For Plato and Aristotle, and likewise for the biblical authors and redactors, justice is primarily a virtue of persons rather than of institutions. Thus, Plato's *Republic* investigates justice in the city only because Plato believes that the city is a plausible analogue to the individual soul, his real topic of interest; so too, Aristotle places his account of justice in his treatise on ethics rather than his treatise on politics. In the Bible, a just community is simply a community filled with just people. In this respect, the classical and biblical sources differ profoundly from contemporary theorists, who treat justice as a property of institutions rather than of persons.

It was Aristotle who first observed that the words 'unjust' and 'just' are ambiguous—the former refers both to 'the lawless man and the grasping or unfair man,' and similarly the latter refers both to the law-abiding and the fair man (*Nicomachean Ethics* Bk. 5, Ch. 1). One form that the virtue of justice assumes, then, is obedience to the law. Related to this form are special virtues of officials—to punish lawbreaking, and to judge impartially (which is a requirement found both in the Hebrew Bible and in Aristotle).

What about *justice simpliciter*, that is, justice apart from law-observance? Both the Jewish and Christian traditions locate the core ideal of justice in the Golden Rule and the injunction 'Love your neighbor as yourself' (Leviticus 19:18; Matthew 22:39), which commentators often regard as alternative formulations of the same duty. In addition, both traditions lay special emphasis on the injustice of neglecting or oppressing the poor. For Jews, loving your neighbor as yourself is so closely identified with the duty to care for the needy that the Hebrew word *tzedakah* carries the double meaning of 'justice' and 'alms-giving.' *Tzedakah* is a duty of the just individual, and a community will be unjust to the degree that it neglects the needy. In contemporary discussions, people often use the term 'social justice' in precisely this way. Similar themes appear in non-Western religious traditions as well (including a version of the Golden Rule in the Analects of Confucius).

This sense of *justice simpliciter* as solidarity with the least fortunate will inevitably generate conflicts with legal justice. Even within Leviticus 19, the duty to care for the needy lies in tension with the duty of judges not to favor the poor. Furthermore, as functionalists argue, laws aim to maintain and preserve a social order; law is an innately conservative institution, whereas the biblical conception of social justice is innately utopian and radical. One cannot really expect that laws in any society will be systematically formulated to enforce wealth-transfers from the prosperous and powerful to the poor and powerless.

There is another reason as well to anticipate divergence between legal and extralegal justice. Since Aristotle, it has been traditional to distinguish distributive justice from corrective justice. The former concerns fundamental questions of distribution in society; the latter deals with the rectification of injuries, both civil and criminal. Legal institutions such as courts deal principally with issues of corrective justice, and have very little to do with distributive justice (which is not to deny that legal decisions often have distributive effects). As writers from Aristotle onwards have observed, corrective justice may run contrary both to moral virtue and distributive justice—if a good man accidentally injures a wicked one, or a deserving poor man injures an unjustly wealthy one, the injurer

will owe compensation, even though in the former case the good man may be ruined for the sake of the bad, and in the latter case the distribution of wealth becomes even more lopsided than it was before. Legal institutions take established distributive principles and patterns as a given, regardless of whether they are just. In this sense, then, even when courts achieve corrective justice, they may well reinforce distributively unjust practices.

3. *Alternatives to Legal Justice*

So far this article has surveyed four conceptions of legal justice: the commonsense conception, according to which legal justice secures the goods of impartial consistency and predictability in the law; the traditional natural law conception, according to which legal justice secures the common good; Fuller's 'procedural natural law,' according to which legal justice provides an intelligible baseline against which people may order their own affairs; and the Aristotelian idea that genuine legal justice combines universal legal standards with equity. However, none of these is able to relieve the tension between legal and extralegal justice. The question remains whether other alternatives do better. Three alternatives have become prominent in contemporary debates.

3.1 *Law and Economics*

One response is simply to deny that achieving extralegal justice is an important aim of legal systems. A particularly influential contemporary version has been offered by law-and-economics theorists. According to Richard Posner (b. 1939), a founder of law and economics, the aim of legal systems is to maximize aggregate social wealth. If legal rules systematically fail to maximize social wealth, disputing parties could realize shared gains by bargaining around the law; inevitably, then, the law gravitates toward wealth-maximizing rules. Furthermore, wealth maximization is a normatively desirable aim, better than utilitarianism because it cultivates productive virtues rather than pleasure-seeking (Posner 1983). Critics, however, have found both the descriptive and normative claims of law and economics exaggerated. Inefficient legal rules sometimes linger for centuries, and the argument that a law prohibiting murder or rape can only be justified if it can be shown to maximize social wealth seems unsupportable (Dworkin 1980, Kronman 1980). (For further discussion of this point, see *Law and Economics: Empirical Dimensions*.)

