognize that this constraint ties their research to other programs aimed at providing a rigorous basis for behavioral inference in archaeology. Thus, it is argued that ethnoarchaeology (O'Connell 1995) and behavioral archaeology (Boone and Smith 1998, Broughton and O'Connell 1999) can render the archaeological record interpretable in behavioral terms, while EE furnishes the theory to explain why particular behaviors have appeared when and where they have in human history. Schiffer (1999), the main architect of behavioral archaeology, approves of the EE focus on behavior, but considers the optimization models of EE useful for explaining only a small part of the range of human behavioral variability.

A somewhat polemical debate between proponents of EE and proponents of EA emerged in the late 1990s. Evolutionary archaeologists contend that diversity and change observed in the archaeological record can be explained by reference to the effects of selection and drift on cultural inheritance. They reject the EE reliance on phenotypic adjustment on the grounds that it ties explanation to individual intent rather than mechanisms (Dunnell 1989, Lyman and O'Brien 1998). EE proponents contend, on the contrary, that many if not most instances of historical change happen too fast to be explainable by reference to the long-term process of natural selection working on culturally inherited traits. They cite the Cree snowmobile case in support of the necessity to consider phenotypic adjustment: the long-term criterion of differential biological success, they argue, simply cannot explain the adoption of snowmobiles in less than one human generation (Boone and Smith 1998, Sects. 146–7).

The EE and EA camps also dispute whether behavior should constitute the object of evolutionary explanation in archaeology. Evolutionary ecologists advocate a hypothetico-deductive approach in which optimization models are the basis for predictions about prehistoric human behavior, and they argue that, with methods of behioral archaeology and ethnoarchaeology, these predictions are testable. From this point of view, the preoccupation with artifacts and their distributions in time and space is a serious limitation of the EA approach (e.g., Boone and Smith 1998, pp. S154–6, Broughton and O'Connell 1999, pp. 158). EA proponents (e.g., Dunnell 1989, Lyman and O'Brien 1998), however, argue that evol utionary models stated in behavioral terms are inherently untestable because the behaviors about which they make predictions are unobservable and can only be inferred from the archaeological record with a leap of faith.

2.3 Approaches based on Dual Inheritance Theory

Dual inheritance theory (DIT) (Boyd and Richerson 1985, Durham 1992) addresses the ways in which the principle of selective retention coupled with the special properties of cultural transmission lead to expectations about the evolution of adaptive and not so adaptive cultural practices, artifacts, and institutions. The theory explicitly incorporates complexities of cultural transmission that are suggested by social learning research. Boyd and Richerson (1985) con-

struct models of how various forms of bias in the transmission process lead to different evolutionary results; Durham (1992) prefers to call the forces of bias 'cultural selection.'

Two main predictions emerge from DIT. First, cultural evolution, which is aided by guided variation and biased transmission (Durham's (1992) 'primary value selection'), can converge on solutions that are adaptive for the human organism faster than evolution that depends exclusively on natural selection of genetic variation. In this case, fitness maximization adequately predicts human behavior. Second, DIT predicts that differential survival of cultural variants may also generate inherited behavior patterns that run counter to the predictions of genetic fitness maximization (Bettinger 1991, Shennan 1991). Indirect bias and frequency-dependent bias (which Durham (1992) calls 'secondary value selection') further enhance the potential for cultural manifestations to be maladaptive in a biological sense.

DIT shares with EA the view that culture constitutes an inheritance system evolving with some degree of independence. However, the EA conviction that variation must be independent of the force of selection for a true Darwinian process to work is violated by guided variation and biased transmission, which are central to DIT. For their part, dual inheritance theorists argue that natural selection is inadequate, on its own, to explain cultural change and diversity (Richerson et al. 1998). Instead, decision making—the ways in which cultural transmission interacts with learning to produce variation that can then be shaped by selection—has to be modeled explicitly if the archaeological record is to be understood in evolutionary terms.

DIT is thus aligned with EE regarding the importance of decision making in cultural evolution. Moreover, the optimality models of EE are regarded as valuable sources of hypotheses that can serve as starting points for archaeological investigation (Bettinger and Richerson 1996). At the same time, however, the independent dynamics of an evolutionary process based on cultural transmission leads to skepticism regarding simple optimality interpretations of human behaviors (Bettinger 1991, Richerson and Boyd 1992, Shennan 1991). People may tend to acquire beliefs, values, practices, and artifacts that are adaptive in the biological sense, but this assumption is limited in its potential to account for the full range of human variation.

Efforts to put DIT to work in the service of archaeology have tended to emphasize means for recognizing archaeologically the various modes of cultural transmission. Bettinger (1991, pp. 203–7), for instance, suggests that the complex of changes associated with the European Upper Paleolithic transition may be explainable as indicators that indirect bias and frequency-dependent bias for the first time came to play important roles in human cultural evolution. Bettinger argues that climatic change and population growth would have favored local subsistence specialization, which in turn would have favored mechanisms (like indirect and frequency-dependent bias) for efficiently acquiring locally adaptive behavioral traits as a complex.

2.4 *Approaches based on Evolutionary Psychology*

Like dual inheritance theorists, Mithen (1989, 1997a, 1997b) believes that simple adaptive models of human behavior such as those that make up EE are insufficient to account for human behavioral variation. However, rather than exploring the implications of cultural transmission mechanisms, Mithen explains departures from adaptive expectations largely by reference to the fact that humans now and in the recent past have lived in environments very different from those in which human cognitive capacities evolved. This viewpoint has been explored most thoroughly within evolutionary psychology. A major implication of this research, accepted by Mithen (1997a, 1997b), is that the human brain consists of various specialized devices designed by evolution to solve specific problems faced by hominids in the past. Mithen (1997a) contends that this modular view invalidates models, such as Boyd and Richerson's, that only indirectly consider the content of cultural transmission.

Mithen's methodological prescriptions converge with those of many other brands of archaeology, especially behavioral archaeology (see Sect. 2.2). The archaeological record is conceived as the aggregate result of active individuals endowed with common psychological propensities making decisions in unique historical contexts, and archaeology's task is to relate the short-term individual behavior to the gross character of the archaeological record (Mithen 1989, pp. 491–2). Evolution enters the picture to the extent that behavioral patterns inferred from the record are eventually interpreted as adaptations, or as the expression of human propensities that are no longer adaptive due to their existence in novel, inappropriate environments, or as the unintended consequences of pleiotropic adaptive traits.

Mithen(1997a, 1997b) also believes that archaeology can contribute to evolutionary psychology by providing better understanding of the evolution of human cognitive capacities (see *Cognitive Archaeology*). As an example of the mutualistic relationship of cognitive archaeology and evolutionary psychology, Mithen (1997a) interprets religious ideas as evolutionary byproducts of increased 'cognitive fluidity' (i.e., increased integration of the brain's modular cognitive capacities) that characterizes the brains of modern humans. Since religious ideas are not in themselves adaptive and may often be maladaptive, the brain has no specific cognitive capacity for transmitting religious ideas. Early modern humans therefore had to develop techniques, including ritual and

art, to ensure religious transmission. Thus, the flowering of Upper Paleolithic art is interpreted as the archaeological expression of evolutionary changes in cognitive architecture associated with the emergence of modern humans.

Proponents of other evolutionary approaches in archaeology have mainly ignored the cognitive archaeology work, despite some severe critiques launched by Mithen (1997a) in the other direction. From the EA perspective, inference of cognitive processes from artifacts would probably be considered informed speculation at best. Evolutionary ecologists, for their part, might observe that optimization models that lie at the core of EE are preferable to antiquated functionalist arguments used to attribute adaptive significance to behavioral patterns inferred model-free from the archaeological record.

2.5 'Memes' and Cultural Virus Theory

In the evolutionary approaches considered so far, artifacts are viewed either as reflections of human behavior (EE, DIT, and evolutionary psychology) or as phenotypic characteristics of individuals (EA). An alternative perspective, considered by some 'the most extreme variant of cultural selectionism' (Maschner and Mithen 1996, p. 7), builds on the meme concept introduced by Dawkins (1976). Memes are cultural replicators, analogous to genes. The only purpose of any replicator, whether it is a gene or a meme, is to make copies of itself. Memes cannot self-replicate, but, like the genetic instructions in viruses, they can harness the capacities of other organisms to get themselves replicated. The last characteristic has led Ben Cullen (1993, 1996), the main proponent of this perspective in archaeology, to propose naming it 'cultural virus theory' (CVT).

To the extent that opportunities for memes to be replicated are limited by the amount of brain space available in a human population, memes 'compete,' just as other replicators (i.e., genes) compete. But the differential persistence of memes need have little to do with the biological reproductive success of human organisms in which they reside. Instead, differential persistence of memes arises purely out of differential success at replicating from brain to brain. The reasons why some memes enjoy relative success at replication can be found in the differential physical effects they have upon the world: under some circumstances, a cooking pot in which water boils in five minutes will have its design memes copied more often than one that requires 10 minutes. Evolutionary ecologists might argue that selection of memes in this case arises in the human cognitive capacity (which was designed by natural selection of genetic variation) to recognize more optimal solutions to problems such as how to boil water. From the meme perspective, however, artifacts, not humans, are the 'interactors' in the evolutionary process. Artifacts are packages of the physical effects of memes, and the success or failure of artifacts determines frequency change in their design memes. Archaeological assemblages, from this point of view, represent ecological assemblages of artifacts as interactors.

Although CVT has been largely ignored by less 'extreme' advocates of evolutionary approaches in archaeology, the artifact-oriented approach of EA can be considered consistent with this perspective. The engineering design approach of O'Brien and Holland (1990) evaluates the fitness of artifacts, thus implying that artifacts are the interactors in the evolutionary process. Likewise, models for predicting the pattern of trait distributions in the archaeological record (e.g., Lipo et al. 1998; Neiman 1995) necessarily ignore the biological reproductive cycles of humans and lead to predictions about the distributions of traits counted on artifacts.

Like DIT and approaches based on evolutionary psychology, memetics (or CVT) predicts the existence of cultural manifestations that are irrelevant to biological success or even patently maladaptive from the perspective of human survival and biological reproduction. However, as the example of the cooking pot mentioned above illustrates, expectations about artifactual evolution can converge with predictions of an optimality argument. More generally, human proclivities and decision-making capacities, fashioned by natural selection in the past, provide selective criteria that help determine the fate of culturally encoded designs

Evolutionary Epistemology

Traditionally, epistemology concerns justifying beliefs. What right do we have to think that our beliefs are true? Evolutionary epistemology is a form of naturalized epistemology. In naturalized epistemology, the

justification provided turns on an appeal to something about the natural world, in this case the evolutionary process. Organisms that do not react appropriately to their environments are not likely to survive to reproduce. In some organisms this reaction can appropriately be termed 'knowledge.' Those organisms that are better at learning about their environments (which includes other organisms) are more likely to survive to reproduce than their less adept congeners. Thus, knowledge of those features of the environment that are relevant to survival and reproduction is to some extent justified. *Homo sapiens* as a species depends for its survival on playing the knowledge game better and more extensively than any other species. Evolutionary epistemologists propose to justify at least some of the beliefs that human beings hold by reference to survival value (for the most seminal paper in evolutionary epistemology, see Campbell 1974).

1. *Gene-based Evolutionary Theory*

In order to understand evolutionary epistemology, one must understand evolution, in particular the distinction between genotypes and phenotypes (see *Genotype and Phenotype*). The genotype of an organism consists in the sequence of bases in its DNA, or rarely, in its RNA. Everything else is part of its phenotype, from its blood type to its behavior. Variations in the genotype of an organism lead, through embryological development, to different phenotypic traits. These genetic variations are caused, totally caused. Among these causes are unequal crossover, increased temperature, and the presence of numerous mutagens. However, to count as Darwinian evolution, no correlation must exist between the variations an organism might need and those it might get; for example, it cannot be 'Lamarckian.' For Lamarckian evolution to occur, some feature of an organism's environment must change the phenotype of that organism in such a way that it is better adapted to the environmental feature that produced this change in the first place. This phenotypic change must then somehow be transmitted to the organism's genes to be passed on to subsequent generations via the genetic material. A mother dog giving fleas to her puppies does not count as Lamarckian inheritance.

Some of the traits exhibited by an organism make it better able to survive and reproduce. As a result, the genes that code for these traits are passed on differentially from generation to generation. However, as organisms become better-adapted to their environments, their environments frequently move out from under them. A few species succeed in surviving through the millennia largely unchanged, but most survive only by evolving. One feature of gene-based selection in biological evolution is that it can occur quite rapidly, as in viruses and bacteria, or quite slowly, as in most larger animals. However, in every case of Darwinian evolution, the relevant traits are inherited literally via the genetic material. Initially, the 'units' used in evolutionary biology were traits because evolutionary biologists had no access to the genetic material. As this access has increased, traits have been replaced by genes as units of inheritance. Unfortunately, the genetic material can be divided up in numerous ways. As a result, biologists concentrate on the 'information' contained in the genetic material.

Advocates of evolutionary epistemology in its most literal sense argue that the preceding story equally applies to some behavioral traits and predispositions. These traits and dispositions are as much phenotypic traits as are hair texture and skin color. Knowledge of the world in which organisms live gets programmed into an organism's genes. For example, fear of heights and the sucking reflex are in some sense programmed into the genes of human beings. The evolution of behaviors and behavioral predispositions has all the usual characteristics of gene-based biological evolution. As traits, behaviors can be adaptive. The inheritance involved is genetic, strictly Darwinian, not Lamarckian, and it can occur at a variety of rates from very slow to very fast.

The majority of epistemologists are not very impressed with evolutionary epistemology, in part because it is naturalistic, and only normative epistemologies are worth the title of epistemology. But a second weakness is that the only beliefs that evolutionary epistemology in this strict sense can even purport to justify are beliefs about entities and processes that the organism can perceive. Evolutionary epistemology might lend some justification for how human beings distinguish species of large organisms, but it cannot justify any beliefs that we have about the millions of tiny microorganisms that fill every nook and cranny of the world, let alone quantum indeterminacy.

2. *Individual Learning*

In 'eusocial organisms,' such as bees and termites, nearly all of the behaviors exhibited by these creatures evolved in a strictly Darwinian fashion. Relatively little learning takes place in the span of a single generation. But many organisms can learn from interacting with their environments. In a second form of evolutionary epistemology, knowledge does not get programmed into our 'genes,' but into our 'brains.' Gene-based selection in biological evolution can handle features of the environment that change relatively slowly, e.g., changes in temperature resulting from continental drift, but some changes are so rapid that organisms with longer generation times cannot adapt to them. One solution to this problem is the

evolution of the 'central nervous system.' Organisms with highly developed central nervous systems can learn about their environments and react to changes in them with greater speed. This information does not get programmed into an organism's genes but into its brain. 'Operant learning' is the simplest form of individual learning. Each kind of organism has a range of behaviors that it tends to emit spontaneously. Feedback from its environment increases or decreases the frequency of these behaviors. Sequential environmental responses shape the behavioral repertoires of these organisms.

The preconditions for operant learning are certainly programmed into the genes of those organisms that are capable of individual learning, and arose through gene-based natural selection. However, the specific learned repertoires cannot be passed on to successive generations. Each organism must learn anew. For better or for worse, calculus is not programmed into the genes of any human being. Each generation must learn it from scratch. If over many generations the same learning regimen is repeated and produces some evolutionary advantage, what was once a learned behavior can to some extent become programmed into the genes. Within a single life-history of an organism, the mechanisms that produce increased knowledge can be viewed as a 'selection process.' However, in this selection process, 'brain states' take the place of genes. Behavioral units can vary from something as brief and discrete as pressing a lever to something as complex and protracted as mowing a lawn. We have yet to discover the size and shape of the brain states that are responsible for the retention of information.

A second solution to the problem posed by differences in reaction times is the 'immune system.' In order to keep up with the rapid rate of reproduction of such antigens as viruses, immune systems evolved in many larger organisms. Within the life of a single organism, selection in the immune system occurs at the cellular level. Antibodies are produced in huge numbers, each with its own reaction site. If any of these antibodies happens upon an antigen that contains a protein that matches its reaction site, this antibody proliferates and, in most cases, eliminates the antigen. Once again, the 'information' garnered through successive invasions by antigens cannot be passed on to later generations. After each invasion, a few memory cells lie in wait for any subsequent invasions. That is all. Although some workers in the early years of modern immunology thought that the process might contain some elements of Lamarckian inheritance, it does not.

3. *Social Learning*

Classic epistemology dealt with individual, isolated cognizers. How much can we learn about our environments in total isolation from all other people? How certain could Robinson Crusoe be, once marooned on his island, of any new knowledge that he obtained? After all, he had no one with whom to check his discoveries. But even the Robinson Crusoe example is not pure enough, because Crusoe brought with him language and a fund of socially acquired knowledge. What about someone who began life totally isolated from all other human beings? In the first place, such an isolated baby would rapidly die, but how about the science fiction case? How about a baby adopted by wolves or some other unlikely creature? How much could it know? How justified would its knowledge be? The answer to both questions is very little. Social organisms can learn more than solitary organisms and be more secure in this knowledge because of culture (see *Cultural Evolution: Theory and Models*).

Most discussions of evolutionary epistemology do not deal with strict gene-based biological evolution or individual learning such as operant behavior, but 'social' learning. In social learning, knowledge acquired by one organism in its lifetime can be passed on to other organisms. This knowledge is transmitted from organism to organism, not through genes, not through the passing on of any brain tissue, but through 'imitation' and 'communication'. As a result, social learning need not proceed vertically, as defined by the direction that genes take in passing from parent to offspring, but horizontally (see Cavalli-Sforza and Feldman 1981). Education in the human species is an example of social learning. Through repeated efforts, teachers succeed in getting at least some of their pupils to be able to solve problems in calculus. Although the ability to learn in this way surely has a genetic component, social learning does not involve transmitting information genetically. As a result, it cannot count literally as Darwinian or Lamarckian. Of course, nothing keeps genes and culture from coevolving. In fact 'gene-culture coevolution' is likely to be of primary importance in human evolution (see Durham 1991, for additional reading, see Boyd and Richerson 1985, Cavalli-Sforza and Feldman 1981, Eldredge and Grene 1992, and Lumsden and Wilson 1981).

4. *Memetics*

At this stage, advocates of evolutionary epistemology as social learning make a significant move. They cease treating bits of knowledge, behavior, and the like as analogous to 'characters' but as analogous to 'genes.' Just as genes get passed on differentially in gene-based biological evolution, 'memes' get transmitted differentially in 'memetic' evolution (Blackmore 1999, Dawkins 1976, and Plotkin 1994). Just replacing genes with memes may not sound like a very profound change, but the implications are significant. Once again, memetic evolution is not in the least Lamarckian. Literally, memetic evolution is not Lamarckian

because nothing is being passed on 'genetically.' Metaphorically, it is not Lamarckian because what is being transmitted is not analogous to 'characters' but to 'genes.' It is the inheritance of acquired memes, not genes or even characters. The reason for emphasizing that memetic evolution is in no cogent sense Lamarckian, is that critics of memetic evolution think that they can dismiss this perspective simply by terming it 'Lamarckian.'

Critics of memetics provide a long list of objections to the memetic form of evolutionary epistemology. First, supposedly memetic evolution occurs so much more quickly than does gene-based biological evolution. But the same variations in speed of transmission can be found in both. Certainly viruses can spread as quickly as any meme. Second, critics complain that the analogy between genes and memes is imperfect. Genes are supposedly absolutely distinct, all of the same size and kind, and do not interact with each other. Supposedly memes exhibit none of these characteristics. Hence, the meme–gene analogy breaks down. But one need not know very much about genetics to know that genes possess none of the characteristics attributed to them by critics of memetics. Some genes are reasonably discrete; many are not, and much of the genetic material cannot be subdivided meaningfully into discrete genes. Genes vary tremendously in size, and numerous different sorts of genes exist (e.g., regulator genes). Also genes interact with each other in extremely complex ways in development. In addition, many elements of knowledge communication possess all of the preceding characteristics reasonably well developed; for example, e-mail addresses.

The chief problem with treating conceptual entities as memes is the difficulty of distinguishing *phenotypic characteristics* in this metaphorical usage. Behaviors count as characteristics in literal evolutionary epistemology. They are analogous to 'genes' in the metaphorical usage. Then what counts as phenotypic characters in the metaphorical usage? Memes get transferred from brains to air waves, to computer chips, to computer screens, to brains, etc. All of this counts as replication because information is being transmitted with relatively little loss. However, every once in a while, 'replication' is interrupted by 'translation.' Knowledge is connected causally to what it is knowledge of: you believe, for example, that barking dogs do not bite, so as you approach a barking dog, you put this belief to the test. The result will modify your belief system. The dog itself is not a meme.

As in other cases of selection, the notion of information plays a central role. One important feature of memetic replication is transmission with relatively little loss of information. One important feature of translation into the phenotype is significant loss of information. Instructions on how to make a Stradivarius violin can be transmitted from agent to agent. Antonio Stradivari might have written down these instructions, and even allowed an apprentice to watch him make a violin. If he had, this apprentice might have been able to make violins of the same caliber as did his master. He might have passed down this combination of knowledge and skill to the present. However, that is not what happened. All we have are Stradivari's violins. As repeated failures have shown, making violins based just on what we can learn from the finished product (reverse engineering) is extremely difficult, if not impossible. Future work in memetics is needed to present adequate analyses of 'information' and the 'genotype-phenotype' distinction.

5. *A General Analysis of Selection*

Early versions of evolutionary epistemology involved reasoning analogously from gene-based selection in biological evolution to knowledge acquisition. The analogical character of this activity has been the source of endless criticism. Evolutionary epistemology is 'merely' an analogy. In these arguments, the peculiarities of gene-based selection have played an inordinately important role in biological evolution. Any departure from gene-based selection in biological evolution, no matter how trivial, is viewed as a lethal disanalogy. However, an alternative view has been suggested periodically. Instead of reasoning analogously from one sort of selection process to another, present a 'general analysis of selection' that is equally applicable to all sorts of selection processes, whether gene-based selection in biological evolution, the reaction of the immune system to antigens, individual learning, social learning, memetics, etc. (Toulmin 1972). Although the father of evolutionary epistemology, Donald Campbell (1974) was one of the strongest proponents of justifying knowledge by reference to gene-based selection in biological evolution. In his later writings he adopted this second program. Evolutionary epistemology is no longer an analogy, but it is a special case of selection. Just as the processes that result in functional organization have been isolated and analyzed as a special sort of process, selection processes warrant an equally careful treatment.

Starting with Lewontin's (1970) classic statement, successive attempts have been made to specify the essence of selection processes. According to Lewontin, the three necessary elements for selection to occur are phenotypic variation (different individuals in a population have different morphologies, physiologies, and behaviors), differential fitness (different phenotypes have different rates of survival and reproduction in different environments), and heritable fitness (there is a correlation between parents and offspring in the contributions of each to future generations). According to Hull's (1980) more general characterization, the selection process is made up of three subprocesses related in very specific ways: (a) replication of information in successive generations with only minimal

modification, (b) environmental interaction that causes the preceding replication to be differential, and (c) some source of variation. The goal is to show that gene-based selection in biological evolution, the reaction of the immune system to antigens, individual learning, social learning, and other processes as well, all exhibit the basic structure of selection processes. However, such general analyses of selection do not provide any epistemological warrant. If evolutionary epistemology is to remain 'epistemology,' then some other source of epistemological warrant must be provided (Hull 2001).

6. Conclusion

Evolutionary epistemology has changed significantly from its slim beginnings. Initially, it dealt only with knowledge that is literally gene-based, e.g., a tendency to group organisms into discrete species. Evolutionary epistemology in this strict sense justified certain beliefs. However, this warrant was neither very strong nor very extensive. Evolutionary epistemology in this sense is limited only to those environmental interactions that are in the range of an organism's sense organs and that matter with respect to an organism's survival and reproduction. Evolutionary epistemology in this strict sense can provide no justification whatsoever for a belief in quantum indeterminacy.

However, the sort of evolutionary epistemology that has received the greatest attention is metaphorical in character. Knowledge is in no sense programmed into the genes to be transmitted to future generations. Instead the transmission is social. The entities being transmitted are in a broad sense memes. Numerous objections have been raised to this metaphorical evolutionary epistemology. First, so it is alleged, memes are not all that similar to genes. However, these objections stem from an unreal view of both genes and memes. The real problem is identifying something that can count as the phenotype in memetic evolution. In the absence of such a distinction, memetic evolution cannot be characterized as either Darwinian or Lamarckian. Once again, a mother dog giving her puppies fleas is not Lamarckian inheritance in either a literal or a metaphorical sense.

Whatever warrant metaphorical evolutionary epistemology provides arises from its analogical connections to literal evolutionary epistemology. Because many species of organism must be able to distinguish members of their own species to reproduce and survive, other beliefs more distantly related to reproduction and survival gain some analogical warrant. One problem with both sorts of evolutionary epistemology is that they do not distinguish between 'success' and 'truth.' Many false beliefs have been proven to be very successful with respect to survival and reproduction, e.g., the belief that God is on the side of one's own group in times of war. For this and many other reasons, a majority of professional epistemologists reject evolutionary epistemology as not being nearly good enough. Of course, professional epistemologists reach the same conclusion with respect to all other epistemological justifications as well, save their own.

A third sort of evolutionary epistemology has gained increased popularity through the years. Instead of reasoning analogically from gene-based to meme-based evolution, a general analysis of selection is produced that equally applies to all sorts of selection processes from the reaction of the immune system to antigens to social learning. As promising as this research program might well be, it has one serious drawback. It supplies no epistemological warrant, at least not in any of the traditional senses. Just because a belief arose through a selection process, it does not follow that this belief is true. It all depends on the character of the selection process. For example, a belief that survives the sort of serious testing that goes on in science is likely to be true, while biblical exegesis is not likely to increase its warrant.

However, during this same period, what counts as 'epistemology' has expanded greatly. Epistemologists are no longer limited just to justifying knowledge. They are engaged in all sorts of other activities as well. For our purposes, the issue is whether or not providing a general analysis of selection can justify certain sorts of knowledge and, if not, whether it counts as 'epistemology' in any of its more recent senses.

D. L. Hull

Evolutionary Selection, Levels of: Group versus Individual

Throughout history, including the history of the social sciences, groups have been compared to individual organisms in the harmony and coordination of their parts. Aristotle compared the various classes of society to a single organism and religious communities are often described in organismic terms: the body of the church, united under the head of Christ. Almost every founder of the social sciences shared this group-level perspective, at least to a degree (Wegner 1986).

In more recent times the social sciences have become dominated by a more reductionistic perspective, sometimes referred to as 'methodological individualism,' in which 'groups and social organizations have no ontological reality—that where used, references to organizations, etc., are but convenient summaries of individual behavior' (Campbell 1994, p. 23). In addition, evolutionary biologists reached a consensus during the 1960s that groups are highly unlikely to have evolved into adaptive units comparable to individual organisms (Williams 1966). These two developments, which occurred largely independently of each other, appeared to relegate the concept of groups as organisms to the antique shop of history.

Developments in evolutionary biology since the 1960s have led to a new consensus that is represented by the term 'multilevel selection' (e.g., Frank 1998, Michod 1999, Sober and Wilson 1998). Natural selection acts on a hierarchy of biological units, from genes within individuals to groups within a metapopulation (a population of groups). Individual organisms are an upper level of this biological hierarchy, social groups that have become so functionally integrated that the whole is more conspicuous than the parts. If individuals are themselves groups, the concept of groups as individuals can no longer be regarded as theoretically improbable. In fact, an especially strong case can be made for human groups as units of natural selection (Boehm 1997). The group-level perspective is back in evolutionary biology, with profound implications for the human social sciences. However, groups can never be assumed axiomatically to function as adaptive units. Special conditions are required and opposing forces always exist, including subversion from within. The modern multilevel view can draw upon the originators of the social sciences for insight, but is not a return to the grandiose and often naïve groupism of the past.

1. Evolution and the Fundamental Problem of Social Life

Prior to Darwin, supernatural agents provided the most ready explanation of purpose and order at all levels, from celestial bodies, to human society, to the actions of individual people and other creatures. Darwin provided the first successful scientific theory of adaptations, which remains today the only theory in an ultimate sense. Human artifacts have a purpose and did not evolve by natural selection in a proximate sense, but the ability of humans to make artifacts with a purpose itself presumably evolved by natural selection. All intentional processes are probably rooted in a process of blind variation and selective retention (Campbell 1960).

Evolution explains adaptations but it is not nearly as permissive as supernatural explanations. In particular, group-level adaptations are not as easy to explain as individual-level adaptations. To see why, consider the evolution of a nonsocial adaptation, such as cryptic coloration. Imagine a population of insects that varies in the degree to which they match their background. Every generation, the most conspicuous individuals are detected and eaten by predators while the most cryptic individuals survive and reproduce. If offsprings resemble their parents, then the average individual will become more cryptic with every generation. Anyone who has beheld an insect that looks exactly like a leaf, right down to the veins and simulated herbivore damage, cannot fail to be impressed by the power of natural selection to evolve breathtaking adaptations at the individual level.

Now consider the same process for a social adaptation, such as members of a group warning one another about approaching predators. Imagine a flock of birds that vary in their tendency to scan the horizon for predators and to utter a call when one is spotted. It is not obvious that the most vigilant individuals will survive and reproduce better than the least vigilant. If scanning the horizon detracts from feeding, the most vigilant birds will gather less food than their more oblivious neighbors. If uttering a cry attracts the attention of the predator, the sentinel places itself at risk by warning others. If these suppositions are correct, then birds that do not scan the horizon and that remain silent when they do see a predator will

survive and reproduce better than their more vigilant neighbors.

These two examples show that the evolutionary concept of adaptation does not always conform to the intuitive concept, especially at the group level. It is easy to imagine a bird flock as an adaptive unit and to predict its properties. We would expect members of the flock to adopt the creed 'all for one and one for all.' We might expect sentries to be posted at all times to detect predators at the earliest possible moment and to relay the information to feeding members of the flock. Unfortunately, individuals who possess these behaviors do not necessarily survive and reproduce better than individuals who enjoy the benefits and do not share the costs. Since Darwin's theory explains adaptations only on the basis of differential survival and reproduction, it appears unable to explain groups as adaptive units. This can be called the fundamental problem of social life. Groups function best when their members produce benefits for one another, but it is difficult to translate this kind of social organization into the currency of biological fitness. Evolutionary theory has difficulty explaining any kind of group as an adaptive unit, including those that might be found in our own species.

2. *Darwin's Solution to the Fundamental Problem*

Darwin was aware of the fundamental problem of social life and proposed a solution. Suppose there is not just one flock of birds but many flocks. Furthermore, suppose that the flocks vary in their proportion of vigilant callers. It is true that vigilant callers do not have a fitness advantage within a single flock, but groups of vigilant callers will be more successful than groups whose members do not look out for one another. Darwin used this reasoning to explain examples of apparent altruism in nonhuman species, such as the bee's suicidal sting, and also human moral virtues that appear designed to promote group welfare. In his own words: 'At all times throughout the world tribes have supplanted other tribes; and as morality is one important element of their success, the standard of morality and the number of well-endowed men will thus everywhere tend to rise and increase' (Darwin 1871, p. 166).

Darwin's solution is elegant and perhaps even obvious in retrospect. If adaptations evolve by differential survival and reproduction, it makes sense that the evolution of adaptive groups requires the differential survival and reproduction of groups. Adaptation at each level of the biological hierarchy requires a corresponding process of natural selection at that level. However, Darwin's solution only shows that adaptive groups can evolve in principle. Conditions are required that may or may not exist in the real world. In addition, the adaptations favored by group selection can be opposed at other levels. In the case of our birds, group selection favors vigilance but selection within groups favors nonvigilance. If we wish to explain bird flocks as adaptive units, not only must we demonstrate a process of between-group selection, but we also must show that it overpowers within-group selection.

Darwin's solution has another disturbing implication, which demonstrates that the biological concept of adaptation remains limited, even in its multilevel form. We have already seen that adaptations at one level of the biological hierarchy can be highly maladaptive at other levels. A male lion that displaces another male and systematically kills his rival's offspring so that he can proceed to mate with the females is behaving adaptively, in a narrow biological sense of the word. However, this adaptation is good only for the individual male; not for the vanquished male, the females, the group, the species, or the ecosystem. It is possible to imagine a process of group selection that favors noninfanticidal males. After all, groups with noninfanticidal males might grow larger by producing more cubs, enabling them to outcompete groups with infanticidal males. However, this would not eliminate conflict so much as elevate it up the biological hierarchy, to the level of between-group rather than within-group competition. The most that group selection can do is evolve groups that are like organisms in the harmony and coordination of their parts. We already know what individual organisms do to one another and nothing different can be expected of groups. Harmony among groups would require a process of natural selection operating at a yet higher level.

3. *Evolutionary Theory's Wrong Turn*

Group selection has been portrayed as a process that can occur but which also must contend with other forces that pull in other directions. As previously mentioned, a consensus emerged among evolutionary biologists in the 1960s that group selection is such a weak force that it can be ignored for most purposes. Even though it is theoretically possible for groups to evolve into adaptive units, it almost never happens in the real world. Of course, group selection could not be rejected without alternative theories that explain apparent group-level adaptations in more individualistic terms. The theories that became the foundation for the evolutionary study of social behavior were kin selection (Hamilton 1964, Maynard Smith 1964), in which individuals evolve to benefit copies of their genes present in genetic relatives,
and reciprocal altruism (Trivers 1971, Maynard Smith 1982, Axelrod and Hamilton 1981), in which individuals indirectly benefit themselves by helping others. With these theories, 'biologists seemed to have little

further need for the metaphor of society as an organism' (Konner 1999, p. 31).

The rejection of group selection was hailed by evolutionary biologists as a great accomplishment but subsequent developments have shown it to be a massive wrong turn from which the field is only starting to recover (see Sober and Wilson 1998 for a detailed historical and conceptual analysis of this period). We can see why by returning to our bird example. Suppose that uttering a cry does not increase the risk of being attacked by an approaching predator. On the contrary, it tells the approaching predator that it has been spotted by the crier and that a less vigilant member of the group should be targeted. If these are the facts of the matter, then the evolution of so-called warning cries could be explained entirely by within-group selection. Individuals who call survive and reproduce better than individuals in the same group who do not call. The function of the adaptation is not to warn other members of the group but to communicate with the predator in a way that actually endangers other members of the group. We would be right to reject group selection in this case. But now suppose that our original story was correct; crying is selectively disadvantageous within groups and evolves only because groups of criers fare better than groups of noncriers. It is still the case that the average crier in the metapopulation is more fit than the average noncrier—that is just another way of saying that the crying behavior evolves—but the evolutionary force that causes the average crier to be more fit is group selection, not selection among individuals within groups.

It follows that distinguishing levels of selection requires several steps. First we must compare the fitnesses of individuals within groups. Then we must compare the fitnesses of groups in the metapopulation. Finally we must combine these effects to determine the bottom line of what evolves. It turns out that many evolutionary models do not follow this procedure. Instead, whatever evolves in the model is vacuously defined as the product of 'individual (or gene) selection,' despite the presence of groups and counteracting selection pressures within and among groups. A good example is n-person evolutionary game theory, which has become the framework for studying reciprocal altruism (Dugatkin and Reeve 1998). The term 'n-person' signifies that a large population is broken into groups of size n within which social interactions occur. The fitness of an individual is given by a payoff matrix and is determined by its own behavior and the behavior of other members of its group. Our bird flock example could easily be modeled with n-person game theory, in which the fitness of an individual depends on whether it is a caller and on the number of other callers in its group. Despite the presence of groups and fitness differences within and among groups that are plain to see in the payoff matrix, the standard procedure in evolutionary game theory is to average the fitness of the alternative behavioral types across groups and to say that the type with the highest average fitness evolves by individual-level selection. Another example is kin selection theory, which implicitly assumes that a large population is broken into groups of genetic relatives, within which social interactions occur.

Elliott Sober and I call the vacuous practice of defining anything that evolves the product of individual or gene-level selection 'the averaging fallacy' (Sober and Wilson 1998). Avoiding the averaging fallacy has two major implications for evolutionary theories of social behavior. First, kin selection and reciprocal altruism become examples of multilevel selection theory rather than alternative theories. When the groups are identified in these theories, it becomes clear that the prosocial behaviors being modeled (e.g., cooperation and altruism) are selectively disadvantageous within groups and evolve only because groups with prosocial members outperform other kinds of groups. Second, not only does multilevel selection theory include kin selection and reciprocal altruism as special cases, but it goes further to explain other cases that are beyond the imagination of these theoretical frameworks. This is fortunate, because kin selection and reciprocal altruism have always seemed poorly suited to explain the kinds of prosocial behaviors that take place in human groups.

4. *Ancestral Human Groups as Adaptive Units*

Our species evolved in small groups that are roughly approximated by the hunter-gatherer societies of today. Prior to the resurgence of multilevel selection theory, evolutionary biologists found it difficult to envision human groups as adaptive units. Genetic relatedness among members of ancestral human groups was only moderate and the principle of reciprocal altruism has always been difficult to extend beyond pairwise relationships. However, modern multilevel selection theory enables human groups to be seen as potent units of selection.

Extant hunter-gatherer societies around the world are remarkably egalitarian. It is not that hunter-gatherers lack selfish impulses, but rather that selfish impulses are effectively controlled by other members of the group. This form of guarded egalitarianism has been called 'reverse dominance' by anthropologist Chris Boehm (1993). In many animal groups, the strongest individuals are usually able to dominate their rivals, taking a disproportionate share of the resources. This is within-group selection, pure and simple. In human groups, an individual who attempts to benefit himself or herself at the expense of others is likely to encounter the combined retaliation of the rest of the group. In most cases even the strongest individual is no match for the rest of the group, so self-serving acts are effectively curtailed. Boehm's survey

of hunter-gatherer societies includes many examples of reverse domination, ranging from ridicule to ostracism, to assassination, of those who attempt to impose their will upon others. Hunter-gatherer societies are first and foremost moral communities with a strong sense of right and wrong that organizes the practices of the group.

The concept of a human group as a moral community shows how much has been missed by the concept of genetic relatedness. In a kin selection model, behavioral uniformity within groups can be achieved only by genetic uniformity. In a moral community, behavioral uniformity can be achieved (or at least approached) by a shared belief in what constitutes right behavior and an ability to discourage wrong behavior effectively. Social norms can create a degree of behavioral uniformity within groups and differences among groups that could never be predicted from their genetic structure and which radically shifts the balance between levels of selection in favor of group selection.

The concept of a human group as a moral community also shows how much has been missed by the concept of reciprocal altruism. Consider a moral community whose members believe that it is right to help others in proportion to need rather than the likelihood of return benefit. Individuals who abide by the norm are rewarded, those who violate the norm are punished, and the group (let us say) prospers compared to groups whose members restrict helping to those who will return the favor. It is true that giving according to need appears less altruistic when enforced by social controls, but social control itself emerges as a group-level adaptation when analyzed in multilevel terms (Boyd and Richerson 1992, Sober and Wilson 1998). Causing others to provide a public good is itself a public good, as economists have long realized (Heckathorn 1993).

Moral communities have both a cultural and an innate psychological component. The specific content of social norms can be modified on the basis of experience and socially transmitted from one person to another. On the other hand, the emotional reactions associated with rightdoing and wrongdoing are almost certainly innate and evolved by genetic multilevel selection. Finally, it should be obvious that wrongdoing remains as much a part of human nature as rightdoing, ready to surface in at least some individuals whenever the maintenance of social norms becomes lax. For this reason alone, human groups can never be axiomatically assumed to function as adaptive units.

Many of these principles that emerge from multilevel selection theory are supported by social psychology experiments that simulate social dilemmas (e.g., Ostrom et al. 1994). In a typical experiment, members of a newly created ten-person group are each given 10 dollars, which they can keep or anonymously put into a central pot where it will be doubled and redistributed to all members of the group. If everyone cooperates they can double their money. However, a single individual who defects keeps his or her 10 dollars and gets 18 dollars back from the central pot, providing a powerful incentive to cheat. If everyone cheats the benefits of group life are lost and no one increases their money. If a single individual cooperates in a group of cheaters, he or she gets a paltry two dollars for his or her investment of 10 dollars, providing a powerful incentive not to cooperate. This is the fundamental problem of social life in a nutshell.

Most people in this experiment initially display a moderate degree of generosity, putting about half their money into the pot, but there is variation around the average. As soon as they realize that others are cheating, the more generous members of the group become both angry and stingy. Of course, there is no outlet for anger within the framework of the experiment so the level of giving quickly drops to zero. In a modified version of the experiment, the members are allowed to contribute their money, not only to the first pot, but also to a second pot that is used to punish the cheaters. Those who contribute to the second pot are second-order public good providers. They enforce contributing to the first pot at their own expense. Nevertheless, when this outlet for righteous indignation is provided within the framework of the experiment, the second pot overflows with contributions!

Generalizing from these experiments, we can provisionally envision a human nature that is reluctant to give in ways that can easily be exploited but is willing and even eager to contribute to building and maintaining a social system that realizes the advantages of social life while preventing exploitation from within. Of course, a well-protected social system is required because at least some people, and perhaps all people some of the time, are inclined to exploit the generosity of others. Furthermore, the whole purpose of a group unified by a well-protected social system may be to exploit other groups. This complicated mix of rightdoing and wrongdoing, and behaviors that change their moral status depending upon the level at which they are viewed, may be the legacy of thousands of generations of multilevel selection operating on human populations that were subdivided into small foraging groups.

5. *Modern Human Groups as Adaptive Units*

A theory that explains small-scale human societies as (largely) adaptive units is an enormous advance over previous theories that seemed restricted to groups of genetic relatives and narrow reciprocators. However, more work is required to explain the nature of human societies at a scale above a few hundred or at most a few thousand individuals. Large-scale societies did not even exist before the advent of agriculture, which is a

short (although not negligible) period of time as far as genetic evolution is concerned (see Durham 1991, Wilson 1994 for discussions of genetic adaptations to modern environments). Nevertheless, this has not prevented cultural processes from creating a parade of new social forms that succeed or fail on the basis on their properties.

Superficially, large-scale human societies appear much less egalitarian than hunter–gatherer groups but the apparent inequalities can be interpreted in two very different ways. On the one hand, social control mechanisms are probably strongest in small groups in which everyone knows and depends on everyone else. Many inequalities that exist in large-scale societies are therefore exactly what they seem: some individuals profiting at the expense of others within the society. These inequities should not be interpreted as group-level adaptations but rather as individual-level adaptations with consequences that are often dysfunctional at the society level. On the other hand, purely from the group-level functional standpoint, societies must become differentiated and hierarchical as they increase in size. Thirty persons can sit around the campfire and arrive at a consensual decision. Thirty million persons cannot. It is therefore an open question whether extreme status differences and other seeming inequalities in large-scale societies represent pure and simple domination or design features that enable the society to function at a large scale, especially in competition with other societies. There can be little doubt that the scale of a society itself is a group-level adaptation. Larger societies tend to replace smaller societies unless their larger size is offset by problems of coordination and internal conflicts of interest. It is possible to imagine human history as a process of multilevel cultural evolution in which smaller groups coalesce into larger groups, just as for long-term biological evolution.

6. *Conclusion*

Despite its turbulent history, the concept of human groups as organismic units can be partially justified by multilevel selection theory. The implications extend the length and breadth of the social sciences; from cognition as a group-level process (Wilson 1997), to individual differences in prosocial and antisocial behaviors (Wilson et al. 1996), to historical and cultural studies (MacDonald 1994), to modern economic policy (Bowles and Gintis 1998). Social scientists have every reason to question the dominance of methodological individualism and to revisit the perspective of the originators of their own disciplines in the light of modern evolutionary theory.