3.2 *Pragmatism*

Another prominent alternative to the commonsense conception of legal justice is *pragmatism*. As one proponent defines pragmatic adjudication, 'a pragmatist judge always tries to do the best he can for the present and the future, unchecked by any felt duty to secure consistency in principle with what other officials have done in the past' (Posner 1998, p. 237). To the objection that this is an invitation to lawlessness, pragmatists respond that doing the best for the present and the future will in some cases require the judge to apply law and precedent in a rigidly formalistic manner; in other cases, however, pragmatism requires judges to look past formalities.

Pragmatists collapse legal justice into extralegal justice, where the latter is understood as achieving the best consequences overall. In one respect, pragmatism descends from the legal realists (see *Legal Realism*), who argued that legal formality is merely a disguise for implicit policy-choices, which should be made explicit and be guided by concern for consequences. In another sense, pragmatism represents a radical version of Aristotle's plea for context-specific equitable standards. The attractions of pragmatism are plain, but the general objection to broad standards applies in an acute form to pragmatism: there will seldom be agreement on what 'doing what is best for the present and the future' requires in any controversial case; thus, the virtues of predictability, transparency, and treating like cases alike will erode from the law.

3.3 *Feminism*

Feminists influenced by the work of psychologist Carol Gilligan have argued that the ethic of impartial justice is a quintessentially male construct—one that is in no way superior to the feminine 'ethic of care.' To illustrate the ethic of care, feminist legal scholars have fastened on the image of Shakespeare's Portia, who pleads that the 'quality of mercy' should replace rigid legal justice. The ethic of care focuses on repairing relationships and is directed toward individual needs rather than rules, policies, or the best overall consequences; unsurprisingly, this leads some proponents of the ethic of care to favor ADR over formal adjudication. On the other hand, other feminists caution that the ethic of care is part of legal justice rather than an alternative to it; conversely, care itself becomes corrupted without the virtues of consistency, integrity, and even-handedness—precisely the virtues promoted by legal justice in its commonsense conception (West 1997). (For further discussion on this point, see *Feminist Legal Theory*).

4. *Conclusion*

It is often unclear whether law and economics, pragmatism, and feminism are intended as alternatives *to* legal justice or as alternative analyses *of* legal justice. In a sense, all the theories surveyed here are responses to two fundamental tensions. The first is the tension between the rule of law, which subordinates particular cases to general rules, and the moral

demand to treat particular cases according to their individualized merits. The second is the tension between the values of consistency, predictability, and stability that legal justice serves and the more utopian values implicit in the broader notion of justice *simpliciter*. It may well be that no intellectual approach can eliminate this tension, or reconcile the competing senses of the word 'justice'

Justice, Access to: Legal Representation of the Poor

History and political theory both underscore the fundamental importance of providing equal access to justice for all citizens no matter what their economic and social status. It was promised to the subjects of emperors and kings long before those subjects began to even dream of the possibility of governing themselves. Then democratic theory, especially the social contract theory so influential with the founders of democracies in Europe and North America, emphasized that no man would surrender his natural right to resolve disputes through force unless government provided a forum to resolve those disputes where all citizens, rich and poor, had an equal chance. Thus, it is no surprise that constitutions of nearly every democracy guarantee their citizens 'due process' or 'fair hearings' and 'equal protection of the laws' or 'equality before the law' (Johnson 2000).

Despite these solemn guarantees, however, for most democratic nations it was well into the twentieth century before governments became serious about offering their lower income citizens equal access to justice. Progress has been uneven, with some countries forging far ahead of others. As of the beginning of the twenty-first century, this has become a field of study for political scientists, sociologists, historians, and legal scholars—seeking to analyze the problems, to devise solutions, to evaluate experimental approaches, to comprehend the political opposition to this goal, and to measure the progress.

1. An Overview Of Access to Justice Strategies

The study of access to justice issues in modern societies begins with an appreciation of the essential role lawyers play in the regular civil courts in every industrial society. In these societies, courts place most of the burden on the parties to investigate the facts, find the applicable law and present the case to the neutral, passive decision-makers—the judges or juries—supplied by the government. This is a heavy, often expensive burden the private parties must discharge and one typically requiring the expertise of lawyers. As a result of this division of responsibility between the government-funded courts and the private litigants, the latter bear most of the cost of the dispute resolution function as carried out in the courts of most modern nations.

This article analyzes how modern nations seek to supply counsel to those unable to afford their own, and also how some nations have sought to restructure the dispute resolution function to reduce the need for counsel. Three basic strategies are covered: (a) pro-

viding government-funded lawyers to disputants who are unable to afford their own legal counsel (II); (b) providing incentives to encourage private lawyers to represent people unable to afford to pay legal fees but without using government funds (III); and (c) providing dispute resolution forums where disputants can participate fairly without the assistance of a lawyer (IV).

2. *Increasing Access to Justice by Providing Government-paid Lawyers to Disputants Unable to Afford Their Own Legal Counsel*

Empirical studies conducted in the USA support the hypothesis that litigants who lack lawyers are severely disadvantaged in the courts, at least as those courts operate at the beginning of the twenty-first century (Galanter 1974). Debtors sued in collection cases who were represented by counsel had a six times better chance of winning than those who defended themselves. A study of unrepresented litigants who brought suit in the Washington, DC courts showed they suffered dismissal at the early stages of the proceedings and not one succeeded in even getting to trial. Also, low-income tenants representing themselves before New York's housing courts suffered eviction in almost every case while 90 percent of those represented by lawyers were saved from that fate.

Most governments did not require empirical research to reach the conclusion that their lower income citizens required free counsel if they were to enjoy effective access to justice in the regular courts. But the level of commitment to equal justice for all citizens and the willingness to fund the lawyers necessary to that goal vary greatly from nation to nation. Nonetheless, there was a trend toward greater access backed by larger government investments during the second half of the twentieth century in nearly all industrial democracies.

However, the legal status of the right to counsel in the regular courts is far different in the USA than elsewhere in Western democracies. While nearly all European and Commonwealth nations have enacted a broad statutory right to counsel in civil cases, as well as criminal cases, neither the federal nor any state government has done so in the USA. England's first such statute was enacted in 1495, France in 1852, Germany in 1877, the rest of Northern Europe in the early twentieth century, Italy in 1923, and most Canadian provinces and Commonwealth countries in the 1960s and early 1970s. In these countries, statutes guarantee low-income people that the government will supply them with a lawyer in any case where they qualify financially for such assistance, although they typically require the litigant's position to have some merit as well. In the past, most countries did not compensate the lawyers appointed to represent needy litigants but expected them to representation on a pro bono basis (Cappelletti et al. 1975). But over the course of the twentieth century more and more of the industrial democracies began to pay the lawyers serving poor people with government funds until by the end of the century a majority of European nations and all of the Commonwealth countries have chosen to do so (Johnson 2000).

Europe and the USA also have gone along different routes in recognizing a 'constitutional' right to counsel for indigent litigants. The courts on both continents have declared a constitutional right to counsel in criminal cases. But despite interpreting nearly identical constitutional language, the US Supreme Court and the European Court on Human Rights have reached opposite conclusions on the right to counsel in civil cases. In 1979, the European Court ruled the 'fair hearing' guarantee found in the European Convention on Human Rights and Fundamental Freedoms required member governments to supply free counsel to indigent civil litigants (Airey vs. Ireland 1979). Two years later, however, in a five-four decision the US Supreme Court held the constitutional guarantee of 'due process' did not require the provision of free counsel to civil litigants in the USA (Lassiter vs. North Carolina 1981). Switzerland, although not part of the European Community, anticipated the decision of the European Court on Human Rights over 40 years earlier when in 1937 the Swiss Supreme Court held that nation's constitutional guarantee that 'All Swiss are equal before the law' required government to provide free lawyers to those Swiss citizens who were too poor to hire their own (Judgment of Oct. 18, 1937, O'Brien 1967).

Lacking either a constitutional or statutory guarantee, poor people in the USA and many other countries around the world have legal assistance with their civil problems only if they can get help from a limited number of lawyers supplied through private or legislative charity (Zemans 1979). Indeed private charity was the only source of legal counsel for the poor during most of US history. It took the 'War on Poverty' declared in 1965 to create even a minimal level of government funding of legal services for the poor in civil cases (Johnson 1978).