Evolutionary Social Psychology

In 1908, McDougall's *Social Psychology* adopted an evolutionary perspective, following Darwin's (1872) suggestion that human social behaviors (including smiles, sneers, and other emotional expressions) were based in dispositions that helped our ancestors survive and reproduce. Evolutionary theory is founded on the idea of natural selection—that characteristics increasing chances of survival and reproduction proliferate because their bearers have more successful offspring. Characteristics well-suited to particular environmental demands are called adaptations. Evolutionary social psychology involves a search for evidence of adaptive mechanisms linked to human interaction.

Although people vary among themselves, both within and between cultures, certain regularities recur in human social interactions the world over. Members of all human groups communicate using complex spoken language, and share emotional expressions such as smiles and sneers, for example. Some social behavior patterns are unique to humans, some we share with many other species—the strong bonds between mammalian mothers and offspring, for instance. Similarly, other animals with slow-developing young often have biparental care of offspring, and other animals that live in small groups tend to have dominance hierarchies.

1. *General Principles Applying Across Species*

Evolutionary theorists search for principles applying across animal species. *Differential parental investment* refers to differences between parents in the amount of resources invested in offspring (Trivers 1972). As either sex increases investment in offspring, they become more selective about choosing mates. Members of the other sex consequently compete to be chosen. In mammals, females have an initially high investment (due to internal gestation and nursing). Because females in most mammalian species contribute substantially to offspring, they are in a position to choose among males demonstrating relatively superior health, attractiveness, or dominance. Hence, mammalian males, compared to females, tend to fight more among themselves, to be physically larger, and to possess more ornaments such as antlers. *Sexual selection* occurs when features are transmitted to offspring because they confer advantages in attracting the opposite sex (as in peacocks' feathers), or in competing with the same sex (as in rams' horns).

A central principle is *inclusive fitness maximization*—the idea that animals are designed not simply to survive and produce their own offspring, but to increase the probability their genes make it into future generations. Inclusive fitness explains many instances of apparently self-sacrificing behavior in animals. Ground squirrels who spot predators are more likely to make alarm calls if neighbors are closely related (Sherman 1981). By slightly increasing their own risk, humans and other animals can gain a net genetic benefit—saving other individuals with copies of their genes.

1.1 *Application to Human Social Behavior*

Evolutionary theorists mine these broad principles for insights about human behavior, and to make predictions about circumstances under which people will be more or less likely to manifest aggression, altruism, or courtship behaviors. For example, men are slightly larger than women and reach reproductive maturity at a later age. Women commit substantially fewer homicides or assaults than men, and male violence is predominantly directed at other males. Across animal species, these are hallmarks of differential parental investment and polygyny. Of 849 societies in the cross-cultural area files, polygyny (one male and multiple females) was either usual or occasional in 708, polyandry (one female and multiple males) was found in only four, and the remaining 137 were exclusively monogamous (Daly and Wilson 1983). Further, the circumstances associated with these variations follow principles found in other species (Daly and Wilson 1983, Crook and Crook 1988). For example, polyandry often involves brothers (who share genetic interests) living in resource-poor environments. Steep polygyny (as in harems) is found in circumstances of relative abundance, steep social hierarchy, and occasional famine (so a female's offspring have a better chance of surviving if she chooses an already married man from a wealthy powerful family over a single poor man). Although polygyny was an option across societies, most marriages are monogamous, because only highly successful men attracted multiple wives. Hence, ancestral males invested most of their reproductive effort in the offspring of a small number of

women (often one). As a consequence, human males are selective about long-term mates, and females will compete with one another for desirable males (Buss 1999, Kenrick and Trost 1993).

2. Cross-cultural Data

Because all human groups involve some common demands, evolutionary theorists assume that people the world over, despite cultural and ecological differences, share common human characteristics. Cross-cultural data reveal some general patterns consistent with principles of differential parental investment and sexual selection (Kenrick and Trost 1993). Adult males have killed one another many times more frequently than adult females in societies ranging from hunter-gatherers in remote jungles to urbanites in modern Asia and Europe, as far back as historical data are available (Daly and Wilson 1988). Likewise, women across societies place more emphasis than men on potential mates' resources and status (Buss 1999).

Other data on mate selection reflect a unique feature of human biology—females reach sexual maturity earlier than males, show a fertility peak in the twenties and early thirties, and then completely cease reproduction despite many remaining years of life. Consistent with this difference in reproductive lifespan, women are attracted to mates several years older than themselves, whereas men change relative preferences as they age. Young men are attracted to women their own age or older; older men prefer women much younger than themselves (Kenrick et al. 1996). These patterns are found around the world, with somewhat stronger sex differences in societies in which women begin reproducing earlier (Kenrick and Keefe 1992).

3. Experimental Data

Evolutionary principles can be used to generate experimental predictions. Experiments are not designed to test basic assumptions about natural selection, but to use the general principles as heuristics. For example, one team of researchers used inclusive fitness theory to generate predictions about helpfulness towards individuals varying in genetic relatedness (Burnstein et al. 1994). Experimental scenarios described helping situations ranging from small errands to rescuing someone in a burning building. For everyday helping, norms of politeness buffered discrepancies based on kinship and reproductive potential (grandmother was more likely to be helped than younger sister, for example). In life or death situations, however, help was focused more on closely related individuals with high reproductive potential (younger sister compared to grandmother or cousin, for example). Another series of studies examined how sex differences in mate selection criteria affect perceptual processes related to judgments of oneself and potential mates (Gutierres et al. 1999, Kenrick et al. 1994). Women rated commitment to male partners lower after exposure to socially dominant, but not physically attractive, men, whereas men's commitment showed the opposite effect. Conversely, women's self-ratings of their mating desirability were diminished more by physically attractive than by socially dominant women, with men's self-ratings showing the opposite effect (diminished by dominant, but not physically attractive men).

4. History and Future Directions

McDougall's (1908) *Social Psychology* assumed human social 'instincts.' The position was much misunderstood and abandoned without an empirical legacy. Decades later, European ethologists began successfully applying evolutionary models to social behaviors of nonhuman animals. In 1975, E. O. Wilson made a controversial suggestion that 'sociobiology' (the evolutionary analysis of animal social behavior) would eventually encompass the social sciences. This stimulated social psychologists to consider empirical applications to their field (e.g., Cunningham 1981). Part of the controversy about the approach stemmed from misunderstandings about genetic determinism. Human social behaviors vary across contexts and cultures, and social scientists assumed sociobiology implied rigid instincts insensitive to environments. Some protested that evolutionary hypotheses were untestable, or required researchers to study genetic biology or archaeology. Evolutionary theorists clarified that environmentally insensitive instincts based on deterministic genes are misconceptions, hardly relevant to invertebrates, much less to mammals (e.g., Alcock 1998, Kenrick 1995). The brains of complex animals contain not rigid programs, but environmentally sensitive psychological mechanisms (Buss and Kenrick 1998, Kenrick et al. 1998, Tooby and Cosmides 1992). Questions about testability were addressed with empirical data and competing evolutionary hypotheses (e.g., Graziano et al. 1997, Gangestad and Thornhill 1997). The position remains controversial, but has moved towards mainstream empirical science (e.g., Buss 1999, Crawford and Krebs 1998, Simpson and Kenrick 1997). Evolutionary psychologists assume the perspective could enrich research on any topic in social behavior, and that other areas of psychology including personality, psychopathology, and cognitive neuroscience are all linked by this perspective. Although the implications for mating behaviors and sex differences have been most thoroughly explored, evolutionary models have implications for understanding kinship and family relationships, intergroup relations, and social cognition. Evolutionary psychologists believe the Darwinian perspective is as relevant to the study of

human beings as it has been to the study of all other living species.

Evolutionary Theory and Education

1. Introduction

In recent years, Darwin's (1859) theory of evolution has guided the theoretical and empirical research of an increasing number of social and behavioral scientists, an approach that is often called evolutionary psychology. The goals here are to consider how evolutionary theory and research in evolutionary psychology can be used to understand children's academic development and to explore related educational issues. Before these issues can be fully appreciated, an overview of the evolutionary approach to cognition and development is needed.

2. Evolution and Cognition

One basic assumption of evolutionary psychologists is that natural selection has resulted in the evolution of cognitive competencies that facilitated the survival

and reproduction of our ancestors (Cosmides and Tooby 1994). It is further assumed that most of these competencies are modular and domain specific, that is, they are supported by neural and cognitive systems that are designed to process only certain types of information. For example, there are dedicated neural and cognitive systems that process basic language sounds (e.g., 'ba,' 'pa') and different systems that process other types of information, such as the visuospatial information involved in navigating in the environment. There are, of course, more general cognitive systems that coordinate and integrate the workings of these specialized systems (Smith and Jonides 1999), but research in evolutionary psychology tends to be focused on domain-specific cognitive modules, such as those associated with language.

The issues of modularity, domain specificity, and the number and organization of any associated cognitive systems are currently debated. Nonetheless, it is clear that there is some degree of inherent and modular structure to the human brain and mind, in keeping with evolutionary theory. The associated neural and cognitive systems appear to be designed to process information corresponding to the domains of folk psychology, folk biology, and intuitive physics (Geary 1998), although there are other modules as well (e.g., for basic numerical abilities; Geary 1995). The cognitive modules associated with folk psychology include language, theory of mind (e.g., being able to make inferences about the intentions of other people), and competencies that allow people to interpret the body language and facial expressions of other people. These skills allow people to monitor and regulate dyadic social interactions and to establish and maintain social relationships. The competencies associated with folk biology include the ability to classify flora and fauna in the local ecology, and learn about the associated growth and behavioral patterns (Atran 1998, Keil 1992). This folk biological knowledge allows people in preindustrial cultures to classify and categorize local species, hunt some of these species, and use plants as medicines, for food and social rituals. Intuitive physics refers to the neural and cognitive systems that engage the physical world, and enable people to navigate in 3-dimensional space; remember the location of objects in the environment, and use objects (e.g., stones) to make tools (Shepard 1994).

The inherent structure and functioning of these modules appears to be skeletal in nature (Gelman 1990). Early in life, the associated neural and cognitive systems direct attention to and the initial processing of domain-specific information, but the normal development of these systems requires input from the environment. Environmental input, in turn, shapes the development of these cognitive modules so that they are adapted, during childhood, to local conditions—nature provides the skeletal structure of evolved cognitive domains and this structure is fleshed out with experience. For example, it appears that children in all cultures are biologically prepared to process and respond to the sounds of all human languages, but the language that eventually emerges is the specific language to which they are exposed (Kuhl et al. 1997). In other words, the neural and cognitive systems that respond to language sounds—and later enable the comprehension and production of human language—are inherent, but the normal development and functioning of these systems requires exposure to language.

3. *Evolution and Development*

A long period of development, as is found in humans, has a clear risk—death before the age of reproduction—and thus would only evolve if there were benefits that outweighed this risk. Comparative studies suggest that one purpose, and an important adaptive benefit, of delayed maturation is the accompanying ability to refine the physical, social and cognitive competencies that support survival and reproduction. As an example, a long developmental period is found in all social mammals and the length of this period increases with the increases in the complexity of the species' social system (Joffe 1997). These patterns suggest that one purpose of childhood is to practice and refine sociocognitive competencies, such as language and other social skills. In short, delayed maturation allows children to practice and refine the physical, social, and cognitive skills associated with the survival (e.g., hunting) and reproduction (e.g., parenting skills) of our ancestors.

Play, social interactions, and exploration of the environment and objects appear to be the mechanisms through which these emerging competencies are practiced and refined during development. Child-initiated social play, exploration, and so forth are intimately linked to cognitive and neural development, in that these activities provide experiences with the social, biological, and physical world. These experiences, in turn, interact with the inherent, but skeletal structure of cognitive modules and ensure their normal development and adaptation to local conditions. In this view, children are biologically prepared to learn about other people, and the biological and physical world and are inherently motivated to seek out experiences that will facilitate this learning.

4. *Implications for Education*

A basic assumption of evolutionary psychology is that modern humans evolved domain-specific cognitive abilities and behavioral strategies to deal with conditions in the environments of our ancestors, but these abilities and strategies may not always be well-suited to contemporary conditions. In fact, much formal education is 'unnatural' in that much of what children

are expected to learn in school involves tasks never encountered by our ancestors (Geary 1995, Rozin 1976). The basic goals of schools and schooling are thus to organize the activities of children so that they acquire competencies, such as the ability to read, that are important in the wider culture but have no evolutionary history. There follows discussion on some of the basic issues that arise from this perspective of education.

4.1 Evolution and Academic Development

Geary (1995) referred to language and other evolved forms of cognition as biologically primary abilities, and skills that build upon these primary abilities but are principally cultural inventions (e.g., reading) as biologically secondary abilities. The mechanisms by which evolved systems are adapted to produce secondary competencies are not yet fully understood, but appear to involve the co-optation of primary systems for secondary learning and access to knowledge implicit in these primary systems (Geary 1995, Rozin 1976).

As an example of the former, consider the relation between language, a primary ability, and reading, a secondary ability. The acquisition of reading-related abilities (e.g., word decoding) appears to involve the co-option of primary language and language-related systems, among others (e.g., visual scanning; Rozin 1976). Wagner et al. (1994), reported that individual differences in the fidelity of kindergarten children's phonological processing systems, which are basic features of the language domain, are strongly predictive of the ease with which basic reading skills (e.g., word decoding) are acquired in first grade. In other words, the evolutionary pressures that are selected for phonological processing systems, such as the ability to segment language sounds, were unrelated to reading, but these systems are used, or co-opted, when children learn how to read.

As an example of the latter, consider that the development of geometry may have been initially based on access to knowledge implicit in the primary systems that support navigation in the physical world. In the development of the basic principles of classical geometry, Euclid apparently 'started with what he thought were self-evident truths and then proceeded to prove all the rest by logic' (West et al. 1982, p. 220). For example, the implicit understanding that the fastest way to get from one place to another is to go 'as the crow flies,' was made explicit in the formal Euclidean postulate, 'a line can be drawn from any point to any point (In Euclidean geometry, a line is a straight line)' (West et al. 1982, p. 221). From an evolutionary perspective, the former reflects an implicit understanding of how to quickly get from one place to another and is knowledge that is built into the neural and cognitive systems that support navigation. The latter was discovered, that is, made explicit, by Euclid. Once explicit, this knowledge was integrated into the formal discipline of geometry and became socially transmittable and teachable.

4.2 Motivation to Learn

One very important implication of the evolutionary perspective is that the motivation to acquire school-taught secondary abilities is based on the requirements of the larger society and not on the inherent interests of children. Given the relatively recent advent of near universal schooling in contemporary societies, there is no reason to believe that the skills that are taught in school are inherently interesting or enjoyable for children to learn. In other words, one important difference between primary and secondary cognitive abilities is the level and source of motivation to engage in the activities that are necessary for their acquisition. This does not, however, preclude the self-motivated engagement in some secondary activities.

Even though reading is a secondary ability that involves the co-optation of primary language systems, many children and adults are motivated to read. The motivation to read, however, is probably driven by the content of what is being read rather than by the process itself. In fact, the content of many stories and other secondary activities (e.g., video games, television) might reflect evolutionarily relevant themes that motivate engagement in these activities, such as social relationships and social competition. Furthermore, the finding that intellectual curiosity is a basic dimension of human personality (Goldberg 1993) suggests that there will be a number of intellectually curious individuals who will pursue secondary activities. Euclid's investment in formalizing and proving the principles of geometry is one example. However, this type of discovery typically reflects the activities and insights of only a few individuals, and the associated advances spread through the larger society only by means of informal (e.g., newspapers) and formal education. The point is, the motivation to engage in the activities that will promote the acquisition of secondary abilities is not likely to be universal.

4.3 Instructional Activities

The basic structure of primary abilities is inherent (Gelman 1990), that is, the supporting neural and cognitive systems automatically orient children to relevant features of the environment (e.g., other people) and process the associated information (e.g., facial expressions or language sounds). As noted above, children are inherently motivated to seek out

experiences, for example, through social play, that ensure the appropriate development of these primary systems. In contrast, there is no inherent structure supporting the acquisition of secondary abilities, nor are most children inherently motivated to engage in the activities that are necessary for secondary learning. While this conclusion might seem self evident, it runs counter to many assumptions about children's learning in contemporary education; for example, that children are inherently motivated to learn secondary abilities and will do so through activities that involve play and social discourse.

Thus, from the evolutionary perspective, one essential goal of schooling is to provide content, organization, and structure to the teaching of secondary abilities, features that have been provided by evolution to primary abilities. Moreover, it cannot be assumed that children's inherent interests, such as social relationships, and preferred learning activities, such as play, will be sufficient for the acquisition of secondary abilities, even though they appear to be sufficient for the fleshing out of primary abilities. Instruction must therefore involve engaging children in activities that facilitate the acquisition of secondary abilities, whether or not children are inherently interested in engaging in these activities. This does not mean that play and social activities cannot be used to engage children in some forms of secondary learning. It does, however, mean that it is very unlikely that the mastery of many secondary domains (e.g., reading or algebra) will occur with only these types of primary activities.

In fact, research in cognitive and educational psychology indicates that some forms of secondary learning will require activities that differ from those associated with the fleshing out of primary abilities (see Geary 1995, for related discussion). These would include, among others, direct instruction, where teachers' provide the goals, organization and structure to instructional activities and explicitly teach basic competencies, such as how to sound out unfamiliar words or manipulate algebraic equations. The mastery of secondary domains also requires extensive exposure to the material, distributed over many contexts and oftentimes over many years, as well as extensive practice in using any associated procedures (e.g., to solve mathematics problems). Extensive exposure and practice also appear to be needed for the development of primary abilities, but this exposure and practice automatically occur as children engage in social discourse, play, and exploration. In contrast, most children will not automatically engage in the practice needed to master secondary domains, and, as a result, this practice needs to be built into instructional activities. For some domains, such as in the biological and physical sciences, mastery will also require many 'hands on' activities, as in conducting experiments, although more traditional methods will be needed as well (e.g., learning basic facts and principles, such as the theory of evolution).

In closing, although not enough is known to draw firm conclusions about which instructional practices can most effectively adapt primary cognitive systems for the secondary learning, the following principles can be used to guide future educational research. First, the process of evolution has provided the basic neural and cognitive structure to primary abilities, such as language, but for secondary abilities, such as reading, this basic structure and organization must come from instructional practices. Second, children are inherently motivated to engage in the types of activities, such as social play, that will facilitate the development of primary abilities, but it is not likely that these same activities will be sufficient for the acquisition of secondary abilities. This is because the brain and mind are inherently designed to be sensitive to and respond to primary activities, as they are related to the development of primary abilities. It cannot be assumed that the brain and mind are equally responsive to the activities that are needed to master secondary competencies, nor can it be assumed that children are inherently motivated to engage in these activities. Finally, primary abilities are universal, but secondary abilities are culturally derived. Thus, educational research must be an on-going process designed to determine the most effective means of instruction for the ever-changing array of secondary competencies needed to function in contemporary society.

Evolutionary Theory, Structure of

1. *The Structure of Evolutionary Models*

Much of evolutionary theory is represented at the beginning of the twenty-first century through mathematical models, especially through the models of population genetics, of the evolution of states of a given system, both in isolation and interaction, through time. This is done by conceiving of the model as capable of a certain set of states—these states are represented by elements of a certain mathematical space, the state space. (Generally speaking, 'models' and 'systems' always refer to ideal systems; when the actual biological systems are being discussed, they are called 'empirical' or 'natural' systems.) The variables used in each mathematical model represent distinct measurable or potentially quantifiable, physical magnitudes. Classically, any particular configuration of values for these variables is a 'state' of the system, the 'state space' being the collection of all possible configurations of the variables.

The theory itself represents the behavior of the system in terms of its states: the rules or laws of the theory (i.e., laws of coexistence, succession, or interaction) can delineate various configurations and trajectories on the state space. A description of the structure of the theory itself therefore only involves the description of the set of models, which make up the theory.

Construction of a model within the theory involves assignment of a location in the state space of the theory to a system of the kind defined by the theory. Potentially, there are many kinds of systems that a given theory can be used to describe—limitations come from the dynamical sufficiency (whether it can be used to describe the system accurately and completely) and the accuracy and effectiveness of the laws used to describe the system and its changes. Thus, there are two main aspects to defining a model. First, the state space must be defined—this involves choosing the variables and parameters with which the system will be described; second, coexistence laws, which describe the structure of the system and laws of succession, which describe changes in its structure, must be defined.

Defining the state space involves defining the set of all the states the system could possibly exhibit. Certain mathematical entities—in the case of many evolutionary models, these are vectors—are chosen to represent these states. The collection of all the possible values for each variable assigned a place in the vector is the state space of the system. The system and its states can have a geometrical interpretation: the variables used in the state description (i.e., state variables) can be conceived as the axes of a Cartesian space. The state of the system at any time may be represented as a point in that space, located by projection on the various axes.

The family of measurable physical magnitudes, in terms of which a given system is defined, also includes a set of parameters. Parameters are values that are not themselves a function of the state of the system. Thus, a parameter can be understood as a fixed value of a variable in the state space—topologically, setting a parameter amounts to limiting the number of possible structures in the state space by reducing the dimensionality of the model.

Laws, used to describe the behavior of the system in question, must also be defined in a description of a model or set of models. Laws have various forms: in general, coexistence laws describe the possible states of the system, while laws of succession describe changes in the state of the system.

Let us discuss in more detail the description of the evolutionary models that make up evolutionary theory. The main items needed for this description are the definition of a state space, state variables, parameters, and a set of laws of succession and coexistence for the system. Choosing a 'state space' (and thereby, a set of state variables) for the representation of genetic states and changes in a population is a crucial part of population genetics theory.

Paul Thompson suggests that the state space for population genetics would include the physically possible states of populations in terms of genotype frequencies. The state space would be 'a Cartesian *n*-

space where 'n' is a function of the number of possible pairs of alleles in the population' (Thompson 1983 p. 223). We can picture this geometrically as n axes, the values of which are frequencies of the genotype. The state variables are the frequencies for each genotype. Note that this is a one-locus system; that is, we take only a single gene locus and determine the dimensionality of the model as a function of the number of alleles at that single locus.

Another type of single locus system, used less commonly than the one described by Thompson, involves using single gene frequencies, rather than genotype frequencies, as state variables. Some of the debates about 'genic selectionism' center around the adequacy of this state space and its parameters for representing evolutionary phenomena (see Lloyd 1988/1994, Chap. 7). With both genotype and gene frequency state spaces though, treating the genetic system of an organism as being able to be isolated into single loci involves a number of assumptions about the system as a whole. For instance, if the relative finesses of the genotypes at a locus are dependent on other loci, then the frequencies of a single locus observed in isolation will not be sufficient to determine the actual genotype frequencies. Assumptions about the structure of the system as a whole can thus be incorporated into the state space in order to reduce its dimensionality. Lewontin (1974) offers a detailed analysis of the quantitative effects of dimensionality of various assumptions about the biological systems being modeled.

Interactions between genotypes, and between one locus and another cannot be represented in a single locus model (with the exception of frequency-dependent selection), for the simple reason that they involve more than one locus (Lewontin 1974, pp. 273–81, Wimsatt 1980, pp. 226–9).

Although all single locus models should, in some sense, be grouped together, they are not all exactly the same model—each particular model has a different number of state variables, depending upon the number of alleles at that locus. Bas Van Fraassen suggests calling the general outline for each model its 'model type' (1980, p. 44). Because a model type is simply an abstraction of a model, constructed by abstracting one or more of the models parameters, a single model can be an instance of more than one model type.

Along similar lines, we may say that each model type be associated with a distinctive state space type. In the preceding example, the single locus model is to be taken as an instance of a general state space type for all single locus models, i.e., the different single locus model types are conceived as utilizing the same state space type. Alternatives, such as two-locus models, must be taken as instances of a different state space type.

'Parameters' are the values that appear in the succession and coexistence laws of a system that are the same for all possible states of the defined system. For instance, in the modification of the Hardy–Weinberg equation that predicts the frequencies of the genotypes after selection, the selection coefficient, s, appears as a parameter in the formula

$$p^2AA + 2pqAa + (1-s)q^2aa = 1 - sq^2$$

There are a variety of methods of establishing the value at which a parameter should be fixed or set in the construction of models for a given real system, e.g., simulation techniques can be used to obtain estimates of biologically important parameters. In some contexts, maximum likelihood estimations may be possible. Parameters can also be set arbitrarily, or ignored. This is equivalent to incorporating certain assumptions into the model for purposes of simplification (Levins 1968, pp. 8, 89).

One expects the values of parameters to have an impact on the system being represented; but variations in parameter values can make a larger or smaller amount of difference to the system. For instance, take a deterministic model that incorporates a parameter for mutation, μ. The rates of change of this model are virtually insensitive to realistic variations in the value of μ. Yet the selection parameters play a crucial role in this same model. A very small amount of selection in favor of an allele will have a cumulative effect strong enough to replace other alleles (Lewontin 1974, p. 267).

Population size is another case in which the value assigned to the parameter has a large impact on the model results. The parameter for effective population size, N, can play a crucial role in some models, because selection results can be quite different with a restricted gene pool size (Mayr 1967, pp. 48–50). In many of the stochastic models involved in calculating rates of evolutionary change, the resulting distributions and their moments can depend completely on the ratio of the mean deterministic force to the variance arising from random processes (Lewontin 1974, p. 268). This variance is usually proportional to $1/N$ and is related to the finiteness of population size. Thus, change in the value of the single parameter, N, can completely alter the structure represented by the theory.

The choice of parameters can also make a major difference to the model outcome. Theoreticians have choices about how to express certain aspects of the system or environment. The choice of parameters used to represent the various aspects can have a profound effect on the structure, even to the point of rendering the model useless for representing the empirical system in question. Group selection models provide a case in which choice of parameters not only alters the results of the models, but also leads to the near disappearance of the phenomenon being modeled (Wade 1978).

Some authors, when discussing genetic changes in populations, speak of the system in terms of a phenotype state space type. This makes sense, because the phenotype determines the breeding system and the action of natural selection, the results of which are reflected in the genetic changes in the population. In

his analysis of the present structure of population genetics theory, Lewontin traces a single calculation of a change in genetic state through both genotypic and phenotypic descriptions of the population. That is, according to Lewontin, population genetics theory must map the set of genotypes onto the set of phenotypes, give transformations in the phenotype space, and then map the set of phenotypes back onto the set of genotypes. We would expect, then, that descriptions of state in population genetics would be framed in terms of both genotypic and phenotypic variables and parameters. But this is not the case—the description can be in terms of either genotypic or phenotypic variables, but not both. Dynamically, then, it seems as if population genetics must operate in two parallel systems: one in genotype state space, one in phenotype state space (Lewontin 1974).

Lewontin explains that such independence of systems is illusory 'and arises from a bit of sleight-of-hand in which phenotype and genotype variables are made to appear as merely parameters that need to be experimentally determined, constants that are not themselves transformed by the evolutionary process' (1974, p. 15).

Now consider a few particular aspects and forms of the 'laws' used in these models. The most obvious differences, in laws as well as in state space types, are between deterministic and stochastic models. Coexistence laws describe the possible states of the system in terms of the state space. In the case of evolutionary theory, these laws would consist of conditions delineating a subset of the state space that contains only the biologically possible states. Laws of succession describe changes in the state of the system. In the case of evolutionary theory, dynamic laws concern changes in the genetic composition of populations.

The laws of succession select the biologically possible trajectories in the state space, with states at particular times being represented by points in the state space. The law of succession is the equation of which the biologically possible trajectories are the solutions. The Hardy–Weinberg equation is the fundamental law of both coexistence and succession in population genetics theory. Even the dynamic laws of the theory are usually used to assess the properties of the equilibrium states and steady state distributions. The Hardy–Weinberg law is a very simple, deterministic succession law that is used in a very simple state space. As parameters are added to the equation, we get different laws, technically speaking. For example, compare the laws used to calculate the frequency p' of the A allele in the next generation. Plugging only the selection coefficient against a recessive into the basic Hardy–Weinberg law, we get the recursion for the dominant allele frequency as $p' = p/(1-sq^2)$. Addition of parameters for the mutation rates yields a completely different law, $p'' = 1-\mu p' + vq'$, where μ is the rate of mutation away from the dominant allele, and where v is the rate of mutation towards it. We could consider these laws to be of a single type—variations on the basic Hardy–Weinberg law—which are usually used in a certain state space type. The actual state space used in each instance depends on the genetic characteristics of the natural system, and not usually on the parameters. For instance, the succession of a system at Hardy–Weinberg equilibrium and one that is not at equilibrium but is under selection pressure, could both be modeled in the same state space, using different laws.

A theory can have either deterministic or statistical laws for its state transitions. Furthermore, the states themselves can be either statistical or non-statistical. In population genetics models, gene frequencies that often appear in the set of state variables, thus the states themselves are statistical entities. In general, a law is deterministic if, when all of the parameters and variables are specified, the succeeding states are uniquely determined. In population genetics, this means that the initial population and parameters are all that is needed to get an exact prediction of the new population state.

In sum, the structure of evolutionary theory can be understood by examining the family of models it presents. In the case of population genetics theory, the set of model types—stochastic and deterministic, single locus or multilocus—can be understood as a related family of models. The question then becomes defining the exact nature of the relationships among them.

2. *Confirming and Testing Models*

The most obvious way to support a claim of the form 'this natural system is described by this model,' is to demonstrate the simple matching of some part of the model with some part of the natural system being described. For instance, in a population genetics model, the solution of an equation might yield a single genotype frequency value. The genotype frequency is a state variable in the model. Given a certain set of input variables (e.g., the initial genotype frequency value, in this case), the output values of variables can be calculated using the rules or laws of the model. The output set of variables (i.e., the solution of the model equation given the input values of the variables) is the 'outcome' of the model. Determining the fit between model and natural system involves testing how well the genotype frequency trajectory calculated from the model (the outcome of the model) matches that measured in the relevant natural (or experimental) populations. It can be evaluated by determining the fit of one curve (the model trajectory or coexistence conditions) to another (taken from the natural system); ordinary statistical techniques of evaluating curve-fitting are used.

Also, numerous assumptions are made in the construction of any model, and testing a model sometimes involves confirming some or all of these assumptions independently. These include assumptions about which factors influence the changes in the system, what the ranges for the parameters are, and what the mathematical form of the laws is. On the basis of these assumptions, the models take on certain features. Many of these assumptions thus have potential empirical content. That is, although they are assumptions made about certain mathematical entities and processes during the construction of the theoretical model, when empirical claims are then made about this model, the assumptions may have empirical significance.

For instance, the assumption might be made during the construction of a model that the population is panmictic, i.e., that all genotypes interbreed at random with each other. The model outcome, in this case, is still a genotype frequency trajectory, for which ordinary curve-fitting tests can be performed on the natural population to which the model is applied. But the model can have additional empirical significance, given the empirical claim that a natural system is a system of the kind described in the model. The assumption of panmixia, as a description of the population structure of the system under question, must be considered part of the system description that is being evaluated empirically. Evidence to the effect that certain genotypes in the population breed exclusively with each other (i.e., evidence that the population is not, in fact, panmictic) would undermine empirical claims about the model as a whole, other things being equal, and even if genotype frequencies provide good instances of fit. In other words, the assumption that genotypes are randomly redistributed in each generation is intrinsic to many population genetics model types. Hence, although the assumption that the population is panmictic often is taken for granted in the actual definition of the model type—i.e., in the law formula—it is interpreted empirically and plays an important role in determining the empirical adequacy of the claim.

By the same token, evidence that the assumptions of the model hold for the natural system being considered will increase the credibility of the claim that the model accurately describes the natural system. Technically, we can describe this situation as follows. From the point of view of empirical claims made about it, the model has three parts: state variables, empirically interpreted background assumptions, and those aspects and assumptions of the model that are not directly empirically interpreted. Because the possible outcomes of the model (along with the inputs) are actually values of the state variables, we can understand the input and outcome of the model as a sort of minimal empirical description of the natural system. If a model is claimed to describe accurately a natural system, at the very least, this means that the variables in which the natural system is described change according to the laws presented in the theoretical model. Under many circumstances, such models, in which only the state variables are empirically interpreted, are understood to be 'mere' calculating devices, because the isomorphism with the natural system is so limited.

Moreover, various aspects of the model—for instance, the form of its laws, or the values of its parameters—rely on assumptions made during model construction that can be interpreted empirically. The assumption of panmixia, discussed above, is an empirically interpreted background assumption of many population genetics models. Because it is empirically interpreted, the presence or absence of panmixia in the natural population in question makes a difference to the empirical adequacy of the model.

Finally, there may be aspects of the model that are not interpreted empirically at all. For instance, some parameters appearing in the laws might be theoretically determined and might have no counterpart in the natural system against which the model is compared.

Given that there can be aspects of the model structure that are not directly tested by examining the fit of the state variable curve, direct testing of these other aspects would give additional reason to accept (or reject) the model as a whole. In other words, it is taken that direct testing provides a stronger test than indirect testing, hence there is a higher degree of confirmation if the test is supported by empirical evidence. Direct empirical evidence for certain empirically interpreted aspects of the model that are not included in the state variables (and thus are confirmed only indirectly by goodness-of-fit tests), therefore provides additional support for the application of the model.

The above sort of testing of assumptions involves making sure that the empirical conditions for application of various parts of the model description actually do hold. In other words, in order to accept an explanation constructed by applying the model, the conditions for application must be verified. The specific values inserted as the parameters or fixed values of the model are another important aspect of empirical claims that can be tested. In some models, mutation rates, etc., appear in the equation—part of the task of confirming the application of the model involves making sure that the values inserted for the parameters are appropriate for the natural system being described. Finally, there is a more abstract form of independent support available, in which some general aspect of the model, for instance, the interrelation between the two variables, or the significance of a particular parameter or variable, can be supported through evidence outside the application of the model itself.

Lastly, variety of evidence, of which there are three kinds, is an important factor in the evaluation of empirical claims. I discuss three kinds of variety of

evidence here: (a) variety of instances of fit; (b) variety of independently supported model assumptions; and (c) variety of types of support, which include fit and independent support of aspects of the model.

First, let us consider variety of fit, that is, variety of instances in which the model outcome matches the value obtained from the natural system. Traditionally, variety of evidence has meant variety of fit. There are two issues that must be distinguished when considering the variety of fit. One involves the range of application of a model or model type, while the other involves the degree of empirical support provided for a single application. Both of these issues involve the notion of independence, which needs to be clarified before continuing.

One point of any claim to variety of evidence is to show that there is evidence for the hypothesis in question from different or independent sources. The notion of independence here is problematic. It is not the sort of independence that is found in the frequency interpretation of probability theory, where the independence depends only on accepting a particular reference class. Rather, in the context of scientific theories, independence is relative to whatever theories have already been accepted.

In evolutionary theory, independence is usually relative to some assumption about natural kinds. Often, empirical claims are made to the effect that a model is applicable over a certain range of natural systems. Inherent in these claims is the assumption that all of the natural systems in the range participate in some key feature or features that make it possible and/or desirable to describe them all with the same model type. Thus, there is some assumption of a natural kind (characterized by the key feature or features) whenever range of applications arises. The scientist, in making a claim that the model type is applicable to such and such systems, is making an empirical assumption about the existence of the key feature or features in the range of natural systems under question. Hence, for evolutionary models, testing for variety of fit depends on accepting an assumption about what constitutes different or independent instances of fit; this in turn, amounts to accepting a particular view of natural kinds. Part of what variety of evidence does, in a bootstrapping effect, is to confirm this original assumption about natural kinds. More technically, variety of evidence confirms the sufficiency of the parameters and state space.

Take the case in which a model type is claimed to be applicable over a more extended range than that actually covered by available evidence. This extrapolation of the range of a model can be performed by simply accepting or assuming the applicability of the model to the entire range in question. A more convincing way to extend applicability is to offer evidence of fit between the model and the data in the new part of the range. Provision of a variety of fit can thus provide additional reason for accepting the empirical claim regarding the range of applicability of the model.

For instance, a theory confirmed by ten instances of fit involving populations of size 1,000 (where population size is a relevant parameter) is in a different situation with regard to confirmation than a theory confirmed by one instance of each of ten different population sizes ranging from 1 to 1,000,000. If the empirical claims made about these two models asserted the same broad range of applicability, the latter model is confirmed by a greater variety of instances of fit. That is, the empirical claim about the latter model is better confirmed, through successful application (fits) over a larger section of the relevant range than the first model. Variety of fit can therefore provide additional reason for accepting an empirical claim about the range of applicability of a model. Variety of fit can also provide additional reason for accepting a particular empirical claim, i.e., one of the form, 'this natural system is accurately described by that model.' That is, variety of evidence can serve to increase confidence in the accuracy of any particular description of a natural system by a model.

Variety of fit is only one kind of variety of evidence. An increase in the number and kind of assumptions tested independently, i.e., greater variety of assumptions tested, would also provide additional reason for accepting an empirical claim about a model. The final sort of variety of evidence involves the mixture of instances of fit and instances of independently tested aspects of the model. In this case, the variety of types of evidence offered for an empirical claim about a model is an aspect of confirmation.

According to the view of confirmation sketched above, claims about models may be confirmed in three different ways: (a) through fit of the outcome of the model to a natural system; (b) through independent testing of assumptions of the model, including parameters and parameter ranges; and (c) through a range of instances of fit over a variety of the natural systems to be accounted for by the model, through a variety of assumptions tested, and including both instances of fit and some independent support for aspects of the model.

Evolutionism, Including Social Darwinism

Evolutionism, the view that present structures and behaviors develop naturally over long periods of time, has taken two forms over the past two centuries. Nineteenth century 'classical evolutionism' (Sanderson 1990) was essentially endogenous, progressionist, and unilinear, that is, it pictured a developmental unfolding of pre-existing tendencies from lower to higher stages along similar lines. In the *Origin of Species* (1859) Charles Darwin instead stressed mechanism (natural selection) over cosmic laws; external (exogenous) pressures over internal tendencies; and a divergent or branching model of change. Whereas classical evolutionists viewed change as the logical outcome of universal laws, Darwin explained it in terms of responses to specific, historical circumstances. Social evolutionist and social selectionist theories apply these biological models to human society and behavior, directly and by analogy. Although social evolutionism and social selectionism are conceptually distinct from one another, and from social organicism and hereditarianism, critics of biologized social theory charge that all are varieties of social Darwinism.

1. Classical Evolutionism: The Nineteenth Century

Evolution in biology first appeared in Erasmus Darwin's *Zoonomia* (1794–6), Jean Baptiste Lamarck's *Philosophie Zoologique* (1809), and Robert Chambers' *Vestiges of the Natural History of Creation* (1844). Lamarck, the most important of the three, argued that traits acquired during an individual's lifetime may be passed to future generations through use-inheritance, a view many biologists embraced into the twentieth century. Although Lamarck held other views equally alien to modern biology (for example, that organisms consciously will changes in their bodily structure), Lamarckianism provided the basis for the social evolutionism that emerged after 1850.

1.1 Social Evolutionism

Varieties of social evolutionism emerged separately during the late eighteenth and early nineteenth centuries, initially in the work of the Scottish philosophers John Millar and Adam Ferguson and of the French theorists Marquis de Condorcet and A.R.J. Turgot. An anti-Enlightenment reaction after 1815 produced somewhat different versions of evolutionism in the work of Claude Henri St. Simon and Auguste Comte. Georg F. Hegel and Karl Marx contributed a third strain of evolutionism destined to play a major role in shaping events in the twentieth century.

The chief representative of the classical social evolutionism of the late nineteenth century was the British philosopher Herbert Spencer. In *Social Statics* (1851) and an essay *Progress* (1857) Spencer described evolution as a redistribution of matter and motion whereby all natural objects (including living organisms) develop from the simple (homogeneous) to the complex (heterogeneous), finally achieving equilibrium with their environment. In *First Principles* (1862) he launched a multivolume *Synthetic Philosophy*, surveying all knowledge from the perspective of evolution. In *The Principles of Biology* (1864–7) he substituted the phrase 'survival of the fittest' for Darwin's 'natural selection,' thus assuring readers that evolution is progressive.

1.2 Evolutionism in Anthropology

Although Spencer gained little following among British or American university professors, other writers won evolutionism academic respectability in the emerging social sciences. In *Ancient Law* (1861), the British jurist Sir Henry Maine traced the movement from 'status' to 'contract' as the legal basis of society from the ancient to the modern era. In *The Origin of Civilisation and the Primitive Condition of Man* (1870) the English naturalist and politician Sir John Lubbock presented prehistoric cultures as part of human social development. In *Researches into the Early History of Mankind* (1865) and later works, Edward B. Tylor, the founder of British anthropology, proposed that certain items of culture are carried as 'survivals' into later social stages. In *Ancient Society*

(1877), a study of American Indians, the American anthropologist Lewis Henry Morgan argued that human history proceeds from savagery to barbarism to civilization, each identified by its stage of technology.

The classical evolutionists' terminology registered their commitment to progress ('barbarism,' 'civilization,' 'fittest') but each insisted that progress was a mixed blessing. Although a champion of *laissez faire*, Spencer conceded that industrialism was 'extremely detrimental' to workers (Peel 1971, p. 216) and criticized the militarism and imperialism of late Victorian England. Tylor stated unequivocally that material progress did not automatically result in moral and political gain. None argued that all societies move without exception through identical stages but only that they develop along roughly similar lines—a loose unilinearism at best.

1.3 Darwinism

In the *Origin of Species* (1859) Charles Darwin focused on speciation rather than evolution in general, arguing that all species develop through a process of natural selection in a struggle for existence. Since individuals vary within species, the better adapted tend to survive and produce more offspring. New species result from changes in conditions and splits in populations. Selection operates on individuals not groups or races, selecting variations, not varieties. Although small and gradual, selected variations do not disappear due to reversion to an original type as critics contended. Individualism and gradualism remained the hallmarks of twentieth century Darwinism.

Darwin unlike Spencer did not view evolution as an *a priori* deduction from general laws. But vestiges of an older evolutionism lingered. Darwin's use of the term evolution and his eventual adoption of Spencer's phrase survival of the fittest suggested a progressionism alien to his own theory. His doctrine of 'sexual selection' echoed Lamarckian agency. Unanswered questions compounded the problem. Physicists argued that the earth was not sufficiently old to allow changes numerous enough to create so many species. Biologists insisted that minor variations in organisms would cancel out. To this last charge Darwin had no reply, being unaware of the genetic theory of mutations formulated by Gregor Mendel in 1869 but unknown in scientific circles until 1900. These vestigial assumptions and unanswered questions left an opening for pseudo-Darwinisns who publicly praised the *Origin* but ignored or muted natural selection.

1.4 Social Darwinism

The result was doubly ironic. The first irony was that Darwin helped legitimate an older tradition of evolutionism even though the vast majority of scientists, clergy, and laypersons rejected his central doctrine. Widely accepted by the 1870s, this pseudo-Darwinian evolutionism was a teleological developmentalism closer in spirit to Larmarck than to Darwin. The second irony was that Darwin's name—in the pejorative phrase 'social Darwinism'—became widely associated with attempts to relate social development to biology or even to 'natural law,' whether or not the theory in question owed any debt to Darwin. This epithet first surfaced about 1880 in the writings of socialists in Italy and France, and by the 1890s appeared in political debates in the USA and Britain.

Darwin's double-edged reputation explains the apparent determination of classical evolutionists to distance themselves from Darwinism. Although Maine, Morgan, and Tylor occasionally used the terms 'struggle,' 'fitness,' and 'natural selection' these passing references showed only that Darwin and his contemporaries shared a common milieu and, in some cases, a common debt to the British economist Thomas Robert Malthus, whose *Essay on the Principle of Population* (1798) was one source of Darwin's theory. In coining the phrase 'survival of the fittest,' Spencer attempted to reconcile the *Origin of Species* with his developmentalism. Tylor, in the preface to the second edition of *Primitive Culture*, insisted that the study followed 'on its own lines' (Sanderson 1990, p. 30) rather than being derived from Darwin or Spencer.