As might be expected, comparative research documents that a statutory or constitutional right to counsel usually leads to a much higher financial commitment to government-paid lawyers for lower income citizens. Table 1 lists several industrial democracies in Europe, North America, and Oceania. The table first compares their total and per capita investments in government-funded civil legal services for those unable to afford lawyers. But the more salient comparison takes account of the relative prosperity of these different countries and reflects how much of a nation's gross national product its government commits to insuring access to justice for its lower income citizens (as measured by legal services investment per $10,000 of per capita GNP). Finally, the last two

Table 1

Comparative civil legal services investments [in US$] [Nations ranked by relative share of GNP invested in publicly-funded civil legal services—lowest to highest]

Nation (or political subdivision of nation, e.g., province, state)	This nation's total government investment in civil legal services (in US dollars) [In US includes Federal, State, local governments, and IOLTA expenditures]	Government's per capita civil legal services investment (in US dollars)	Government's civil legal services investment per $10,000 of GNP (in US dollars)	Total US governmental investment in civil legal services if US invested as much of its GNP as this nation does on civil legal services	Total English governmental investment in civil legal services if England only spent as much of its GNP as this nation does on these services
United States (FY 1998)	$600 million [population = 270 million]	$2.25	$0.70 [= 70 cents]	$0.6 billion [e.g., $600 million]	$80 million
Germany (1996)	$390 million [population = 80 million]	$4.86	$1.90	$1.6 billion	$200 million
France (1994)	$270 million [population = 59 million]	$4.50	$1.90	$1.6 billion	$200 million
Australia (FY 1998–99)			[Each state has its own program]		
–New South Wales	$31 million [population = 6 million]	$5.12	$2.75	$2.3 billion	$320 million
Canada (FY 1998–99)			[Each province has its own program]		
–Quebec	$52 million [population = 7.3 million]	$7.07	$3.50	$3.0 billion	$400 million
–Ontario	$82 million [population = 11.5 million]	$7.06	$3.60	$3.0 billion	$400 million
–British Columbia	$32 million [population = 4 million]	$7.80	$4.00	$3.34 billion	$465 million
Netherlands (1998)	$150 million [population = 15.5 million]	$9.70	$4.20	$3.5 billion	$480 million
New Zealand (FY 1998–99)	$27 million [population = 3.8 million]	$7.10	$5.10	$4.25 billion	$560 million
England (1999)	$2 billion $1.35 billion [population = 53 million]	$39.00 $26.00	Gross = $17.00 Net = $12.00	$14.2 billion $10.1 billion	$1.35 billion

1.2 *Note: An online version of this chart [updated periodically] can be found at http://www.equaljusticeupdate.org*

columns of the table illustrate what the total budget would be for two countries—England and the USA—were their investments the same per GNP as the other nations portrayed in this study. (These two nations are chosen because they represent the most generously funded (England) and least generously funded (USA) civil legal services programs included in these comparisons.)

Nations also differ in how they deliver their government-subsidized legal services. There are three common models: compensated private counsel, salaried staff attorney, and mixed systems.

Under the compensated private counsel model private lawyers represent lower-income people just as they would paying clients. But when serving those low-income clients the lawyers submit their bills to the government. The low-income clients, in turn, can usually choose any lawyer who has expressed a willingness to participate in the government program. This is the predominate delivery system in most countries, including England, the largest nations of continental Europe, and the Commonwealth countries.

Under the salaried staff model the government establishes separate legal aid offices, often in 'clinics' or 'neighborhood law offices' in close proximity to concentrations of low-income people. The offices are staffed with salaried lawyers, usually employed full-time. When poor people have legal problems they bring them to one of these offices and are represented by these salaried lawyers. The USA is the largest country that primarily relies on this delivery model.

A number of empirical studies have evaluated the costs and benefits of compensated private counsel vs. salaried staff delivery systems. Most comparisons suggest salaried staff programs deliver services at lower cost per case (Currie 2000). Both models score high on client satisfaction, but a substantial percentage also place a high value on the ability to choose their own lawyer—a feature of the compensated private counsel model. At the same time, salaried offices are better able to address community issues faced by the residents of low-income areas (Cappelletti et al. 1975).

Partly in response to the results of these studies and also in order to reduce program costs, several nations have moved to a mixed system that attempts to combine the virtues of the other two. Some of these mixed systems, such as those in Quebec, Canada and Sweden, adopt a 'client option' approach, allowing clients to choose between salaried staff lawyers and compensated private attorneys to represent them in a given case. Others, such as those in Ontario and British Columbia, divide legal problems between the two systems on a subject matter basis—typically with clients required to take all 'poverty law' cases to salaried attorney offices and the more traditional legal problems such as divorce to compensated private counsel.

Some countries using the compensated private counsel model to implement a right to counsel have experienced ever-expanding legal aid budgets. These budgetary considerations have led some governments, most notably in England, to begin exploring modifications calculated to reduce costs. These measures include 'franchising' where the government signs contracts with certain private lawyers and law firms to provide services at reduced fees. They also include variations of a 'capitation' approach where lawyers agree to handle all the legal problems generated by the entire low-income population in a defined geographic area for a fixed per capita sum (Moorhead 1998). British Columbia in Canada uses a form of 'managed care' common in some health delivery systems in which staff members closely monitor each litigation investment decision a compensated private lawyers might make during the course of a representing a poor person. In 1999 and 2000, England introduced several cost-control measures as part of a major overhaul of legal aid and the entire civil litigation process in that country (Regan et al. 1999).

3. Arrangements Which Encourage or Require Private Attorneys to Represent Lower Income People Without a Government Subsidy

In some nations, government-subsidized lawyers coexist with fee arrangements that encourage private attorneys to represent lower income clients without government funding in certain categories of cases. The most common of these are: (a) contingent fees, (b) conditional fees, and (c) court-awarded fees. In addition to these economic incentives, in many countries—especially those like the USA where government-funded legal services are in short supply—public policies encourage or require private lawyers to devote some of their time to the representation of poor people on a pro bono (uncompensated) basis (see Sect. 3.4).

3.1 Contingent Fees

The USA is almost unique in allowing lawyers to represent clients on a 'contingent fee' basis. Under fee contracts allowing them a percentage (typically 33 to 40 percent, but sometimes lower for early settlements and higher for trials) of the client's recovery, lawyers agree to assume the risk of failure, not charging any fee if they lose. Thousands of the poorest citizens are represented each year in cases where they are suing for a substantial sum of money and have a good chance of winning. At the same time, the contingent fee system offers no help to low-income people who are defendants, or who are plaintiffs in the many categories of legal disputes that do not involve monetary stakes or where the potential financial recovery is too modest to cover the risk of loss (Regan et al. 1999).

The contingent fee system is not without its critics. Some charge the fee percentages are too generous to lawyers, leaving their clients with less than full compensation for their injuries. Others, however, respond that if the percentages are set too low, lawyers will not find it economically feasible to take cases offering only modest potential recoveries or posing a significant risk of loss. Without the bonus of substantial fees when they win, contingent fee lawyers cannot afford to take riskier or smaller cases and thus can contribute less to increasing access for the low-income population (Regan et al. 1999).

Other studies have applied economic analysis to suggest the typical contingent fee structure places lawyers and their clients in a conflict situation. The lawyers maximize their profits when they get a decent recovery with a minimal investment of time while the client is best served by the largest possible recovery no matter how much time and effort the lawyer must expend. As a result, contingent fee lawyers may be inclined to settle too early and for too little, from the client's perspective. A recent empirical study, however, suggests contingent fee lawyers may come closer to maximizing their clients' returns than economic analysis predicted (Kritzer 1998a).

3.2 Conditional Fees

Most countries, other than the USA, use a 'loser pays' rule in allocating legal fees. That is, losing litigants pay not only their own lawyers but are required to pay at least a 'reasonable fee' to the winners' lawyers. A few nations, Ireland and at the beginning of the twenty-first century England, modify this rule in a way that may allow lawyers to serve low-income clients without a government subsidy in some cases.

In 1995, England introduced a modified form of the 'conditional fee' model, one that as of 2000 applies to nearly all civil litigation involving monetary stakes no matter the economic means of the parties. Under this model lawyers do not charge their clients a fee if they lose, but can charge an 'uplift' of up to 100 percent, in effect doubling their fee, if they win, with that 'uplift' payable out of the clients' monetary recovery. However, the total amount of the fee including the 'uplift' cannot exceed 25 percent of that recovery. Should they lose, clients are not relieved of their obligation to pay the other side's fees. But, if they can afford it, they can purchase insurance to cover this risk.

The UK government expects the 'conditional fee' system to supplant legal aid for the claimant's side of most cases offering the prospect of a monetary recovery. Critics point out the prospects of success must be unusually favorable before lawyers will be willing to provide representation under a 'conditional fee' system. They will not get a fee from either side if they lose and the 'reasonable fee' they do receive will ordinarily be less generous than the 33 to 50 percent of the judgment that contingent fee lawyers typically earn when they win at trial (Moorhead 2000).