The celebrated opposition of Yale professor William Graham Sumner and the Smithsonian scientist Lester Frank Ward in the 1880s underscored these ironies. A leading advocate of *laissez faire*, Sumner based his economics on the Malthusian struggle of people against nature. In the early 1880s, he assigned his students Spencer's *Study of Sociology* and occasionally stated that the alternative to the survival of the fittest was the 'survival of the unfittest,' meaning that economic competition maximized success in the collective struggle against nature. His use of Spencer, still considered subversive at Yale, almost cost him his job, while his rhetoric brought immediate criticism and eventually a reputation as America's leading 'social Darwinist.' The irony was that Sumner distrusted all metaphysics and had little use for Spencer's evolutionism. In the face of criticism, he quickly dropped references to the 'unfittest' and remained ignorant of Darwin's work until late in his career. *Folkways* (1906), Sumner's sociological masterpiece, was neither evolutionist nor social selectionist.

Lester Ward, the founder of American sociology, argued in *Dynamic Sociology* (1883) and *The Psychic Factors of Civilization* (1893) that, whereas blind struggle and selection are laws of nature, the appearance of the human mind allows conscious direction of previously wasteful forces. A prominent neo-Lamarckian, Ward made use-inheritance the basis of his faith in education and advocated a 'sociocracy' in which social scientists direct public policy. Although

historians later termed Ward a 'reform Darwinist,' in tribute to his evolutionist arguments for positive government, 'social Lamarckian' is a more appropriate description.

2. Challenge and Crisis 1890–1920

Renewed interest in natural selection after 1890 altered the discussion. Attempts to demonstrate natural selection statistically, begun by Francis Galton in the 1870s, paid off in William Weldon's study of crabs (1894), the first demonstration of natural selection in nature. The Austrian biologist August Weismann argued that the egg and sperm are immune from environmental influences, making natural selection the sufficient cause of evolution. Although flawed by later standards, this 'neo-Darwinism' (as opponents and then supporters soon labeled it) undermined the tacit compromise many pseudo-Darwinians had effected between Larmarck and Darwin. The rediscovery of Mendel's laws in about 1900 by Hugo DeVries and others provided a missing key to understanding inheritance.

Ironically, however, these discoveries resulted in a temporary 'eclipse of Darwinism,' despite the now well-established belief in evolution. A school of neo-Larmarckians arose to challenge Weismann. Other anti-Darwinians defended orthogenesis, the view that evolution results from internally generated variations that are nonadaptive and immune to selection, the result potentially being the extinction of a species. Mendel's mutations, although later a building block of modern Darwinism, were seen initially as a sufficient explanation of evolution, not materials for selection. An acrimonious battle between Mendelians and biometricans, a group of statistically minded Darwinians, muddied the waters, the central issue being whether variation was sporadic and discontinuous or gradual and continuous.

2.1 Sociology and Anthropology

In American and British sociology, social and selectionist evolutionism continued to flourish. In *The Principles of Sociology* (1896), Franklin Giddings of Columbia University (New York) described social evolution as a threefold process of aggregation, association, and selection, a view perpetuated in *An Introduction to the Theory of Social Evolution* (1913) by a Giddings student, F. Stuart Chapin. In *Societal Evolution* (1915) and *The Science of Society* (1927) Sumner's protégé and successor Albert G. Keller argued that folkways and mores (Sumner's terms) were the result of variation, selection, and cultural transmission. Leonard T. Hobhouse, professor of sociology at London University, explored the evolution of mind in human history in *Mind in Evolution* (1901), *Morals in Evolution* (1906), and *Social Evolution and Political Theory* (1911).

But reaction was already underway. In Europe, the sociologists Max Weber and Émile Durkheim in different ways treated societies and cultures as discrete entities not to be evaluated by comparison with others or ranked hierarchically. Giddings himself gradually abandoned evolutionism for a rigorously objective sociology grounded in statistics, a battle led during the 1920s by his students Chapin and William Fielding Ogburn. Since the probabilistic thinking at the heart of this 'new statistics' was itself a legacy of Darwinism, evolutionism can be said to have contained the seeds of its own demise.

In anthropology Franz Boas and his disciples meanwhile attacked classical evolutionism for its use of the comparative method, for underestimating the role of cultural diffusion, and for ranking cultures from lower to higher. In the interwar years, Boasian cultural relativism informed such popular classics as Margaret Mead's *Coming of Age in Samoa* (1928) and Ruth Benedict's *Patterns of Culture* (1934).

2.2 Evolutionism and Social Reform

Evolutionism also shaped political debate from the 1880s to 1920. In *Cooperative Commonwealth* (1884), Laurence Gronlund combined Marx and Spencer to advocate socialism. In *Looking Backward* (1888), Edward Bellamy popularized a tradition of evolutionary Utopianism that later included Charlotte Perkins Gilman's *Herland* (1915). After 1890, selectionist language shaped discussion of race and gender. Science, wrote Tulane professor William Smith in *The Color Line* (1905), showed that the heights of civilization had been achieved through the 'Selection … of favored individuals and favored races' (Bannister 1979, p. 193). Whereas in *Physics and Politics* (1872) the British journalist Walter Bagehot described international competition in terms of cultural selectionism, a new breed of militarists and imperialists depicted a physicial and often bloody struggle. After 1900, eugenicists increasingly invoked Darwinian rhetoric of struggle and selection to support measures that ranged from stricter marriage laws to sterilization of the 'unfit.'

Although these new manifestations of social Darwinism (as it was now widely termed) may appear at odds with the temporary eclipse of Darwinism in biology, the appearance is deceptive and the label inaccurate. Racism and militarism were established traditions in nineteenth century thought and continued to flourish independently of any Darwinian references. Although Darwin himself sometimes echoed the racist views of contemporaries, he insisted that neither Lamarckian adaptation nor natural selection explained racial differences. Prominent racialists and even eugenicists were often outspoken anti-

Darwinians, for example Arthur de Gobineau, author of *The Inequality of the Human Races* (1853–5) and American eugenicist Charles B. Davenport, an early Mendelian. Many self-proclaimed Darwinians opposed racism and militarism. 'Peace eugenicists' stressed war's dysgenic function in killing the ablest of a nation's male population.

Darwinian metaphors, in fact, typically prefaced proposals to avoid the consequences of uncontrolled natural selection, drawing on long-standing distrust of this aspect of Darwin's theory. American and British reformers argued for government regulations and welfare measures on the ground that *laissez faire* was nothing more than a Darwinian struggle. Others called for more extreme forms of order imposed by the state: in colonial policy, sterilization laws, legalized racial segregation, or, for some socialists, in public ownership and an end to private property.

A few prominent social Darwinists were recognized extremists whose Darwinism was barely skin deep, for example Friedrich von Bernhardi author of *Germany and the Next War* (1914). When war came, the fact that Germanic names such as Ernst Haeckel and Weismann were prominently associated with extremes of Darwinism gave the charge new power. Even Friedrich Nietzche, a philosopher who rejected Darwinism, was included in the ranks of the social Darwinists. In the interwar years, and again during WW II, the phrase social Darwinism proved to be a powerful weapon against evolutionism and selectionism in the social sciences and in popular discourse.

3. *1920s–1990s: Revival and Controversy*

In the interwar years, developments in biology paved the way for a revival of evolutionism and selectionism. Combining Mendel, Darwin, and population genetics, biologists viewed evolution as acting less on individual organisms than on gene frequencies within populations, mutations providing the materials for selection rather than being the sole source of evolutionary change. This 'modern synthesis' was articulated in Theodosius Dobzhansky's *Genetics and the Origin of Species* (1937), Ernst Mayr's *Systematics and the Origin of Species* (1942), Julian Huxley's *Evolution, The Modern Synthesis* (1942), and George Gaylord Simpson's *Tempo and Mode in Evolution* (1944). In 1953, James Watson and Francis Crick successfully constructed a molecular model of DNA. In works such as Crick's *Of Molecules and Men* (1966), Jacques Monod's *From Biology to Ethics* (1969) and Francois Jacob's *The Logic of Life* (1973), these molecular biologists reduced all life to the impersonal operations of coding, copying, selection, and survival.

The newly professionalized field of ethology, the comparative study of human and animal behavior, furthered the rebiologizing of social theory. Influenced by the earlier work of Konrad Lorenz as summarized in *On Aggression* (1966), ethologists and anthropologists provided accounts of territoriality and aggression among humans in such best-selling books as Robert Ardrey's *The Territorial Imperative* (1966), Desmond Morris's *The Naked Ape* (1967), and Lionel Tiger's *Men in Groups* (1969).

Neuropsychologists meanwhile explored the link between physical states of the brain and human behavior, while behavioral geneticists identified mutations that affect behavior. In 1964, William Donald Hamilton coined the terms 'inclusive fitness' and 'kin selection' to explain patterns of animal behavior that contribute to group genetic fitness (the flocking of birds, for example, or sterile cases of insects) in Darwinian terms without resorting to 'group selection.'

3.1 *Revival in Anthropology*

In the social sciences, evolutionism and Darwinian selectionism re-emerged independently. In anthropology, social evolutionism in the 'classical' mode first resurfaced in V. Gordon Childe's, *Man Makes Himself* (1936) and *What Happened in History* (1942), and in Julian Steward's *Theory of Cultural Change* (1955). Unlike their nineteenth century predecessors, these social evolutionists were consistently materialist; eschewed an unfolding model of social change in favor of ordinary causal explanations; stressed exogenous as well as endogenous factors; and employed the comparative method judiciously. After 1960, a younger generation of anthropologists continued to work in this materialist tradition, among them Marshall Sahlins and Elman Service in *Evolution and Culture* (1960) and Marvin Harris in *Cannibals and Kings* (1977) and *Cultural Materialism* (1979).

Other anthropologists called for a return to social selectionism. Writing in 1965, Donald Campbell distinguished theories that explain the 'mechanism' of change from those that merely describe its 'fact and course,' calling his version of the former the 'variation-and-selective-retention model' (Sanderson 1990, p. 170). Although cultural variations are random, Campell argued, the cumulative effects are increasingly complex, better-adapted sociocultural forms. In *Cultural Transmission and Evolution* (1981), an ambitious example of cultural group selectionism, L. Luca Cavilli-Sforza and Marcus W. Feldman of Stanford proposed that sociocultural variations are often directed and purposeful, making their case with sophisticated mathematical modeling. In both versions, the concept of fitness was purely cultural, not biological as with sociobiology.

3.2 *Sociological Neoevolutionism*

Evolutionism and selectionism emerged belatedly and more reluctantly in sociology, a bastion of opposition to all forms of biologized social theory since the 1920s.

From the 1960s to the 1980s, sociologists Robert Nisbet and Anthony Giddens led the attack against classical and contemporary evolutionist theories (Nisbet 1969, Giddens 1984). However, in *Social Change in the Industrial Revolution* (1959), Neil Smelser offered an evolutionist explanation of modernity based on a model he developed with Talcott Parsons. Parsons extended the analysis in *Societies* (1966) and *The System of Modern Societies* (1971), the fullest statements of sociological 'neoevolutionism,' so labeled because of Parsons' efforts to distance himself from the classical evolutionism of Spencer. Avoiding all reference to cosmic law, Parsons explained that societies, as goal-oriented systems, adapt to changing environment through 'structural differentiation' and 'adaptive upgrading.' Although Parsons denied that his system was progressionist, idealist (in the sense of privileging values and ideas as causative factors), or unilinear, critics argued that his theory was teleological and ethnocentric. By the early 1970s, Parsonian neoevolutionism virtually disappeared, although a decade later there were signs of a 'Parsons revival' in Jeffrey C. Alexander's *Theoretical Logic in Sociology* (1983, Vol. 4) and Niklas Luhmann's *The Differentiation of Society* (1982).

Selectionism proved an even harder sell in sociology. Historically, Marxist sociologists rejected selectionist analogies despite the efforts of Friedrich Engels and others to give Marxism a Darwinian twist. Among non-Marxists, Max Weber rejected social selection (*soziale Auslese*) as having no explanatory value. Methodologically, sociologists could not see how Darwinian theory related to industrialization, stratification, social mobility, and other problems they addressed. In 1998, however, British sociologist Walter G. Runciman, in the wake of the success of sociobiology, called for a sociological rethinking of the 'selectionist paradigm' (Runciman 1998).

After the mid-1970s, the best-known and most controversial application of Darwinian selectionism to human society was sociobiology. In *Sociobiology: The New Synthesis* (1975) Harvard entomologist and population geneticist Edward O. Wilson presented an extreme version of genetic selectionism wherein the organism is, in a widely quoted phrase, 'only DNA's way of making more DNA.' Altruism serves this end, Wilson argued. Although he devoted only one chapter of *Sociobiology* to human behavior, Wilson expanded the ethical and political implications in his Pulitzer prize-winning *On Human Nature* (1978). Sociobiology was further popularized in David P. Barash's *Sociobiology and Behavior* (1977), Richard Dawkins's *The Selfish Gene* (1976), and Richard Alexander's *Darwinism and Human* Affairs (1979).

Criticism quickly followed. A Boston-based Sociobiology Study Group, Marxist in orientation, combined some reasonable questions regarding Wilson's biological reductionism with *ad hominem* attacks linking him to Nazi racial science and other forms of social Darwinism. In *Use and Abuse of Biology* (1976), Marshall Sahlins, having repudiated his earlier support of cultural evolutionism, launched a similar attack on the concept of 'kin selection.'

By the early 1980s, sociobiologists were exploring the interaction of genes and culture, soon termed coevolutionism, the best-known examples being Wilson and Charles J. Lumsden's *Genes, Mind, and Culture* (1981) and Robert Boyd and Peter J. Richerson's *Culture and the Evolutionary Process* (1985). Although Wilson argued that culture is important in its own right, one critic characterized coevolutionism as 'sociobiology in drag' (Sanderson 1990, p. 175) since the entire process appeared biased toward the biological.

In the 1980s, biologists resumed debate of evolutionism and selectionism. In 1968 the Japanese population geneticist Motoo Kimura launched a 'neutral theory' of the evolution of proteins, expanded in *The Neutral Theory of Molecular Evolution* (1983). Kimura demonstrated that protein formation and gene function are controlled by a regular, continuous process relatively immune to natural selection. Meanwhile, other biologists argued that entire species might be units of selection rather than outcomes of it *and* that speciation occurs sporadically and cataclysmically, not continuously and gradually, a theory of 'punctuated equilibrium' first proposed by Harvard professors Stephen Jay Gould and Niles Eldredge in 1972.

During the 1990s the evolutionist divide deepened. Anti-Darwinians under the banner of 'intelligent design' seized upon the debate among biologists to mount a new crusade. In *Darwin on Trial* (1991) Phillip E. Johnson mounted scientific arguments sufficiently sophisticated to draw a lengthy rebuttal from Gould (1992 *Scientific American* **267**:118–21). In *Darwin's Black Box* (1996), Michael J. Behe, a biologist at Lehigh University, argued that gradual, undirected evolution could not explain cellular biochemistry's 'irreducibly complex' adaptive systems.

Darwinians also pushed their arguments to new extremes. Under the banner 'evolutionary psychology' academic contributors to John Barkow et al. The Adapted Mind (1992) called for renewed study of the human mind within a Darwinian framework, an argument popularized in Matt Ridley's *The Origins of Virtue* (1997) and Steven Pinker's *How the Mind Works* (1997). British zoologist Richard Dawkins followed *The Selfish Gene* with *The Blind Watchmaker* (1986), *River Out of Eden* (1995), and *Climbing Mount Improbable* (1996), in which he explained how natural selection could produce the improbable perfection evidenced in the human eye.

Just as earlier theorists were branded and dismissed as neo-Darwinists and social Darwinists, so these new selectionists were termed 'ultra-Darwinists' or 'ultra-social Darwinists' (*Wilson Quarterly* 1996). Although the Darwinian modern synthesis continued to enjoy widespread support among mainstream biologists,

cultural and political opposition to biological and social evolutionism remained almost as strong as a century earlier.

Exchange in Anthropology

The terms 'gift' or 'reciprocal exchange' are used to describe the forms of exchange that anthropologists traditionally have described and analysed. These forms of exchange coexist with market exchanges such as barter, buying and selling, and money lending. Exchanges of the latter type have been the traditional concern of economists but anthropologists have also produced detailed ethnographic descriptions of markets, especially the periodic market systems found in rural areas around the world. There has been much debate in the anthropological literature about the defining characteristics of gift exchange systems, how they are distinguished from commodity exchanges, and of the manner in which they articulate with the market exchanges both locally and globally.

This article focuses on nonmarket exchanges and consists of four parts: the first examines exchange as a general concept and defines some key terms; the second looks briefly at the history of anthropological theories on the subject; the third presents some illustrative examples; and the fourth examines some attempts to understand the historical transformation of gift exchange systems in the context of globalization.

1. *The Concept of Exchange*

An exchange can be defined as a *transaction* that is *reciprocated*. A *transaction* is the process whereby one transactor transfers an object to another transactor. This can be represented formally, as

$$A \xrightarrow{x} B \qquad (1)$$

where A is the giver, B the receiver, and x the object transferred.

Reciprocation is the process whereby the initial transaction is reversed such that the receiver becomes the giver. This can be represented formally as

$$A \xleftarrow[y]{} B \qquad (2)$$

where A is now the receiver, B the giver, and y the object reciprocated. The reciprocation can be *simultaneous* in time or *delayed*. When it is *simultaneous* it takes the classic form of an exchange

$$A \underset{y}{\overset{x}{\rightleftarrows}} B \qquad (3)$$

where A gives B the object x in exchange for the object y. When the reciprocation is *delayed* in time it is called a delayed exchange. Exchanges, whether simultaneous or delayed, define three distinct relations—*value*, *property*, *and social*—the significance and meaning of which will vary depending on the social context.

Value relations refer to those that hold between the objects and can be expressed formally as x:y. These relations may be quantitative or qualitative and involve either the same object or a different object. If the qualitative dimension is held to be more significant, as it is in many culturally specific contexts, the size, shape, color, age, and history of an object is more important than the number given. Most gift exchanges involve valuations of this kind. They are analogous to that between playing cards where we find, for example, that a ten of clubs has a higher qualitative rank than a five of clubs rather than being twice its quantitative size.

Property relations refer to those relations that hold between the object and the person giving it; they can be expressed formally as A:x and B:y. Market exchanges involve private property rights that give the possessor the legal right to alienate the object in question. The exchanges that anthropologists study often involve different forms of nonprivate property rights of a personal, inalienable kind. Objects of this kind can be detached and given away but the sentimental bond between the giver and the object is often deemed not to be broken. An example here is the exchange of hair that young children sometimes make to affirm a friendship.

Social relations refer to those that hold between the transactors to an exchange. The transactors can be kin, friends, or strangers. The purpose of an exchange may be to reproduce existing relations, to break them, or to create new relations; in other cases the purpose of an exchange may be to obtain an object of utility rather than to create social relations.

Anthropological studies of exchange have tended to concentrate on those exchanges that involve qualitative value relations rather than quantitative ones, on those concerned with inalienable property relations rather than private property, and on those concerned with the establishment of social relations rather than the quest for an object of utility. This is the theore-

tical domain that the theory of reciprocity and the gift has tried to illuminate.

2. Anthropological Theories of Exchange

Anthropological theories of exchange arose out of the attempt to present a synthetic account of the pioneer ethnographic research of scholars such as Boas (1897) and Malinowski (1922) at the turn of the twentieth century. These theories, in turn, were modified and developed by subsequent ethnographic research in different historical and political contexts.

Boas (1897) described the spectacular *potlatch* of the Kwakiutl people of northwest America. This is a system of competitive gift giving among chiefs where one chief struggles to outdo a rival by out-giving him. The competition sometimes ended with chiefs destroying large amounts of property.

Malinowski (1922) described the equally spectacular *kula* system of the people of the Milne Bay area of Papua New Guinea. Here, people went on overseas expeditions to exchange high ranking armshells for necklaces.

The incremental giving in the *potlatch* system bore formal resemblance to market transactions involving interest and Boas himself used this term to describe it. The *kula*, for its part, had formal similarities with barter exchange. Malinowski, though, was of the opinion that conventional economic theory had no role to play here for this was something radically different to commodity exchange.

This theme was developed in Mauss's (1925) classic essay *The Gift*, one of the first syntheses of the comparative literature. His greatest contribution was to pose a new question that focussed on social relations between transactors rather than value relations between objects. Whereas the economists posed the question of price determination, Mauss posed the question of transactor obligation. He argued that we should not enquire into the determinants of the exchange rate of armshells for necklaces in a *kula*, but into the question of the obligations transactors are under to give, receive, and repay gifts.

This question led anthropologists to seek the answer not in the sphere of production or consumption, as the economists were wont to do, but in the sphere of reproduction and political authority, i.e., in the sphere of kinship and chieftainship.

Polanyi (1944), for example, emphasized the key role of reciprocity and redistribution and argued that the former had its basis in the 'give and take' of kinship relations and the latter in centralized political relations where the chief pooled gifts given to him and redistributed them in grand rituals. Polanyi's principal concern, however, was the 'great transformation' that led to a self-regulating market economy.

Lévi-Strauss's (1969) theory of kinship, which was developed around the same time as Polanyi's theory, is an attempt to answer Mauss' question about the obligation to give, receive, and repay. He argued that a woman given in marriage was the 'supreme gift' and that the incest taboo, whose universality he saw as deriving partly from nature, was the supreme rule of the gift. His argument has been challenged by feminist anthropologists who have shown that marriage systems are patriarchal, cultural constructions with no basis in nature.

Lévi-Strauss distinguished three forms of gift exchange—restricted, delayed, and generalized—and showed how they are the result of three different types of marriage—respectively, bilateral cross-cousin marriage, patrilateral cross-cousin marriage, and matrilateral cross-cousin marriage. Restricted exchange has the general form of simultaneous exchange, delayed exchange is where the reciprocated transaction occurs a generation later, and generalized exchange is a chain of one-way transactions that may feed back on itself to form a circle.

Sahlins (1972) developed this idea by showing how exchanges involving objects, and the form of reciprocity underlying them, are related to kinship distance; he also showed that political rank could transform the principles of reciprocity into a system of redistribution whereby gifts are channeled upwards to a chief who subsequently redistributes them to maintain his status.

Gregory (1982) has attempted to synthesize this anthropological tradition of thought with that of the political economists (Smith, Ricardo, Marx, and Sraffa) on commodities in order to develop a conceptual framework for understanding the particular situation in Papua New Guinea where gift exchange has effloresced under the impact of colonization and globalization.

Interest in the theory of the gift has continued to flourish in the last quarter of the twentieth century but it has taken new directions. Godbout and Caillé (1998) return the debate to one of Mauss' original concerns, the political implications of the gift for French capitalism and European society more generally. Anthropological theory, especially the work of Weiner (1992) and Godelier (1999), has begun to problematize those things that are kept but not given, i.e., things that are neither gifts nor commodities. Examples here include family heirlooms and the crown jewels. The theoretical and ethnographic study of these objects raises questions about lineages, inheritance, religion, and cultural identity.

3. Some Illustrative Examples

The theory of reciprocity and redistribution, and the particular theories of value, property, and social relations informing it, are best illustrated by means of some examples that illustrate the problems of taking a market-centric approach to gift exchange.

Restricted exchange is a type of reciprocity based on 'sister exchange.' Figure 1 illustrates this. Here, the

Figure 1

transactors are two men, A and B, who exchange their sisters x and y. Exchanges of this type are formally equivalent to barter but, from a social point of view, radically different. This is because the property relation between brother and sister cannot be reduced to a private property relation. The women are, from a male point of view, equivalent in some sense but the value relation cannot be reduced to that of price. Finally, an alliance is created here between two exchanging groups. Repeated exchanges of this type between the male descendants of these men create cross-cousin marriage systems, which are still of great importance in south India and many other parts of the world. In some of these places, such as the Sepik area of Papua New Guinea, the two exchanging groups are exogamous marriage moieties who maintain their alliances by seasonal exchanges of yams. The ideology is that these yams must be balanced, such that if a 2-meter long yam is received a yam of the same length must be returned. According to some theorists, yams serve as the symbolic substitutes for the women. This is called 'balanced reciprocity' and it associated with marriage of the sister-exchange type.

Delayed exchange, in Lévi-Strauss's terms, is where a man, 1A, gives his sister, x, away and receives back his sister's daughter, y, as a wife for his son, 2A, a generation later. Figure 2 illustrates this. Taking the perspective of the man 2A, it is clear that he marries a woman who is his father's sister's daughter, i.e., his patrilateral cross-cousin. Marriages of this kind are the preferred type in some areas of the highlands of Papua New Guinea. Interestingly, this is also where the famous *moka* system of incremental gift exchange is found which has led some to speculate that the *moka* gifts, too, are symbolic substitutes for women. In a *moka* system the increment, today measured in pigs, shells, and money, is called *moka* and it creates a new gift rather than being the 'interest' necessary to cancel an old debt. Thus, if 100 pigs are given and 120 are repaid at a latter date, this return gift includes 100 pigs, which cancels the old debt, and an increment of 20 pigs, the *moka*, which creates a new debt. The effect of competitive incremental gift giving is to create what Strathern (1971), the ethnographer of *moka*, calls 'alternating disequilibrium' because now one trans-

Figure 2

Figure 3

actor, now the other, is indebted because of the last incremental gift. The concept has no meaning in an exchange where the increment takes the form of interest. This is because interest cancels debts rather than renews them.

Redistribution, the process whereby objects are pooled by a chief and then redistributed, raises the question about the means by which the chief accumulates the objects. In places such as the Trobriand Islands in Papua New Guinea this is done by means of polygyny along with an ideology that obliges brothers to give yams, and husbands to receive them, at the annual harvest. Figure 3 illustrates this. Here, the two brothers, A and B, of the wives of the chief, C, give yams to the chief. He stores the yams in a large prestigious storehouse, which acts as a symbol of his status. On certain ceremonial occasions these are then redistributed. Redistribution transforms the ideology that it is 'better to give rather than to receive' into one which says that this is only true when a chief gives.

4. *Historical Transformations*

An early, and ingenious, attempt to understand the historical relationship between gifts and commodities

was Bohannan (1959) who sought to explain the impact of money on the Tiv economy of West Africa. For him, the problem was to understand the process by which the 'multicentric' gift economy was destroyed by the 'unicentric' commodity economy. His theory stressed the differences between the qualitative rank order of value relations characteristic of gift economies with the quantitative value relations characteristic of commodity economies. The Tiv classified the pounds, shillings, and pence of the colonial money system by quality rather than quantity; but the implicit quantitative order underlying notes and coins, he argued, 'flattened' the gift economy.

Whatever the merits of this explanation in Africa, the theory fails elsewhere, not because of any logical flaws, but because it asks the wrong question. In places like Papua New Guinea the problem to be explained was the efflorescence of gift exchange under the impact of colonization and the global market. Such was the problem Gregory (1982) sought to explain. More recent approaches of greater generality, such as the work of Appadurai (1986), focus on consumption and the 'social life of things,' the idea that things have a biography and that that they change their social form as they move from one context to another. For example, a pig may be raised as a pet, given away in a *moka* gift exchange, then sold on the market a number of times, reused in a gift exchange, and eventually given away as pork in a pig kill ceremony to be finally eaten. Other works have examined the morality of money in different social settings (Parry and Bloch 1989).

Barter, a category economists consigned to the prehistory of economic development, is emerging as a category of ethnographic and theoretical importance (Humphrey and Hugh-Jones 1992). Anthropologists working in the postsocialist states have noticed its re-emergence in these states where it seems to be related to the disintegration of the economies in these areas.

Ethnographic research over the twentieth century has presented many problems for theorists of exchange and many significant theoretical advances have been made. The twenty-first century will no doubt pose new problems for ethnographic description and analysis.

Exchange: Social

Social exchange theory has its origins in the field of sociology in the work of George C. Homans and Peter Blau. Homans' (1958) famous paper entitled 'Social Behavior as Exchange' laid the foundations of this orientation to the study of behavior. He subsequently expanded these ideas in *Social Behavior: Its Elementary Forms*, published in 1961 (1974). The primary focus of his work is what he referred to as 'sub-institutional' or elementary behavior, the actions of individuals in direct interaction with one another that form the bedrock of groups and organizations. He contrasted elementary behavior with institutionalized forms of behavior, such as that involved in conforming to norms or to role prescriptions for appropriate behavior. For Homans, institutionalized behavior and elementary forms of behavior were most often distinct. He argued that elementary behavior could sometimes 'crack the institutional crust,' forcing changes in the institutionalized ways of doing things (e.g., the changes in social behavior and institutions forged by rebellions and revolutions).

1. Major Theoretical Formulations: Blau and Homans

Blau (1964), in his famous book, *Exchange and Power in Social Life*, developed a much more extensive

treatment of the links between microlevel social behavior and the groups, organizations, and institutions it constitutes. A major difference between the perspectives of Homans and Blau is the latter's recognition of 'emergent' processes at more complex levels of social organization. For Blau the whole is more than the sum of its parts. Relationships between the parts or elements of the structure create emergent processes that evolve from the interaction of the parts, but are not reducible to properties of the individual elements. Homans, in contrast, adopted a reductionistic orientation to explanation using exchange principles arguing that many of the 'laws' of social organization could be understood in terms of the behavior of the interacting parts, typically individuals. For this reason, according to Homans, psychological principles ultimately laid the foundation for the laws of elementary social behavior.

While Homans's efforts were aimed at understanding elementary behavior, Blau's aim was much more macro in focus. He intended to formulate a theory of social structure and institutions based upon a sound microfoundation. He presents his book on social exchange as a prolog to a theory of social structure. The origin of Blau's vision of social behavior was not behaviorism, as in Homans's case; rather, it was a more sociological version of microeconomics, which he labeled 'social exchange theory,' borrowing the term from Homans. (For a lengthy critique of Blau's use of microeconomic reasoning see Heath 1976, among others.) In many ways Blau's work was one of the first major theoretical efforts to extend the logic of microeconomics to the analysis of social behavior, a task that much later won Gary Becker the Nobel Prize in Economics. Homans instead based his analysis of the social behavior he called 'exchange' on principles of behavioral analysis derived from the work of the behaviorists famous at the time he wrote. A major influence upon his theoretical work was the empirical research of B. F. Skinner, his well-known colleague at Harvard.

Both Homans and Blau addressed indirect exchange processes, though such processes form a much more significant component of Blau's theoretical formulation. Homans acknowledged the importance of the indirect ties that actors have who are in direct exchange with the same sets of individuals. For example, employees of the same employer have indirect exchange relations with each other through their direct contacts with their employer. Blau extends the analysis of indirect exchange, acknowledging the role it plays in larger and more complex collectivities. In particular, Blau views indirect exchange as the basis for coordinated action in complex social structures (and the substructures of which they are composed). This coordination of action through indirect exchange in larger collectivities necessitates mediation by common values, which can be the focus of opposition and conflict, especially as the social structures involved become more complex. Blau discusses group formation, cohesion, integration, differentiation, opposition, conflict, and dissolution as forces of structural change and stability in complex social structures. These forces play a major role in his theory of social exchange as he endeavors to provide a comprehensive microfoundation for macrosociology. Homans and Blau were both engaged in distinctive efforts to produce a coherent theoretical alternative to Parsonian functionalism, the dominant paradigm in sociology until the late 1960s.

2. *The Roots of Social Exchange Theory*

Somewhat independently, Homans and Blau developed their theories of social exchange even though each had been well-versed in functionalism and Parsons's social systems approach to the analysis of society. The vestiges of both traditions are clearly evident in Blau's treatment of social exchange, though much less so in the work of Homans who labored skillfully to ground his theory of exchange explicitly on Skinnerian principles of behavioral analysis, repudiating the need for more macrolevel concepts and principles. Blau's goal was to produce a theory of social structure by clarifying the nature of the social processes and associations that generate the more complex structures of organizations, communities, and societies. He explicitly attempted to link the sociology of everyday life popularized in the work of Simmel and Goffman with the broad theories of society characteristic of Weber and Parsons. Unlike Homans, however, his focus on the interpersonal was primarily as the basis for theorizing about more complex forms of association.

2.1 *Psychological Roots*

Besides functionalism and Parsons's version of systems theory other influences on the development of social exchange theory came from an eclectic set of sources including pragmatism, utilitarianism, behaviorism (for Homans), and conflict theory (in the case of Blau's work). Turner (1986) provides a fairly accurate and detailed account of the various roots of social exchange theory in his discussion of the development of this theoretical orientation and its impact in the field of sociology. In addition to these sources of influence, the major works of several psychologists and anthropologists provided further impetus to the development of the exchange paradigm in sociology. The dominant contribution from psychology is the work of John Thibaut and Harold Kelley (1959), *The Social Psychology of Groups*. This volume presents a lengthy treatment of the forms of interdependence among individuals engaged in various types of social interaction. In matrix format it lays

out the rewards and costs attached to different behaviors under varying conditions of interdependence. The framework is used to make predictions about behavior given different types of control over the outcomes of the other actor(s) in the situation. For example, Thibaut and Kelley (1959) distinguish behavior control from fate control in social relationships using their basic orientation to interdependence. Their work formed the basis of much experimental research over the next two decades, particularly on cooperation, competition, negotiation, and coalition formation. It also dovetailed nicely with the emergence of game theory in the social sciences as a tool for understanding strategic interactions.

2.2 Anthropological Roots

The early work of anthropologists like Levi-Strauss ([1922] 1969), Malinowski (1922), and Mauss (1925) influenced exchange theory in an entirely different way. Sociologists drew upon the fieldwork of these scholars to provide examples of the significance of social exchange, often contrasted directly with economic exchange. Malinowski (1922), for example, in his comprehensive analysis of the Kula Ring among the Trobriand Islanders, argues that the exchange of arm bands for necklaces across the islands over time was an important source of social solidarity, the significance of which far exceeded the economic value of the items exchanged. Blau (1964), and subsequently Richard Emerson (1972, 1981), developed conceptions of indirect exchange and generalized exchange based to some extent upon Malinowski's extensive fieldwork. Mauss's (1925) complex analysis of the gift also provided input to the development of theory concerning generalized exchange and reciprocity (see also Molm, 1997, on reciprocal or non-negotiated exchange).

3. Exchange Theory: Empirical Research

Homans and Blau popularized exchange theorizing in sociology in the late 1960s and early 1970s, but sustained empirical research on the topic did not begin until the mid-1970s largely as a result of the influence of Emerson's (1972) more formal theoretical work, based upon his earlier treatment of power-dependence relations (1962). Ironically, Emerson's work on power-dependence relations also influenced Blau's (1964) discussions of power and power gaining strategies. Emerson built a conception of social exchange around his fundamental insights concerning power in social relations. He, like Blau, made power and inequality central to his treatment of exchange processes. Similarly, like Blau, he viewed his theory of social exchange as the beginning steps toward formulating a general theory of social structure. In Emerson's case, however, the structures of primary interest were the networks formed as a result of the connections among a set of actors engaged in social exchange with one another. Two of Emerson's distinct contributions to exchange theory in sociology are his fundamental insight into the relational nature of power and his extension of exchange theory to analyze the social networks created by exchange relations.

Before expanding upon these two major contributions to the development of exchange theory it is worth noting that Emerson's first efforts to formulate a theory of social exchange had more in common with Homans's work than that of Blau, despite their common goal in building a theory of social structure. In the two papers written in 1967 (and subsequently published in 1972) in which Emerson laid out the foundations of his theory of exchange, he formulated a model of the actor built on principles of behavior analysis adopted from Skinner via Homans. Key concepts include reward (positive reinforcement), cost (rewards foregone), alternative exchange relations, dependence, and balance. Propositions are formulated based upon the basic reinforcement notions of behavior first introduced into exchange theory by Homans.

3.1 Emerson's Theory of Exchange Relations

A central focus of Emerson's theoretical framework is the exchange relation as the unit of analysis. As Turner (1986) notes, this move makes exchange theory less vulnerable to charges of tautology and reductionism. Emerson's goal is to present a theory of the formation, maintenance, and termination of exchange relations and the forms of social structure created by connected exchange relations (e.g., networks of exchange). Less critical in this theoretical formulation is the precise nature of the values of the actors involved or the cognitive structure of their interests. Assuming actors enter exchange relations for reasons of reward (or avoidance of negative reinforcement in alternative relations), the focus shifts to understanding aspects of the exchange relations and the structure of the networks or groups in which they are embedded. The emphasis on the social relation as the unit of analysis distinguishes Emerson's work from that of Homans and Blau and allows Emerson to present a more coherent theory of social structure.

3.2 Power and Dependence in Exchange

The primary legacy of Emerson's work on social exchange is his conception of how power is determined by the dependence of one actor upon another in an exchange relation and how dependence is structured by the nature of the connections among actors in networks of exchange opportunities that deny or

provide access to exchange alternatives. The key definition of power in Emerson's formulation is: The power of actor A over actor B in the Ax:By exchange relation (where x and y represent resources of value) increases as a function of the value of y to A, and decreases proportional to the degree of availability of y to A from alternative sources (other than B). These two factors (resource value and availability) determine the level of B's dependence upon A and thus A's power over B. That is, the power of A over B is a direct function of B's dependence upon A in the A:B exchange relation. The more dependent B is upon A, the more power A has over B. Embedding this relationship in a network of exchange opportunities creates the basis for a structural theory of power in exchange networks.

Exchange relations are connected to the extent that exchange in one relation affects or is affected by the nature of the exchange in another relation. The connection according to Emerson's work can either be positive or negative. A negative connection means that exchange in one relation reduces the amount or frequency of exchange in another exchange relation involving one of the same parties (e.g., the A–B and B–C exchange relations are negatively connected at B if exchange in the A–B relation reduces the frequency or amount of exchange in the B–C relation). A connection is positive if the amount or frequency of exchange in one relation increases the amount or frequency of exchange in an exchange relation involving at least one of the parties to both exchanges (e.g., the A–B relation is positively connected to the B–C relation if exchange in the A–B relation increases the frequency or amount of exchange in the B–C relation). These are modal cases; however, exchange in two relations may also be 'mixed,' involving both positive and negative exchange connections relating to different aspects (or dimensions) of exchange. Exchange in more complicated networks often involves both positive and negative connections (see Cook et al. 1983).

3.3 Exchange Networks

Emerson (1972, 1976, Cook and Emerson 1978, etc.) expanded this important direction of development in exchange theory in subsequent publications formulating what is now known as 'exchange network theory.' A similar perspective was developed later by Markovsky et al. (1988) that came to be known as 'network exchange theory.' It derives from Willer's (e.g., Willer and Anderson 1981) 'elementary theory' of social relations that has an affinity with exchange concepts, but is not derived from Emerson's power-dependence perspective. These traditions of work in recent research have much in common, despite the remaining subtle differences in assumptions about actor behavior, network connections, and bases of power. In all of these programs of research the main focus of the early empirical work was determining the structural determinants of the distribution of power in networks of varying configurations.

Early debates about the value of exchange theory in the social sciences centered on the role of rationality, tautology, and reductionism (see Emerson 1976). These debates gave way during the 1980s and 1990s to more sophisticated arguments in the field concerning theoretical strategy and the best ways to develop microlevel models of exchange that inform macrolevel processes. More complex theoretical formulations emerged during this period based on the results of careful empirical work, much of it experimental, testing the fundamental propositions derived from exchange theory. Emerson's formulation provided the impetus for much of this empirical work primarily because he formalized the theory to make it more precise and therefore testable. Subsequent formulations adopted a similar theoretical strategy (e.g., Markovsky et al. 1988, Bonacich 1998, Bienenstock and Bonacich 1992, Friedkin 1992, Skvoretz and Willer 1993, Yamaguchi 1996).

3.4 Key Assumptions of Exchange Theory

The key assumptions of exchange theory summarized recently by Molm (1997, see also Molm and Cook 1995, p. 210) include: (a) behavior is motivated by the desire to increase gain and to avoid loss (or to increase outcomes that are positively valued and to decrease outcomes that are negatively valued); (b) exchange relations develop in structures of mutual dependence (both parties have some reason to engage in exchange to obtain resources of value or there would be no need to form an exchange relation); (c) actors engage in recurrent, mutually contingent exchanges with specific partners over time (i.e., they are not engaged in simple one-shot transactions); and (d) valued outcomes obey the economic law of diminishing marginal utility (or the psychological principle of satiation). Based on these core assumptions various predictions are made about the behavior of actors engaged in exchange and the effects of different factors on the outcomes of exchange. The power-dependence principle, in addition, allows for the formulation of predictions concerning the effects of increasing the value of the resources involved in the exchange and the availability of resources from alternate sources.

4. Power Inequalities

Empirical work since the early 1980s has established several primary facts about exchange in networks of social relations. Power inequalities in networks of exchange are determined by access to valued resources in the network. The networks structure this access by

providing connections or links to certain actors and restricting access to others. The structure of the network determines the accessibility of resources and thus the nature of the distribution of power in the network (see, e.g., Cook and Emerson 1978, Cook et al. 1983, Markovsky et al. 1988, Whitmeyer 1999).

In exchange relations characterized by power inequalities the use of power varies depending upon whether the actors control positive or negative outcomes. Extending the theory to deal with the exercise of coercive power within social exchange relations, Molm (1997) has produced new insights into the nature of power relations in situations in which the actors have not only reward power, but also punishment power. Comparing the behavioral effects of the use of different bases of power in social exchange relations, Molm demonstrates that the results that hold for the exercise of reward power do not hold for the use of punishment. Specifically, punishment power is used much less frequently, in part because it carries with it the risk of withdrawal from the relationship on the part of the target of the punishment to the extent that the relationship can be exited. (Molm focuses primarily on exchange relations that are voluntary; that is, both parties have some degree of control over their involvement in the exchange and can exit if they so desire.) However, when punishment power is used it tends to be very effective in modifying behavior to make the relations more mutually rewarding in the long run. According to Molm (1997, p. 268): 'When punishment is administered contingently and consistently, coercion is a powerful means of getting what one wants.' However, coercive power is used rarely.

4.1 Coercive Power

Integrating the analysis of coercive power with reward power in social exchange relations allows for the investigation of a wider range of social situations in which more complex exchanges occur. Frequently, those involved in ongoing exchange relations have control over both rewards and punishments (even if it is only the withholding of rewarding behaviors). In addition, Molm's (1997) work has made a major contribution to the analysis of the strategic use of structurally based power advantages and disadvantages. As she correctly notes, the missing link in Emerson's (1962, 1972) original work on power-dependence relations was the nature of the precise mechanisms that relate structural determinants of power with the actual use of power by those in positions of power. In this effort norms of fairness or justice and attitudes toward risk play a key role. Conceptions of fairness constrain the use of power under some conditions, especially the use of coercive power, and aversion to risk makes some actors unwilling to use the structural power at their disposal for fear of loss.

4.2 Risk and Uncertainty

Recently additional empirical research has been conducted that extends exchange theories to deal with the effects of important factors such as uncertainty and risk on the nature and structure of social exchange. Facing uncertain environments, actors involved in exchange are more likely to seek to form committed exchange relations (Cook and Emerson 1978, Kollock 1994, Lawler and Yoon 1996). Commitment reduces the extent to which actors seek exchange with alternatives and thus serves to reduce the power inequalities both within the exchange relation and within the network in which the relation is embedded. As Kollock's (1994) work demonstrates, uncertainty not only results in commitment formation as a means of reducing uncertainty, it also tends to be correlated with perceptions of trustworthiness of the actors involved in the exchange relations.

Yamagishi et al. (1998) report that trust emerges in exchange relations under conditions of high uncertainty as actors form commitments to exclusive exchange in an attempt to avoid the possibility of exploitation by unknown actors who enter the exchange opportunity structure. Under conditions of low uncertainty actors are much more likely to continue to 'play the market' and to avoid forming commitments to specific partners in order to maximize their access to valued resources. (Uncertainty in these experimental studies referred to the likelihood of being exploited by a new partner in an exchange network of opportunities that changes over time.) In the current work on trust, uncertainty and vulnerability are often defined as two of the key elements of situations in which trust considerations are paramount (e.g., Heimer 2001).