3.3 Court-awarded Fees

Many jurisdictions in the USA depart from the general 'American' rule and shift fees to the losing party in certain categories of cases: (a) Statutory fee-shifting—in lawsuits under statutes specifically authorizing fee-shifting in favor of private parties whose cases enforce the public policies embodied in those statutes; (2) Public interest fee-shifting—in lawsuits where the court, rather than the legislature, determines that the public interest will be promoted by awarding winning litigants the bonus of requiring the loser to pay their legal fees.

Both statutory fee-shifting and public interest fee-shifting offer an alternative source of funding for those unable to afford their own counsel. They are especially important in major litigation not offering the possibility of a substantial monetary recovery, such as those seeking injunctive relief ordering the government or some other institutional defendant to change its policies in the future (Cappelletti et al. 1978–79). Where a case satisfies one of these standards, these fee awards can be more generous than either contingent or conditional fees, and frequently are. The court is typically not limited by the size of the winning party's economic recovery, which often is nothing, but can award winning lawyers their regular full hourly fees for the time they spent on the case. Beyond that, they can apply a 'multiplier,' doubling or tripling the lawyers' fee in order to recognize the riskiness, complexity, or significance of a particular piece of litigation (Regan et al. 1999).

3.4 Voluntary and Mandatory Pro Bono Legal Services

As mentioned earlier, most European countries originally implemented the statutory right to counsel by appointing lawyers to provide free legal representation to poor people without compensation—a form of mandatory pro bono services. During the twentieth century most of these nations found this approach unsatisfactory and shifted to a system that compensated the lawyers representing the poor (Huls 1994, Johnson 1994), although a few, like Italy, still depend on drafting lawyers to provide legal aid (Cappelletti et al. 1975).

Voluntary pro bono services depend entirely on the charitable impulses of the private legal profession. Faced with a shortage of government-funded legal aid the USA in the last decades of the twentieth century has attempted to encourage more private lawyers to volunteer time to represent the poor. Many states and cities have organized pro bono programs supervised

by staff. Others require private lawyers to report annually on the hours devoted to pro bono services. A national program issued a 'pro bono challenge' to the 500 largest law firms, asking them to commit 3 to 5 percent of the firm's billable hours to pro bono representation of the poor—and had mixed results. Some other nations—Sweden and Australia, among them—also have begun to look to pro bono services to fill some of the gaps created by reductions in government legal aid budgets (Regan et al. 1999).

There is serious question, however, whether societies can expect pro bono legal services to play more than a limited, supplementary role in the delivery of legal representation to low-income people. Is there any more reason to expect lawyers to supply enough services on a pro bono basis to meet the low-income population's total need for legal services than to expect medical doctors and hospitals to supply enough of their services pro bono to replace the present government-funded health care systems for the poor? —e.g., Medicare and Medicaid in the USA, the National Health Service in the UK etc.

4. *Increasing Access to Justice Without Supplying Free Lawyers, Government Paid or Otherwise*

Professional lawyers appear essential to fair proceedings in the regular courts of most modern countries, as the European Court on Human Rights held in Airey vs. Ireland (discussed in Sect. 2). The legal rules governing the decisions are complex, the procedures intricate, and investigatory techniques difficult to master. For all these reasons, unrepresented parties seldom have a chance for a 'fair hearing' in the regular courts.

Yet the European Court on Human Rights also recognized it may be possible for governments to create forums—for some cases at least—where the assistance of lawyers is not crucial and thus effective access to justice can be achieved without providing free counsel to lower income disputants (Airey vs. Ireland 1979). It is possible to identify four approaches that various countries have tried, alone or in combination, in an attempt to de-professionalize dispute resolution: (a) simplified forums; (b) law simplification; (c) technological substitutes for legal expertise; and (d) the use of less expensive, non-lawyer advocates.

4.1 *Simplified Forums*

For simpler disputes it may be feasible to construct simpler dispute resolution processes. Early in the twentieth century, several countries started 'small claims courts' to hear disputes involving minor stakes. Using simple procedures and expecting the judges to take a more active role in developing the facts, these courts were designed to function well without lawyers. Some criticize small claims courts for pitting poor people against lawyers hired by institutions such as credit companies, landlords, and businesses. A few jurisdictions responded by banning lawyers entirely from these courts. Studies of small claims courts have arrived at mixed findings about their fairness to individual litigants, especially in cases involving institutional opponents (Yngvesson et al. 1979).

Some jurisdictions also have created specialized courts roughly based on the small claims court model to handle certain narrow categories of cases (housing courts, labor courts, social welfare courts, and the like) with the expectation that their simplified processes would allow many disputants to represent themselves. Once again, the results are mixed (Cappelletti et al. 1978–79).

In addition to simplified courts within the court system itself, some jurisdictions have created administrative bodies empowered to resolve certain categories of disputes. For example, in England, 'tribunals' composed of part-time volunteers decide most disputes arising out of public housing and other government benefit programs. In British Columbia, Canada, an agency called the 'Rentalsman' determines most landlord–tenant disputes. In many jurisdictions administrative hearings decide whether a worker is entitled to compensation for job-related injuries and how much. Once again, the procedures are simple compared to the regular courts and typically disputants are encouraged to appear without lawyers—and sometimes lawyers are barred entirely (Cappelletti et al. 1978–79).

In recent years, private mediation and arbitration (often called Alternative Dispute Resolution or simply 'ADR') have emerged as major alternatives to the regular civil courts, especially in the USA. The primary motive behind the growth of these alternative forums, however, arises not from a desire to increase access to justice for lower income individuals, but to reduce delay and expense for more affluent litigants (Abel 1982).

While private mediation and arbitration have not proved a significant strategy for increasing access to justice when the disputes pit individuals against institutions, they have offered a useful alternative to litigation in disputes between evenly matched individuals (Menkel-Meadow 1999). Some communities in the USA have started neighborhood (or community) dispute resolution centers to help people settle disputes—especially those between family members or neighbors—without resorting to the courts. The services are usually free or require only nominal fees (Singer 1979).

4.2 *Simplification of Substantive Legal Rules Governing Disputes*

One of the major reasons people must employ lawyers to represent them is the complexity of the legal rules

the judge or jury will apply to decide who wins. Some suggest we can reduce the need for lawyers and thus improve access for lower income disputants by simplifying those rules. In some jurisdictions, for example, legislatures enacted no fault divorce laws and authorized couples to obtain 'summary divorces' if they had no children, limited property, and short-term marriages. Presumably, these statutory changes allow most people who qualify for such divorces to do so without a lawyer (Cappelletti et al. 1978–79). In an ever more complex society, however, it is questionable whether simplification of the legal rules will emerge as an important strategy for increasing access to justice in any but very limited circumstances.

4.3 Technological Substitutes for Legal Expertise

Starting in the late 1980s software developers produced a host of computer programs designed to offer average citizens the ability to generate legal documents such as wills and contracts. In the 1990s court systems and others desiring to increase access to justice for lower income individuals began developing programs which use similar technology to generate litigation documents that can be filed in common cases such as landlord–tenant, child custody, and spousal abuse cases. As of 2001, however, there has been no assessment of the issue whether these computer-generated litigation documents help litigants if they lack legal representation when they appear in court.

However, technology, computer technology in particular, may have only begun to transform the dispute resolution process in ways which could improve access for lower income litigants. Conversely, technology may reduce access to justice by increasing still further the cost of the litigation process and compounding the advantages higher income parties already enjoy. In fact, this phenomenon so evident in the health care field, can also be observed in the law. Only the party with considerable resources can afford many of the expensive scientific tests and fancy computer-generated graphics which enhance the chances of victory in the modern court room.

4.4 Use of Less Expensive, Non-lawyer Representatives

Some specialized lower-cost forums permit non-lawyers to represent parties appearing before them. Some even rely exclusively on non-lawyer advocates for this role. Presumably the use of these less educated and less expensive personnel enhances access by lowering the cost of representation to the parties or to the government employing the advocates.

A recent study tested the difference between representation by lawyers and representation by lay advocates in these administrative forums. The study suggests only marginal differences in the quality of representation or the results achieved. It says little if anything, however, about the comparative performance in the regular courts or other forums that decide a broader range of disputes requiring advocates possessing a greater body of legal knowledge and skills (Kritzer 1998b).