5. Relational Cohesion and Social Exchange

Lawler and his collaborators (e.g., Lawler and Yoon 1993) have developed a new theory of relational cohesion based on principles of social exchange. The focus of this work is to examine the conditions under which social exchange relations emerge out of opportunities for exchange and are linked to the emergence of positive emotions about the exchange relation. These positive emotions and subsequently conceptions of cohesion or solidarity, Lawler argues, develop based upon positive evaluations of the outcomes of exchanges between actors and the frequency of their exchange. Low frequency and unfavorable (or less favorable) outcome exchanges are much less likely to lead to commitment to the relation, to positive feelings about the exchange, and to feelings of cohesiveness or solidarity (i.e., what Lawler terms a 'we-feeling'). The significance of this new line of research is that it returns to some of the earlier anthropological work that examines the links between exchange and solidarity in social relations. It also integrates into existing

theoretical conceptions of exchange theory important considerations of the emotional bases of exchange and commitment.

6. Applications of the Theory

Applications of exchange theory and power-dependence concepts extend from dyadic relations like dating and longer-term relationships including marriage (e.g., Sprecher and Metts 1999) to often short-term relations characteristic of various practitioner–client interactions (such as physician–patient meetings under managed care, see Grembowski et al. 1998). In these contexts the focus of the analysis is often on the nature of the relationship and the factors that predict satisfaction (or dissatisfaction) and longevity (or termination) of the relation. Two dimensions that are frequently investigated in this respect are the degree of power imbalance in the relationship and the extent to which the relationship is embedded in a network of other important exchange relationships. Power imbalance in partnerships often creates additional tension in the relation as actors try to manage the resource differences between the parties to the exchange and attempt to maintain commitments in the face of alternatives. Within an organizational structure such as that produced under managed care in the health care delivery system, choice of provider is often limited exacerbating patient concerns with their dependence upon the available physicians. Mechanisms are put into place to provide patients in these settings access to redress if the power of the physician is abused. These include increased professional and utilization reviews by colleagues, administrators, and those who insure the patients. In all cases in which a power imbalance exists in an exchange relation there is the potential for exploitation, thus widely differing mechanisms have been created that serve to provide some monitoring to insure the equitable and fair treatment of those who are most dependent and thus vulnerable to the abuse of power. A prime example is the oversight demanded frequently in nursing homes that must deliver care to one of the most dependent populations in the USA, the infirm aged. Aspects of both power-dependence theory and exchange theory have proven useful in the study of power processes in many contexts.

At the more macro level, exchange networks now represent an interesting framework for analyzing the Internet revolution in business, as well as the reorganization of the workplace and the rapid increase in interpersonal connections over the World Wide Web. As this encyclopedia is going to press the world of business relations across the globe is being transformed, as B2B (business to business) commerce becomes the dominant mode of conducting transactions at the macro level. Business to client (B2C) relations has now been superseded in significance by the global transformation of corporate relations. These relations represent complex networks of exchange and trade that include not only economic, but also political and social dimensions of transnational significance. Future research will likely see the expansion of exchange analyses of power in global networks of trade embedded in complex social and political realities.

K. S. Cook

Executive Branch, Government

'Executive' has two meanings, one of which is a subset of the other. It can either be one branch of government (to be distinguished from the legislative and the judiciary branches), including the head of state, the government, political staff, the civil service, the armed forces, and all other government employees engaged in the implementation of laws (down to policemen, school teachers, etc.). This is the broadest definition. The second meaning of 'executive' is that of the political part of the executive branch. There is, however, no easy answer where precisely to draw the boundaries between the political part and the remainder of the executive. Consequently, the term 'executive' means different things not only between countries and periods but often also between authors writing about the same countries or periods.

1. Origin

Executives in the modern sense emerged through the piecemeal splitting-off of state functions from a traditionally undivided central government (mostly a monarch) (Shepard 1931, King 1975). In order to limit the government's power, judicial functions were transferred to courts and legislative functions to parliaments. This process began in twelfth- and thirteenth-century England. It had many national

variations and in Europe was not completed before the twentieth century. The constitutional doctrine of the separation of powers—as developed first and foremost by Locke, Montesquieu, and Madision—provided a normative justification for the separation of legislative, judicial, and executive institutions which was seen to guarantee liberty and justice (Vile 1967).

In practice the state functions were never separated as neatly as envisaged by normative theorists. The executive has retained important legislative functions, in particular drafting legislation and issuing government decrees and ordinances (Carey and Shugart 1998). With the full democratization of polities and political parties establishing themselves as the main mechanism to structure elections and to co-ordinate incumbents, executives have gained almost a monopoly in lawmaking in parliamentary systems. In presidential systems this is not true to the same extent, but executives also exercise large influence on legislation. Although recognized early in the literature, this gap between the division of labor between the branches of government as laid down in the constitution and political practice has received much attention in empirical studies of parliamentary systems.

2. *Types of Executives*

The shape of the executive and executive–legislative relations traditionally have been crucial for the classification of regime types. In the contemporary world the most important regime types are (a) presidential systems, (b) parliamentary or cabinet systems, and (c) semipresidential systems. In presidential systems the chief executive is elected directly for a fixed term and appoints and dismisses the members of the government. These cannot be dismissed by parliament. In a parliamentary or cabinet system the executive, whether appointed by a head of state or directly created by parliament, remains fully accountable to parliament. Although the prime minister typically has a gate-keeper function, at least formally controlling access to and dismissal from cabinet, formal decision-making is collective for important matters. Less important matters fall in the jurisdiction of individual cabinet ministers. A semipresidential system combines a directly elected and powerful head of state with a prime-minister and government who are accountable to parliament.

There is, however, no full agreement of how precisely to define these regime types or whether the semipresidential type indeed constitutes a distinct regime type (Sartori 1997, Lijphart 1999, Elgie 1999, Strøm 2000). In addition to these widespread regime types, those of assembly government and collegial (or 'directorate') government can be identified. In assembly government, decisions are indeed made in parliament and the cabinet is not more than the assembly's executive secretariat. With the exception of the French Third Republic, it has existed in its pure form only for short periods, often after a revolutionary regime change. There is only one case of collegial (or 'directorate') government—Switzerland. There, the cabinet is elected by parliament for a fixed term, that is, it is not accountable to the assembly, and it is fully collegial, with even the chairmanship rotating among its members.

Nondemocratic regimes typically claim to conform to one of the regime types presented here, though they may give other actors, such as the 'state party,' special constitutional status.

While these five regime types have belonged to the arsenal of political science for many decades, a new demand for constitutional engineering (which came with the new waves of democratization of the 1970s and particularly the 1980s and 1990s) and the new theoretical research agenda of neo-institutionalism have created new interest in them. The questions which are common to constitutional engineers and neo-institutional theorists are: what types of output are these regime types likely to generate in terms of the maintenance of democracy, the accountability of public officials, and public policy? The best research has demonstrated that each regime type is likely to maximize some effects, but at the costs of others. Hence, the appropriateness of regime types and of specific institutions within the confines of a regime type depend on the most important challenges a polity faces (Weaver and Rockman 1993, Linz and Valenzuela 1994, Moe and Caldwell 1994, Sartori 1997, Lijphart 1999, Strøm 2000).

3. *The Study of Executives*

Research on the political executive is a large and increasingly diverse field, including studies on presidents and prime ministers, cabinets, the top layer of bureaucracy, their interaction, and their interaction with other actors.

Classic institutionalism had not much to say about the executive *per se*. The executive mainly was characterized through its relations with other state institutions, which in turn were important for the classification of regime types. The behavioral revolution inspired many studies in the elite research tradition, which compiled and analyzed data on the social background and career patterns of people in executive functions (e.g., Blondel 1980, Blondel and Thiébault 1991). While certainly valuable to demonstrate cross-national differences and the impact of social and political change of great magnitude, it has remained doubtful that inferences can be made from this data on the behavior of incumbents. At best, plausible hypotheses have been proposed, for example, inferring the relative ineffectiveness of incumbents from short office periods. The bulk of research on the executive, however, always has been historic–qualitative, building on *mémoires*, media reports, the occasional interview, private papers of former members of the

executive, and other archival sources. Notwithstanding some impressive individual scholarship, this research traditionally has suffered from three problems. First, with the exception of the US presidency, research on the executive is rare, in particular given the relevance of its subject and compared to the attention other political phenomena have received. Second, compared to other research fields, fewer attempts at original and systematic data collection have been made in executive studies. This partly reflects properties of the research objects, namely small numbers (of chief executives, cabinets, cabinet ministers, and top bureaucrats) and limited access (because they are busy people with greater secrecy requirements). Finally, much research on the executive has also been quite idiosyncratic and more rooted in national peculiarities than, for instance, research on electoral behavior or parliaments.

Although these three points are still valid to some extent, executive research has made important achievements since the 1980s. First, the number of studies in the historic-qualitative tradition has increased. Second, the best work has become much more rigorous, building, for instance, on systematic interviews with former cabinet ministers and theory-guided case studies of executive decisions (e.g., Burch and Holiday 1996, Rhodes and Dunleavy 1995; for research on the US presidency see Edwards et al. 1993). Finally, executive studies have become more theory-guided and comparative. The fact that country expertise is probably more crucial here than in any other subdiscipline is reflected by much cross-national collaborative work. Chief executives traditionally receive most attention (e.g., Rose and Suleiman 1980, Jones 1991), but more recently systematic comparative research on Western Europe has also highlighted cabinet decision-making, the impact of individual ministers (Blondel and Müller-Rommel 1993, Laver and Shepsle 1994), the mechanisms of coalition governance (Müller and Strøm 2000), and the impact of parties on government decision-making (Blondel and Cotta 2000). However, comparative work which includes executives from both sides of the Atlantic is still rare (Weaver and Rockman 1993, Weller et al. 1997).

New frontiers of research are defined by both real world and theoretical developments. Thus, executive studies have begun to explore how European Union member states meet the challenge of multilevel governance, that is, the participation of all levels of the national executive in the decision-shaping and decision-making in EU institutions (e.g., Kassim et al. 2000). A rapidly increasing body of literature is concerned with the changes of the executive below its top political level, in particular the introduction of New Public Management and 'agencification' (for a general picture see Peters 1996). At the forefront of theory-inspired research, agency theory has been applied to executive–legislative relations (e.g., Epstein and O'Halloran 1999, Saalfeld 2000) and intra-executive relations (e.g., Andeweg 2000).

W. C. Müller

Exhaustible Resources, Economics of

This article reviews research into how an economy uses natural resources, the inputs to production and human enjoyment received as part of nature's bounty. The resources examined are termed exhaustible because, in principle, their stocks are subject to exhaustion as a result of human consumption. This is clearly evident for coal, oil, and gas, and concern that humankind will run out of these resources has provided much of the impetus for the development of natural resource economics, as a field of study. Populations of fish and other species are also depletable, in the sense that their stocks can be extinguished. Through growth these resources are capable of providing continuous flows of consumption, however, and for this reason are called renewable. Resources incapable of growth are called nonrenewable.

The fields of natural resource and environmental economics are closely connected, not just by common intellectual roots, but by a simple physical identity. Natural resource economics is concerned with the study of how naturally occurring commodities, fossil fuels, metallic minerals, fish, wood, and water, are used as inputs by an economy. Environmental economics is concerned with the emission of waste or residual products; substances that cause air pollution, water pollution, and litter from the economy into the environment. Because matter can neither be created nor destroyed, the mass of natural resource inputs withdrawn from the environment and put to work in an economy must be matched in the long run by an equal mass of waste products back into the environment. This connection makes it difficult, and sometimes arbitrary, to separate natural resource and environmental economics as subdisciplines.

This discussion is organized by individual resources. Nonrenewable resources are examined first, and the discussion here focuses mainly on fossil fuels. This is followed by a general introduction to topics in renewable resources, with specific subsections on fisheries, forestry, and water resources. (The examination of water is confined to groundwater, and excludes issues of water rights, surface water management, and water pollution. These topics arguably belong to the fields of agricultural and environmental economics.) Space limitations have forced the omission ofsome important areas of research from this survey. These are noted in Sect. 3, which also points to areas where research activity is presently most active.

1. *Nonrenewable Resources*

A natural resource is nonrenewable if it does not grow naturally, and if the sum of future consumption services it can yield is therefore bounded by the existing stock. (Nonrenewable resource theory is treated in detail in Dasgupta and Heal 1979, Chaps. 6–8, 10–12, and 15 and in Fisher 1981, Chaps. 2 and 4. A recent review of nonrenewable resource scarcity is Krautkraemer 1998.) Natural gas, petroleum, and coal are nonrenewable resources because the act of consuming a unit reduces the stock, and hence future consumption opportunities, by a like amount. Metals such as copper are also nonrenewable, although consumption must be carefully defined in such cases to account for recycling. (Recyclable natural resources are still nonrenewable, because it is impossible to completely recover scrap.)

Public concern regarding nonrenewable resource scarcity is nothing new. Concern is particularly urgent when the resources in question are the energy inputs so vital to an industrial economy and exhaustion, or even a sharp price increase, would have large macroeconomic effects. The fact that consumption must eventually go to zero leads to an obvious question: when? Common measures express scarcity as the ratio of the existing resource stock to current consumption; if consumption continued at current levels, this would represent the number of years remaining until exhaustion.

Measuring scarcity in this way is misleading for two reasons. First, as explained shortly, the basic economic model of nonrenewable resource use predicts that resource prices will rise continuously as depletion proceeds. This will cause resource users to seek substitutes, reducing consumption and mitigating scarcity. Second, there are several physical measures of the existing resource stock, and their economic relevance varies from measure to measure. The largest possible measure is crustal abundance—the physical stock in some portion of the Earth's crust. This measure surely overstates ultimate consumption, as

much of the planet's endowment is technically impossible or extremely expensive to extract. A second measure is current or proven reserves—known deposits that can be profitably extracted at current prices and extraction costs. As prices rise, proven reserves will expand, so this measure surely understates ultimate consumption. 'Ultimately recoverable' reserves are proven reserves plus deposits that are currently not profitable but are expected to be in the future. Such measures depend on prices and costs, which presumably reflect scarcity. (These measures do provide a way to trace the inventory of minerals over time. The reserves-to-consumption ratio for petroleum increased over the second half of the twentieth century, indicating that discovery and cost saving innovation outpaced extraction over this period.) Economists generally prefer to assess resource scarcity from prices and costs directly. Aboveground prices, extraction costs, and mineral rights prices all reflect scarcity to some degree, as the following theoretical discussion indicates.

A nonrenewable resource deposit is an asset. To induce an owner to hold it, the deposit must generate a return that is competitive with other assets. Abstracting from differences in risk, asset market equilibrium implies that a resource stock must yield a rate of return equal to the real interest rate. Nonrenewable resource deposits do not yield a flow of consumption service, nor do they grow or depreciate physically. Thus, the only return an owner can receive from holding it rather than consuming it immediately comes from an expected increase in the asset's price. Because this capital gain is the only return a nonrenewable deposit can earn, in expectation it must be equal to the real interest rate. (As explained later, this must be amended if mineral rights ownership is monopolized to some degree.) The level of this increasing price path is determined by a requirement that prices rise to choke off demand as the resource stock approaches depletion. More precisely, demand for the resource must equal zero on the date when the resource is exhausted. (This will occur on a specific date, if there is a finite price above which the demand equals zero. It will occur only in the limit if price increases cause demand to approach zero asymptotically.) This general theory was developed by Harold Hotelling in 1931.

This result applies to prices for unextracted resources, or mineral rights, but it has direct implications for prices of extracted minerals, which are more commonly observed. If mineral extraction is competitive, the price of a unit of the extracted resource will equal the price of a mineral right plus the marginal cost of extraction. Accordingly, the Hotelling model makes the following prediction: the expected 'aboveground' price of a nonrenewable resource less marginal extraction costs will increase at the rate of interest. As exhaustion nears, the aboveground price approaches the 'choke price,' the lowest price at which quantity demanded equals zero. The exhaustible nature of such resources is socially important, as it implies that price will increase continually. The actual event of exhaustion is not a particular concern, however, because it occurs only after prices have risen high enough to reduce demand for the resource to zero.

This simple result holds only for a resource that exists in deposits of homogeneous quality. In practice, resource deposits typically vary in mineral concentrations, cost of extraction, or other attributes. Under common conditions, profit-minded mining firms will extract the most valuable deposits first, as to do otherwise would not minimize the present value of extraction costs. Suitably amended, the Hotelling rule predicts that deposits will be extracted in order of their quality or grade, with the highest grade extracted first. Within each grade, price minus marginal extraction cost will increase at the rate of interest. The lowest grade extracted is exhausted when price rises to the 'choke price.' Over time, the mineral rights price for the grade being extracted tends to rise, but mineral rights prices fall when extraction switches from higher to lower quality grades. Once the possibility of variations in quality and extraction costs is introduced, it is clear that some deposits may never be extracted, because their costs of recovery exceed their value to consumers.

Attempts to test the Hotelling model have focused on the simple uniform grade case, and the hypothesis that mineral rights prices will rise over time at approximately the rate of interest. This research, reviewed later, has found limited support at best. In hindsight, this lack of success is not terribly surprising. Hotelling's theory predicts that the entire price path for a resource will shift in response to unanticipated changes in interest rates, extraction technologies, input prices, demand conditions, knowledge about the extent of deposits, tax policy, degrees of monopoly power, and other factors. Attempts to test the theory generally have not controlled for changes in these factors. It is instructive to illustrate some of the model's predictions in this regard. An unanticipated increase in the rate of interest reduces the value of returns from future extraction relative to returns from extraction in the present. The predicted response is a reallocation of mineral extraction from future to present. This causes an abrupt drop in price and hastens the date of exhaustion. As extraction proceeds, price minus marginal extraction cost increases at the (now higher) rate of interest.

Changes in other factors will shift price paths in different ways. An increase in extraction cost should cause the aboveground price to jump, but by less than the cost change. Price starts higher and, as before, must reach the choke price at the date of exhaustion. Because price is higher on each date, consumption is reduced and the period of time over which extraction takes place is extended. Discovery of a new deposit should cause a discontinuous drop in the mineral

rights price, subsequent price increases following the Hotelling rule, and a later date of exhaustion. Among the many possibilities for unanticipated shifts in demand, one case has been singled out for detailed study—discovery of a renewable energy source that is highly substitutable for fossil fuel energy. Invention of a nuclear fusion reactor or perfection of a low cost photovoltaic device are potential examples. In this case the Hotelling model predicts an immediate reduction in the aboveground rights price followed by resumption of price increases, with exhaustion occurring when the aboveground price reaches the cost of the renewable substitute.

Shifts from competition to monopoly ownership of energy resources have been studied in detail to gain insights on how OPEC (the Organization of Petroleum Exporting Countries) has affected energy markets since the early 1970s. OPEC, acting as a cartel, seeks to control petroleum prices by coordinating the production decisions of its member nations. The simple Hotelling model predicts that, under plausible conditions, monopolization will cause an abrupt jump in price followed by relatively modest price increases until the choke price is reached upon exhaustion. The overall period of extraction is longer with monopoly than with competition. While OPEC is far from a perfect monopoly, these prescriptions are broadly consistent with energy price patterns and observed OPEC behavior since the 1970s.

An important policy issue arises when there is an absence of clear ownership claims. Crude petroleum and natural gas exist under pressure in subsurface natural deposits. Extraction from one portion of a deposit can cause part of the stock to flow from other regions toward the point of extraction. This creates a management problem when portions of the land overlying the deposit are owned by different individuals. Each landowner has an incentive to extract rapidly and thereby capture part of the stock presently underlying a neighbor's property. Because all landowners have the same incentive, the result is a rush to extract, and thus there is inefficient rapid depletion. An efficient policy response is unitization, whereby the entire reservoir is placed under unified management and each landowner receives a share of the net proceeds.

Another important policy issue arises when resource use causes environmental damage. If damage results from the extraction process, as may occur with open-pit mining and offshore oil production, the correct policy response is to charge the extracting firm an amount that reflects this damage. This gives the producer an incentive to reduce such damage. The effect on resource markets is to raise price when the charge is imposed, slow the rate of production, and render some deposits uneconomic. Environmental damage sometimes cumulates with the total amount extracted. When fossil fuels are extracted and combusted, carbon dioxide is released. Carbon dioxide does not decay rapidly, but rather accumulates in the atmosphere, where it is believed to contribute to climate change. In this case, the appropriate charge for extraction must reflect the fact that emitting a unit of the gas will cause damages that persist for a long time. Also, the charge will generally increase over time as concentrations grow.

The 'strong' prediction of a uniformly increasing price path has been tested in a variety of ways, which are outlined here. But, as mentioned earlier, a proper test would require accounting for the many variables that can shift extraction and price paths. If these factors change over time, comparing price changes to the interest rate does not provide a valid test.

Neither extraction costs nor mineral rights prices are easily observed. Some studies have instead focused just on aboveground prices, while others have attempted to estimate marginal cost statistically. Much of this research has found that prices of many resources are falling over time. A falling resource price could be consistent with the Hotelling model temporarily if deposits were being found or extraction costs being reduced, but price must eventually turn back upward as depletion approaches. This suggests the possibility of U-shaped price paths for some resources and some early evidence supported this for petroleum. Subsequent evidence, however, was contradictory. Studies using estimated extraction costs to construct series of mineral rights prices (the proper object of study) have also failed to support the simple prediction of price increases.

The Hotelling Valuation Principle provides an alternative test. The Principle states that the average asset value of a unit of a nonrenewable resource reserve should equal the current price net of extraction cost. This implies, remarkably, that the average reserve value is independent of future prices and extraction costs. The value of a firm's reserve is estimated from financial data and the implication is tested by comparing the average value of firms' reserves to resource prices net of extraction costs. Again not suprisingly, tests of the strong prediction tend to be rejected.

2. *Renewable Resources*

Renewable resources are exemplified by forests, fish populations, and water. In each case the stock available for consumption at any point in time is, or can be, regenerated by a natural process. Because such resources can grow, the cumulative future consumption service that a renewable resource stock can provide is not bounded. (The general theory of renewable resources is developed in Dasgupta and Heal 1979, Chap. 5 and in Fisher 1981, Chap. 3. Brown 1999, provides a perceptive and entertaining review of management issues related to renewable resources.)

A renewable resource stock is also an asset, so it must generate a return competitive with other assets to

induce an owner to hold it. The phenomenon of renewability causes the behavior of associated markets to differ fundamentally from what we observe for nonrenewable resources, however. Physical growth, as with biomass in a population of fish and in forests, represents a return to the owner. Some renewable resource stocks can also yield flows of consumption services for their owners, for example, forests can provide habitat for wild game and aesthetic benefits for those who enjoy looking at them or walking in them. A larger population of fish generally benefits the harvester by lowering search costs. Hence, the returns earned by renewable resource stocks are multidimensional, complicating the equal returns condition.

An important caveat is that equalization of returns across assets follows from the behavior of owners who rationally seek to maximize their returns. As we shall see, some important renewable resource stocks, particularly fish, tend to be unowned. In these cases the equalization of returns condition can serve as a guide for efficient management, but it will not describe how unowned, unregulated resources are used in practice.

2.1 Fisheries

A fish population is a living, mobile resource, capable (within limits) of regenerating itself if part of the stock is harvested for human consumption. If the stock performed no economic function other than supporting growth, an efficient manager would seek a stock size that equates the proportionate rate of growth to the real rate of interest. The long run efficient annual harvest would then equal the stock's annual growth. (In this simple model, a higher interest rate implies a smaller equilibrium stock and a larger annual harvest. The first implication tends to hold true in more complex settings. For simplicity, we are abstracting from the possibility of ongoing price changes or from price changes related to changes in the volume of harvests.)

As this simplified discussion shows, the natural population growth process must play an important role in any economic analysis of the fishery. Most economic treatments have adopted the simple logistic description of population growth and have specified a production technology in which the factors of production are of two sorts: (a) the inputs engaged in fishing effort, for example, crew, vessels, and gear, and (b) the stock of fish itself. A larger stock aids harvesting due to search costs—less effort need be expended to catch a ton of fish where the population is plentiful. This cost reduction is an additional return the stock earns, beyond the return it generates by supporting growth. Accordingly, the efficient stock in the presence of search costs is greater than would be implied by simply equating the proportionate rate of growth to the interest rate. The value of avoiding extinction provides another reason for a larger stock, since this generally lowers the probability of extinction. (Brown 1999, p. 22 notes that larger stocks of elephants may impose costs, rather than benefits, on some members of society by terrorizing farmers and destroying crops.)

The management strategy implied by equalizing rates of return will maximize the present value of net economic returns from harvesting the resource. Alternative management goals have often been pursued in practice. One such goal is maximizing sustainable yield (MSY), and another is management to protect stocks from falling below biologically critical levels. Economists have generally been critical of MSY as a management goal, since it amounts to maximizing output without considering either the value of that output or the cost of producing it. The economic arguments against MSY are illustrated by the fact that a doubling of fish prices, or a halving of fishing input costs, would have no effect on the management strategy this goal prescribes.

Generally, there is no private owner who controls how the population is used. This is due partly to the fact that fish are mobile and difficult or impossible to monitor. Hence, enforcing ownership to all or part of a population would be impossible or prohibitively costly. This explanation for the typical lack of ownership in fisheries is reinforced by the observation that the few instances of partial private ownership tend to be cases where the species are sedentary and harvesting is easily detected (for a general discussion of communal management of renewable resource, see Brown 1999, pp. 38 ff). The term 'open-access' is used to describe such unowned fisheries if they are unregulated. While the equal rates of return rule remains valuable for policy, the self-interest of asset owners cannot be relied upon to achieve efficient management where ownership is lacking.

Economic reasoning can characterize how an unowned fishery will be exploited by profit-minded harvesters. The structure of this analysis resembles a predator–prey system in ecology. Individual firms (boats) combine fishing inputs in a profit maximizing way, given the fish population available for them to exploit. Each regards its own catch as too small to have any appreciable effect on the stock it encounters. Positive profits attract new boats to the fishery, increasing fishing pressure. Added fishing pressure drives the stock down, increasing harvesting costs and reducing profits. When excess profits have been eliminated, entry stops and the industry is in long run economic equilibrium. The stock itself earns no economic return—fishing revenue just covers the cost of labor, vessels, and gear. While the population is clearly capable of generating a positive economic return in the form of growth and reduced search costs, this return is not realized in open access equilibrium.

This model has implications for harvesting activity in an open access fishery. Higher fish prices or lower prices of fishing inputs will increase fishing effort and reduce the stock; the harvest could either increase or decrease, depending on the initial stock level and the shape of the biological growth function. Populations exhibiting particular biological growth characteristics can face the possibility of extinction due to open access harvesting. (The presence or absence of critical depensation, which is characterized by a minimum viable population size below which the population cannot survive, is key consideration.) This is a rare outcome, but it becomes more likely if fish prices are high, fishing input prices are low, and search costs are unimportant.

Recognition that a lack of ownership is a cause of inefficiency points the way to more effective regulatory approaches. The Individual Transferable Quota (ITQ) is the most important regulatory innovation proposed by economists. It operates by transforming a fishery-wide restriction on catch into quantitative harvest rights that can be bought, sold, and owned by individual harvesters. One such right entitles its owner to harvest, for example, one ton of a particular species of fish in a designated area during a specified period of time. These rights are of obvious value, so command a positive price. ITQ prices represent an economic payment for use of the stock, and force harvesters to recognize that the stock is a valuable input. This induces efficiency in combining use of the stock with other fishing inputs in the harvesting process. ITQ fishery policies have been implemented in New Zealand, Iceland, Greenland, the Netherlands, and Australia.

Fisheries utilizing ITQs generally experience greater returns for harvesters, and no nation adopting the ITQ approach has subsequently abandoned it (Brown (1999) Table 1 and pp. 34 ff). In practice ITQs are often allocated to those who can demonstrate a historic involvement in the subject fishery, and this no doubt accounts for some of their political popularity. An alternative allocation would have government claiming initial ownership of ITQ rights and then auctioning them to harvesters. Economic theory, *per se*, gives no reason for preferring one initial allocation to another, and actual allocations are driven more by considerations of political feasibility and equity. (The ITQ operates by charging harvesters a price for each unit of the stock captured. One could charge the price directly, without the ITQ device, by imposing a fee or tax on fish landings. Policy economists proposed this long ago, but were ignored for political and equity reasons.)

The ITQ approach requires first setting an overall target catch. The correct economic criterion for choosing the target is maximization of the present value of net receipts, suitably adjusted to recognize that some values, for example, the value nonusers of the resource may place on avoiding extinction, are not matched by monetary payments. Traditionally, the goal of regulation was to avoid endangering stocks from a purely biological perspective. This goal was often approached by restricting fishing to only part of the year, by prohibiting the use of particularly effective fishing techniques or equipment, and by limiting the number of fishing boats allowed to operate. Economists have leveled two sorts of criticisms at such regimes. First, they often do not generate any economic return for society. While they do protect stocks, restricting fishing times or the kinds of gear used simply raises harvest costs. If costs had been raised by imposing a harvest fee, the resulting stock, catch and harvester profits could have been similar and the fee revenue would represent a net economic benefit for society. Second, harvesters will find ways around such regulations and this can magnify inefficiencies. When regulators limit the number of boats in a fishery, harvesters tend to invest in larger, faster boats with larger crews to increase fishing effort despite the regulation. When regulators limit the time available to fish, harvesters fish more intensively during the open season, raising costs, lowering fish quality, and expanding effort back toward its pre-regulation level.

2.2 Forestry

The study of renewable resources dates to a fundamental forest management problem first addressed in the eighteenth century. An early example of both intertemporal and biological components in economic models, this classic problem considers a decision facing an owner of a growing stand of trees: when to cut and harvest them for timber. The first proper economic treatment of this problem is attributed to Martin Faustmann in 1849, but in part because the solution is subtle, the optimal rotation age of a tree has since received a great deal more attention in economics. Other, more modern issues in forestry are outlined later, following a brief description of this basic model.

A tree is an asset whose return to the owner is assumed to derive only from the simple fact that it grows. (The logic of this problem is equivalent whether looking at a stand of trees of the same age or one tree.) If the price of timber remains constant, the rate of growth in value equals the rate of growth of biomass. A wealth-maximizing owner will harvest when annual growth in the tree's biomass (the benefit to leaving it standing) is equal to the sum of two distinct opportunity costs. This first cost is the rate of return that could be earned cutting and selling the resource and earning interest on the proceeds. The second cost is the land rent and represents the return that could be earned by the land the tree occupies. At the wealth-maximizing harvest age, the net rate of return earned

by the standing biomass (the value of growth minus land rent) just equals the interest rate.

The forest's biological growth function plays a key role in determining the harvest age. When a tree is young and growing quickly, the return to leaving it standing exceeds the relevant opportunity costs. As the resource matures and the growth rate falls to the level of the combined opportunity costs, the time has arrived to cut. The reasoning at the heart of this solution is that part of the cost of waiting to harvest a stand of trees is that an older tree takes up space that a younger, faster growing tree could occupy.

Investigating how this optimal harvest age responds to changes in the price of timber, replanting costs, and the market interest rate yields useful insights. When replanting is costly (in the absence of replanting costs, the optimal rotation age does not depend on the price of timber; this, perhaps surprising, result derives from the fact that all of the costs and benefits are proportional to this price) a higher price of timber will shorten the optimal harvest age and a higher replanting cost will lengthen it. These results follow from the fact that a higher price or lower replanting cost will increase the maximum value of forest land, and therefore increase the land rent. An increased rent, by raising the opportunity cost of letting the forest stand, induces the owner to harvest earlier. A higher rate of interest tends to reduce the harvest age. Intuitively, this occurs because the forest's net rate of return (growth minus land rent) tends to fall as the forest matures. It will, therefore, reach equality with the interest rate at a younger age when the interest rate is higher. To summarize, a higher interest rate causes the forest to be cut sooner.

These results have implications for the supply of timber. An increase in the price of timber increases the value of land in forestry and therefore is likely to increase acreage in forest. This increase reduces the average quantity of timber produced on each acre, however, due to the shortened harvest age. (This is true if the optimal harvest age is less than the age that maximizes sustainable yield.) As a result, the net effect of a price increase has an ambiguous effect on timber supply. The exact opposite is found for replanting costs. An increase in the interest rate unambiguously reduces timber supply as a higher interest rate reduces both land rents in forestry and the harvest age, and both effects reduce supply.

Other management goals, particularly maximizing sustainable yield, are sometimes advanced as criteria for publicly owned timber. Economists have criticized MSY in this context for essentially the same reasons they have criticized it for fisheries. While the determination of optimal harvest age is a classic problem in resource economics, other issues of forest management have become arguably more important. These include the land use decision, especially at the margin between uses in forest and agriculture, management under imperfectly defined property rights, and the external (nontimber) value of forests. These subjects are briefly discussed in the remainder of this section.

There are, of course, competing uses for a parcel of land and efficiency requires choosing the use with the greatest discounted net benefit. Importantly, the costs and benefits appropriate for this criterion include some that may be external to the owner. Such external benefits range from the services of carbon sequestration, habitat for a large fraction of the world's species, and recreational or general aesthetic value. (CO_2 captured by a growing forest is 'sequestered' from the atmosphere, where it would contribute to a potential greenhouse effect. The value of biodiversity is in both potential medical services and less tangible human preferences.) In general, if a standing forest provides benefits not captured by the landowner, and if those benefits increase with the age of the stand, then the private owner's harvest age will be too short and there will be an inefficient bias toward nonforest land uses. This observation suggests a role for government policy related to land use and harvest age on both private and public lands.

Ownership of forest land is often incomplete. In many areas of the world the ubiquitous property rights regime is 'common property' or 'communal management,' where a village or otherwise organized group of people share ownership of land used alternatively for agriculture, fuel wood, forest products, and other services. Without collective action to regulate individual behavior, each member of the community has an incentive to clear more forest land for agriculture, and to allow livestock to overgraze common pasture, etc. An individual farmer considers the private cost of converting common forest to agriculture, for example, the reduced availability of fuel wood for him personally, but ignores the cost borne by every other member of the community. This incentive is magnified by the realization that failure to appropriate a piece of the commons today only decreases the probability that it will be available for appropriation in the future.

The difference between common property resource management and open access (a concept developed in the fisheries section) relies on the effectiveness of informal controls. Effective common property management requires a set of rules or norms, and a binding enforcement mechanism that promotes socially efficient resource use. While the requisite conditions are not well understood, informal solutions to commons problems should be more common when bargaining, enforcement, and information about resource use are inexpensive relative to the gains from efficient management. This seems more likely when the resource is small and scarce, and perhaps where the number of actors is small. Another seemingly important ingredient is a long-established community that shares traditional norms of behavior and a common technology. Empirical work suggests that actual common

property arrangements internalize some, but not all, of the relevant social costs.

2.3 Groundwater

Groundwater exists in subsurface reservoirs, or aquifers, that usually are replenished by percolation of water from the surface. As with oil and gas, groundwater is mobile and does not respect the boundaries of individual parcels of land that overly it. Absent of regulation, one can therefore expect groundwater stocks to be overused.

Water in an aquifer is an asset and the problem of efficient management can again be guided by the principle that rates of return be equalized. As water in storage is depleted, the distance it must be pumped to the surface increases, raising costs. Water in storage thus earns a return by reducing pumping costs. It can also earn a return associated with the fact that withdrawing groundwater can cause the overlying land surface to subside, damaging structures or otherwise reducing the land's value. Similarly, withdrawing groundwater near an ocean shoreline can cause saltwater to intrude and degrade the quality of water in an aquifer. In both cases, leaving more water in storage reduces the damage, or makes it less likely, adding new components to the return that water in storage yields.

As with fish and unowned petroleum reservoirs, groundwater will not be efficiently managed if left to the choices made by individuals withdrawing from a common aquifer. Policies similar to ITQs in fisheries, or unitization with oil and gas are viable management instruments in principle. They have not generally been adopted, however, owing in part to the unique legal institutions that apply to property rights for water.

3. Conclusions and New Directions

Several important topics were not discussed due to a constraint on space, and some trends in the study of exhaustible resources are worthy of mention. These are briefly broached these here, and the interested reader is directed to more detailed discussions in Brown (1999), Krautkraemer (1998), and Dasgupta and Heal (1979).

The study of nonrenewables has largely shifted from optimal extraction and scarcity measurement to the environmental impacts of fossil fuel consumption. The traditional concern was that energy would become expensive as coal, petroleum, and natural gas reserves were depleted. Prices of these inputs have not risen consistently, but today it is recognized that energy consumption is expensive in a sense historically not properly accounted for. A ton of coal in the ground provides few external costs or benefits, but a ton of coal burned spreads damages widely in the form of acid rain and greenhouse gases. This link between nonrenewable resources and environmental policy is central to the field today.

There are several directions in which the theory of fisheries and fishery regulation is being extended at present. First, most economic models of fisheries do not incorporate state-of-the-art ecological models of the resource. Fisheries ecology has moved far beyond the simple logistic models of population dynamics that are still a mainstay of fisheries economics. Second, economic analyses of fishery regulation have, with a few recent exceptions, made no attempt to study the motives and the behavior of the regulator. Third, economic models of fisheries tend to ignore spatial considerations in the distribution of fish populations or fishing activity. As this very active area of natural resource economics develops, it seems likely that each of these topics will receive attention.

While the optimal harvest age is the textbook forestry topic, the total stock of forests is more sensitive to the factors that determine land use. This is particularly true as it becomes clear that the conversion of land to agricultural uses drives much of global deforestation. Recent study has focused on how ownership security, agricultural and trade policy, and the functioning of related input markets affect land use decisions. Empirical attempts to measure the external value forests provide, through the services of carbon sequestration and biodiversity habitat, are met with great interest.

This article has ignored a large and important literature incorporating exhaustible resources into the theory of economic growth. This literature has traditionally treated exhaustible resources as capital necessary for production but substitutable with other inputs. Whether exhaustible resources represent 'limits to growth' is certainly an issue that commands attention far outside the field of economics.

Nearly all of the basic models described here ignore the fact that the world is an uncertain place. An owner of a resource is assumed to know what will happen to future prices and costs. How poor an approximation of behavior is it to replace random variables with their expected values? The degree to which people are averse to, and able to insure against, risk, are key aspects of investment behavior that shed light on resource management problems. Optimal resource use is also likely affected if relevant events are irreversible, a point distinct from risk aversion. Irreversibility is key to the study of species extinction and climate change in the modern literature.

Existential Social Theory

Modernity, as the continuing project of human self-understanding and human self-making, is both the historical foundation of social theory and an existential perspective on the world. All modern social theory, thus, insofar as it reflects upon the experiential character of social life, is to some degree existentialist.

1. *Max Weber's Fundamental Contribution to Existential Social Theory*

The centrality of an existential perspective to social theory is nowhere clearer than in the work of Max Weber (1864–1920), who must be accounted its most formidable advocate. The existential character of Weber's perspective is most evident in his essays on politics and science and, more especially, in his methodological writings. These stress both the centrality of meaning to a proper understanding of social action, and the essential freedom of humans in relation to the values that ultimately confer meaning on events. In a radical fashion Weber insists that meaning flows from an existential 'orientation to the world' and does not inhere in any objectively given reality. Weber's sociology, thus, is concerned primarily with the typification, on a world historical scale, of an extraordinarily varied range of such meaning complexes, their historical contextualization, and the existential orientations within which they were formed and enacted.

Weber's social theory also established critical insight into the existential problems of modern society. On the one hand, he argues that modernity can be understood in terms of a specific set of values which he typifies as the 'spirit of capitalism' or 'modern rational capitalism'; while, on the other hand, he argues that modernity is characterized above all by the 'disenchantment of the world,' which involves nothing less than the annihilation of value as such. Not only are these two very different conceptions, but the notion of disenchantment seems to contradict his philosophical-methodological premise that all human activity be inherently open to meaning through its relation to extra-rational ends. This duality in Weber's characterization of modern life in fact brings to light the seriousness of the struggle in modern society to create and maintain a sense of individual human worth and dignity in the face of powerful processes of rationalization. He traces this theme substantively to the Reformation and the 'unprecedented inner loneliness' which was its religious expressions and the historical foundation of the anxiety which has become a general condition of modern existence. In this approach it is clear that Weber was influenced by Friedrich Nietzsche (1844–1900) and Søren Kierkegaard (1813–55). Indeed, a remark of Nietzsche's might well stand as an epigraph for his existential sociology;

> Man first implanted value into things to maintain himself—he created the meaning of things, a human meaning! Therefore he calls himself: 'Man,' that is; the evaluator … Evaluation is creation.

2. *Kierkegaard and the Origins of European Existential Thought*

But it is to Kierkegaard that we must turn as the originating source of the varied forms of modern existential thought. Not only in his work do we find the first modern account of human reality focused directly on the elusive and difficult character of 'existence,' we also discover, linked to it, a significant social theory of modernity.

Kierkegaard's writings provide a rich exploration of all the forms of existence which have become possible in the modern world. Rather than analyze these positions in terms of an abstract analytic framework—itself presumed to be outside of any of their existential determinants—he presents them as the self-expressed orientations of a number of pseudonymous authors. This semi-fictional method draws author, subject matter, and reader into an existential complicity and Kierkegaard uses this technique to mount a powerful attack on all modern (especially Hegelian) forms of scientific abstraction and objectivity which have been misleadingly applied to problems of existence.

This method, inaugurated in the celebrated *Either/Or* (1987 [1843]), is neither a form of pure 'subjectivism' nor does it result in chaos of arbitrary life-

views. In fact the authorship reveals a specific, albeit complex, structure which conditions all subjective contents of experience, whatever position is adopted by the protagonist. This structure—a kind of existential map of modern society—is characterized by Kierkegaard in terms of 'existence-spheres' within which a number of positions are inter-related. Thus, the aesthetic mode of existing is organized around the polarities of pleasure and unpleasure, and is characterized by successive phases of enthusiasm and boredom; the ethical sphere is ordered in terms of the distinction of good and evil, and emerges in a more concrete selfhood of resolution and guilt; and the religious sphere crystallizes and takes form in the opposition of faith and sin. The fluid interchange and dialogic structure of the authorship, in opposition to any systematic theory of experience leaves this existential experimenting incomplete and unresolved.

Kierkegaard, under his own name, but in the form of a lengthy book review rather than a direct essay, also provided a suggestive existential theory of the social and cultural tendencies of his own time (*Two Ages* 1978 [1845]). What he called the Present Age (as distinct from a previous Revolutionary Age) is characterized by superficiality, bourgeois philisitinism, empty conventionalism in public life, and a general process of leveling in which all social differences are obliterated in favor of a new 'mass' culture. The Present Age, like Hegelian philosophy, has become abstract and empty, obsessed with public opinion and meaningless 'chatter'; it is the mere play of forms which lack the seriousness of any of the positions explored in the pseudonymous authorship. The Present Age is not at all 'interesting,' in the significant sense of engaging the self and enriching its interrelational structure with authentic life-contents; everything happens as if one were a spectator of a remote and detached world. Yet it is just the character of existence that it is and remains interesting, that the pervasive boredom of the Present Age, at the same time discloses the possibility of a new reality and prompts the continual renewal of groundless but not hopeless existential experimenting. The pseudonyms, thus, choose boredom over conventionality, propelling themselves into new and unpredictable projects of existence.

The existential value of 'authenticity,' it should be noted, is not associated in Kierkegaard's seminal writings with the romanticism of 'self-positing' and the self-realization of a specific inner 'personality,' but with the decisive character of 'choosing.' This is not conceived in a utilitarian market sense as deciding among available alternatives but, rather, is constituted as a transformative 'leap' into new forms of existence. To 'choose' is simultaneously to be chosen, to surrender to a value outside the self, only thus can it genuinely become part of the self; it is like falling in love, a possibility which the rationalizing conditions of the Present Age make daily more difficult.

Kierkegaard's extraordinary writings were for a long time all but ignored and it is only relatively recently that his work has been read again as a creative and significant contribution to modern social theory. His influence was felt more directly in the philosophical tradition. First, through Karl Jaspers (1883–1969), himself a friend of Max Weber's and also an ardent reader of Nietzsche, who, in addition to his major philosophical works, in *Man in the Modern Age* popularized Kierkegaard's social criticism of the *Two Ages* and in an original fashion opened up a vast field of psychopathology to existential investigation (Jaspers 1963). Second, through Martin Heidegger (1889–1976) whose *Being and Time* (1962 [1927]), which is hardly conceivable without Kierkegaard's *Concept of Anxiety* (1980 [1844]), made existence once again a central preoccupation for contemporary philosophy.

Jaspers represents a turn away from nihilistic interpretations of existentialism back to an appreciation of the positive insights of Kierkegaard and Nietzsche. His view of existence is explicitly social in character; 'Since man only exists in and through society … we must study his nature by studying society.' And, although in Jaspers view, 'owing to the turmoil of modern life, what is really happening eludes our comprehension,' he proposes a conception of modern society as a dynamic structure rather than an undifferentiated crowd; 'there are only diverse masses which form, dissolve, and reform … articulated masses are mutable, diversified, transitory expressions of some specific historical outcome of human existence.' But, as 'even an articulated mass always tends to become unspiritual and inhuman,' modern existence is generally inauthentic.

Heidegger marks a turn from nihilism towards primitivism; an approach to human existence as primordial Being. For Heidegger authentic Being is always preconceptual and unthematized, it is founded upon a rejection of the world of modernity rather than an encounter with, or within, it. In the extraordinary elaboration of this project he introduces a new language of Being in which all subsequent existential reflection took place. In this language he emphasizes and makes his own Kierkegaard's rejection of every misdirected form of objectifying thought: 'Philosophy cannot base itself on the illusion of making man a disinterested spectator of himself.'

The openness of existential reflection to new realities and new interpretations of reality is evident both from its originating variety and in the ideological diversity of its followers. Whatever the political, religious, or ethical tendency favored by its major proponents, however, each has been distinguished by fearless radicalism. In its still best known version, indeed, existentialism and radicalism become synonymous. What had begun as a pitiless anatomy of despair was transformed by Jean-Paul Sartre (1905–80) into a new, optimistic but equally uncompromising vision of

liberation. Reading Heidegger in relation to Hegel he produced in *Being and Nothingness* (1956 [1943]) an impressive restatement of the entire project of modernity as the discovery of human autonomy. Here the commitment to freedom as the fundamental prerequisite for any valued form of human being is restated with unsurpassed determination. The result is less a secular version of a Christian notion of existence (Kierkegaard) than the consecration of a particular kind of Romanticism (Fichte). This is characteristic also of Albert Camus (1913–60), whose *The Rebel* (1954) returned to nineteenth-century Russian literature for an understanding of nihilism as the most consistent and fearless of existential views of the human world. Only the free act could be considered authentically human, and as conformity to any existing convention was tainted with coercion, acts of rebellion bore the only indubitable sign of freedom and, therefore, of authenticity.

Sartre increasingly sought for his existentialism a larger and more dramatic stage; history and the collective subject, rather than the small individual acts of everyday life, supplied the setting for the working out of the great refusal; the negation of everything intolerable in modern life. The attempted synthesis of existentialist and Marxist traditions resulted, in *Critique of Dialectical Reason* (1976 [1960]), in a social theory paradoxically 'founded' on 'anti-foundational' existential insights. Through this Sartre sought to establish praxis relevant to contemporary life rather than an explanation of its various features.

His views, thus, remain rooted in existential insight; 'The only concrete basis for the historical dialectic is the dialectical structure of individual acts.' The radical freedom central to *Being and Nothingness* is somewhat muted here—reciprocity and otherness, mediated through a series of 'objective' forms (dyad, triad, serial group, fused group, statutory group, organization, class), are conceived as pre-given and as essential aspects of, and constraints upon, every human project. However the subversive genius of its empty form is also invoked: 'For freedom is nothing other than a choice which creates for itself its own possibilities.' The human remains the being for whom 'The upsurge of freedom is immediate and concrete.'

Existential social theory seeks to realize two distinct and seemingly incompatible values; the absolute and untrammeled freedom of the subject; and the actualization of authentic selfhood. Much of the development of existentialism is an attempt to reconcile these two values and to imagine a social world in which they could be harmonically interrelated. The urgency and difficulty of such a task is the source of the pathos, which distinguishes all serious existential social theory.

Expectations, Economics of

'Expectations' in economics refers to the forecasts or views that decision makers hold about future prices, sales, incomes, taxes, or other key variables. The importance of expectations is due to their often substantial impact on the current choices of firms and households, and hence on current prices and the overall level of economic activity.

1. Expectations in the History of Thought

Modern economic theory recognizes that the central difference between economics and natural sciences lies in the forward-looking decisions made by economic agents. Therefore expectations are a basic building

block of economic theories. For example, in consumption theory the paradigm life cycle and permanent income approaches stress the role of expected future incomes. In investment decisions present value calculations are conditional on expected future prices and sales. Equity prices, interest rates, and exchange rates all clearly depend on expected future prices.

A central aspect of economic theories is that expectations influence the time path of the economy, and conversely one might reasonably hypothesize that the time path influences expectations. The current standard methodology for modeling expectations is to assume *rational expectations* (RE), which is in fact an equilibrium in this two-sided relationship.

RE modeling is a recent key step in a long line of dynamic theories which have emphasized the role of expectations. The earliest references to economic expectations or forecasts date to the ancient Greek philosophers and the Bible. Systematic economic analyses in which expectations play a major role began as early as Henry Thornton's treatment of paper credit, published in 1802, and Émile Cheysson's 1887 formulation of a framework which had features of the 'cobweb' cycle. The role of expectations was given some attention by the classical economists, but their method of analysis was based on the stationary state in which perfect foresight prevails. Expectations were equated with actual outcomes, which downplayed their significance.

Alfred Marshall is credited with the notion of 'static expectations' of prices. The *'cobweb' model* of a market with a production lag was one of the first formal models with expectations in the 1930s. In the same decade, the *temporary equilibrium* approach, initiated by the Stockholm school, explicitly introduced expectations of future prices influencing current demands and supplies. John Muth (1961) was the first to formulate the notion of rational expectations and did so in the context of the cobweb model.

In macroeconomic contexts the importance of the state of long-term expectations of prospective yields for investment and asset prices was emphasized by John Maynard Keynes (1936) in his General Theory. Keynes stressed the central role of expectations for the determination of output and employment, but did not have an explicit model of how expectations are formed. He even sometimes suggested that attempting to forecast very distant future events can virtually overwhelm rational calculation. In the 1950s and 1960s expectations were introduced into almost every area of macroeconomics, including consumption, investment, money demand and inflation using *adaptive expectations* or related schemes.

Rational expectations made the decisive appearance in macroeconomics in the work of Robert E. Lucas Jr. and Thomas J. Sargent in the beginning of 1970s. Many of the key contributions are collected in Lucas and Sargent (1981) and Lucas (1981). The RE hypothesis became widely used in the 1970s and 1980s and it is currently the benchmark paradigm in both micro- and macroeconomics. Some recent research has gone beyond RE by developing models of *learning behavior* with explicit theories of data collection and forecasting.

In this article we review developments in the modeling of expectations formation, with an emphasis on rational expectations and learning behavior. RE modeling is the subject of many books, e.g., Sargent (1987) and Farmer (1999). Evans and Honkapohja (2001) is a treatise on the learning approach.

2. *Traditional Models*

We will illustrate the modeling of expectations with some well-known simple models. The first example is the cobweb model. Consider a single competitive market in which there is a time lag in production. Demand is assumed to depend negatively on the prevailing market price:

$$d_t = m_I - m_p p_t + v_{1t} \tag{1}$$

while supply depends positively on the expected price:

$$s_t = r_I + r_p p_t^e + v_{2t} \tag{2}$$

where m_p, $r_p > 0$ and m_I and r_I denote the intercepts. We have introduced shocks to both demand and supply. v_{1t}, v_{2t} are exogenous *iid* (identically and independently distributed) random variables with mean zero and constant variance.

The interpretation of the supply function is that there is a one-period production lag, so that supply decisions for period t must be based on information available at time $t-1$. For simplicity we make the representative agent assumption that all agents have the same expectation. Extensions to heterogeneous expectations have been analyzed in the literature.

We assume that markets clear. The observed price is then obtained by equating s_t and d_t, which leads to

$$p_t = \mu + \alpha p_t^e + \eta_t \tag{3}$$

where $\mu = (m_I - r_I)/m_p$ and $\alpha = -r_p/m_p < 0$. $\eta_t = (v_{1t} - v_{2t})/m_p$ so that we can write $\eta_t \sim iid(0, \sigma_\eta^2)$, i.e., η_t is an *iid* random variable with mean zero and variance σ_η^2.

Equation (3) is an example of a temporary equilibrium relationship. It illustrates the central role of expectations by showing how the current market-clearing price depends on expected prices. Developments since the Stockholm School and Keynes can be seen as different theories of expectations formation, i.e., how to close the model so that it constitutes a fully specified dynamic theory. We now describe briefly some of the most widely used schemes with the aid of this example.

2.1 Static Expectations

Naive or *static expectations* were used widely in the early literature. In the context of the cobweb model they take the form

$$p_t^e = p_{t-1} \tag{4}$$

Once this is substituted into Eqn. (3) one obtains $p_t = \mu + \alpha p_{t-1} + \eta_t$, which is a stochastic process known as an autoregressive process of first order (AR(1)). This and related stochastic processes are studied in standard textbooks on time series analysis and econometrics.

In the early literature there were no random shocks, yielding a simple difference equation $p_t = \mu + \alpha p_{t-1}$. This immediately led to the question of whether the generated sequence of prices converged to the stationary state over time. The convergence condition is, of course, $|\alpha| < 1$. Whether this is satisfied depends on the relative slopes of the demand and supply curves. In the stochastic case this condition determines whether the price converges to a stationary stochastic process. (Loosely speaking, a stationary stochastic process is a non-explosive process with statistical properties that are unchanging over time.)

2.2 Adaptive Expectations

The origins of the *adaptive expectations* hypothesis can be traced back to Irving Fisher. It was formally introduced in the 1950s by Phillip Cagan, Milton Friedman, and Marc Nerlove. In terms of the price level the hypothesis takes the form

$$p_t^e = p_{t-1}^e + \lambda(p_{t-1} - p_{t-1}^e) \tag{5}$$

For the cobweb model it can be shown that both expectations and prices converge to stationary stochastic processes, provided the stability condition $|1-\lambda(1-\alpha)| < 1$ is met.

Adaptive expectations can equivalently be written as a distributed lag with weights declining exponentially at rate $1-\lambda$. Besides adaptive expectations other distributed lag formulations were used in the literature to allow for extrapolative or regressive elements.

Adaptive expectations played a prominent role in macroeconomics in the 1960s and 1970s. For example, inflation expectations were often modeled adaptively in the analysis of the expectations augmented Phillips curve.

3. Rational Expectations

The RE revolution begins with the observations that adaptive expectations, or any other fixed weight distributed lag equation, may provide poor forecasts in certain contexts and that better forecast rules may be readily available. The optimal forecast method depends on the stochastic process of the variable being forecast and this implies interdependency between the forecasting method and the economic model. On this approach we write

$$p_t^e = E_{t-1} p_t \tag{6}$$

for the cobweb example. $E_{t-1}p_t$ denotes the mathematical expectation of p_t conditional on variables observable at time $t-1$ (including past data).

RE is an equilibrium concept. The actual stochastic process followed by prices depends on the forecast rules used by agents, so that the optimal choice of the forecast rule by any agent is conditional on the choices of others. An RE equilibrium imposes the consistency condition that each agent's choice is a best response to the choices by others. In the simplest models we have representative agents and these choices are identical.

For the cobweb model we have $p_t = \mu + \alpha E_{t-1} p_t + \eta_t$. Taking conditional expectations E_{t-1} of both sides yields $E_{t-1}p_t = \mu + \alpha E_{t-1} p_t$ so that expectations are given by $E_{t-1}p_t = (1-\alpha)^{-1}\mu$ and we have $p_t = (1-\alpha)^{-1}\mu + \eta_t$. This is the unique way to form expectations which are 'rational' in the model (3).

Two related observations should be made. First, under RE the appropriate way to form expectations depends on the stochastic process followed by the exogenous variables, η_t in the example. If these are not *iid* processes then the RE will themselves be random variables, and they often form a complicated stochastic process. Second, neither static nor adaptive expectations are in general rational, except in special cases.

Next, we consider some key aspects of RE models.

3.1 Forward-looking Character

In the cobweb model expectations pertain only to current prices. Most economic models have forward-looking elements, so that expectations about future periods appear. A simple example is the *Cagan model of inflation* which postulates that the demand for money depends linearly on expected inflation:

$$m_t - p_t = -\psi(p_{t+1}^e - p_t) + \zeta_t, \quad \psi > 0 \tag{7}$$

where m_t is the log of the money supply at time t, ζ_t is an *iid* money demand shock with zero mean, p_t is the log of the price level at time t, and p_{t+1}^e denotes the expectation of p_{t+1} formed in time t. Solving for p_t we obtain the equation

$$p_t = \alpha p_{t+1}^e + \beta m_t + v_t \tag{8}$$

where $\alpha = \psi(1+\psi)^{-1}$, $\beta = (1+\psi)^{-1}$, and $v_t = -(1+\psi)^{-1}\zeta_t$. Note that $0 < \alpha < 1$ and $\beta = 1-\alpha$.

The same formal model arises in other contexts, e.g., the standard model of asset pricing with risk neutrality

takes the form of Eqn. (8) with different values for α and β. Under RE the model is

$$p_t = \alpha E_t p_{t+1} + \beta m_t + v_t \tag{9}$$

Assume that m_t follows some general exogenous stochastic process. One can show that the expression

$$p_t = v_t + \beta \sum_{i=0}^{\infty} \alpha^i E_t m_{t+i} \tag{10}$$

solves the model, provided that the sum converges. Given an exogenous stochastic process for m_t, techniques are available for computing the forecasts $E_t m_{t+i}$ and hence the RE solution (10).

An important feature of the solution (10) is its forward-looking character. The current price level is a sum of expected values of future money stocks. If, for example, there is a change in monetary policy which is anticipated to lower the money stock from some specified future date $T > t$, this will be reflected in the price level already at time t. Previously unexpected changes in policy will affect p_t from the moment they become known.

3.2 Solutions to Linear RE Models

Equation (9) is a simple example of a linear RE model. More general models allow for a dependence on lagged values of the endogenous variable p_t, expectations formed at different times and over various horizons, and more general exogenous processes. Generalizations to multivariate frameworks are particularly important in practice.

A number of techniques are available for obtaining solutions under RE. Undetermined coefficient methods are often particularly convenient. Frequently, as in the model (9) with $|\alpha| < 1$, there is a unique nonexplosive solution, given nonexplosive exogenous variables. In this case a method called the Blanchard–Kahn technique can be used to compute this solution.

4. Econometric Issues with Rational Expectations

4.1 Testing for Rationality

If the RE hypothesis is correct, then expectations obey very strong assumptions. The law of mathematical conditional expectations, from probability theory, states that $E(E(p \mid I) \mid S) = E(p \mid S)$ if S and I are alternative information sets with $S \subset I$. Here $E(p \mid \Omega)$ denotes the mathematical expectation of p conditional on an information set Ω. This result immediately implies $E(e \mid S) = 0$, where $e = p - E(p \mid I)$.

This result, called the *orthogonality principle*, implies that the RE forecast error e must be uncorrelated with every variable in the information set.

If data on expectations, for example from surveys, are available, then this provides a straightforward way to test for rationality. Suppose we have time series data on, say, the average one-period ahead forecast f_t of p_t, where the forecast f_t is made based on I_{t-1}, the information available at time $t-1$. Under RE $f_t = E(p_t \mid I_{t-1})$ and we therefore test whether $E(e_t \mid I_{t-1}) = 0$, where $e_t = p_t - f_t$. In practice, the test is implemented by a regression:

$$e_t = \phi' z_{t-1} + u_t \tag{11}$$

where z_{t-1} is a vector of variables in I_{t-1}. Under the null hypothesis of RE the restrictions $H_0: \phi = 0$ hold and u_t is serially uncorrelated. H_0 can be tested using the standard F-test under some additional assumptions. The intuition for the tests is straightforward. If $\phi \neq 0$ then forecast errors are systematically correlated with z_{t-1} and the information in z_{t-1} is not being fully exploited.

Tests can also be conducted using forecast data with multiple period horizons and/or panel data, although these lead to econometric complications. In practice, tests of rationality using survey data on forecasts typically lead to rejections of rationality, although the interpretation of these results is controversial. Supporters of RE often argue that the individuals surveyed are not the relevant group of agents or that the expectations are measured with error. However, rejections of rationality also raise the possibility that agents do deviate from full RE owing to learning, forecasting costs, and/or strategic uncertainty. See Pesaran (1987) for further discussion of econometric tests of the rational expectations hypothesis.

4.2 The Lucas Critique

During the 1950s and 1960s, applied macroeconometric models explicitly or implicitly assumed that expectations were given by adaptive expectations or by some related lag scheme. The estimated systems were used for policy analysis by evaluating the effects of alternative policies. This implicitly assumed that the estimated coefficients reflect a structure that is invariant to alternative policies. Lucas (1976) criticized this approach, arguing that if expectations are rational, then the coefficients relating target variables to policy instruments will change when the policy process changes.

As an example, consider the Cagan model (9) with $\beta = 1 - \alpha$ and assume that money supply follows the rule

$$m_t = \mu + \rho m_{t-1} + w_t \tag{12}$$

where $|\rho| < 1$ and w_t is an (unforecastable) mean zero *iid* shock. In this case the solution (10) reduces to

$$p_t = \delta + \gamma m_t + v_t \tag{13}$$

where

$$\delta = (1-\alpha\rho)^{-1}\alpha\mu \quad \text{and} \tag{14a}$$

$$\gamma = (1-\rho\alpha)^{-1}(1-\alpha) \tag{14b}$$

The 'traditional' approach to policy would estimate δ and γ from historical data and use the estimated version of Eqn. (13) to evaluate the effects of alternative policy sequences m_t on the price level. However, it is clear from Eqn. (14) that γ is not invariant to the policy rule since, for example, a change in the policy parameter ρ affects the value of γ. Thus, under RE, the response of target variables to policy variables depends on the form of the policy rule.

The effect of the 'Lucas critique' has been to shift attention to estimation of deep parameters (such as α in the above example), which do remain invariant to policy changes and to use these estimates to evaluate alternative policy rules under RE.

4.3 Estimation and Testing of RE Models

When data on expectations are not available, it is still often possible in the context of structural models to both estimate the models under the assumption of RE and to test the RE assumption. In this case the RE assumption is being tested jointly with the model. A simple example is the Cagan model (9), with $\beta = 1-\alpha$, together with the money supply rule (12). Equations (12) and (13) can both be estimated, but Eqns (14a,b) imply that there are nonlinear cross-equation parameter restrictions that are imposed by the RE hypothesis. The system can be estimated under these overidentifying restrictions. The restrictions can also be statistically tested, in effect testing RE jointly with the model.

Another strand that has arisen recently is the estimation and testing of Euler equations. These are dynamic equations, relating, e.g., current consumption to expected future consumption and interest rates, which arise as optimality conditions from dynamic utility maximization. Under RE testable overidentifying restrictions again arise.

5. Multiple Equilibria and RE

Many RE models can have *multiple equilibria*. The existence of rational speculative bubble solutions besides the fundamental equilibrium illustrates this phenomenon. The standard model of asset pricing is formally identical with the Cagan model (8) if we set $v_t \equiv 0$, $\beta = 1$, $\alpha = (1+r)^{-1}$, where r is the real net interest rate. Here m_t represents the dividend at t and p_t is the price of the asset. Then Eqn. (10) is called the 'fundamental solution,' i.e., the present value of anticipated future dividends. A 'rational bubble solution' is the sum of the fundamental solution and a bubble, which is any process B_t satisfying $E_t B_{t+1} = \alpha^{-1}B_t$. The *bubble solutions* are 'explosive' since $\alpha < 1$, and macroeconomists are often content to assume away 'explosive bubbles,' although rational bubbles that burst periodically can be constructed. In models with carefully elaborated microfoundations, explosive solutions can often be ruled out theoretically. Nonetheless, the empirical issue of whether rational (or almost rational) bubbles affect asset prices is still debated.

Other models have multiple RE solutions, none of which are explosive. As a simple example, consider the model $p_t = \alpha E_t p_{t+1} + \beta m_t + v_t$ with $|\alpha| > 1$. (This case can arise from linearized versions of the overlapping generations model of money under some specifications of preferences.) If m_t is *iid* with mean $\bar{m}$, from Eqn. (10) there is the RE solution $p_t = (1-\alpha)^{-1}\alpha\beta\bar{m} + \beta m_t + v_t$. However, there are also solutions of the form

$$p_t = \alpha^{-1}p_{t-1} - \beta\alpha^{-1}m_{t-1} - \alpha^{-1}v_{t-1} + \varepsilon_t \tag{15}$$

where ε_t is an arbitrary process, observable at time t and satisfying $E_{t-1}(\varepsilon_t) = 0$.

These solutions are well-behaved nonexplosive processes. The variable ε_t is often called a 'sunspot' variable and the corresponding equilibrium a '*sunspot solution*.' The term sunspot is used to indicate the arbitrary nature of the variable. The solution depends on ε_t only because everyone believes that it does. It does not appear in the basic model structure. Guesnerie and Woodford (1992) provide a review of the results on sunspot equilibria and *endogenous fluctuations*.

It has been demonstrated formally that sunspot solutions can exist in overlapping generations models in which the microfoundations are carefully constructed. More recently it has been shown that, with increasing returns to scale and monopolistic competition, sunspot solutions can exist in variations of common business cycle models. These models raise the possibility that business cycle fluctuations may be due to random but rational fluctuations in household and firm expectations as a '*self-fulfilling prophecy*.' The empirical significance of self-fulfilling prophecies remains an open issue.

There are numerous other examples of multiple equilibria under RE. One example is provided by a variation of the Cagan model $p_t = \alpha E_t p_{t+1} + \beta m_t$, where now money supply is assumed to follow a feedback rule $m_t = \bar{m} + \xi p_{t-1} + u_t$. (Here also for convenience $v_t = 0$). This leads to the equation

$$p_t = \beta\bar{m} + \alpha E_t p_{t+1} + \beta\xi p_{t-1} + \beta u_t \tag{16}$$

For many parameter values this equation yields two RE solutions of the form

$$p_t = k_1 + k_2 p_{t-1} + k_3 u_t \tag{17}$$

where the k_i depend on the original parameters $\alpha, \beta, \xi, \bar{m}$. In some cases both of these solutions are stochastically stationary.

Other types of multiplicity of RE solutions arise in nonlinear models. Many nonlinear models can be put in the general form

$$y_t = F(y^e_{t+1}) \tag{18}$$

where random shocks have here been left out for simplicity. If y_t is increasing in y^e_{t+1}, i.e., $F' > 0$, there may be multiple steady states that satisfy $\bar{y} = F(\bar{y})$, i.e., that occur at the intersection of the graph of $F(.)$ and the 45° line. This possibility can arise in models with increasing returns to scale in production, externalities, or monopolistic competition. y is often a measure of output or aggregate economic activity and the low steady states represent inefficient '*coordination failures*' (Cooper 1999). Other specifications of Eqn. (18) have multiple perfect foresight equilibria taking the form of regular cycles in addition to a steady state.

Nonlinear models can also exhibit sunspot equilibria, taking the form of a finite state Markov process. For example, in models with two steady states it can be shown that there are RE solutions, depending on a two-state Markov sunspot process, in which the solution alternates between values close to the perfect foresight steady states.

6. *Learning*

The RE approach presupposes that economic agents have a great deal of knowledge about the economy. Even in the simple examples, in which RE are constant, computing these constants requires the full knowledge of the structure of the model, the values of the parameters and that the random shock is distributed *iid*. In empirical work economists, who postulate RE, do not themselves know the parameter values and must estimate them econometrically. A more plausible view of rationality might thus be that the agents also act like statisticians or econometricians when doing the required *forecasting*. This insight is the starting point of the *adaptive learning* approach to modeling expectations formation.

Taking this approach immediately raises the question of its relationship to RE. In many cases learning can provide at least an asymptotic justification for the RE hypothesis. For example, in the cobweb model (3), if agents estimate an unknown constant expected value by computing the sample mean from past prices one can show that expectations will converge over time to the RE value. In more general models convergence to RE can occur if agents use the appropriate econometric functional form and run regressions in the same way that an econometrician might.

Another major advantage of the learning approach arises when there are multiple equilibria. Consider the above example with a monetary feedback rule in which there are two solutions of the form (17). For the pure RE approach this is a conundrum. Which solution should we and the agents choose? Similarly, in nonlinear models of the form $y_t = F(y^e_{t+1})$ with multiple steady states, cyclic solutions or sunspots, one can ask which equilibria are stable under learning. The adaptive learning approach provides answers to all these questions, as discussed in the next section.

Finally, the transition under learning to RE may itself be of interest. The process of learning adds dynamics that are not present under strict rationality and they may be of empirical importance. In the cases just described these dynamics disappear asymptotically. However, there are various situations in which one can expect learning dynamics to remain important over time. For example, if the economy undergoes structural shifts from time to time then agents will need periodically to relearn the relevant stochastic processes.

6.1 *Statistical Approach to Learning*

In the adaptive learning approach economic agents behave like statisticians or econometricians when forecasting economic variables needed in their decision making. The economy is taken to be in a temporary equilibrium in which the current state of the economy depends on expectations. The learning approach to expectations formation makes the forecast functions and the estimation of their parameters fully explicit. A novel feature of this situation is that the expectations and forecast functions influence future data points.

As an illustration, consider again the cobweb model (3). Assume that agents believe that the stochastic process for the market price takes the form $p_t = constant + noise$, i.e., the same functional form as the RE solution. The sample mean is the standard way for estimating an unknown constant, and in this example it is also the forecast for the price. Thus agents' expectations are given by $p^e_t = \frac{1}{t}\sum_{i=0}^{t-1} p_i$. Combining this with Eqn. (3) leads to a fully specified stochastic dynamic system. It can be shown that the system under learning converges to the RE solution if $\alpha < 1$.

If the economic model incorporates exogenous or lagged endogenous variables, it is natural for the agents to estimate the parameters of the perceived process for the relevant variables by means of least-squares regressions. As an illustration suppose that an observable exogenous variable w_{t-1} is introduced into the cobweb model, so that Eqn. (3) now takes the form

$$p_t = \mu + \alpha p^e_t + \delta w_{t-1} + \eta_t \tag{19}$$

It would now be natural to forecast the price as a linear function of the observable w_{t-1}. In fact, the unique RE solution is of this form:

$$p_t = \bar{a} + \bar{b} w_{t-1} + \eta_t \tag{20}$$

where $\bar{a} = (1-\alpha)^{-1}\mu$ and $\bar{b} = (1-\alpha)^{-1}\delta$ and the corresponding rational forecast is $p_t = \bar{a} + \bar{b}w_{t-1}$.

Under *least-squares learning* agents would forecast according to

$$p_t^e = a_{t-1} + b_{t-1}w_{t-1} \tag{21}$$

where a_{t-1} and b_{t-1} are parameter estimates obtained by a least-squares regression of p_t on w_{t-1} and an intercept, using the data available through time $t-1$. It can be shown that (a_t, b_t) converges to the unique REE $(\bar{a}, \bar{b})$ if $\alpha < 1$.

6.2 Stability Under Learning

In general, when expectations are modeled by least-squares learning there is convergence to the REE as $t \to \infty$ provided that a stability condition is met. The stability condition can usually be obtained by the *expectational stability* approach.

To illustrate this approach for the cobweb model (19), suppose that expectations are based on the *perceived law of motion* (PLM) $p_t = a + bw_{t-1} + \eta_t$ and hence given by $p_t^e = a + bw_{t-1}$, where (a, b) may not be the REE values. Substituting this into Eqn. (19) we obtain the corresponding *actual law of motion* (ALM):

$$p_t = (\mu + \alpha a) + (\delta + \alpha b)w_{t-1} + \eta_t \tag{22}$$

This yields a mapping from the PLM parameters (a, b) into the ALM parameters $T(a, b) = (\mu + \alpha a, \delta + \alpha b)$. Only at the REE values does one have $T(a, b) = (a, b)$. Expectational stability (*E-stability*) looks at whether the REE is the stable outcome of a process in which the parameters of the PLM are adjusted slowly toward the parameters of the ALM that they induce. Formally, this adjustment is described by a differential equation and E-stability corresponds to local stability of the REE under these dynamics. For details, see Evans and Honkapohja (2001).

In the cobweb model the E-stability condition is given by $\alpha < 1$. Even in fairly complicated models it is often straightforward to compute E-stability conditions and these appear generally to govern convergence of statistical learning rules.

Local stability under adaptive learning, or E-stability, provides a selection criterion in models with multiple RE equilibria. For example, in the Cagan model with policy feedback (16) there are two RE solutions of the form (17), but only one of these is E-stable and hence stable under least-squares learning. The other solution, although rational, is therefore unlikely to arise in practice. Similarly, in the nonlinear model $y_t = F(y_{t+1}^e)$, only the steady states with slope $F'(\bar{y}) < 1$ are E-stable. This model can also have sunspot solutions and it has been shown that an appropriate form of adaptive learning can converge to rational sunspot equilibria, provided the corresponding E-stability condition is satisfied.

6.3 Other Approaches to Learning

There are some other recent approaches to modeling expectation formation. '*Eductive learning*' and '*rational learning*' are closer to RE than adaptive learning. In the former agents engage in a process of reasoning using common-knowledge assumptions and the learning takes place in logical or notional time. Rational learning takes place in real time, but retains the RE equilibrium assumptions at each point in time.

In contrast, the adaptive learning approach assumes that agents possess a form of *bounded rationality* which may, however, approach rational expectations over time. Besides the statistical formulation outlined above, alternative models of bounded rationality learning have been studied. Concepts from *computational intelligence*, such as genetic algorithms, neural networks and classifier systems, have been used as models of adaptive learning in economics.

Finally, we note that the literature has also considered learning in situations with structural shifts and/or misspecification of the perceived stochastic process. Certain learning rules, such as constant gain algorithms, can track structural changes more accurately than least-squares algorithms, although they often fail to converge fully to an RE equilibrium if the economic structure is in fact constant. Such procedures can lead to new forms of persistent *learning dynamics* which may be empirically important.

Experiential Psychotherapy

1. Introduction

The term *experiential* is defined in the *Concise Oxford Dictionary* (1990) as 'involving or based on experience' and experience is defined as the 'actual observation of, or practical acquaintance with, facts or events' or 'to feel or be affected by (an emotion, etc.).' A distinction between two ways of knowing, knowledge by acquaintance and knowledge by description, first made by St. Augustine, and later emphasized in the epistemologies of William James and Bertrand Russell, helps describe the essence of experiential therapy. Experiential therapy is an approach to therapy that focuses on promoting knowledge by acquaintance. Here a person does not come to know something about him- or herself conceptually but rather has an emotional experience of it. In experiential therapy the clients' experiencing process is kept as a continuous point of reference for all therapist responses and change is seen as occurring by the promotion of new in-session experience.

Although the term experiential therapy first arose to refer to Whitaker and Malone's approaches to psychodynamically oriented family and individual therapy (Whitaker and Malone 1953), this approach has subsequently grown out of a variety of 'third force,' humanistic, approaches. These include client-centered (Rogers 1959), Gestalt (Perls et al. 1951), and existential therapy (May and Yalom 1995), as well as other approaches that emphasize working with the clients in-therapy experiencing process (Greenberg et al. 1998). Experiential therapy consists of those approaches that, within the context of a facilitative human relationship, focus on the creation of new meaning by the symbolization of experience in awareness. The two major foci of experiential therapy practice are the personal presence of the therapist in the provision of an emphatic and facilitatively genuine therapeutic relationship, and increasing clients' awareness of internal experience by focusing them on their moment by moment subjective experience.

2. View of Human Nature and Functioning

Experiential therapy adopts an existential view of human nature, one that sees existence as preceding essence. People are seen as active agents in the construction of their own realities and choice is seen as the final arbiter in human functioning. Individuals are seen as being born morally neutral with a penchant both for health and sickness, and good and bad. What is essential, however, is that people are seen as having innate worth, the ability to know the difference between good and evil, and the capacity to choose. Free will thus is the foundational principle and therapy involves facilitation of the actualization of the potential for healthy functioning. Health is seen as arising from the ability to symbolize experience in awareness and to integrate different parts of the self to create equilibrium and coherent meaning.

Experiential theory of personality proposes a process model of the self. The self is seen as a dynamic experiential system that is in a continual process of self-organization. Experiential theory is constructivist in nature, and adopts a dynamic and dialectical view of functioning. It emphasizes that meaning is created by human activity, in dialogue with others, that change is an inherent aspect of all systems and that this occurs by a synthesis of parts. Meaning construction is viewed as being constrained by a bodily felt emotional experience but as influenced by language and culture and ultimately as created by a synthesis of experience and symbol (Gendlin 1962, Greenberg et al. 1993, Greenberg and Pascual-Leone 1995). Emotional experience is seen as both creating and being created by its conscious symbolization and expression. This view casts people as creators of the self they find themselves to be. In addition, experiential therapy, by adopting a relational view of functioning, sees the self as coming into existence at the boundary between inside and outside, between organism and environment, by a synthesis of bodily experience, symbol and interpersonal validation.

Emotional experience, although seen as a basically healthy resource, is viewed as capable of either providing healthy adaptive information based on its biologically adaptive origins or, in certain instances, as having become maladaptive through learning and experience. The most basic process for the individual in therapy is thus one of developing awareness of emotion and discriminating which emotional responses are healthy and can be used as a guide, and which are maladaptive, and need to be changed.

2.1 Goals

The general goals of treatment are to promote more fluid and integrative self-organizations. Therapy focuses on the whole person, i.e. it is person centered rather than problem or symptom focused, but within this wholistic focus, the underlying determinants of different types of self-dysfunction are also an important point of focus. Thus both a change in manner of functioning of the whole self and changes in particular problems in self-organization are viewed as important. For example, a client may be seen as changing the manner of functioning both by becoming more empathic to the self and by being able to symbolize bodily felt experience, as well as changing

by resolving a specific problem such resolving unfinished business with a significant other. Thus treatment in addition to promoting self-acceptance and a strengthening of the self also aims at solving particular problems of self-organization that emerge in treatment. The problems that are focused on emerge in a collaborative fashion over the course of treatment.

3. *Basic Principles of Practice*

Experiential therapy recognizes both the power of the understanding relationship and the importance of different in-therapy tasks in promoting different types of therapeutic change. The quality of the bond between participants as well as collaboration on the tasks and goals of therapy are seen as essential in creating a good therapeutic alliance. The bond is warm, respectful, empathic, and validating, while the goals and tasks focus on increasing awareness, deepening experience, and resolving specific in-session emotional problems.

The relational bond is seen as involving three main healing ingredients: first, a more transcendent aspect, the human *presence* of the therapist, witnessing and validating the other's humaness; second, a set of more explicit facilitative *attitudes* that create a safe working environment; and third, a set of specific interpersonal *behaviors* that facilitate growth and provide new interpersonal experience. Buber's (1958) 'I–thou' relationship, involving such elements as presence, commitment to dialogue, and nonexploitiveness, and the Rogerian triad (Rogers 1957) of empathy, positive regard, and congruence together describe the general nature of the relationship. Empathy is seen as a complex cognitive/affective process of imaginative entry into the world of the other and involves understanding, in addition to being with, the other and the promotion of deeper experience. This process helps the client to feel connected, to regulate affect, and to construct new meaning.

A relational bond of this type is seen as both confirming the client as an authentic source of experience and as providing the optimal context for helping the client to attend to and become aware of prereflective experience and to communicate and explore it without fear of evaluation. The facilitative relationship, in addition to being curative in and of itself, also provides a safe environment for working on particular problems. Finally, not only does the relationship serve as a confirming environment and as a context for specific forms of intrapsychic work, but it is itself also a medium for specific corrective interpersonal experiences. Thus certain forms of work on the relationship between client and therapist are also seen as mutative.

In addition to the provision of a 'healing' relationship, facilitating work on particular therapeutic tasks is also seen as a core ingredient of experiential therapy (Greenberg et al. 1993). The most central task of experiential therapy is that of deepening the clients experiencing. This involves focusing clients on their internal experience, helping them to symbolize it in words, and create new meaning. The therapist promotes different internal processes at different times to aid experiential processing. The processes facilitated range from, symbolizing a bodily felt sense, to evoking memories, to letting an intense feeling form, to expressing feelings, to reflecting on experience to create new meaning. The client in addition is encouraged to engage in such activities as psychodramatic enactments, or exercises in imagination to help address particular emotional issues. Specific tasks such as resolving problematic reactions, or resolving splits between parts of the self, are worked on in therapy. Resolving problematic reactions for example involves re-evoking the situation in a vivid manner in order to re-experience what occurred in order to develop a new view of self and situation. Resolving splits involves the promotion of separation and contact between two parts of the self in a dialogue to facilitate self-acceptance. In these tasks the client is seen as an active agent engaging in an exploratory process, and the tasks are viewed as being done *by* clients rather than done *to* them.

3.1 *A Process Theory*

An important distinguishing characteristic of experiential therapy is that it offers a process theory of how to facilitate knowledge of acquaintance, rather than a content theory of personality or psychopathology. A process theory of this type specifies both the moment by moment steps in the client's process of change and the therapist interventions that will facilitate these steps. The emphasis in each step always is on how to promote the direct sensing of what is concretely felt in the moment to create new meaning.

There is an explicit assumption that within each individual there is a flow of experiencing to which the person can refer in order to be informed about the personal meaning of particular experiences. The main principle of the experiential method is to have people check whatever is said or done against their own concretely felt experience. Change is seen as emerging from a growing awareness of previously unsymbolized experience and the bringing of this experience into dialectical interaction with words or symbols and other aspect of experience to create new meaning.

The key to experiential therapy is to have clients experience or become acquainted with any manner of content in a new way such that this new experience will produce a change in the way they view themselves, others, and the world. Experiential therapy thus adds to the other approaches the emphasis that symbols, schemes, and even behavior must interact with the body based, experiential, level of existence in order to produce change. It thus offers a process theory of how body and symbol interact, and a set of methods for promoting this process.

Experiential therapy theorists have specified patterned sequences of change processes and events, the explicit connections of which are spelled out by their experiential theories of change. Three such characteristic sequences are described below. One sequence offered by Gendlin (1996) includes three fundamental client change events: (a) the client focuses on a directly felt meaning; (b) the client allows feelings, words, and pictures to arise from this inward focusing, and attends to the generated feeling; (c) the client receives a new felt meaning that emerges from the ensuing shift in body experience. Another experiential sequence (Mahrer 1989) consists of four client basic change events: (a) the client attains a level of strong feeling; (b) the client welcomes and appreciates the accessed inner experiencing; (c) the client becomes the inner experiencing in the context of earlier life scenes; (d) the client becomes and behaves according to the inner experiencing in the context of imminent future life scenes.

A third sequence specified by Greenberg and Paivio (1997) involves six basic change events: (a) the client experiences the problematic bad feelings in the session; (b) the client accesses, allows, and receives deeper core emotions and needs in the session; (c) the patient and therapist together explore whether the core emotion is adaptive or maladaptive; (d) if judged to be adaptive, the core feelings are used as a guide, and if judged to be maladaptive, alternative adaptive emotions and needs are accessed; (e) the core maladaptive emotions and associated beliefs are challenged from within by the newly adaptive emotions and needs; (f) new meaning is created based on the new experience that emerges from the dialectical interaction of adaptive and maladaptive parts of self.

In these processes, the therapist is seen as an expert on how to facilitate new steps in the client's experience rather than an expert on the content of the client's experience. Therapists thus avoid interpretations of the content of a client's experiences that tell the patient why he or she does things and that are theory-driven rather than experience-near. Responses that are conceptual or explanatory, or are expressed as fact, or that give the message that truth comes from the therapists' professional knowledge are avoided in favor of phenomenologically refined exploration of the client's experience. Experiential therapy thus attempts to eliminate any interpretations that are based on the therapist's theory of how people are, or should be, or that attempt to reveal hidden 'truths.'

The experiential approach rather places great emphasis on, and respect for, what the patient experiences, and pays special attention to what the patient experiences in the relationship with the therapist. Experiential therapy involves consistent listening from within the patient's frame of reference. Hence sustained empathic inquiry is a central part of the practice. However, although this empathic emphasis is necessary for good psychotherapy, it is not necessarily sufficient for the best psychotherapy. The most effective psychotherapy also requires therapist practices of a technical nature, such as phenomenological focusing, experimentation, and behavioral observation (Gendlin 1996, Perls et al. 1951). Diagnostic understanding of the individual, and also understanding the social, cultural, and institutional forces affecting the individual, are also required.

Notwithstanding the fact that what the patient experiences is the indispensable essence of psychotherapy, and that it is imperative that this be the subject of respectful ongoing inquiry by therapist and patient, what the patient does not experience is also an indispensable and critical component of what happens in therapy. Important factors that are kept from the patient's conscious experience that do not become figural in awareness also need to be the subject of phenomenological exploration. In experiential therapy there is a special emphasis on bringing into awareness the processes that regulate this process of awareness/unawareness (Polster and Polster 1973, Yontef 1993). This work is codirected by therapist and patient and is not based on any alleged higher truth of the therapist. It is based on a joint empathic exploration that may include observation, experimentation, and dialogue.

4. *Conclusion*

In the experiential approach, an empathic focus on the patient's actual experience is seen as indispensable, but the therapist is also seen as making contributions in addition to sustained empathic inquiry. Therapists complement the empathic inquiry with a variety of therapeutic interventions that can help the patient learn how efficiently to focus awareness and distinguish actual phenomenological experience, that can highlight the processes essential to the patient's characterological organization by sophisticated and competent understanding that includes understanding theories of healthy functioning and psychopathology.

Experiential therapy has been demonstrated to be effective in treating depression, anxiety, childhood maltreatment, and marital distress in addition to some personality disorders and a variety of other problems in living (Greenberg et al. 1994, 1998).

Experiment, in Science and Technology Studies

Experiment was a major concern of science and technology studies (STS) during the last quarter of the twentieth century. This is because certain views of experimentation as a privileged way of making knowledge about nature were important focuses of dissent during the specialty's early career. Various versions of the so-called 'received view' of science prevalent in Anglo-American philosophy of science in the period following World War II, with their roots in logical empiricism, held up experiments as the crucial empirical elements of scientific knowledge. Whether the logic employed in their modeling of scientific reasoning was falsificationist or conformationist, versions of the 'received view' represented theories as conceptual structures that coordinate with the world through independent experimental tests of their predictions. This article will survey some of the major developments that have emerged to modify those older views.

1. Development of New Approaches to Experiment: Challenges to the 'Received View'

In the 1950s and early 1960s, one of the central assumptions of the 'received view' was seriously challenged. The presumed independence of experimental and observational data from contamination by the very theories that the data were intended to judge was challenged by W. V. O. Quine (Quine 1953), Norwood Russell Hanson (Hanson 1958), and Thomas S. Kuhn (Kuhn 1970 [1962]). Quine showed, using an argument similar to one used by Pierre Duhem (1954), early in the twentieth century, that empirical data always underdetermine the theories that can rest upon them. In Duhem's hands, the argument rested on a position of 'conventionalism,' whereby the relationship between items of discrete empirical data and the theories employing those data was seen to be underdetermined; in particular, Duhem argued that there could be no such thing as a 'crucial experiment' that could decide definitively between two alternative theories. A result inconsistent with one of the theories need not be attributed to an inadequacy in the target theory itself, but might instead be attributed to error in a subsidiary theory (such as one relating to observational instruments) that had not initially been in question. Possibilities of that sort amounted to decisions, according to Duhem, and were consistent with a conventionalist view of scientific theories, whereby pure convention determined which in a network of theories would be preserved and which amended so as to fit experimental results.

Hanson and Kuhn went further, with their arguments in favor of the 'theory-ladenness of observation.' They held that a pure observation language was in principle impossible, and that, accordingly, the results of experiments and observations of nature always implicated theoretical concepts in their very formulation. This position blurred the distinction between empirical data on the one hand and the theories that are justified by those data on the other. Both Kuhn and Hanson likened empirical data to the psychologist's gestalt experiments, wherein, for example, the 'same' image can sometimes be seen as a duck and sometimes as a rabbit; the difference, they claimed, was that in science there is no possibility of resting one's description on an account of the underlying set of lines. Instead, the scientist sees a duck or a rabbit, with no further reduction to a common

observational base being possible. All empirical data are already interpreted; that is, seen in a particular way (cf. Fleck 1979 [1935], an acknowledged source for Kuhn).

2. *Sociological and Historical Exploitations of New Theoretical Arguments*

These challenges to the 'received view' of science provoked much debate in the 1960s and into the 1970s. In its wake, however, there arose attempts to exploit the ideas of such as Hanson and Kuhn in the service of sociological projects aimed at making sense of scientific knowledge seen as a social product. In the early days of the 'sociology of scientific knowledge' (SSK), the Duhem–Quine 'underdetermination' thesis became a standard in-principle justification for sociological studies of the acceptance of knowledge claims by scientific communities (e.g., Mulkay 1979, Knorr-Cetina and Mulkay 1983). This was so because it was argued that the inadequacy of empirical evidence to necessitate any particular theoretical belief in science left room for social explanations regarding which belief among the manifold logical possibilities was the one actually chosen. At the same time, however, a more fundamental theoretical challenge to the self-sufficiency of 'received view' accounts of the role of experiment in science was being developed by H. M. Collins, drawing on a sociological reading of Wittgenstein (Winch 1958, cf. Bloor 1983).

Wittgenstein had argued that rules do not contain rules for their own application; such a position, in the form of 'finitism,' also applies to practices of classification (see, for a summary of its relevance to STS, Barnes et al. 1996). The basic claim amounts to observing that every new situation, every new occurrence of some kind of event, is in its own way unique; it therefore requires indeterminate judgments of similarity and difference to decide whether a new event or instance is or is not a legitimate member of a given category. In articles from the mid-1970s onwards, and culminating in a book of 1985 (Collins 1985), Collins developed empirical case studies that exploited Wittgenstein's arguments to show how the participants in actual scientific controversies resolve problems of the ambiguity of experimental outcomes. In work on claims to the detection of high-flux gravitational radiation in the 1970s, as well as in the transfer of skills relating to the successful replication of TEA-laser technology, Collins developed the notion of the 'experimenters' regress,' which he saw as an application in the domain of the sociology of science of Wittgenstein's 'indeterminacy of rules.' In the case of an experimental result, a judgment must be made that involves deciding whether the experiment or experimental run was competently conducted. If yes, then the outcome can be used to assess an associated theoretical claim (which would then open up Duhem–Quine issues), whereas if not, then the outcome will be irrelevant to the claim. Collins showed that, routinely, such assessments of experimental competence were central to scientific controversies. The ultimate criterion for judging the competence of an experiment, according to Collins, was whether the experimental outcome was correct or not. In the case of experiments the results of which were taken to depend on unknown or controversial aspects of the natural world, therefore, controversy over nature was coextensive with controversy over which experiments were fit to judge concerning that feature of nature. This, then, is the essential paradox designated by the term 'experimenters' regress': it is only possible to know whether an experiment was competently performed if it is known what the correct outcome should be, but (in an empiricist epistemology) the correct outcome can only be known as a consequence of the performance of competent experiments.

The sort of empirical studies of scientific practice conducted by Collins also yielded fruitfully to analysis in terms of the Duhem–Quine thesis. Trevor Pinch's *Towards an Analysis of Scientific Observation* (Pinch 1985) introduced the idea of 'externality' in understanding the role and fate within the scientific community of experimental work. Pinch noted that knowledge-claims made on the basis of experimental studies could themselves be couched in alternative ways that maximized or minimized the likelihood that the competence and reliability of the experiments themselves would be questioned. An experimentally based assertion with high externality would be one that used the experimental outcome to make far-reaching inferences about some domain of existing knowledge; an assertion with low externality would depart but little from a bald statement of the local circumstances of the experimental situation, and could provoke but little controversy. Andrew Pickering (Pickering 1984) examined similar professional dynamics in the work that established the existence and characteristics of quarks in the 1970s.

Together, the Duhem–Quine thesis, finitism, and the experimenters' regress had opened up, by the mid-1980s, a vast terrain within which sociologically informed study of the experimental dimensions of scientific knowledge could be conducted. A landmark study that fully exploited the new possibilities was Steven Shapin and Simon Schaffer's *Leviathan and the Air-Pump* (Shapin and Schaffer 1985). This historical study directly challenged the older 'received view' conception of the role of experiment in making scientific knowledge, and did so by investigating a classic, oft-cited historical example usually held to exemplify that view. The subject chosen in the book was the air-pump work of Robert Boyle in the 1660s. Boyle's work had been presented (Conant 1970 [1948]) in one of the *Harvard Case Histories in Experimental Science*, dating from the late 1940s and 1950s. These were publications that, importantly, had shaped the

teaching and scholarship in the history of science for many years, and which were consistent with the usual conception of experiments as unequivocal arbiters of theoretical ideas. Shapin and Schaffer thus accepted Boyle's air-pump experiments, for the sake of argument, as an exemplary model of scientific procedure. They then attempted to show how a close examination revealed that Boyle's experiments and their associated knowledge claims were far from unequivocal—were, in fact, strongly contested—and that the interpretation of them advanced by Boyle and his allies could also be understood as part of a political vision of the proper social constitution and conduct of a philosophical community. In order to achieve this purpose, Shapin and Schaffer used the criticisms of Boyle advanced by the philosopher and mathematician Thomas Hobbes, a man whose view of the proper way to make natural knowledge differed significantly from that of Boyle and whose associated conception of the place and legitimacy of knowledge in a polity also differed markedly from Boyle's. Hobbes's detailed criticisms of Boyle's air-pump work revealed an alternative set of values and commitments regarding the best way to achieve social stability and consensus, a way that invalidated experimental work as an effective means of securing knowledge claims. An alternative approach to similar issues (Dear 1985, 1987, 1995) focuses on conventions of knowledge making that were less local than those examined by Shapin and Schaffer, and which support a view of much more mediated connections with social organization. Dear's main argument is that the modern 'experiment' as a historically specific, contrived event was a development of seventeenth-century Europe, and had close filiations with disciplinary approaches employed in mathematical sciences that stressed operationalism.

3. *Laboratory Studies and Naturalistic Approaches*

By the mid-1980s, in addition to the work already discussed, a number of so-called 'laboratory studies' were being published. These studies also had a strong influence on views of experiment in science, but, in contrast to the approaches considered above, they tended to eschew, often explicitly, an overt engagement with the 'received view' philosophies of science. Instead, the methodological and/or epistemological approaches that were central to laboratory studies drew from such traditions as those of anthropology, ethnomethodology, and phenomenology. The three crucial and exemplary lab studies from this period were Latour and Woolgar's *Laboratory Life* (Latour and Woolgar 1979/1986), Karin Knorr-Cetina's *The Manufacture of Knowledge* (Knorr-Cetina 1981), and Michael Lynch's *Art and Artifact in Laboratory Science* (Lynch 1985). These three have in common a naturalistic stance towards the work of the laboratory, rejecting presuppositions as to the character of that work. Thus, they have no *a priori* interest in studying laboratory work as a means of learning how 'reliable,' or 'true,' or 'epistemologically privileged' knowledge results from laboratory practices. Instead, they treat their particular laboratories as sites where activities are carried out, and attempt to describe and account for the nature of those activities. A notable feature of the rapidly changing intellectual landscape on which these laboratory studies were performed is the existence, in the first edition of *Laboratory Life*, of the subtitle *The Social Construction of Scientific Facts*, and its replacement in the second edition, seven years later, by the less doctrinaire *The Construction of Scientific Facts*. The change signals the way in which, in the years surrounding 1980, the rhetoric of SSK, with its insistence on 'social construction' as the crucial mechanism by which scientific knowledge was made, dominated science studies. By 1986, this insistence was already looking rather hackneyed and uninformative in some quarters.

The place of experiment in the tradition of laboratory studies is less clear-cut than it was in the mainstream SSK tradition, because the former were not reacting directly to the epistemological highlighting of experiment characteristic of the philosophical 'received view.' Thus, experiments were less likely to be seen as obviously individuated events, instead falling within an overall passage of scientific activity. The highlighting of particular experiments as especially significant cognitive elements of such passages now became contingent on the behavior and utterances of the scientists being studied, rather than being self-evidently central to an understanding of scientific work.

A collection of papers originating in a conference of 1985 on 'The Uses of Experiment' (Gooding et al. 1989, see also Le Grand 1990 for a similar collection) attempted to shed light on experiment as a category used by scientists rather than as an epistemologically significant item singled out by philosophers. The contributors made use of the new work in science studies to lay out, chiefly by means of empirical studies of contemporary and past science, the multifarious ways in which experiment has been used as a rhetorical and practical tool in the establishment of knowledge-claims and in the consolidation of scientific communities of practice. One especially notable concept deployed in this volume, centrally in the contribution by Simon Schaffer (Schaffer 1989), was that of experimental 'transparency.' This concept designated situations in which an experimental apparatus becomes so unproblematic and theoretically unquestioned that the phenomena to which it affords access are seen directly, as it were, as if no theoretically justified experimental device intervened between observer and phenomena. In such cases, in effect, the apparatus has changed from being an experimental set-up to being a scientific instrument. For example,

such, was the fate of the mercury barometer in the seventeenth century, which began life as an experiment intended to examine the pressure of the air and the possibility of a vacuum but which, by the end of the century, had become an instrument for measuring atmospheric pressure as an aid to understanding the weather. These kinds of conceptualization also hark back to the much earlier work of the French philosopher Gaston Bachelard, who spoke of the artificial creation of phenomena by apparatus, using the term *phénoméno-technique* (e.g., Bachelard 1938, see Gaukroger 1976 for a lucid introduction).

The second half of the 1980s also saw the appearance of empirical studies of modern physical experimentation that adopted attitudes quite different from those of the advocates of SSK. Peter Galison, in his book *How Experiments End* (Galison 1987), examined several episodes in post-WWII high-energy physics in the United States. The book's intention was to describe the ways in which experimental closure was brought about in the episodes discussed, but in a way explicitly opposed to that of such as Collins; that is, Galison's aim was to show that social mechanisms were insufficient to explain the outcome of the experimental work. Allan Franklin also published work on modern experimental physics with broadly the same aim (Franklin 1986, 1990). In both cases, the role of an independent physical world in creating sometimes-unexpected outcomes to experiments was emphasized, to reduce the role of social actions and social structures in determining outcomes: in Franklin's case, at least. It was argued that social considerations become irrelevant in light of the overwhelming influence of objective experimental outcomes and their correct rational assessment. Franklin's position, however, appears largely to ignore the epistemological problems that fueled SSK.

Discussions of experiments and the best ways of understanding their role in science also went well beyond issues of their direct epistemological function. Historical studies, pre-eminently Shapin and Schaffer's *Leviathan and the Air-Pump*, were by now having an impact on wider conceptions of the ideological structure and social meaning of science. The most important example of that impact was Yaron Ezrahi's *The Descent of Icarus* (Ezrahi 1990). This took Shapin and Schaffer's presentation of Robert Boyle's kind of experimental science as the model for science ever since the seventeenth century, and adapted their view of its political meaning to an account of the development of modern liberal ideology and, subsequently, modern liberal states from the eighteenth to the twentieth centuries. In Ezrahi's view, the legitimacy of experimental knowledge claims in science became the accepted norm for knowledge claims in the political arena as well. Shapin and Schaffer had stressed the role of 'witnessing' in Boyle's kind of experimental science, whereby many people, either directly or through the reading of detailed reports ('virtual witnessing'), came to attest the truth of an asserted experimental outcome and thereby its associated factual knowledge claim. Ezrahi suggested that a similar visibility, or transparency, of political actions and the reasons for them became the political ideal, along with the notion of the accountability of political leaders. Ezrahi's ideal-type of such a polity, the United States in the twentieth century, thus placed great stress on the possibility of citizens seeing what their government was doing and in assessing the grounds for and wisdom of those actions (see also Latour 1993 for different political extrapolations).

4. *Latour on Experiments and their Mobility*

Other aspects of experimentation were also investigated in the 1980s and early 1990s, most notably in the work of Bruno Latour. Latour's naturalistic approach to scientific practice, which had been explicitly anthropological in inspiration in *Laboratory Life*, extended his representation there of laboratory science as an enterprise centrally concerned with the production of 'literary inscriptions' (any kind of trace inscribed on paper). This extension took the form, in his *Science in Action* (Latour 1987), of an analysis of the structure of experimental papers. That structure, he argued, reveals the agonistic logic of experimental procedures through a kind of shadowboxing, whereby the paper's authors attempt to anticipate and head off skeptical criticisms of their claims, such as might be put forward by a determined opponent. Thus, the experimental paper (and, by implication, the experimental protocol itself) takes the form of one side of a dialogue aimed at silencing the critic through anticipation of all plausible objections. Part of the power of this analytical approach supposedly resides in Latour's stress on semiotic analysis (Latour and Bastide 1986), which connects with his emphasis on taking into account 'natural actants' in accounts of scientific activity (cf. also Latour 1988). Thus semiotic actors in the experimental account which are normally taken to refer to things in the natural world (such entities as subatomic particles, or microbes, etc.) are treated on a par with those semiotic actors normally taken to refer to things in the social world (pre-eminently, the scientists performing the experiment). Thus, they are understood in exactly the same way. Latour therefore claims that there is no justification for treating social actors as real while treating 'natural actors' as simply social constructs, which is what the SSK approach advocates. Problems seem to arise in Latour's approach, however, when the question of shifting between the analytical level of the semiotic and the analytical level of the putatively 'real' is considered; Latour is obscure on the point.

One especially influential idea in Latour (Latour 1983, 1988) concerns a way of understanding how experimental outcomes can be mobile; that is, how a

successful experiment conducted in a specific laboratory is made to be successful at other locations. This issue has been referred to as the 'problem of constructivism' in Golinski (1998); although Latour would not count himself as a 'constructivist' in the SSK sense, his similar stress on the work that goes into creating an experimental 'fact' leaves him with the same problem. The difficulty that Latour purports to solve is to explain how, if experimental facts are made in situations whose specificity and locality ('natural' and 'social') are taken as crucial to explaining the particular outcome, that outcome is seen to be reproduced in significantly different settings. The traditional ('received view') answer is that the experimental outcome is simply a reflection of the way that nature works, and an implicit principle of the uniformity of nature therefore implies that the same experiment, in the sense of the same material set-up and procedure, will yield the same result wherever it is conducted. The constructivist, however, because of a conviction that 'social' elements (however defined in detail) are essential to producing the outcome, appears to have difficulty in explaining this mobility of experiment (cf. Collins 1985 on the TEA-laser). Specifically, Latour explains the apparent paradox of experimental success outside the laboratory setting, using Louis Pasteur's field trials of his anthrax vaccine as an example, by denying that the laboratory has ever really been abandoned. Instead, when, for instance, Pasteur managed to create a vaccine found to work on animals in carefully controlled laboratory conditions, his demonstration of its effectiveness on actual farm animals involved, according to Latour, transferring his laboratory to the farm. It was not that Pasteur's vaccine worked in the laboratory and on the farm; the vaccine only ever worked in the context of the laboratory trial. Pasteur's trick was in turning the farm into a laboratory while maintaining the illusion that it was still a farm. Hence, experiments can be spread, on this view, only via networks of laboratories or laboratory-equivalents; they do not in fact work everywhere.

5. *Experimental Systems*

In the 1990s, there appeared a number of new conceptualizations of experiment, including an important collection of essays concerning the life sciences, *The Right Tools for the Job* (Clarke and Fujimura 1992), and significant discussions of various experimental practices and regimes in Peter Galison's *Image and Logic* (Galison 1997). These new conceptualizations had in common a more expansive and complex view of the ways in which experiment forms a part of elaborate systems of scientific practice. Andrew Pickering's *The Mangle of Practice* (Pickering 1995) developed from and built upon his earlier SSK-influenced work by attempting to understand scientific practice as a pragmatic interaction between experimental procedures, theoretical models, and physical reality. The constraints on scientific ideas resulting from the interaction between these theoretical and material practices had become in Pickering's work an important and central feature that rejected any attempt at pure sociological reductionism (although whether this has ever truly existed in STS is a debated point). Pickering saw scientific work as an ongoing enterprise aimed at stabilization: theory and experiment cooperate, at least for a time, in producing mutually consistent, intelligible interactions between human beings and the world. By placing experiment within this more complex structure of scientific practice, Pickering thus endeavored to move beyond the sociological insights of science studies and to regain a connection with the natural reality with which science has always claimed to deal.

Similar pragmatic moves had also appeared in an important study by the historian Robert Kohler. In his *Lords of the Fly* (Kohler 1994), Kohler studied the early decades of *drosophila* (fruit-fly) research in the United States, centered on the laboratory of Thomas Hunt Morgan at Columbia University and subsequently at the California Institute of Technology. Kohler described the operations of Morgan's fly lab in terms of the exploitation of the capabilities of the materials, centrally including the flies, with their particular breeding and variation characteristics. The whole taken together, and crucially including material practices (given some precedence in this study over intellectual practices), was characterized by Kohler variously in terms of 'experimental practice,' 'experimental production,' or as a 'system of experimental mass production.' The term 'experimental system' was also used by Hans-Jörg Rheinberger in an ambitious study, *Toward a History of Epistemic Things* (Rheinberger 1997). Rheinberger, following the same general tendencies as Kohler and others, and with an important nod to Fleck, represented his project as being directed against the old philosophical tendency to view experiments as isolated epistemological elements, instead focusing his attention on the integration of experiment within a multifaceted system of practices which together constitute the modern scientific enterprise (cf. also Knorr-Cetina 1999, especially pp. 39–43). Consequently, experiment has lost much of its former philosophical mystique.

Experimental Design: Bayesian Designs

This article provides an overview of experimental design using a Bayesian decision-theoretic framework. Scientific experimentation requires decisions about how an experiment will be conducted and analyzed. Such decisions depend on the goals and purpose of the experiment, but certain choices may be restricted by

available resources and ethical considerations. Prior information may be available from earlier experiments or from conjectures which motivate the investigation. The Bayesian approach provides a coherent framework where prior information and uncertainties regarding unknown quantities can be combined to find an experimental design that optimizes the goals of the experiment.

1. Introduction

Experimentation plays an integral part in the scientific method. Conjectures and hypotheses are put forth based on the current state of knowledge. Experimental data may be collected to address unknown aspects of the problem. Finally, analysis of experimental results may lead to one hypothesis being favored over others or may lead to new questions and investigations, so that the process is repeated, with the accumulation of additional knowledge about the scientific process under investigation.

In some fields of scientific inquiry, physical models can be used to describe the outcome of an experiment given certain inputs with complete certainty. In the majority of applications, one cannot describe the scientific phenomena perfectly, leading to a distribution of possible outcomes, which can be described by probability models. For example, in comparing a new therapy to an existing treatment, individuals receive one of two treatments. The outcome or response is an indicator of 'success' or 'failure' of the given treatment, which can be modeled using Bernoulli distributions with unknown success probabilities. In psychological or educational testing, the outcome may be scores on a battery of tests. The outcomes or responses may depend on many other factors besides the assigned treatment, such as age, education, gender, or other explanatory variables. Hypotheses or quantities of interest are often phrased in terms of parameters θ of statistical models which relate the distribution of outcomes Y to levels of explanatory variables.

In conducting an experiment, there are many design issues to resolve, including deciding which treatments to study, which factors to control, and what aspects of an experiment to randomize. Other aspects of experimental design—such as how many experimental units are needed, how many observations should be allocated to each treatment, or what levels of other input or control variables should be used—have traditionally fallen under the umbrella of statistical design (see *Experimental Design: Overview*). Because of costs, ethics, or other limitations on resources or time, sample sizes are usually restricted, and efficient use of available resources is critical. The purpose of optimal experimental design is to improve statistical inference regarding the quantities of interest by the optimal selection of values for design factors under the control of the investigator, within, of course, the constraints of available resources. Decision theory (see *Decision Theory: Bayesian*) provides a mathematical foundation for the selection of optimal designs. Prior information from earlier related experiments, observational studies, or subjective beliefs from personal observations, can be valuable in deciding how to allocate treatments efficiently, leading to more informative experiments. The Bayesian approach to experimental design provides a formal way to incorporate such prior information into the design process.

2. Bayesian Optimal Designs

The statistical aspects of an experiment e may be formally described by the sample space Ω (possible outcomes for the response Y), the parameter space Θ, and a probability model $p_e(y \mid \theta)$ that represents the distribution of observable random variables Y indexed by a parameter θ, an element of the parameter space Θ. Sample sizes, treatment levels, number of treatments, levels of explanatory variables, or other aspects of the design to be selected are implicitly contained in $p_e(Y \mid \theta)$. The primary goal(s) or terminal decision(s) of an experiment may include, but are not limited to, estimating θ or other quantities of interest that are functions of θ, predicting future observations, selecting among competing models, or testing other hypotheses.

Lindley presented a two-part decision theoretic approach to experimental design, which provides a unifying theory for most work in Bayesian experimental design today. Lindley's approach involves specification of a suitable utility function reflecting the purpose and costs of the experiment; the best design is selected to maximize expected utility. In this framework, an experiment e is selected from the possible collection of experiments E (the first decision problem). After choosing an experiment e, outcomes Y are observed. Based on the observed data Y and experiment e, a terminal decision d is selected from possible decision rules D, which addresses the terminal goal(s) of the experiment. A utility function in the form $U(d, \theta, e, Y)$ encodes the costs and consequences of using experiment e and decision d with data Y and parameter θ. Assuming that the goals of an experiment and terminal decision can be formally expressed through a utility function, the Bayesian solution is to find the best design and best decision rule that maximize expected utility.

While the process of experimentation followed by inference/decision making proceeds in time order, it is easier to solve the optimal decision problem in reverse time order. The terminal-stage decision problem involves finding the best decision rule d given the observed data Y under experiment e that maximizes the *posterior* expected utility,

$$\max_d \int_\Theta U(d, \theta, e, Y) p(\theta \mid Y, e)\, \mathrm{d}\theta = U(e, Y) \quad (1)$$

Here, the expectation or averaging over θ accounts for uncertainty regarding the unknown θ. The expectation is taken with respect to the posterior distribution of θ, which properly reflects uncertainty in θ at the terminal stage after Y has been observed under experiment e.

As the experiment e must be selected before data Y are observed, the second-stage optimization problem involves finding the best experiment e that maximizes the *preposterior* expected utility. The preposterior expected utility is obtained by integrating the result in Eqn. (1) over possible outcomes in the sample space Ω,

$$U(e) = \int_{\Omega} U(e, Y)p(Y|e)\,\mathrm{d}Y = \int_{\Theta}\int_{\Omega} U(e, Y)p_e(Y|\theta)p(\theta)\,\mathrm{d}\theta\,\mathrm{d}Y \quad (2)$$

This integral is with respect to $p(Y|e)$, the marginal distribution of the data under experiment e, which is obtained by integrating $p_e(Y|\theta)$, over possible *prior* values for θ, described by prior distribution $p(\theta)$. The Bayesian solution to the experimental design problem is provided by the experiment e^* which maximizes $U(e)$:

$$U(e^*) = \max_e \int_{\Omega} \max_d \int_{\Theta} U(d, \theta, e, Y) = p(\theta|y, e)p(y|e)\,\mathrm{d}\theta\,\mathrm{d}Y \quad (3)$$

This general formulation can be used to find optimal designs for a single experiment, and can be extended to optimal selection of a sequence of experiments and sequential decision making (Lindley 1972).

3. *Choice of Utility Functions*

It is important that utility functions be tailored to the goals of a given problem. Optimal designs for discriminating between two different models may be quite different from designs for prediction. In a one-way analysis of variance model, the best design for comparing k treatments to a control group, is not necessarily the optimal design for estimating the effects of $k+1$ treatments, as these experiments have different goals. While taking an equal number of observations in each of the $k+1$ treatment groups is a possibility, other arrangements may provide more information, particularly when data from previous experiments are taken into account. For example, several previous studies may be available using an existing therapy, but limited information may be available on a new treatment. Differential costs of treatment also need to be considered, which may lead to other allocations of sample sizes or choice of experiments. Ethical considerations may also be incorporated that may constrain the assignment of treatments (Kadane 1996).

Many of the papers in Bayesian design have based utility functions on Shannon information or quadratic loss. Motivation for these choices is discussed below. The reader is encouraged to refer to Chaloner and Verdinelli (1995) for additional details on these criteria, references, and relationships of other Bayesian utility functions to standard optimality criteria.

3.1 *Shannon Information*

Shannon information is appropriate for inference problems regarding θ or functions in θ, without specification of particular hypotheses. The expected utility function is based on the expected change in Shannon information or equivalently the Kullback-Leibler divergence between the posterior and prior distributions. As the prior distribution does not depend on the design, this simplifies to the expected Shannon information of the posterior distribution,

$$U(e) = \int_{\Theta}\int_{\Omega} \log\{p(\theta|U, e)\}p_e(y|\theta)p(\theta)\,\mathrm{d}Y\,\mathrm{d}\theta \quad (4)$$

thus the design goal is to find the design that maximizes the information provided by the experiment. In normal linear models with normal prior distributions, this leads to a criterion related to the well-known D-optimality from classical design,

$$U(e) \propto \log|(X_e^T X_e + R)/\sigma^2| \quad (5)$$

where X_e is the design matrix for experiment e and R/σ^2 is the prior precision matrix (inverse of the prior covariance matrix).

If prediction of future observations is important, the expected gain in Shannon information for a future observation Y_{n+1},

$$U(e) = \int \log(p(Y_{n+1}|Y, e)p(Y_{n+1}|Y, e)p(Y|e)\,\mathrm{d}Y\,\mathrm{d}Y_{n+1} \quad (6)$$

may be relevant. In normal linear models with prediction at a new point x_{n+1} this leads to

$$U(e) \propto \log[\{x_{n+1}^T(X_e^T X_e + R)^{-1}x_{n+1} + 1\}^{-1}/\sigma^2] \quad (7)$$

a Bayesian version of c-optimality.

3.2 *Quadratic Loss*

Point estimation based on quadratic loss leads to the expected utility function

$$U(e) = -\int_{\Theta}\int_{\Omega} (\theta + \hat{\theta})^{-T} A(\theta - \hat{\theta}) \quad (8)$$

where A is a symmetric non-negative definite matrix. The matrix A can be used to weight several different

estimation problems where interest may be in estimating individual components of θ or linear combinations of θ. Under the normal linear model and normal prior distribution this results in

$$U(e) = -\sigma^2 \mathrm{tr}\{A(X_e^T X_e + R)^{-1}\} \tag{9}$$

a Bayesian generalization of the A-optimality design criterion.

3.3 Other Utility and Loss Functions

Utility functions may be based on other loss functions besides quadratic loss. While a quadratic loss function may be appropriate in many cases, there are times when underestimation of a quantity incurs greater losses than overestimation. In such situations, asymmetric loss functions are more appropriate for design and inference (Clyde et al 1996). Discussion of other utility functions related to prediction, hypothesis testing and model discrimination and applications can be found in Chaloner and Verdinelli (1995).

3.4 Multiple Objectives

An experiment may often have several, possibly competing objectives which cannot be easily characterized by only one of the standard optimality criteria, and several design criteria may be appropriate. Weighted combinations of utility functions are still valid utility functions, so optimal designs for multiple objectives can be handled within the maximizing expected utility framework. For examples see Verdinelli (1992), Verdinelli and Kadane (1992), Clyde and Chaloner (1996). A difficulty with this approach is that utilities may be expressed in different scales which must be accounted for in the choice of weights. Equivalently, one can find the optimal experiment under one (primary) optimality criterion, subject to constraints on the minimal *efficiency* of the experiment under criteria for other objectives. These approaches are a potential way to address robustness of experimental designs under multiple objectives, models, and prior distributions.

4. Prior Distributions

Prior elicitation is an important step in designing Bayesian experiments, as well as analysis. Clyde et al (1996) use historical data from previous experiments to construct a hierarchical prior distribution to use for design of future experiments. Kadane (1996) considers many of the practical issues in subjective elicitation for clinical trials. Tsai and Chaloner (2001) describe a design problem where prior distributions are elicited from more than 50 clinical experts

While some researchers may agree to using prior information to help design an experiment, they may want to have their final conclusions stand on their own, such as in a frequentist analysis. One of the goals of the experiment may be to convince a skeptic, who has different beliefs from the designer of the experiment, that a treatment is effective. In such cases the prior distribution used in constructing the posterior distribution $p(\theta \mid Y, e)$ in the expected utility Eqn. (1) for the terminal decision problem may be different from the prior distribution $p(\theta)$ used in finding the best design in Eqn. (2). Etzioni and Kadane (1993) consider the problem of design when the designer and terminal decision maker have different prior beliefs corresponding to different decision rules.

5. Calculations

Calculation of expected utility, as in Eqns. (1) and (2), requires evaluation of potentially high-dimensional integrals, combined with difficult optimization problems, and in part, has limited the use of Bayesian optimal design in the practice. In normal linear models for many of the standard utility functions presented, the terminal decision rule can be solved in closed form and integrals can be computed analytically, leaving the optimization problem of finding the best experiment e^*. Except in special cases, numerical optimization must often be used to find the optimal design.

One can often relax the problem in the following way. Finding optimal 'exact' designs is often a difficult problem (similar to the traveling salesman problem). Designs can often be viewed in terms of a collection of support points (treatment levels) with weights that indicate the number of observations to be assigned at each support point. An exact design is one where the number of observations at each support point is an integer. A 'continuous' design is obtained by allowing the solution for the weights to be any real number. Rather than finding the optimal exact design, in the relaxed problem, the class of experiments is enlarged to include continuous designs. Mathematically, finding the optimal design in the continuous problem is easier to solve, and methods for checking optimality are often feasible. If the solution corresponds to an exact design, one can then show that it is the globally optimal design. While continuous designs cannot be used in practice, rounding of continuous designs provides exact solutions that are often close to optimal.

For nonlinear models, generalized linear models and other 'nonlinear' design problems (i.e., interest in nonlinear functions in an otherwise linear model), expected utility generally cannot be calculated in closed form and must be approximated. Many of the results for nonlinear design rely on asymptotic normal approximations in calculating expectations (Chaloner and Verdinelli 1995). Integrals may also be approxi-

mated by numerical quadrature, Laplace integration or Monte Carlo integration. With advances in computing resources, simulation-based optimal design is now an option, although methods often have to be designed for each specific application (see Müller 1999 for an overview of this area). As utility functions in many problems have been selected for their computational tractability, simulation-based design may soon open the way for greater use of scientific-based utility functions that better match the goals of the experiment. Hierarchical models are becoming increasingly important in modelling latent and random effects and accounting for subject-to-subject variability, for example. Advances in Bayesian computation, such as Markov chain Monte Carlo, now mean that inference in such models can be carried out in real problems. It is becoming easier to accommodate hierarchical and other complex models in the design of experiments with simulation-based optimal design schemes. Clyde et al (1996) compare analytic approximations and Monte Carlo-based design schemes for a hierarchical binary regression model using an asymmetric loss function.

6. *Applications*

Pilz (1991) covers Bayesian design and estimation in linear models, although from a rather mathematical viewpoint. Atkinson (1996) reviews both classical and Bayesian optimal design for linear and nonlinear designs, and presents recent applications such as design for clinical trials. Chaloner and Verdinelli (1995) provide a thorough review of literature on Bayesian designs and applications, which includes experimental designs for linear models such as regression and analysis of variance models, factorial and factional factorial experiments, variance component models, mixtures of linear models, hierarchical models, nonlinear regression models, binary regression models, designs for clinical trials and sequential experimentation. The article includes several worked-out examples, including design for one-way analysis of variance. The article by Clyde et al (1996) explores simulation-based design for a hierarchical logistic regression model, and illustrates how to construct prior distributions based on previous experiments. Other examples of simulation-based design appear in Müller (1999). For an example related to social sciences, see *Experimental Design: Large-scale Social Experimentation*.

The area of Bayesian design and analysis for clinical trails in both sequential and nonsequential designs is an exciting and active area, with many practical developments. For a survey of literature on sequential design, see *Sequential Statistical Methods*. The volume edited by Kadane (1996) describes a complete case study and discusses many of the critical issues in design and analysis of clinical trials, considering ethics, prior elicitation, randomization, treatment allocation, utilities, and decision making. Tsai and Chaloner (2001) describe the design of two large clinical trials, where prior distributions are based on eliciting prior opinions from over 50 clinicians. The design problem involves finding a sample size so that consensus of opinion is met with high probability, where consensus means that all clinicians would prescribe the same treatment based on their posterior opinions after the trial. Other recent examples include Rosner and Berry (1995), Simon and Freudman (1997).

While the increased use of Bayesian design in applications is especially encouraging, specialized software is often required. There is a growing need for reliable, user-friendly software for Bayesian design so that the methods can be more accessible and see greater applicability.

7. *Example*

The following design problem is concerned with choosing a sample size for an experiment to confirm results from an earlier study. All individuals in the first study had been diagnosed with breast cancer. Each individual had a biopsy of tumor tissue analyzed for expression levels or a protein implicated in progression of the disease; measured protein expression levels were scored between 0 and 8. All 135 individuals received a chemotherapeutic agent, with the goal of achieving pre-operative tumor regression. The measured outcome for each subject was a binary indicator of tumor regression. The researchers expected that the probability of tumor regression would increase as protein expression levels increased, and were surprised that the estimated probabilities reached a maximum around an expression level of 5, and then declined with higher levels. A logical regression model (see *Multivariate Analysis: Discrete Variables* (*Logistic Regression*)) was used to relate expression 1evels to clinical outcome (indicator of tumor regression). The linear predictor in the logistic regression model included a term with a parameter θ, such that for $\theta \geqslant 1$ the probability of tumor regression increases with expression level, while for $\theta < 1$ the probability of tumor regression increases up to a level of 5, then decreases. From a statistical perspective the evidence in favor of $\theta < 1$ was weak with a Bayes Factor of 1.65 ('not worth a bare mention' on Jeffreys' scale of interpretation for Bayes Factors (Kass and Raftery 1995). The goal of the second study is to investigate whether this decline was a chance occurrence. If the decrease is real, then this may suggest that a higher dose is necessary at higher expression levels, leading to other experiments.

Spezzaferri (1998) presented a utility function for model discrimination which can be used in designs for testing $H_0{:}\theta \geqslant 1$ versus $H_1{:}\theta < 1$. Spezzaferri's criterion can also incorporate parameter estimation, but

Figure 1
Smoothed expected utility for model discrimination vs. costs; the points indicate simulated expected utilities which exhibit Monte Carlo variation

Figure 2
Combined utility for model discrimination with a penalty for costs; the triangle indicates the combined utility at the optimal design

for simplicity only model discrimination is considered. The expected utility function for model discrimination can be represented as

$$U(e) = \int_{\Omega} Pr(\theta < 1 \mid Y, e) p(Y \mid e, H_1) \mathrm{d}Y$$

where $p(Y \mid e, H_1)$, is the marginal distribution of the new data under $H_1: \theta < 1$.

The experimental design involves selecting the total sample size N_e, as individuals with specific protein expression levels cannot be selected in advance due to costs of obtaining the results. The expected utility versus negative costs ($-\$2000 \times N$) is illustrated in Fig. 1, and was constructed using smoothing of utilities generated using Monte Carlo experiments (Müller 1999). While analytic calculations are intractable, calculation of utilities for this model are straightforward via simulation. The marginal distribution for Y given an experiment with sample size N must incorporate averaging over different configurations of expression levels among the N subjects and the unknown parameters in the logistic regression model. Configurations of size N are generated using a multinomial distribution, with a probability vector π. The expression level distribution from the first study is used to construct a conjugate Dirichlet prior distribution for π. Data from the previous experiment is used to construct the prior distribution for θ and other parameters in the logistic model, and construct the predictive distribution of the new data given a vector of new expression levels. For each set of stimulated data under the new study $Pr(\theta < 1 \mid Y, e)$ is calculated, which incorporates both the old data (in the prior distribution) and the new data. For each sample size N, protein expression levels and outcomes are repeatedly generated from their predictive distributions, and the average $Pr(\theta < 1 \mid Y, e)$ over experiments e with the same sample size N_e provides an estimate of the expected utility for e. These averages were smoothed in order to eliminate Monte Carlo variation in their estimates and are plotted in Fig. 1.

For the above criterion, expected utility will increase with the total sample size, and as formulated the design problem has an infinite solution. Each point on the curve (Fig. 1) is a combination of $U(e)$ and cost. Expected utility has a maximum at 1, which is obtained as N goes to infinity (and with infinite costs). The experiment which minimizes costs is given by $N = 0$, where the posterior probability that $\theta < 1$ given the data from the previous study was 0.85. The researchers want to minimize total costs, but at the same time find a sample size such that the expected utility is above 0.95 (corresponding to a Bayes factor above 3, which would provide strong evidence in favor of H_1). Combining costs and model discrimination, the combined expected utility function can be written as

$$U(e) - \lambda(\$2000 * N_e) \tag{10}$$

where λ reflects the trade-off between for discriminating between the two hypotheses and costs of subjects. In general, it is difficult to specify these trade-offs explicitly, as the different components are often measured in different units. Verdinelli and Kadane (1992) illustrate choosing λ when there are trade-offs between two components in a utility function. If the expected utility for model discrimination is selected as 0.95, then the corresponding cost is \$421,327 (the point represented by the triangle in Fig. 1), and λ corresponds to the negative of the slope of the curve at this point ($\lambda = 0.0001961/\$2{,}000$). Figure 2 shows the combined utility given by Eqn. (10) using this value of λ. The maximum (marked by the triangle) corresponds

to an optimal sample size of 211. For utilities which combine more than two objectives, graphical solutions may not be feasible, but a constrained optimization approach can be used to determine the trade-off parameters (Clyde and Chaloner 1996).

8. Summary

Bayesian experimental design is a rapidly growing area of research, with many exciting recent developments in simulation-based design and a growing number of real applications, particularly in clinical trials. By incorporating prior information, the Bayesian approach can lead to more efficient use of resources with less costly, and more informative, designs. Utility functions can be explicitly tailored to the given problem and can address multiple objectives. Models, prior distributions, and utility functions have often been chosen to permit tractable calculations. However, with increased computing power, simulation-based methods for finding optimal designs allow for more realistic model, prior and utility specifications. Optimal designs have often been criticized because the number of support points in the design equals the number of parameters (in nonlinear Bayesian design this is not always the case), which does not permit checking the assumed model form. Model uncertainly is almost always an issue in inference, and certainly at the design stage. Bayesian model averaging has been extremely successful in accounting for model uncertainly in inference problems, and has great potential for use in Bayesian experimental design for constructing more robust designs.

M. A. Clyde

Experimental Design: Compliance

Subject noncompliance with, or nonadherence to assigned treatment in randomized experiments designed to evaluate the relative efficacy of two or more treatments or interventions may seriously jeopardize the interpretation of results from such studies. Essentially, the noncompliant subject self-selects his or her treatment and/or treatment level, thereby disturbing the covariate balance (Rosenbaum 1995, pp. 14–15) and accompanying safeguard against confounding factors afforded by randomization (see *Experimental Design: Randomization and Social Experiments*; *Experimental Design: Large-scale Social Experimentation*). Attributing subject outcomes to the treatments under study when subjects are noncompliant is stymied by confounding factors introduced by that noncompliance. For example, in a study to evaluate the relative efficacy of mental health interventions on the quality of life for breast cancer patients (Helgeson et al. 1999), women were asked to attend eight sessions of either an informational seminar or peer support group during the course of their adjuvant chemotherapy and/or radiation treatments. In this case, women's lowered attendance at their assigned interventions may have been related to how well they were tolerating their drug or radiation

treatments, which at the same time may have affected their quality-of-life outcomes, so that the effects of the interventions are obscured.

1. Difficulties with Noncompliance

The complication of noncompliance necessitates the clear distinction between treatment *assignment* and treatment *exposure*. In randomized experiments with perfect compliance, these are the same; but when some subjects are noncompliant, assignment and exposure are different for those noncompliers. This distinction represents the crux of the problem induced by noncompliance: if a study is analyzed without regard to differences in assignment and exposure (e.g., using an intention-to-treat analysis) then the research question that is answered may not be the one that is posed (see *Causal Inference and Statistical Fallacies*).

Boruch (1997) takes a strong stand for analyzing studies as they are randomized (i.e., without accounting for noncompliance), since compliance behavior during a randomized trial is likely to approximate that same behavior in the general population were the interventions under study to be applied more broadly. Indeed, substantial noncompliance in itself may speak to the efficacy of assignment to the interventions under study. Nevertheless, understanding the relative efficacy of exposure to interventions and possible relationships between compliance behavior and subject outcome warrants a deeper examination of compliance.

Consideration of the statistical problems induced by subject noncompliance has taken place primarily in the field of clinical trials in cases where subjects take less of their assigned drug treatment and/or supplement their treatments with medications or activities other than the ones under study. A direct translation of the compliance problem from the medical setting to the behavioral or education setting comes from considering attendance at sessions of experimental interventions as a 'dose' or 'treatment level.' Alternatively, non-compliance with behavioral interventions might be as simple as subjects not taking advantage of an offered program, such as a family's decision to keep their child in public school even after they have been selected by lottery to attend a private school (see Barnard et al. 1999).

Regardless of the manifestation of noncompliance, questions regarding causal effects of interventions under study remain. Holland (1986) provides an extensive overview of causal inference in statistics, making use of the counterfactual model, the seeds of which date at least to Fisher (1918) and Neyman (1923), and which has been refined over several years by Rubin (1978, 1980; see *Causal Inference and Statistical Fallacies*). This model, relating exposure and outcome, is summarized here to provide a framework for illustrating the noncompliance problem and for describing methods for describing existing methods for addressing that problem (Dawid 2000 argues for causal modeling without using counterfactual outcomes, though addressing noncompliance is greatly facilitated by their use; see discussions following this article).

2. The Counterfactual Model

The foundation of the counterfactual model is the notion of potential outcomes, which are the collection of outcomes that would be observed for a subject if that subject were exposed to all possible treatments. The words counterfactual and potential suggest quantities that are not observed—outcomes 'counter to the fact,' or that 'might be observed.' Consider N subjects, and let T_i denote the treatment assignment and X_i the treatment exposure for subject i. For simplicity, let T_i and X_i assume binary values, 0 and 1, representing a control and active treatment, respectively.

The specific quantities of interest for causal inference are subject outcomes under each treatment: $Y_i(0)$ is the outcome that would be observed for subject i if he or she were exposed to treatment 0, and $Y_i(1)$ is the outcome that would be observed for the same subject if he or she were instead exposed to treatment 1. Typically, only one of $Y_i(0)$ or $Y_i(1)$ is observed for each subject. The observed outcome for subject i, Y_i (or $Y_i(X_i)$), is linked to the counterfactuals via the consistency relation

$$Y_i = Y_i(1)X_i + Y_i(0)[1 - X_i], \tag{1}$$

that is, the observed outcome *is* the potential outcome under the observed treatment exposure.

It should be noted that $Y_i(0)$ and $Y_i(1)$ are reduced from their general form as functions of the entire vector of treatment exposures via the *stable unit treatment value assumption* (*SUTVA*) of Rubin (1980). This assumption asserts that each subject's potential outcomes depend only upon his or her own treatment exposure and not those of any other subjects. In clinical trial settings, where subjects typically do not interact, SUTVA may be a reasonable assumption. In studies of behavioral or educational interventions, however, where subjects may interact with each other extensively, this assumption must be examined more carefully, and the causal conclusions that are based on it may be tenuous (Gitelman 1999).

The potential outcomes just defined, and SUTVA, are sufficient for defining an individual causal effect (ICE). This is simply the effect, for subject i, of exposure to treatment 1 vs. exposure to treatment 0

$$Y_i(1) - Y_i(0). \tag{2}$$

Alternative individual causal effects such as the ratio of these individual potential outcomes or the difference

of their logs could be considered, though the causal parameter obtained by taking the expectation of the difference in Eqn. (2) argues for using this simpler form. The average causal effect (ACE) is the individual causal effect averaged over the space of subjects

$$\theta = E[Y(1) - Y(0)] = E[Y(1)] - E[Y(0)]. \quad (3)$$

The probability distribution over which these expectations are taken is induced by the process by which subjects enter, or are selected for, the study.

In general, θ is nonidentifiable without further assumptions. Rubin (1978) showed, for instance, that θ is identifiable when treatment exposure is 'ignorable,' meaning that each subject's treatment exposure is stochastically independent of his or her collection of potential outcomes (this independence is expressed using the symbol $\perp\!\!\!\perp$, following Dawid (1979)

$$\{Y_i(0),\ Y_i(1)\} \perp\!\!\!\perp X_i. \quad (4)$$

Under randomized treatment assignment and complete compliance, treatment exposure ignorability holds, since $X_i \equiv T_i$ for all subjects i. In this case

$$\begin{aligned}\theta &= E[Y(1)] - E[Y(0)] \\ &= E[Y(1)|X = 1] - E[Y(0)|X = 0] \\ &= E[Y|X = 1] - E[Y|X = 0] \\ &= \alpha \end{aligned} \quad (5)$$

where the second equality follows from ignorability and the third from the consistency relation in Eqn. (1). α is called the apparent treatment effect, and it can be estimated by the difference in sample means of the group of subjects exposed to each treatment, perhaps appropriately scaled by a standard error estimate. Notice that α is typically identifiable regardless of treatment exposure ignorability—it is its equivalence to θ that is afforded by ignorability.

If treatments are randomly assigned, but some subjects are noncompliant, then treatment exposure is probably *not* ignorable. In that case, the apparent treatment effect is not a good estimate of the average causal effect. Specifically, there may be some characteristic of the subject (e.g., in a study comparing educational interventions, his or her academic ability) that predisposes him or her to be noncompliant with treatment assignment. This very characteristic may also be reflected in his or her potential outcomes under that treatment, and therefore his or her outcome cannot be attributed solely to the treatment in question.

One option when faced with noncompliance is to estimate the *intention-to-treat* effect, and use it as an estimate of the average causal effect. The intention-to-treat effect is given by

$$\alpha_{\text{itt}} = E[Y|T = 1] - E[Y|T = 0] \quad (6)$$

which can be estimated by the difference in sample means of the two treatment groups. This effect explores the relationship between assignment and outcome. Alternatives to this approach that seek to illuminate the relationship between exposure and outcome are described next.

3. Simple Noncompliance

In the case of binary treatment assignment and binary treatment exposure, noncompliance with treatment assignment manifests as 'treatment switching.' That is, a subject assigned to the active treatment is noncompliant if he or she switches to the inactive treatment (for instance by not taking the treatment at all). Similarly, a subject assigned to the control treatment is noncompliant by switching to the active treatment. This is essentially the situation described in Barnard et al. (1999), wherein families participated in a lottery to receive funding and other support for private school attendance. Some families, even though they 'won' the lottery, decided to keep their children in public schools—hence, these families are the 'noncompliers.'

3.1 Modification of the Counterfactual Model

The counterfactual outcomes described previously depend upon treatment exposure only, whereas to account for noncompliance they must be altered to depend also on treatment assignment. Following Angrist et al. (1996), let $X_i(0)$ and $X_i(1)$ denote potential or counterfactual exposures for subject i; these are the treatments subject i would be exposed to (i.e., based on his or her compliance behavior) under assignment to treatments 0 and 1, respectively. Let $Y_i\ (T_i,\ X_i(T_i))$ denote the potential outcome of subject i, under treatment assignment T_i and exposure $X_i(T_i)$. Expression of both the potential exposures and potential outcomes again rely on Rubin's SUTVA. In the binary assignment and binary exposure case, each subject has four potential outcomes, one for each assignment/exposure pair

$$\{Y_i(0,0),\ Y_i(0,1),\ Y_i(1,0),\ Y_i(1,1)\} \quad (7)$$

For instance, $Y_i(1, 0)$ is the outcome subject i would experience had he or she been assigned to the active treatment and been noncompliant with that treatment, thereby receiving the control treatment.

As in the case of the simpler potential outcomes $Y_i(0)$ and $Y_i(1)$, the outcomes in Eqn. (7) are related to the observed outcome via a consistency relation

$$Y_i = \sum_{t=0}^{1} \sum_{x=0}^{1} Y_i(t, x) I_{\{T_i = t,\ X_i = x\}} \quad (8)$$

Where $I_{\{\cdot\}}$ is the indicator function. As before, the observed outcome is the potential outcome that corresponds to the observed treatment assignment/exposure pair. Nonidentifiability is more drastic in this setting, however, as there are now four counterfactual outcomes to consider for each subject instead of just two.

The causal parameters of interest are the expected values (with expectations taking over the space of subjects) of the potential outcomes in (7); namely

$$E[Y(0,0)],\ E[(Y(0,1)],\ E[Y(1,0)],\quad \text{and } E[Y(1,1)]$$

With noncompliance, exposure is not ignorable, and so it is not necessarily the case that $E[Y(0, 0)]$ equals $E[Y(1, 0)]$ or that $E[Y(0, 1)]$ equals $E[Y(1, 1)]$. That is, the average subject outcome of a noncompliant subject assigned to the treatment arm will not, in general, be the same as that of a *compliant* subject assigned to the control arm. Methods to address this complication are described next.

3.2 Bounds for ACE Using an Instrumental Variable

A variable T is an *instrumental variable* if the distribution of another variable, Y, depends on T only through a third variable, X. Instrumental variables have been popularized in the econometrics literature (see *Instrumental Variables in Statistics and Econometrics*); they have been used to address noncompliance in other settings (e.g., Angrist et al. 1996). Ideally, T and X should be correlated, and T and Y uncorrelated conditionally on X. Then T can be used as a surrogate or *instrument* for X. An instrumental variable, then, is a variable that is partly defined by a conditional independence relationship, known as the *exclusion restriction*, or *instrumental variable assumption*

$$T \perp\!\!\!\perp Y|X \tag{9}$$

and partly by the required correlation between T and X. Angrist et al. (1996) translate this assumption into the language of potential outcomes, using assignment as an instrument for exposure

$$Y_i(T_i, X_i(T_i)) = Y_i(X_i(T_i)) \tag{10}$$

that is, a subject's potential outcomes do not depend on the treatment assignment directly, but only through that assignment's effect on the treatment exposure. Angrist et al. (1996) show the equivalence of the counterfactual and structural (or simultaneous) equation models (see *Simultaneous Equation Estimation: Overview*).

The instrumental variable assumption in Eqn. (10) has the effect of reducing the number of potential outcomes from four, as in Eqn. (7) to two, simply $Y_i(0)$ and $Y_i(1)$. For each subject, however, each of $Y_i(0)$ and $Y_i(1)$ can be observed in one of two ways, either by the subject's compliance with assigned treatment or their noncompliance with the opposing treatment. By using assignment as an instrument for exposure the average causal effect, θ can be bounded by taking minimums or maximums over these two ways of observing each treatment exposure (of course, these bounds also depend upon the responses having bounded expectations). Balke and Pearl (1994) produce the tightest possible bounds for θ (under binary assignment, binary exposure, and binary outcome) using the instrumental variable assumption and linear programming results.

Angrist et al. (1996) use the instrumental variable assumption, combined with a monotonicity assumption, to estimate θ rather than bound it. This monotonicity assumption applies to the counterfactual exposures—it is assumed that a subject will only be noncompliant by switching from the active treatment to the inactive control, but not vice versa, whereby $Y_i(1, 0)$ is eliminated from the collection in Eqn. (7). Because it relates exposure under an active treatment to that under a control treatment, this monotonicity assumption only is applicable in trials that compare an active treatment (or treatments) to a control.

4. Noncompliance as Underdosing

A more complicated noncompliance situation occurs when noncompliant subjects take a lower-than-intended dose of their assigned treatment (or attend fewer-than-intended sessions of their assigned intervention), rather than switching between treatments. For simplicity, treatment assignment remains binary in this discussion. The counterfactual exposures, $X_i(0)$ and $X_i(1)$, now take categorical or even continuous values, however, and there is no switching between treatments except perhaps in the case of a subject taking a zero dose of an active treatment. In a randomized dose-response experiment, subjects are randomly assigned to different doses of a treatment (i.e., dose is ignorable); but with noncompliance the subjects *choose* those doses (i.e., compliance 1evels), and so the resulting treatment outcomes cannot be attributed to dose or compliance levels alone.

In a direct extension of the simple compliance case discussed previously, Goetghebeur and Molenberghs (1996) model counterfactual compliance-response curves (similar to dose-response curves) for categorical exposure levels and binary outcomes, Their model relies on a different monotonicity assumption (this one asserts that increased compliance cannot lead to decreased probability of a successful outcome); an instrumental variable type of assumption and a constant global odds ratio assumption. A subsequent contribution, Goetghebeur et al. (1998), relaxes this

last assumption somewhat. An essential difficulty with these models, however, is that due to the need for modeling counterfactual (i.e., unobservable) outcomes, rather strong, untestable assumptions are needed. For example, the constant global odds ratio assumption is untestable, and it dictates an artificial relationship between the counterfactual compliance-response curves.

Efron and Feldman (1991) take the approach of modeling compliance behavior as a fixed attribute of the subject, rather than as a response to treatment assignment. As a fixed attribute, each subject's compliance behavior remains the same, regardless of the treatment to which he or she is assigned—this eliminates the problem of having to address counterfactual exposure levels. Compliance-response curves are estimated with this approach, and with additional modeling assumptions (e.g., linearity of the dose-response relationship), portions of the 'true' dose-response curves are recovered, Again, the true dose-response curves can be fully estimated only if dose level is ignorable.

Robins (1994) explores the slightly different setting of sequential randomized trials, in which subjects are assigned to treatment regimes in series, interspersed with assessment of their medical condition. In this work it is assumed that, conditional on all observable covariates, the treatment exposure regime is ignorable.

5. *Addressing Noncompliance in Practice*

When subjects are noncompliant with assignment to experimental interventions, a study loses the solid footing afforded by randomized treatment assignments. The essential question of interest regarding the effect of exposure to interventions is now compromised by the subject's selection of their intervention and/or intervention level. The counterfactual model provides a foundation for examining the relationship between exposure and outcome, though careful consideration of the assumptions of both that model and the additional modeling components needed for identifying causal parameters of interest are crucial and may depend upon the type of study.

When faced with compliance problems, or the possibility of compliance problems, the researcher may be best served by careful planning of intervention delivery with an eye toward averting attendance problems or other lapses in the integrity of the intended treatment (Meyer and Fienberg 1992). Furthermore, by collecting as many relevant covariates as possible, differential, subject-selected treatment exposure can be alleviated, in part by adjusting for these covariates using, for example, propensity score matching (Rosenbaum and Rubin 1983). If sufficient subject covariates are observed, it may be reasonable to assume that treatment exposure level is ignorable conditional on these covariates, whereby the causal parameters of interest can be identified. For compliance problems that cannot be addressed *a priori*, however, the bounding (e.g., Balke and Pearl 1994) and modeling (e.g., Angrist et al. 1996, Barnard et al. 1999) methods described herein provide useful options.

Experimental Design: Large-scale Social Experimentation

An experiment is a deliberately planned process to collect data that enable causal inferences and legitimize treatment comparisons. Random assignments of subjects to treatments (including control groups) allow statistically significant differences among treatment outcomes to be attributed solely to the treatment differences. Without strong additional assumptions, observational studies and quasi-experiments cannot justify drawing causal inferences, because only experiments, by definition, assign the treatments randomly (see *Experimental Design: Quasi-experimental Designs*; *Experimental Design: Randomization and Social Experiments*; *Experimental Design: Compliance*).

Public welfare relies on experiments for many purposes, including to approve medicines, medical procedures, new foods, and product reliability. Large-scale social experiments differ from most of these experiments, even from many that involve human subjects, in that the treatments in social experiments are social programs, the subjects are humans, and the responses measure outcomes for these people (or families) as they make decisions under different possible programs.

Large-scale public policy experiments in the United States generally are considered to have started with the New Jersey Negative Income Tax Experiment 1968. Orr (1999) puts the number of social experiments (not all large scale) launched per decade in the US at six in the 1960s, at 49 and 84 in the next two decades, and then at 56 for 1991–95.

These experiments were fielded to gather scientific information so policy makers could know as accurately as possible the costs and benefits of possible social programs. Most social experiments have been initiated and funded by agencies (national, state, or at other political levels) concerned with the welfare of large populations. While these large experiments were costly and time consuming, they found sponsors because their costs were dwarfed by the costs of actual programs.

1. Some Examples

Much has been written about social experiments. Greenberg and Shroder (1997) summarize the duration, cost, treatments, measured outcomes, sample sizes, design, funding sources, developers, evaluators, and results of over 100 of them. Orr (1999), Fienberg et al. (1985), and others in the references here, review some of the main studies and list further sources. This article describes several of the better-known public policy social experiments, each of which monitored human subjects for several years as they made personal or family economic decisions while eligible for benefits provided by an experimental policy to which they were randomly assigned.

1.1 The New Jersey Negative Income Tax Experiment (NJ–NIT)

The NJ–NIT experiment (Fienberg et al. 1985, Greenberg and Shroder 1997, Orr 1999, Hausman and Wise 1985) was inspired by the thesis of Ross (1966) while she was a PhD student in economics at MIT. Ross argued that only a social experiment could resolve disputes over how work patterns of the poor might change if the government were to adopt a Negative Income Tax (NIT) program to supplement their incomes. The Office of Economic Opportunity in the Department of Health, Education, and Welfare (HEW) funded the initial Income Maintenance Experiment (IME) to begin in 1968. Mathematica Policy Research, commissioned to design and field it, randomized a total of 725 experimental households into nine treatment groups, and another 632 households into a control group, with welfare and near welfare households in four New Jersey cities being enrolled for three years each. The nine experimental treatments in this response surface design involved two main variables, one providing a range of income guarantees, and the other providing a range of tax rate reductions to families as incentives to earn additional income. The NJ–NIT objectives were to estimate, mainly via regression analyses, how work hours, rates of high school graduation, and other outcomes depended on these factors.

Difficulties encountered in the NJ–IME included significant nonstationary participant behavior at the outset caused by participants needing time to become familiar with their program incentives, and toward the end caused by some gaming behaviors. The NIT design deliberately correlated the random treatment assignments with family incomes in order to reduce experimental costs. That strategy complicated the

analyses and risked compromising the experiment's randomization. Other design problems included differences between treatment and control participants in their initial income reporting, and using of total income as an eligibility criterion at enrollment with a resulting underrepresentation of working wives.

1.2 The Health Insurance Experiment (HIE)

The need for a health insurance experiment was recognized during the Nixon administration when for the first time the government was considering possible forms of a national health insurance program. Congressional leaders held widely divergent views about possible costs of a national program, and especially about the elasticity of demand for health care. If demand were completely inelastic, previously insured individuals would continue to purchase medical services at the same rate. That would make government sponsorship more affordable. While no experiment could provide all needed information, policymakers funded the HIE because it would narrow the range of disagreements, and help avoid disastrous errors in a national program.

The HIE was fielded in 1974 as the income maintenance experiments wound down. The Office of Economic Opportunity, and later HEW, asked the Rand Corporation to design and conduct the HIE, ultimately detailed in 'Free for All' (Newhouse 1993) by its principal investigator.

The HIE was designed to assess the demand for healthcare and many other questions, including whether health benefits might derive from a national health insurance program. Nearly 3,000 families, each for three to five years, were randomized to one of 14 insurance plans, including an HMO group. Insurance plans had two main dimensions, with varying coinsurance rates that families faced, and with varying deductible limits (after reaching the limits families were exempted from any further expenses for the years remaining). Anticipating that the world might differ considerably after the results of an eight year experiment became available, the HIE treatments included no particular proposal, but instead were chosen to provide a range of rates and benefits that could be used reliably to extrapolate HIE results to future legislative proposals.

Demand in the HIE was ultimately found to be elastic. Perhaps primary among HIE findings have been the elasticity estimates that legislators still use when comparing the costs of new health insurance proposals (Newhouse 1993, Orr 1999).

1.3 JOBSTART, a Demonstration

The rate of new social experiments continues to increase as the technology for doing them matures, and as new research groups and firms develop the skills to design, conduct, and analyze them. The newer experiments tend to be smaller and more focused than the first ones, many having been designed to demonstrate the effectiveness of an existing program, and to identify areas for improvement. These 'demonstration' experiments are simpler to field than those, like the IME and the HIE, that are designed to provide information on a wide range of unspecified programs.

Perhaps politicians are partial to demonstrations because of their lower costs and because they focus on concrete legislation. Demonstration experiments cost less because some of the participant funding comes through an existing program's benefits, and because focus is exclusively on one treatment and a control group. A complication is that control group subjects, if matched to treatment subjects, will be eligible for the same program benefits and so must be allowed to access them. One way to counter this is to have the treatment to be an encouragment for eligible subjects to take advantage of an underused program.

JOBSTART was a demonstration experiment to evaluate the Job Training Partnership Act (JTPA) of 1982 (Greenberg and Shroder 1997, Cave et al. 1993). Sponsored jointly by the US Department of Labor and by several private foundations, JOBSTART was designed and evaluated by Manpower Demonstration Research Center (MDRC) between 1985 and 1992, and administered by the Local Service Delivery Areas in 13 geographically disparate US sites. Subjects were randomized into treatment and control groups, with about 1,150 subjects in each. All subjects were JTPA eligible (a national program), being economically disadvantaged, high school dropouts aged between 17 and 21 years, and all were poor readers. Treatment interventions included two summers of vocational and educational training, support services, job placement assistance, and incentive payments. Subjects were monitored for four years.

JOBSTART found that the treatment group had a dramatically higher rate of high school completion. Women who had no children before the demonstration, but who gave birth afterward, were less likely to receive AFDC payments. The opposite result was found for women who started with children. No major long-term differences were found for employment, earnings, or welfare measures.

1.4 The Housing Assistance Supply Experiment (HASE)

Economic theory predicts an elastic supply response to increased demand, so that benefits received by individuals do not necessarily rise in proportion to the dollars provided. Even so, almost all large-scale social experiments have measured demand only, mainly because a supply response is extremely difficult to

produce in an experiment. HASE is a notable exception (Lowry 1983). While Housing Allowance Demand Experiments had been fielded to evaluate new housing policies (Bradbury and Downs 1981), evaluating the supply response to alternative housing programs requires a long-term saturation experiment in which all eligible members of an entire community participate in an experimental program. A supply experiment takes longer because the supply side needs adequate time to respond to new demand, generally much longer than individuals need to respond to new opportunities.

The Department of Housing and Urban Development sponsored HASE to learn how the supply side would respond if individuals and families received increased government assistance for making home improvements. HASE ran from 1972 to 1982 in Green Bay, Wisconsin and in South Bend, Indiana, selected as two small, stable communities in which a meaningful supply response might be stimulated. Long-term benefits were guaranteed to all eligible families for 15 years, well beyond the length of the experiment, to give the construction community sufficient incentive to relocate workers and businesses into these regions.

Supply experiments are extremely ambitious, but the questions they address are crucial.

2. *Alternatives to Social Experiments*

Less expensive alternatives must be considered before undertaking a social experiment. These include expert (and nonexpert) opinions, theoretical models, surveys, observational studies, quasiexperiments (see *Experimental Design: Quasiexperimental Designs*), and, if they exist, appropriate 'natural experiments.' Because these alternatives usually are cheaper, faster, and easier than an experiment, they will be preferred whenever they can provide valid predictions. Even if they cannot produce valid predictions, their consideration is vital to designing an efficient social experiment.

These alternatives all have drawbacks. Expert opinions and theoretical models are no better than the experts or models. While surveys can sample randomly from a target population, they cannot assign treatments randomly, and surveyed subjects rarely would know how they would respond to a hypothetical future program. Nonexperimental data, quasiexperiments, and observational studies (both synonyms for nonrandomized studies) might be used to extrapolate from data on existing programs to predict outcomes of untried programs. Such predictions, however, are especially unreliable for major program changes, and self-selection in such data may bias results. Natural experiments might occur if a comparable country or region adopts a policy similar to one under consideration, but they usually do not exist, and if one does occur, results still must be extrapolated to another country or population.

As none of these alternatives has randomly assigned treatments, selection bias will be present and causal inferences will be suspect. Drivers who use seat belts have lower traffic fatality rates, but those rates are confounded with the same drivers being generally safer drivers. Similarly, individuals who choose health insurance plans with less generous coinsurance rates generally consume fewer health services. Is that only because some of them, knowing they are healthier, choose less generous insurance plans? If so, their behavior in a future health insurance program that includes everyone will not be predictable from their past utilizations. A health insurance experiment offers an alternative option to using observational data for predicting the costs of proposed national health insurance programs.

3. *Risks of Social Experiments*

Being costly and time-consuming, social experiments have been used sparingly. They might not provide useful information for many years, risking their irrelevance. Human subjects can refuse to enroll, and enrollees can drop out before completion. If that happens with regularity, randomization fails, and so the experiment fails (see *Errors: Nonsampling Errors*).

If large experiments become too visible, their subjects may feel that the situation is artificial and act differently.

Drastic political, social, legislative, or economic changes can occur during an experiment and invalidate it. However, a control group can be protective in such situations, to the extent that the shock affects all treatments and controls equally. Orr (1999), who as a government economist helped spawn and plan several early public policy experiments, reviews such concerns about social experiments, and he discusses how experiments can protect themselves. Besides the issues mentioned here, he discusses whether and how experiments have affected policy, their credibility, time considerations, communication issues, their generalizability, relevance of their results, the policy environment, and policy links.

4. *Design Issues*

Those who design social experiments make numerous crucial choices. They must choose treatments that span the policies that are likely to be considered without picking an overly large range that provides too little information on the policies that ultimately matter. How many sites are needed? Too many sites are difficult to manage, and for a fixed budget, increased

management costs must be paid for by decreased sample sizes. Too few sites restricts generalizability. Should sites be chosen randomly? Probably not if the number of sites must be kept small, because then randomization provides little basis for inference.

More subjects are better, but too many subjects make an experiment unfeasibly expensive. Without strong reasons to do otherwise, it helps to keep the percentage of subjects allocated to each treatment the same in every site. Balanced samples, which means matching the key characteristics of the sample across sites and treatments, have various optimal properties in experimental design, and they enjoy considerable face validity (Morris and Hill 2000).

Enrollment participation must be long enough for individuals to learn how to take advantage of experimental programs (and so to reach steady state), and perhaps to discount the times at the beginning and/or the end of the experiment when subjects may act differently than they would in a continuing government program. However, overly long enrollments waste time because early results are better for policy, and because, assuming positive correlations within individuals, one individual provides less information per unit time than two independent individuals. These transitory issues may make it necessary to field a longer experiment, or at least to guarantee treatment benefits beyond the actual measurement period.

Decisions about what data to collect, about the design of questionnaires, and about how much and how frequently to interview subjects may be as crucial as other statistical design decisions. Interviewing subjects too often risks overstimulating them ('Hawthorne effects'), so that subjects become overly aware of participating in an experiment and behave artificially. Respondent burden can cause dropouts, careless responses, and selective nonresponse. Interviewing subjects too infrequently sacrifices potentially important data. Experimenters can give a better understanding of respondent burden by subjecting themselves to the same interviewing processes which experimental subjects face.

While large-scale social experiments encounter difficulties beyond those of smaller experiments, they will have greater financial resources to deal with them. Some potential difficulties that concerned HIE designers included: creating Hawthorne effects by frequent interviewing; activating participants by obtaining a medical screening examination at enrollment; stimulating health expenditures by having to pay participation incentives to families; and not being sure of the best time horizon (Newhouse et al. 1979). The HIE budget allowed for four (balanced) 'subexperiments' within the main experiment to measure these effects. In one subexperiment, half of the HIE subjects were chosen at random for weekly interviews, and half for bi-weekly. Similarly, 60 percent of the HIE subjects were randomly selected for initial screening exams, and the rest not; and 70 percent were randomly assigned for three-year enrollments, and the other 30 percent for five years. This allowed testing for these effects and, if found, adjusting for them.

5. *Further Reading*

Orr (1999) provides an overview and first-hand examples of the design and implementation of social experiments. Greenberg and Shroder (1997) summarize 143 completed social experiments in the United States, and 75 others that were ongoing at the time of their publication. Each summary describes the target population, policies tested, experimental design, sites, findings, sources of further information, and public access to the data. Campbell's fundamental work in social experimentation is summarized in Campbell and Russo (1999). Boruch (1997) provides reference material on randomization in field experiments and Neuberg (1989) discusses anomalies of social control experimentation.

Experimental Design: Overview

Many scientific discoveries are made by observing how a change in a stimulus that is presented to a subject or object affects the response (measurement) given by that subject or object. In an experiment, the investigator has direct control over which stimuli are presented to which subjects in which time periods. This control, when exercised correctly, enables the investigator to deduce a 'cause and effect' relationship, that is, the investigator can deduce that a given change in a stimulus causes a given change in the measured response. The plan of how an experiment is to proceed is called the 'design of the experiment.' The art of experimental design is the art of devising an experimental plan which maximizes the information that can be obtained on the effects of the stimuli.

1. *Terminology*

Experimentation is used in almost every branch of science, with the result that the terminology used in experimental design is not quite standardized. For example, in some fields, the subject or object which is to be presented with a stimulus and then to be measured is called a 'unit' or 'experimental unit.' The stimulus, itself, may be called the 'treatment' or the 'level of a factor' or the 'level of an independent variable.' In factorial experiments, where a subject is presented with a combination of different types of stimuli (such as a particular light intensity together with a particular noise level), the combination may be called a 'treatment combination' but, for simplicity, the term 'treatment' may be taken to mean either a single stimulus or a combination of stimuli, depending on the context.

In some experiments, measurements are made on each subject over several time periods. These are known as 'repeated measurements.' The terminology concerning the associated designs again differs between disciplines. The term 'repeated measurements design' may refer solely to a design involving repeated measurements on a subject to whom a single treatment has been administered or it may include designs in which the treatment is changed before each measurement. The latter type of design is also known as a 'within subjects design' or a 'block design' or a 'cross-over design.' All of these designs are grouped under the heading of 'split-plot designs' by some authors, while others reserve this last term for a design with two types of treatment, one of which is held constant throughout the repeated measurements on a subject and the other of which changes before each measurement see Sect. 9.2.

2. *The Purpose of Experimental Design*

The pioneer in statistical experimental design was Sir R. A. Fisher (Fisher 1951) who was concerned with maximizing the amount of information about agricultural crop production. In the Social and Behavioral Sciences, the questions of scientific interest are very different, but the art of good experimental design is similar.

Every experiment has a budget (time and money) and a limit as to the number of subjects that can be recruited. Also, every experiment has inherent variability; subjects differ from one another in fundamental ways, technicians differ in how they read measuring instruments, subjects and instrument readings vary over time, and so on. Variability translates into uncertainty and uncertainty reduces the amount of useful information. Information gained from an experiment may be viewed either from a sampling perspective or from a Bayesian perspective. In the former, hypothesis tests and confidence intervals are generally used, and the most informative experimental designs yield the most powerful tests and the shortest intervals, whilst producing unbiased results. (E.g., *Estimation: Point and Interval*; *Hypothesis Testing in Statistics*). For a Bayesian analysis, the most informative designs are those which maximize the expected utility (e.g., *Experimental Design: Bayesian Designs*).

The purpose of designing an experiment is (a) to maximize the amount of information that can be gained within a given budget or (b) to minimize the budget required to obtain a given amount of information. Maximizing information is done by controlling and reducing the effect of extraneous variables and by the removal of confounding variables and bias, as described in Sects. 3.2 and 3.3.

3. *Features of Good Design*

3.1 *Comparison*

Experiments, by their nature, tend to be comparative. Questions of interest tend to be of the type 'does this treatment elicit a "better" response than that treatment?' and, if so, 'how much better?.' Even if a single treatment appears to be the only one of interest,

information about its effect on a subject is usually of no value without a comparison with other treatments. For instance, Moore and McCabe (1999, chap. 3) cite an example of a medical study that showed a gastric freezing technique to be a good treatment for ulcer pain, but in later comparative experiments it was shown that the pain relief using freezing was no better than the relief achieved using the same technique but with no freezing solution. Apparently, the pain relief was due to nothing more than doctors showing concern for their patients (a placebo effect) and the freezing technique was abandoned. A good design for evaluating the effect of a single treatment will, therefore, always include a second treatment, called a control or control treatment, for comparison purposes. In some experiments, the control is the treatment in current use, and in other experiments it is the 'absence of a stimulus.' An experiment with more than one treatment needs no control since the experimental treatments can be compared among themselves. Nevertheless, a control can often add extra information. For example, in an experiment on how different types of background music (such as 'classical,' 'rock,' 'rap,' etc.) affect the time taken to learn a new task, a control treatment might be the absence of background music.

3.2 Control of Extraneous and Confounding Variables

A good experimental design allows a particular set of stimuli to be compared with each other with high accuracy. Therefore, any other variable (or factor) that causes the experimental measurements to vary at best reduces the efficiency of the experiment and at worst completely masks the true effect being investigated. For example, in an experiment to investigate the effect of employing different types of memory aid in memorization, the IQ of the subjects may play an important role. The variability of IQ of subjects in the experiment would then contribute to the variability in the measured memorization scores. One way of controlling the effect of such an extraneous variable is to hold the variable fixed during the experiment. For instance, IQ could be held more-or-less fixed by using as subjects only people with a tested IQ within a certain range. Although it reduces variability and avoids masking the effects of the memory aids, this strategy limits the applicability of the conclusions of the experiment since the results would apply only to the people in the population with IQ within this range. A preferable method of controlling extraneous variability is to use a matched design (see below).

An extraneous variable whose effect is completely muddled with that of the factor(s) of interest is called a confounding variable. In the above example, if all the subjects with high IQ were to be tested using the first memory aid and all those with low IQ tested using the second, then, if high IQ is correlated with memorization ability, the first memory aid will inevitably appear to be the better, regardless of its true merits.

The masking effect of a confounding variable can be reduced by randomization (e.g., *Experimental Design: Randomization and Social Experiments*). The simplest form of randomization leads to a 'completely randomized design' (see Sect. 7.1); subjects are recruited from the general public as randomly as is possible (see Sect. 5) and then assigned to the stimuli at random in such a way that every subject has the same chance of being assigned to any one of the stimuli. In such a design, it is likely, although not guaranteed, that each stimulus will receive roughly the same distribution of values of the extraneous variable. If a completely randomized design is used in the above example, the memory aids should receive roughly similar ranges of subject IQs.

In all experiments there are confounding variables that have small effects which are ignored by the experimenter and confounding variables that are accidentally overlooked. The use of randomization helps to spread out the effects of these variables so that the response given to any one stimulus is less likely to be inflated upward or downward due to extraneous factors. For a discussion of random assignment using a random number table or a computer random number generator, see for example, Dean and Voss (1999, chaps. 1, 3), (e.g., *Random Numbers*).

A more foolproof method of ensuring similar distributions of IQ levels for each memory aid in the above example is to divide the subjects into groups so that subjects within the same group have similar IQs, and then to make the random assignment of subjects to stimuli within each group separately. The division into groups provides the control necessary for removing the variability and masking due to the extraneous IQ variable, while maintaining the applicability to the general population. This type of design is called a 'matched design' or 'block design' (see Sect. 7.2). Matched designs and completely randomized design are examples of 'between subjects designs' (Sect. 7).

A further possibility is to measure each subject under a sequence of different treatments—a 'crossover design' or 'within subjects design' (see Sect. 8). The use of such a design in the above example would completely control the extraneous variable since it would ensure that the distribution of IQs assigned to each memory aid is identical. However, new extraneous variables have now been introduced, such as fatigue on the part of the subject over the course of the experiment. If the effects of the new extraneous variables are likely to be small, they can be ignored, but if they are large, then the variables should be controlled by making sure that subjects are assigned the memory aids in different orders. The orders can be assigned at random for each subject separately—a

'block design,' or by deliberately making sure that each stimulus is viewed by the same number of subjects in each time period—a 'latin square design.'

3.3 Removal of Bias

Since each experiment is run with a particular purpose in mind, experimenters tend to have inbuilt, although perhaps subconscious, biases towards or against certain treatments. A random assignment of subjects to treatments and a random ordering of observations ensures that experimenter bias cannot consciously or unconsciously favor one treatment above another.

Subjects' own biases towards the treatments can affect their responses. It may or may not be possible or ethical to conceal the true nature of the experiment from the subjects. It may be possible, however, to mask from both the subjects and the person(s) running the experiment which of the stimuli is the experimental treatment(s) and which is the control (a 'double blind experiment'). Leach (1991 Sect. 24, Appendix 1) discusses ethical issues of concealing information from subjects and lists the guidelines published by the British Psychological Society. Kirk (1982 Sect. 1.5) gives references to ethical guidelines put out by the American Psychological Association, the American Sociological Association, and other bodies.

4. Planning an Experiment

Guides to planning experiments can be found in many texts; for example, Myers (1979, chap. 1), Cox (1958) Dean and Voss (1999, chap. 2), Leach (1991 Sects. 5–9). A protocol, which gives in great detail, step by step, how the experiment is to proceed, is usually prepared well in advance. The protocol includes details about subject selection, measurement, and data collection methods, preparation of materials, preparation of subjects, and a draft statistical analysis.

A pilot experiment, in which a small number of observations is collected, is often run early in the planning stage. Although these observations will usually be thrown away when the main experiment commences, the pilot experiment gives an opportunity to check that the experimental procedure will work as planned and that the required analyses are possible. It also gives indications of unexpected important confounding variables and the likely accuracy of the results. It allows problems to be detected and corrected before they arise in the main experiment.

5. Selection of Subjects

Ideally, the subjects taking part in the experiment are selected at random from the population to which the conclusions of the experiment will be applied (the 'target population'). Since this is not always possible, the experimenter may be forced to use volunteers who will inevitably come from a subset of the population. The results of the experiment may or may not then apply to the entire target population.

The number of subjects required to achieve the goals of powerful hypothesis tests and short confidence intervals, or of maximum expected utility, can be calculated using statistical formulae (e.g., see *Estimation: Point and Interval*; *Hypothesis Testing in Statistics*; *Experimental Design: Bayesian Designs*). The required number of subjects depends upon the design selected for the experiment, on the comparisons of interest, and on the variability of the responses of subjects when assigned the same treatment under identical experimental conditions. In general, 'between subjects designs' require many more subjects than 'within subjects designs.' Between subjects designs are used in fields where subjects can be assigned only a single treatment (as in the evaluation of different teaching methods) and/or where subjects are sufficiently plentiful to off-set the subject-to-subject variability. Within subjects designs are preferred in fields where subjects are scarce or highly variable.

The length of the sequence of treatments that can be presented to any one subject depends upon the nature of the experiment. For example, in experimentation involving multiple visits to a laboratory, subject tolerance can be as low as two or three visits. In experiments in which treatments can be changed rapidly with no long term effect on the subject, a much longer sequence of treatments can be used, requiring fewer subjects in total. There are exceptional circumstances in which an experiment is conducted on a single subject (see Wilson 1995, Kratochwill and Levin 1992), but such experiments cannot give conclusive information about the population as a whole and are not used in standard experimentation.

6. Models and Analysis

The model links the dependent (response) variable(s) to all of the factors (independent variables) that could influence the response, such as the various stimuli, the subjects, time periods, extraneous variables that were used in determining the design, and other important variables that can be taken into account only during the analysis (called 'concomitant variables' or 'covariates': see, e.g., Maxwell and Delaney 1990, chap. 9). All extraneous variables that were ignored in the design are grouped together in a single 'error variable.' A measurement on a subject during a time period before the experiment begins is called a 'baseline measurement' and can be used to increase the accuracy of the results (see, e.g., Jones and Kenward 1989, chap. 2, Sect. 4.4; Cotton 1998, chaps. 9, 10).

If the distributions of the error variables are identical and approximately normal distributions, then standard analysis of variance techniques can be used (e.g., *Analysis of Variance and Generalized Linear*

Models). Analysis of designs in which treatments are assigned the same numbers of subjects and the same numbers of time periods are the easiest to analyse and interpret. They are also the least sensitive to assumptions about normality of the error distributions and equal variances (e.g., *Errors in Statistical Assumptions, Effects of*; *Statistical Analysis, Special Problems of: Transformations of Data*). When the errors do not follow a normal distribution, other types of analysis are needed such as analysis of generalized linear models (e.g., *Analysis of Variance and Generalized Linear Models*), nonparametric analysis (e.g., *Nonparametric Statistics: Rank-based Methods*), and categorical data analysis (e.g., see Ratkowski et al. 1993, chap. 7, Jones and Kenward 1989, chap. 3, Crowder and Hand 1990, chap. 8).

Repeated measurements on a subject under a particular treatment may require a time series or regression analysis, (see Crowder and Hand 1990), (e.g., *Linear Hypothesis: Regression (Basics)*). Bayesian techniques in analyzing cross-over designs are mentioned by Jones and Kenward (1989, pp. 80, 235) (e.g., *Experimental Design: Bayesian Designs*). In the case of correlated responses per subject, multivariate analysis is used for normally distributed errors (see, e.g., Winer et al. 1991, chap. 4, Johnson and Wichern 1992, Maxwell and Delaney 1990, chaps. 13, 14, Crowder and Hand 1990, chap. 4, Jones and Kenward 1989, chap. 7, Myers 1979, chap. 18), (e.g., *Multivariate Analysis: Overview*).

7. Between Subjects Designs

7.1 Completely Randomized Designs

In a completely randomized design, each subject is assigned to just one treatment. The assignment is done completely at random so that each subject has exactly the same chance of being assigned to each possible treatment (stimulus or combination of stimuli). Often a restriction is applied so that each stimulus receives the same number of subjects.

Completely randomized designs are simple to use and simple to analyse. They are most suited to situations where subjects are plentiful, where subjects' responses would not be too variable if they were all given the same stimulus under the same experimental conditions, and where experimental conditions can be held constant throughout the experiment.

If there are extraneous variables which add variation to the responses and which can be measured during the experiment (such as age or IQ), their effects can be removed during the analysis (analysis of covariance) (e.g., Winer et al. 1991 chap. 10). However, where it is possible for the extraneous variables to become confounding variables in an unfortunate randomization, a matched pairs design, block design, or within subjects design would be preferred (see Sects. 7.2 and 8).

As in all designs, it is possible to take repeated measurements in completely randomized designs. Each subject is measured for some number of time intervals after administration of the single treatment. Cotton (1998) calls such a design a 'multigroup split-plot design.'

7.2 Matched Pairs and Block Designs

If there are just two treatments of interest, the variability in the responses (observations) due to differences in the subjects themselves can be reduced by pairing the subjects so that, within each pair, the subjects are alike as possible. For each pair separately, the two subjects are assigned at random to the two treatments (a matched pairs design).

When there are t treatments with $t > 2$, the subjects are matched into groups (or blocks) of size t and, within in each group, the subjects are assigned at random to the t treatments. This type of design is usually known as a 'randomized block design.'

Block designs are also appropriate when the extraneous variation is due to variables unrelated to the subjects. Experimental conditions cannot always be held constant throughout the experiment, as for example, changes in the weather, use of different testing centers, use of different laboratory technicians, etc. To combat this, the subjects would be put into groups of size t (not necessarily matched) and, apart from the assignment to different treatments, all subjects within a group would be tested under the same experimental conditions.

If the number of treatments, t, to be compared is large (as is often the case in a factorial experiment where the treatments are combinations of several stimuli), there may not be enough subjects to form groups of t similar subjects, nor may it be possible to hold conditions constant for t measurements. In this case, an incomplete block design can be used, where each group of $s(< t)$ subjects is assigned at random to a preselected subset of s treatments (see, e.g., Winer 1971, chap. 9, Dean and Voss 1999, chaps. 11, 13).

8. Within Subject Designs

In a within subjects design, each subject is essentially matched with himself or herself and assigned a sequence of some or all of the treatments. The order or presentation is decided using randomization for each subject separately. The comparison of any two treatments is made for each subject ('within' each subject) and then averaged over all the subjects. This has the advantage that subject to subject variability does not play a part in the comparison of the treatments.

In experiments where stimuli are presented to each subject in quick succession, 'carry-over effects' can be a problem. For example, a subject asked to work in bright light followed by normal light may perceive the normal light to be darker than if it had been preceded

by dim light. These carry-over effects can be mitigated by separating the trials by a period of time, called a 'washout period,' in which the subject is asked to do something completely different in some control state. If a long enough washout period cannot be arranged, then the experiment usually is counterbalanced (see Sect. 8.3). Carry-over effects are also known as 'residual effects' and the effect of the treatment administered in the current time period is called the 'direct treatment effect.'

8.1 Cross-over Designs

In the simplest within subjects design, any randomization of the order of treatments for any subject is accepted. However, if time period effects or carry-over effects are thought to be important and are to be included in the model, then it is desirable to exercise control over which treatment sequences are used. In most cases, the carry-over effect from a given treatment will be assumed to be the same no matter which treatment follows it. If the treatments interact, then this assumption may not be valid and larger designs and more complicated analyses are needed.

When there is a small number of treatments, say two or three, and the subject can be measured over several time periods, then each subject can be assigned some or all of the treatments more than once. For three time periods and two treatments (one assigned to one period and one assigned to two periods), there are six possible treatment sequences; with four time periods and two treatments (each assigned to two periods), there are fourteen possible treatment sequences; with four time periods and four treatments (each assigned to one period), there are twelve possible sequences, and so on. If there are sufficient subjects, all the possible sequences can be used an equal number of times. If the number of subjects is small, however, it may not even be possible to use each sequence once. Information must then be used about which set of sequences provides the best design. Among the possibilities are 'variance balanced designs' (Sect. 8.2) and 'latin squares' (Sect. 8.3).

In general, if it is possible to avoid them, two-period designs are not recommended. Not only can the carry-over effects not be estimated independently of the treatment by period interaction, but also three-period designs are considerably more efficient (Jones and Kenward 1989, Sect. 4.16).

8.2 Balanced Cross-over Designs

Cross-over designs that allow differences between all pairs of treatments to be estimated with the same precision are called 'variance balanced.' Variance balanced designs include cross-over designs that use all possible treatment sequences, and counterbalanced latin square designs (see Sect. 8.3). Variance balanced designs, efficient for comparing all pairs of treatments, are tabulated by Ratkowski et al. (1993, chap. 5) and also by Jones and Kenward (1989, pp. 212–4, 223–4). The latter authors also list designs efficient for comparing test treatments with a control.

The treatment given in the last period of a cross-over design can be repeated in an extra period. Such designs, called 'extra period designs,' allow the carry-over from the last treatment to be measured, thus increasing the precision of the treatment comparisons.

Balanced designs typically require a large number of subjects when the number of treatments is large and so cannot always be used. An alternative is to use an efficient 'partially balanced' design. These designs allow treatment differences to be estimated with two or three different precisions that are fairly close in value. When the treatments are factorial in nature, the effects of the individual factors (main effects) and the interactions between the factors are usually of primary interest. Variance balance is then desirable for the comparisons of the levels of each factor separately (see Jones and Kenward 1989, pp. 222–8, Ratkowski et al. 1993, chap. 6, for tabulated designs).

8.3 Latin Squares

A latin square design is ideal for any experiment in which it is possible to measure each subject under every treatment and, in addition, it is necessary to control for changing conditions over the course of the experiment. A latin square is a design in which each treatment is assigned to each time period the same number of times and to each subject the same number of times (see Dean and Voss 1999, chap. 12). If there are t treatments, t time periods, and mt subjects then m latin squares (each with t treatment sequences) would be used.

Carry-over effects are controlled by using latin squares that are 'counterbalanced' (Cotton 1993). This means that, looking at the sequences of treatments assigned to all the subjects taken together, every treatment is preceded by every other treatment for the same number of subjects. Counterbalanced latin squares exist for any even number of treatments and for some odd numbers of treatments (e.g., $t = 9$, 15, 21, 27; see Jones and Kenward 1989 Sect. 5.2.2, for references). For other odd numbers, a pair of latin squares can be used which between them give a set of $2t$ counterbalanced sequences.

If a carry-over effect is expected to persist for more than one time period, then the counterbalancing must be extended to treatements occurring more than one time period prior to the current treatment.

9. Other Designs

9.1 Nested or Hierarchical Designs

It is not unusual for extraneous variables to be 'nested.' For example, if subjects are recruited and tested

separately at different testing centers, the subjects are 'nested within testing center.' If subjects are animals such as mice or piglets, then the subjects are naturally nested within litters, which are nested within parent, which may be nested within laboratory. The nesting information can be used in matched designs, since the nesting forms natural groupings of like subjects. For within subjects designs, the nesting information can be used during the analysis for examining the different sources of extraneous variation (e.g., *Hierarchical Models: Random and Fixed Effects*). Designs in which different levels of nesting are assigned different treatment factors are called 'split-plot designs' (see Sect. 9.2).

A second type of nesting is a nesting structure within the treatment factors being examined. Examples given by Myers (1979) include memorization of words within grammatical class; time taken to complete problems within difficulty levels. Models and analyses used in such experiments must reflect the nested treatment structure.

9.2 Split-plot Designs

An experiment with more than one type of stimulus (factor) can be run as a split plot design with a level of one or more factors being applied to a subject throughout the course of the experiment (as for a between-subjects design), and the levels of the other factor(s) being changed for each time period (as for a within subjects design). Such designs are sometimes called 'mixed designs.' The stimuli applied as the within subjects design will generally be measured more accurately than those applied as the between subjects design, since subject to subject variability enters into the comparison of the latter.

Split-plot designs are useful when it is difficult to change the levels of one of the factors. For example, Dean and Voss (1999, chap. 19) cite an example of an optokinetic experiment on the drift of focus of a subject's eyes from the center of a rotating drum measured under two different lighting conditions. The change of lighting conditions was a time-consuming process, whereas it was simple to change the speed of rotation of the drum. Consequently, each subject was assigned a single lighting condition throughout an entire viewing session, and during the viewing session the subject was assigned a sequence of different speeds.

10. Optimality and Efficiency of Designs

As pointed out by Cotton (1998), designs that are best (i.e., optimal) for one purpose are not necessarily best for another purpose and compromises may need to be made. The optimal design for investigating the effects in one model may be totally unsuitable for a different model. For example, in a cross-over design with two treatments and two time periods, a set of counterbalanced latin squares provides an optimal design for estimating direct treatment effects and carry-over effects. This design does not, however, allow estimation of both a carry-over effect and an interaction between treatments and time periods. Thus, if both of these effects are required in the model, then more than two time periods must be used in the experiment (e.g., *Statistical Identification and Estimability*).

As a general rule, the most balanced designs are optimal when interest lies equally in all treatment comparisons. The following features are typical characteristics of balance; every treatment is assigned the same number of subjects, every treatment is observed in every time period the same number of times, every treatment is preceded by every other treatment (including itself, if possible) for the same number of subjects and in the same number of time periods. When balance is not achievable, computer programs for generating optimal designs are commercially available. For other settings, where comparison of all treatments is not the main goal of the experiment, more sophisticated algorithms are needed see, for example, Atkinson and Donev (1992). For a discussion of design optimality from a Bayesian perspective, see for example, *Experimental Design: Bayesian Designs*.

Experimental Design: Randomization and Social Experiments

1. *Definition, Functions, and Rationale*

In a randomized field trial, a sample of individuals or of entities, such as schools or hospitals, are randomly assigned to one of two or more interventions. These interventions may be different programs or variations on the same program, different intensities of social service, different mixes of therapies, and so on. The interventions may include a 'control' condition in which no services, or services that are ordinarily available, are provided (see *Experimental Design: Overview*).

For example, to understand whether a new employment and training program works well, one randomly allocates some eligible individuals to the new program. All or some of the remaining eligible individuals are randomly allocated to the alternative intervention. This alternative may be a normally available training service, i.e., a control condition, or a program with lower levels of service, or a different service.

This random assignment of individuals to a new employment and training program and to an alternative program permits one to make a fair comparison of the wage rates achieved by the people who were assigned to each group. The value that is added by a new program can be estimated well because the people who were assigned to the conventional services and to the new program are equivalent on account of the random assignment. Furthermore, one can take into account the chance statistical differences among individuals who were assigned to each group, a fact that is important in science and law (Kaye and Freeman 1994).

The logic that underlies a randomized trial is as follows. To estimate the relative effect of a particular intervention, one has to estimate the status of individuals (or entities) had they not had the intervention. At times, a precise forecast can be made about how individuals or entities would fare in the absence of the intervention. Also at times, one may be able to construct what appears to be a fair comparison group that represents the state of people (or institutions) in the absence of the particular intervention. Under these circumstances, quasi-experiments or observational studies might then be employed to generate evidence about the relative effectiveness of programs. These approaches try to make a fair comparison of the outcome of alternative interventions based on sophisticated statistical models of how people and entities behave, and on conscientious attention to competing explanations about why a difference in the effects of interventions might appear. See Maynard and Chalmers (1997) and *Quasi-Experimental Designs*.

Often, the researcher cannot make good forecasts, construct defensible *ad hoc* comparison groups, or account for competing explanations for a difference among interventions in a quasi-experiment. A randomized trial may than be warranted because it assures that the prediction is fair: the comparison is fair simply because people or entities are randomly allocated into two or more equivalent groups. It assures that competing explanations for people's (or entities') behaviors are taken into account because both groups are subject to the same influences, apart from the interventions.

Social and behavioral scientists and statisticians use phrases other than 'randomized field trial' to describe this approach to generating evidence. These phrases include randomized experiment, randomized trial, randomized clinical trial (RCT) in medical research, and controlled experiment. Different phrases are used to identify trials in which entities such as schools or hospitals are randomly assigned to different interventions. These descriptors include cluster-randomized trials, group randomized experiments, macro-experiments, and place-based trials (Murray 1998, Boruch and Foley 2000).

2. *Examples of Randomized Field Trials*

Good examples of randomized trials are not difficult to locate, although such trials are in the minority of studies on the effects of interventions. Boruch (1997) gives many such examples. In Switzerland, for example, randomized trials have been carried out to understand the effects of heroin therapy vs. conventional treatment of drug addicts and to estimate

the effects of community service vs. imprisonment. In Germany, community rehabilitation programs in prisons have been assessed vs. conventional prison programs in randomized trials. In the US, randomized trials have been carried out to learn the effects of arresting people for misdemeanor domestic assault, new approaches to courts' handling of certain cases, intensive police patrol strategies, and other interventions. A main outcome variable in such experiments is recidivism. See the special issues of *Crime and Delinquency*, 2000, for details on these and other trials.

Measures of academic achievement and related outcomes have also been important in randomized trials to estimate the effects of new approaches to tutoring in England and the United States (Fitz-Gibbon 1990, Fuchs et al. 1997); reducing the size of elementary school classrooms in the United States (Mosteller 1999); radio-based mathematics education in Nicaragua (Jamison et al. 1980); cultural enrichment programs for children in the barrios in Colombia (McKay et al. 1978); and cooperative group learning in elementary grades in Australia (Gillies and Ashman, 1998).

Randomized trials have also been mounted to test programs that were purported to reduce individuals' dependence on public welfare. The United States has been the site for many studies on training and employment, housing, and welfare reform. Greenberg et al. (1997) summarized over 140 such trials, including a Canadian study of tax rates and guaranteed annual income and a Dutch experiment on intensive job assistance services for the unemployed.

Many randomized field trials have been used to test behavioral and social approaches to health care, including reducing HIV risk exposure or the risk of sexually transmitted diseases. See, for instance, reports on tests of husband-oriented approaches to enhancing the use of contraceptive devices in Ethiopia by Terefe and Larsen (1993), AIDs education in the Philippines (Alplasca et al. 1995), among others.

3. History

Claude Bernard's *Introduction to the Study of Experimental Medicine*, first published in 1865 in France, outlined a framework for controlled comparisons. Bernard, however, said nothing about the topic of randomized trials.

Scientists' use of randomization in order to construct groups that do not differ systematically, apart from chance and effects of interventions, is more recent. In the late 1890s, for instance, researchers in Denmark used randomized groups to understand whether certain diphtheria serum worked (Hrobjartsson et al. 1997). During the same period, psychophysical experiments in German laboratory studies employed random assignment (see Stigler 1986). For history on the idea of randomized experiments in health and other sectors and of comparisons, see www.rcpe.ac.uk/cochrane, Maynard and Chalmers (1997), and Marks (1997).

Large-scale randomized controlled trials (RCTs) in medicine appear to antedate randomized field trials (RFTs) in the social sector. Contemporary RCTs have their origins in trials during the 1940s and 1950s, undertaken by Bradford Hill and others in the United Kingdom to generate high-quality evidence on the effectiveness of streptomycin in treating tuberculosis (Marks 1997). Later, Jonas Salk, Paul Meier, and others in the United States successfully mounted randomized trials to discern the effects of vaccine on the incidence of poliomyelitis (Chalmers 1999).

Some contemporary history of randomized trials in the social sector is given in Boruch (1997) and Oakley (2000). See both books for references to the examples that follow. In criminological research, the Manhattan Bail Bond experiment of the 1960s is a classical case. It involved randomly eliminating bail for some people to understand whether bail bond requirements actually work to assure that people appear for a trial. More recent and remarkable trials are described in the University of Maryland's report to the US Congress (http://www.nijrs.org and http://preventingcrime.org).

Advances in the economic arena include the graduated work on incentive trials of the 1970s, tests of employment and training programs in the 1980s, and trials on welfare programs in the 1990s. Fienberg et al. (1985) discuss these and other large-scale economic and policy experiments, and how substantive theory is important in the experiments' designs. Many of these studies are abstracted in Greenberg et al. (1997). See the website for the Social Research Demonstration Corporation for information on related work in Canada (http://www.policyresearch.gc.ca).

In the 1960s, the Perry Preschool/High Scope trial on preschool education is a precedent that is well known by people who want to understand the effects of early childhood intervention programs (Boruch 1997). Taroyan and others (2001) have mounted a similar trial in England. No reports on a large-scale randomized trial on the effects of reducing classroom size were reported until the 1990s. The Tennessee STAR trial is a remarkable exception covered in a special issue of *Education Evaluation and Policy Analysis* (2000), Mosteller (1999), and Finn and Achilles (1990).

4. Ethics and Law

The ethical standards for research on human subjects in many countries have been influenced heavily by the Nuremberg Code and the Helsinki Declaration on medical research. Elements of these codes have been adopted, at times, to assure that the rights of people

are protected in social, criminological, and educational research. The codes are pertinent to randomized field trials as they are to other kinds of studies.

Such codes require, for instance, that individuals be informed that their engagement in a study is voluntary, and that they can decline to participate or, having agreed to participate, that they can withdraw. Codes regard it as essential to obtain the participant's informed consent, based on a well-specified statement of possible risks and benefits to the participant. Moreover, an institutional review board is often required to examine the experiment's design in order to assure that certain ethics' standards are met.

In the United States, for example, the US Code of Federal Regulations (45 CFR 46) requires that most research organizations in the United States abide by this kind of standard. Canada, the United Kingdom, and the Nordic countries have similar codes. Such governmental rules can be found at times on worldwide web sites such as www.helix.nih.gov. Research journals and books also provide important information. See, for instance, see Sieber (1992) and articles in two special issues of *Crime and Delinquency*, 2000, **46**(2–3), for specific references.

Many professional associations in social research have adopted codes of conduct that enlarge on the international codes and government standards. For instance, members of the Board of the American Criminological Association have (a) reiterated the need to attend to the ethics of research on human subjects and (b) emphasized the ethical responsibility of service providers, as well as researchers, to generate good evidence through randomized trials about the effectiveness of interventions in justice research. The Board also reminded readers that it is unethical for professionals in the service delivery arena, such as the courts, to require that individuals receive treatments whose effectiveness is unknown (*Crime and Delinquency*, 2000, **46**(3)).

One of the paradoxes of codes of ethics for researchers is that codes of research ethics have not been applicable to professionals who experiment in an uncontrolled way by 'trying something out.' Despite the absence of unequivocal evidence on a treatment's efficacy, for example, a physician may use the treatment on a patient without any ethics board review and without the informed consent that is required in a randomized trial. Similarly, a teacher who tries out new ways of teaching may do so without oversight by any institutional review board.

Ethical standards are often reified in law. That is, legislatures, diets, parliaments, and other law-making bodies can influence decisions about whether randomized trials are run. In the United States, for instance, welfare laws that were enacted during the 1990s permitted various states of the US to depart from national rules. This permission to depart from national law was in the interest of testing unconventional approaches to enhancing the education and employment status of low-income families. Such 'waivers' are an important vehicle for allowing ordinary societal interest in improvement, to deploy and test the innovation.

More generally, the designer of a randomized field trial can use at least four simple strategies to tailor the trial's design so as to conform to good standards of ethics and law. In the first place, if a purportedly effective service is in short supply, relative to the demand for the service, random assignment of people to the service can often be justified. That is, many people regard a lottery as the fairest way to allocate a scarce resource.

Second, people recognize that the eligibility of individuals for a particular intervention is an important ingredient in their design of a trial. For example, some criminal offenders clearly need to be jailed. Other offenders clearly ought not be put into jail. For still others, the effectiveness of jail would not be known. The randomized study would focus then only on those for whom the benefit of jail to the individual is unpredictable. That is, one designs the trial so as to include only those for whom the intervention's effectiveness is uncertain.

A third strategy to the ethical design of randomized field trials involves a wait-list approach. That is, equally eligible people are randomly allocated into a group that receives treatment early and others are randomized to receive treatment later. The experiment then compares the state of two groups after the first has completed treatment and before the second group has begun.

A fourth strategy recognizes that, in some cases, random assignment of individuals to treatments is unethical (or infeasible) but recognizes that the random assignment of entities to different interventions is ethical. The trial's designer, for instance, may find that local juvenile facilities are unwilling, on ethical grounds, to assign individuals randomly to different treatments in their facility. The trialists may also find, however, that the same facilities are willing to try out interventions whose effectiveness is unknown, so long as the entire facility is assigned (randomly) to the intervention. Boruch and Foley (2000) and Murray (1998) reviewed randomized trials of this kind. Hospitals, factories, schools, geopolitical jurisdictions, police precincts, and other entities are the units of random allocation and analysis.

5. *Institutional Capacity for Randomized Trials*

A randomized field trial requires resources. To judge from experience in different countries, an essential resource is people who are willing to support and contribute to studying the effects of innovations such as policy makers and practitioners. The Tennessee Legislature's support of the State's trial on reducing the sizes of classes in schools is a case in point. See the

special issue of *Educational Evaluation and Policy Analysis*, 2000, **20** (Nov. 10).

Doing a randomized field trial also requires understanding of managerial issues in field research and how to handle the cultural and other political-institutional factors that must be taken into account. Organizations and teams that are capable of running the experiment are important. Over the past 20 years, organizations such as Manpower Demonstration Research Corporation, Abt Associates, and Mathematica Policy Research have emerged in the United States to conduct large-scale experiments. In Canada, the Social Research and Demonstration Corporation has done so. Other organizational arrangements have been developed in universities to conduct small- to medium-scale trials. In the United Kingdom, for instance, see Fitz-Gibbon (1990) on school-based interventions. Martin Killias and his colleagues in Switzerland and Rudiger Ortmann and his colleagues in Germany built teams to mount randomized trials in the crime prevention arena. (See the special issue of *Crime and Delinquency*, 2000, **46**(2).)

6. *Complications and Issues*

When a simple randomized trial involving two interventions is well designed and deployed, the statistical analysis and inferences are usually straightforward. Trials are not always simple. Nor are all such studies implemented without problems.

Trialists know how to randomize and check the integrity of the randomization. See Boruch (1997) and *Experimental Design*: *Overview*. Nonetheless, randomization can be corrupted especially when the trial is run in an unfamiliar context. If the randomization is subverted, it is often difficult if not impossible to take this into account in a satisfactory way.

Further, trialists capitalize on contemporary statistical methods and software to design a trial that maximizes the experiment's statistical power under different scenarios. This assures that real differences among programs can be discerned. In novel contexts, however, it may not be possible to use this technology easily because little is known about the target groups, programs, and context. More important, such power analyses help to discount small sample size and other design factors as a reason for finding no remarkable differences among programs. The trialist must usually get beyond this, addresssing questions such as: did the interventions and control conditions really differ in character or operation? Is there something wrong with the theory underlying the new program or one's understanding of the problems it was designed to resolve? See *Experimental Design: Compliance*.

The advice to 'analyze the units as you have randomized them' is wise in that this approach preserves the benefits of randomization. That is, when individuals have been randomly allocated, they are then the units of analysis. When institutions have been randomly assigned to alternative programs, then these are the units of statistical analysis. In some trials, matters are more complicated. Schools may be randomly assigned to interventions; teachers within schools may or may not be randomly assigned to children within classrooms and schools. Designing these more complicated trials depends on the knowledge base in education and in statistics, including understanding of hierarchical and mixed statistical models.

Accumulating and synthesizing results of randomized trials is obviously important in building the knowledge base about the effectiveness of social innovations. Advances in meta-analysis and systematic reviews can help to do this. There are complications of course. In any given area, randomized trials vary in quality and trustworthiness and so ought not be given equal weight. Despite the threats to validity of nonrandomized trials, some of these trials produce evidence that is as defensible, under certain assumptions, as the evidence in randomized trials. Learning how to put the two together depends on new statistical methods such as propensity scoring, access to original microrecords, and substantive knowledge about programs, target populations, and contexts. See *Meta-analysis*: *Overview* and Sect. 7.

7. *International Information on Randomized Field Trials*

Until the early 1990s, there existed no central source of information on randomized trials undertaken by health care researchers. In 1993, the international Cochrane Collaboration (Maynard and Chalmers 1997) was created to prepare, maintain, and disseminate systematic reviews of studies on the effects of health care programs. As part of its mission to produce systematic reviews, the Collaboration evolved into an important major source of information on randomized trials. The Cochrane Library is accessible through subscription on the worldwide web site (ww.cochrane.ac.uk).

Until the year 2000, no organization had been invented to provide ready access to randomized trials in education, crime and justice, social work and social welfare, and other social sectors. The international Campbell Collaboration was developed as a younger sibling to the Cochrane Collaboration. The Campbell Collaboration's mission, in part, is to identify, maintain, and make accessible, randomized field trials done in all social sectors. The collaborators use this registry resource to generate systematic reviews of the effectiveness of interventions (http://campbell.gse.upenn.edu).

R. F. Boruch

Experimental Economics

Why do scientists perform experiments? Ostensibly, they want to test their operating understanding of the principles or theory that give coherence to the phenomena that interest them. They are interested in knowing if and how their conceptual schemes work, when tried. Experimental economics asks whether, and under what conditions, our models of decision, strategic interaction, and markets work in the sense that the implications of the principles are consistent with what we observe. But experimentalists everywhere—including economics—soon discover that their theoretical (conceptual) framework is inadequate to embrace all of their observations, and they (should) ask why? At this point experimentation takes on a life of its own. To the extent that experimentalists get interested in that life, learn to like it, and pursue it, they become phenomenologists seeking a deeper understanding of behavior. Such phenomena can lead to a fundamental restructuring of theory; until the restructuring occurs, commonly the phenomena exist as a way of thinking about the world that provides an engine for generating hypotheses that only indirectly connect with theories that might have motivated the initiating experiments. This is a potent source of experimental knowledge driven by empirical/theoretical probes of behavior and its interpretation outside the boundaries of standard theory.

This article provides an introduction to laboratory methodology in economics, an overview of a small selection of results indicating examples of what has been learned from this research with an emphasis on how such learning can be linked with data and theory outside of traditional economics. Also the use of the laboratory as a test-bed for economic systems design is briefly discussed. Where possible, references will be to citations and discussion in Davis and Holt (1993), Friedman and Sunder (1994), Kagel and Roth (1995), and Smith (1991).

1. What is an Economics Experiment?

Every microeconomy (laboratory or field) can be represented by three elements. (Smith 1991, pp. 255–71). The first is the environment, specifying agent characteristics that motivate action. In neoclassical economics this included agent endowments, preferences, and technology (costs). In laboratory experiments monetary rewards are most often used to induce a specific value/cost environment and to motivate decision. The institution defines the language (messages) of agent communication, the rules (property rights) governing the exchange of information, allowable actions (moves), and how messages/actions lead to valued outcomes. Laboratory experiments use instructions and decision forms (often computer controlled) to define the institution. Finally, there is the observed behavior of agents/subjects given the environment and institution. Here are three examples of laboratory microeconomies

1.1 Trust Game (*Fig. 1*)

1.1.1 Environment. The alternative payoffs are shown in the outcome parentheses for (DM1, DM2), where DM_i is decision-maker $i = 1, 2$. Thus, at the bottom of the decision tree, conditional on reaching node 2, if DM2 moves down, the payoffs are (DM1, DM2) = (\$0, \$40).

1.1.2 Institution. Subjects, for example, in groups of at least 12, are randomly and anonymously paired, and randomly assigned the roles (1 or 2). DM1 moves first, choosing right, in which case the game ends with payoffs (\$10, \$10), or down. If down, DM2 chooses right yielding (\$15, \$25) or down (\$0, \$40). Each player sees the moves in sequence of the other. No communication is permitted (except the moves); neither DM knows with whom he/she is paired. Variations on this institution might include players not seeing each other's moves; being able to communicate or play might be repeated with the same unknown person. The experimental protocol—rules and procedures—define the institution in an experiment.

Figure 1
Trust game: moves and payoffs for (decision-maker 1, decision-maker 2); game ends at payoff node

1.1.3 Behavior. Shown next to each payoff outcome is the (proportion; percentage) of all subjects ending at the indicated payoffs for each of two subject population samples:

(a) Undergraduates (U) with various majors; the typical subject.

(b) Graduate (G) students in economics, from across the US and Europe in their third or fourth year of study, attending a workshop in experimental economics.

For a discussion of bargaining experiments and further references see Davis and Holt (1993, pp. 241–75), Friedman and Sunder (1994, pp. 56–60), Kagel and Roth (1995, pp. 253–348), and McCabe et al. (1996).

1.2 Auction Experiments

1.2.1 Environment. Subjects, for example, in groups of four, are each assigned one value, $V_i^t \varepsilon$ [0, \$10], chosen independently with replacement, where each value is equally likely to be drawn for each i in each auction period, $t = 1, 2, \ldots, T$, where T is unknown to the bidders. V_i^t is the maximum-willingness-to-pay of i for one unit of the abstract good in period t, since if i wins the auction he/she earns $V_i^t - (\text{price paid})_i^t$. At each t one unit is offered for sale to the four competing bidders at zero supply price.

1.2.2 Institution (sealed high-bid auction). At t each i submits a bid, $b_i^t \geqslant 0$, the high bidder wins and pays a price equal to the amount bid. Hence, if $i = 1$ is the high bidder, his/her earnings are $V_1^t - b_1^t$.

1.2.3 Behavior. Subjects tend to submit bids that are approximately proportional to their assigned value, i.e., $b_i^t = \hat{\alpha}_i V_i^t$, where $\hat{\alpha}_i$ is i's estimated bid coefficient based on all observations (b_i^t, V_i^t). If all bidders are risk neutral, the Bayes–Nash theory predicts $\alpha_i = \frac{N-1}{N} = \frac{3}{4}$, with $N = 4$, for all i. If agents are risk averse, their bid coefficient is $\alpha_i > \frac{3}{4}$. This is because, so it is argued from the theory, that they are willing to accept less profit, $V_i^t - b_i^t$, to increase the chances of being the high bidder. Almost all bidders (over

Figure 2
Oral double auction experiment: supply and demand, plot of contract prices

90%) in high-bid experimental auctions bid as if they are risk averse. See Davis and Holt (1993, pp. 275–308), Friedman and Sunder (1994, pp. 107–9), Kagel and Roth (1995, pp. 501–85), and Smith (1991, pp. 509–661) for references and discussion of experimental auctions.

1.3 Double Auction Stationary Supply and Demand Experiment

1.3.1 Environment. M buyers are assigned one or more positive values in period 1. Each buyer earns $V_i - P_i$ for each unit with value V_i that is purchased at price P_i; each of N sellers earns $P_j - C_j$ on each unit sold at price P_j, where $C_j > 0$ is one of the costs assigned to seller j in period 1. The same values and costs might be assigned in period 2 and all subsequent periods, defining a stationary replicating economic environment.

An example is provided in the experiment of Fig. 2 in which there are six buyers, each with a capacity to buy up to three units. Buyer 1 has a three-unit demand schedule. His three maximum willingness-to-pay limit prices are at \$20, \$13.50, and \$13.20 as indicated by the three units designated by B1 in Fig. 1. If B1 buys a first unit, he earns \$20 minus the purchase price; a second unit earns \$13.50 minus its purchase price and so on. Other buyers have limit price demand schedules as shown. When all limit prices are pooled and sorted from highest to lowest this defines the market demand schedule of prices and corresponding maximum purchase quantities.

Similarly, sellers are assigned minimum willingness-to-accept limit selling prices. For example, seller S4 can sell up to three units at unit costs \$7.00, \$13.50, and \$14.50, respectively. When all seller limit prices are sorted from lowest to highest we get the market supply schedule, shown in Fig. 2.

Each buyer and seller only knows his or her private local supply or demand schedule. As Hayek would say, information is dispersed; each agent knows his or her own particular circumstances of time and place which we summarize in the form of the indicated limit values and costs in Fig. 2 (Hayek 1945, cited in Smith 1991, p. 234). Supply is to order in the environment shown in Fig. 2 so that there is no carryover of units

not sold and therefore not supplied. In a multiple period competitive market experiment the supply and demand schedules so defined become flows per period. Note that any P_E in the interval (\$12.30, \$13.20) is a competitive equilibrium that clears the market of 12 units. The theoretical gains from exchange are represented by the shaded area of Fig. 1. Keep in mind that no subject in the experiment knows this, and none sees before them a chart like Fig. 1. This information is unnecessary.

1.3.2 Institution. We also need an institution that defines the language of the market and its operating rules. In the example of Fig. 2 we use the bid-ask double auction rules common in financial and commodity markets. Any buyer (seller) can announce a bid (ask) price to buy (sell). Agents are recognized one at a time with bids and asks written into a spread sheet in sequence on an overhead. Once a bid (ask) is established a new bid (ask) must be higher (lower). Hence, the bid-ask spread is required to narrow. At any time any buyer (seller) can accept the standing ask (bid) to form a contract. For example, seller S1 might sell her first unit to buyer B6 at price \$12. The seller earns a profit of \$12 − \$8.20 = \$3.80 and the buyer a profit of \$20 − \$12 = \$8. This process continues for, say, 5 minutes or until no new contracts are forthcoming. The first market period ends, and the market opens for a new trading period. There are many software programs allowing these rules to govern trading via computer terminals.

1.3.3 Behavior. With M, $N = 3$ or more, the sequence of contract prices tends to be volatile at first, then converge, within a few trading periods, to near the competitive equilibrium price and quantity that equalizes the quantities demanded and supplied (Smith 1991, Davis and Holt 1993, Chap. 3). But in Fig. 2 the subjects (Department of Energy administrators) were especially good traders, and prices stayed very close to the P_E interval during the first period. The contract prices for each trade are plotted as dots in the order of their occurrence: the first at \$12, then \$12.40, etc., the 11th and 12th at \$13. Although 12 units traded the market was 97 percent efficient (not shown), just short of 100 percent. Efficiency is the percentage of the shaded area that is collected as gains from exchange (profit) in any period. What was the source of inefficiency? Buyer B2 bought his third unit (the 13th market demand unit in order; value \$12.30) from one of the lower cost sellers at the price \$12.20 on the 9th contract as plotted. If a demand unit below P_E trades, this displaces one of the higher value demand units that must trade if the market is to be 100 percent efficient. Full efficiency is achieved only if the highest 12 demand units are satisfied by the 12 lowest cost supply units, with all other units not trading. Otherwise, further gains from exchange can be realized. In this case buyer B2 could resell his unit to the higher value buyer he displaced, yielding a profit for each. In the experiment shown, no provision was made for such retrading.

Double auction markets are studied in Davis and Holt (1993, pp. 125–72), Friedman and Sunder (1994, pp. 18–20), Kagel and Roth (1995, pp. 368–72), and Smith (1991, Parts I and II).

2. *What Have we Learned from Experiments?*

2.1 Personal vs. Impersonal Exchange: Reconciling Cooperative and Noncooperative Behavior

The results reported in the trust game of example 1.1 above contrast with those in the single unit auction, example 1.2, and the double auction example 1.3, posing an anomaly. Why do half of the subjects choose cooperative strategies in anonymous two-person games, such as Fig. 1, while, universally, subjects behave noncooperatively in anonymous interaction first price auctions and in double auctions (Fig. 2)?

To see the problem, consider the predictions of theory in the game of Fig. 1. Agents are assumed to be self-interested maximizers who choose dominant strategies, and who assume that any paired counterpart does the same. Thus, if player 2 gets a chance to move, she receives \$40 by moving down, \$25 by moving right. Player 1, expecting player 2 to choose her dominant strategy (\$40), will not play down. Thus, the noncooperative equilibrium (NE) of the game is for player 1 to move right yielding (\$10, \$10).

An alternative theory, prominent in social and evolutionary psychology, postulates that there are reciprocity types in the population who follow reputational lifestyles in social interactions, normally cooperating with other like persons. They also reciprocate when others offer cooperation to them. All social exchange among friends, associates, and in-group members involves trading favors, services, and gifts, with deep roots across all cultures including hunter-gathers. The sense of indebtedness for a favor is expressed in the common phrase, 'I owe you one.' For such types a move down by DM1, followed by a move right by DM2, constitutes an exchange. Each incurs a potential opportunity loss (Player 1, \$0 − 10 = −\$10; player 2, \$25 − 40 = −\$15) for a potential gain of 50 percent for player 1 and 150 percent for player 2 relative to NE. The exchange requires trust by DM1 and trustworthiness by DM2. Experimentalists originally used anonymous matching protocols to control for such pair-bonding. Therefore one of the

Figure 3
Dividend (fundamental) value: mean double auction prices by period for two subject groups

important discoveries was that this protocol controls very poorly for such phenomena.

Even graduate students in economics with knowledge and training in game theory do not predominantly apply the NE model in Fig. 1. One interpretation is that the reciprocity model is so strong and innate that it overcomes the effect of such training.

Thus, in an important sense, reciprocity behavior in Fig. 1, and noncooperative behavior in experimental markets, such as Fig. 2, are not anomalous: both achieve efficient–maximum gain—outcomes. In the former, an example of personal exchange, coordination on efficient outcomes, requires shared attention, intentionality detection, and 'mindreading' (Baron-Cohen 1995) by reciprocity types; in impersonal exchange in markets, coordination through a pricing institution achieves efficient outcomes which are not part of the intention of agents who, noncooperatively, seek only their own gain. One cannot speak of an identifiable 'other mind' to be read. In Smith (1998) it is argued that reciprocity, in the extended family and the tribal societies of our hunter-gatherer ancestors, would have laid the exchange foundation for specialization and wealth creation millennia before the emergence of long-distance exchange based on barter, and, ultimately, something that would be called 'money.' (Also see North 1990 on personal vs. impersonal exchange and the emergence of long-distance trade.)

2.2 Institutions Matter

The rules governing social and economic interactions matter because they affect the state of agent information, perception, and incentives, which in turn affect decisions. Because information on value (cost) is dispersed among agents the frequency and content of the messages exchanged are important elements in equilibrium price discovery. This is demonstrated at the elementary level in single-object auctions. In the English 'open outcry' auction (E), if each bidder knows only his own value, then after the initial bid

each bidder has an incentive to raise the standing last bid if it is below the bidder's valuation for the item, but never to raise his own standing bid. Consequently, the bids increase until the highest value bidder eventually raises the standing bid until it is equal to or just above the second highest value bidder, and he or she is awarded the item at the price equal to the last bid. The award is thus efficient, and experiments tend to confirm the high efficiency and price predictions of this theory. The E auction, however, is vulnerable to collusion, since a subset of friends/associates may refrain (reciprocally) from raising each other's bids even in the absence of formal agreement. In the absence of collusion, no one is motivated to invest in information about the values or bidding strategies of others (which would be socially wasteful) because bids and withdrawals are public information, although the identity of those taking the actions may not be public.

In the first price sealed bid auction (F), the high bidder also wins and pays his bid price, but each bidder bids once, blind to the bids of others. In F, bids are also related to value, but also to what a bidder may know, guess or believe about the valuations of others, and, theoretically, to his own attitude toward risk. Information on the bids or values of others is informative, and bidders are motivated to invest in acquiring such information. Knowing the highest bid of your competitors enables you to win with a slightly higher bid, and leave no money on the table.

A variation of the F auction is the second price sealed bid auction (S), in which the highest bidder wins but pays the seller a price equal to the second highest bid submitted. Whoever wins is put in the position of being a price-taker, i.e. the amount of the winning bid determines the probability of winning but has no effect on the profit from bidding. Therefore it is a dominant strategy to bid your value, thus maximizing expected profit; if all do this, the high value bidder wins at a price equal to the second high value. This logical characteristic of S auctions is not immediately transparent to unsophisticated bidders, although many learn over time to bid their value without necessarily being able to articulate why.

In the Dutch auction (D) the price starts high and descends until the first bidder stops the clock (in Dutch flower auctions) or yells 'mine' (in Spanish fish auctions): the auction is over with the first (public) bid. It is a theorem that the D and F auctions are isomorphic: it is rational to stop the clock at the price you would bid in the F auction. Behaviorally, in D auction experiments, on average, subjects tend to let the clock run below the level at which they would bid in an F auction (Cox et al. 1983 in Smith 1991, pp. 580–94). Note that collusion is difficult in D auctions because no one knows what might be the highest of your competitor's bids because it is never observed.

Theoretically, under the Vickrey assumptions (e.g., risk-neutral bidders), the above auctions all yield the same efficient allocations and expected price. With risk averse bidders, the E and S auctions are still equivalent and efficient, the D and F auctions are equivalent, but not efficient, and yield higher average prices than E and S. This is an example in which the environment interacts with the institution: with risk aversion bidders' behavior in D and F diverges from that in E and S. Behaviorally, in lab experiments, E and S auctions are roughly equivalent, and highly efficient, with comparable average prices. The D and F auctions are not equivalent; F prices are higher, and have higher efficiency: in both D and F bidders bid as if they were predominantly risk averse. (For surveys see Davis and Holt 1993, Friedman and Sunder 1994, Kagel and Roth 1995, and Smith 1991.)

2.3 Stock Market Bubbles are Common in the Laboratory

Finance theory teaches that the value of an equity share is determined by its fundamental value: the expected discounted value of its future yield (or dividends). Consider a simple environment for testing this hypothesis: $N = (9 \text{ or } 12)$ subjects are each given an endowment of cash and shares; at the end of each of 15 trading periods a dividend is drawn from the four alternatives (0, \$0.08, \$0.28, \$0.60), each with a probability of one-quarter of yielding an expected dividend of \$0.24 per period. Hence, during the first period each individual has a right to 15 draws from this dividend distribution, so that fundamental value is $15 \times (\$0.24) = \$3.60$; during the second period the right is to 14 draws, and value is $14 \times (\$0.24) = \$3.36$, and so on. This information and these calculations are displayed to all subjects to guard against any misunderstanding (see Smith et al. 1988 in Smith 1991, pp. 339–71).

In Fig. 3 the white bars plot the declining theoretical (dividend) value, from \$3.60 in period 1 to \$0.24 in period 15. A typical experiment using inexperienced undergraduate subjects is indicated by the black bars that plot the average double auction contract price by period: average prices start below fundamental value, rise over time to above this value, then crash a few periods before the end, approximating the fundamental value by periods 14–15. Perhaps 100 such experiments have been reported in the literature documenting this bubble/crash behavior for inexperienced subjects, and the fact that only when a group is brought back for a third session do prices finally approximate the fundamental value. The interpretation is that common information is not sufficient to yield common fundamental value expectations; it is not enough because each person still has uncertainty about the behavior of others. It is through a common experiential process that subjects resolve this behavioral uncertainty and approach common expectations.

But suppose that advanced graduate students participate in this experiment. A subset of 22 subjects from the sample who participated in the trust game, whose results are depicted in Fig. 1, also participated in an asset trading experiment, yielding mean prices represented by the gray bars in Fig. 3: mean prices deviate no more than five cents from fundamental value. Hence, in this market game, advanced students in economics are rational, and expect others in their group to be rational. Common information and knowledge of others' types is sufficient to yield common rational expectations. For a comprehensive survey of asset trading, see Sunder, pp. 445–500 in Kagel and Roth 1995).

2.4 Rewards and Decision Costs Matter

The examples of environments in Sect. 1 all use salient cash rewards for the subjects; i.e., payment is directly related to earnings from decisions. Subject moves in Fig. 1 have substantial payoff consequences, while in market experiments buyers are motivated to buy at low, and sellers to sell at high, prices (see Davis and Holt 1993, pp. 24–26). There are many studies over the past 40 years showing that reward level matters. There are also cases showing that increased rewards do not improve performance (Smith and Walker 1993). Even when the central tendencies of the data support theoretical predictions, increased reward can cause the variance of the observations to decline as the data clusters more closely around theoretical predictions. Where the data do not support the predictions of a theory, increased payoffs may cause the data to move closer to those predictions, although statistically the predictive hypothesis is still rejected (see Smith and Walker 1993 for a survey). Psychologists sometimes interpret this to mean that rewards have 'little or no effect.' (Certainly the 'effect' may not rescue the theory.) Alternatively, when theory fails, a common critique from economists is that the payoffs, in particular the payoff deviations from the predictions, were inadequate (Kagel and Roth 1995, pp. 66–7). This is the methodological problem of flat maxima: even with substantial rewards, as in an auction experiment, bidding above or below the optimum may reduce payoff by only a small amount.

Notice that the findings that the variance, or distance, of the observations from the predictions declines with rewards, and the interpretations, that the rewards have little effect, or change only slightly with deviations from optimality, are all extra theoretical issues. The theory predicts the unique optimum, with zero deviation/variance, however gently rounded is the payoff function. Thus, the *ex post hoc* claim that the opportunity cost of deviating from optimality is 'too low' is implicitly a claim that other resource costs, pertinent to a decision, are not included in the theory. If the rewards are adequate, then such costs would be overcome and the decision would be closer to the theory. Economic theories of optimal behavior ignore decision costs—the costs of thinking, calculating, attention, monitoring, deciding, etc. Stakes are not a formal part of the theory, and payoff adequacy tends to surface only as an afterthought when a theory performs poorly in tests.

This problem illuminates the key methodological issue in any experiment: an experiment is a joint test of a theoretical hypothesis and everything you choose to do (procedures, relative and level of payoffs, information provided, etc.) to implement the test. This is why, whenever a theory fails replicable testing, it is most important to re-evaluate both the theory and the testing apparatus (laboratory or field) as a system. Otherwise, one can always interpret the test as rejecting the auxiliary hypotheses used in the test, and not the theory: every time you double the stakes, the test either succeeds or fails; if it fails one concludes that the stakes were inadequate; if it succeeds one concludes that the theory is correct. This defines a process in which the theory cannot be falsified. Yet in traditional economics all basic theory development tends to abstract from the issues that arise in implementing a test. In the above example, the pattern of observed deviations from predictions begs for some formal extension of theory that takes rewards into account. (For a discussion of methodology in experimental economics, see Smith 1991, pp. 783–801.)

We briefly outline a simple such extension based on a model of subjects' decision cost (Smith and Szidarovszky 1999). Consider an interactive game among N decision-makers, with payoffs $\pi_i(y_1,\ldots, y_N)$ given the decision choices, y_i, for each i. Let $y_i = x_i^*$ define a Nash equilibrium in the standard paradigm of unbounded, costless, rationality. Now let $y_i = x_i^* - \varepsilon_i(z_i)$ where $\varepsilon_i(z_i)$ is agent i's error deviation from equilibrium, depending on the cognitive effort, $z_i \geqslant 0$. More effort is productive, implying that $\varepsilon_i(z_i)$ is decreasing in z_i. But reduced error increases payoff. From the perspective of the decision-maker, reward net of cognitive cost, $C_i(z_i)$, is $\pi_i(x_1^* - \varepsilon_1(z_1),\ldots, x_i^* - \varepsilon_i(z_i),\ldots, x_N^* - \varepsilon_N(z_N))$-$C_i(z_i)$. This defines a modified equilibrium in which effort cost is balanced against its value in reducing error. For optimal $z_i > 0$, we get the testable implication that increasing payoffs reduces average error, and the variance of error.

This model also explains what can go wrong when increasing the stakes has an insignificant effect on performance, as is often found across the range of experiments: the decision task has very high effort cost and/or effort has low productivity in reducing error. Then, decision costs may dominate the effect of larger rewards. Also it can be seen why subject experience might be as, or more, important than reward level. Experience allows decisions to become routine, with reduced attentional effort. Learning initially to play a Bach sonata may be arduous even for a skilled pianist,

Independent auction compared with combinatorial auction in primary market and in subsequent after market trading for inexperienced and experienced subjects

who performs with little effort and without conscious thought once it is mastered. Thus, rewards may sometimes be more effective for inexperienced than experienced subjects (see Jamal and Sunder 1991, cited in Friedman and Sunder 1994, p. 220).

3. How Can Experiments be Applied in the Field?

Beginning over 30 years ago experimental methods have been employed to study a wide variety of phenomena with direct application outside the laboratory (Smith 1991, pp. 511–14). The worldwide privatization/deregulation movement over this period has created a great demand for 'test bedding,' the use of the laboratory to test the performance properties of new kinds of markets and to train participants in the field. (For some discussion and further references see Davis and Holt 1993, pp. 296–304, Kagel and Roth 1995, pp. 119–21, Friedman and Sunder 1994, pp. 32–7, Smith 1991, pp. 662–702, Rassenti and Smith 1998).

Thus, laboratory experiments have been used to inform the design of pollution credit trading, natural gas production, delivery and transmission, spot markets in electricity, and recently the auction of rights to the spectrum.