5. Future Issues in the Movement Toward Equal Access to Justice

The major issues for government-funded legal aid and equal access to justice in the twenty-first century include: (a) whether a 'globalization of constitutional values' will lead courts in the USA and elsewhere to join the majority of industrial democracies in recognizing a constitutional right to counsel in civil cases; (b) whether those nations which already have such a right as a matter of statute or constitutional interpretation will develop delivery mechanisms and alternative dispute resolution policies allowing them to guarantee effective access for lower income citizens at politically sustainable levels of public investment; and (c) whether the vital importance of equal access to justice for democratic government and political stability will cause developing countries and former communist nations to institute significant legal aid programs. As it has in the past, social science will have much to contribute not only to the design of these initiatives, but more importantly to their evaluation. The insistence on empirical proof will offer the most effective guarantee that what emerges indeed grants every citizen, irrespective of means, the right to equal justice that democratic societies promise to all.

Justice: Philosophical Aspects

Justice is a central moral notion, associated with fair and impartial decision procedures (procedural justice) as well as with persons and groups being treated even-handedly (formal justice, treating like cases alike) and in a morally fitting way (material or substantive justice). The demands of justice are frequently presented as uncompromising (strictly required) and contrasted with the more flexible—and sometimes conflicting—demands of mercy, charity, humanity, beneficence, and equity, which may be merely supererogatory.

Justice is predicated mainly of three kinds of iudicanda, namely subjects (persons and collectivities), the conduct of subjects (actions and omissions: decisions, accusations, policies, wars, etc.), and social rules (e.g., social institutions, laws, conventions, practices, economic arrangements, educational and health-care systems). In recent decades, discussion has focused on the justice of social rules (i.e., on social justice).

Justice is often differentiated by theme. Thus distributive justice governs the assignment of benefits and burdens (e.g., rights, duties, property, income, taxes), commutative justice governs economic exchanges, while corrective and retributive justice govern, respectively, compensating the victims and punishing the perpetrators of prior wrongdoing. International justice is typically viewed as a separate area, in which the four mentioned themes are overshadowed by reflections on the just use of force. Just war theories are generally organized around two themes: just cause in going to war (*ius ad bellum*) and just ways of fighting a war (*ius in bello*). Kant adds a third theme: the just way of concluding a war so as to lay the foundation for a stable peace (*ius post bellum*; Kant 1996, § 58).

The manifest complexity of the notion of justice makes it doubtful that any unified account of justice can be adequate across iudicanda and themes. In response to such doubts, it is tempting, as numerous historical examples attest, to simplify matters through reductionist moves. One such move, prominent among deontological conceptions of ethics, is to reduce judgments of character to judgments of conduct, e.g., by holding that a just subject is one stably disposed toward just conduct, independently defined. (One may object that the justice of subjects is in part a function also of their inner states: of their feelings and attitudes in the case of individuals and of their internal mode of organization in the case of organized collectivities. Thus, the city-state of Athens may be called unjust not merely on account of its unjust conduct toward Socrates and the Melians, but also on account of the injustice of its social rules, which severely disadvantaged women, metics, and slaves.) Following Aristotle, some conceptions of ethics have proposed the reverse: to reduce judgments about conduct to judgments about the character, or virtues, of subjects. Just conduct is then conduct a just agent might engage in. (One difficulty here is that, to avoid circularity, the virtue of justice must not be characterized in conduct terms.) Locke and Nozick have proposed a third kind of reduction: that social rules are just if and only if they were, or at least could have been, established through just conduct. Conversely, Rawls has suggested that persons and conduct are just when they support and follow just social rules that apply to them and help establish just social rules insofar as such are still lacking (Rawls 1971, pp. 115, 334).

Other reductionist attempts seek to reduce judgments about various kinds of iudicanda to judgments about states of affairs. One simple consequentialist reduction of this sort holds that subjects, conduct, and social rules are just in proportion to their tendency to promote the overall goodness of the world (or of that part of the world to which they have a special responsibility). A more complex such reduction, of judgments about social institutions to judgments about distributions (Rawls), is discussed below.

While it is quite possible to embed some such reductions within a theory of justice, their plausibility still depends on the overall plausibility of this theory, which in turn depends on whether the evaluative and normative judgments derivable from it are morally sound. So far no detailed theory of justice, reductionist or otherwise, has managed to cover several themes and kinds of iudicanda in a plausible way. And contemporary writers have therefore tried, more modestly, to develop limited conceptions of justice. The paradigmatic effort in this vein (Rawls 1971), is focused narrowly on how distributive justice might be instantiated in the most important and pervasive rules ('basic structure') of a self-contained society.

1. *The Theory of John Rawls*

A criterion of justice should entail plausible absolute and comparative judgments about feasible basic structures, actual or proposed. Rawls seeks a criterion that, in addition, facilitates agreement among citizens accepting it on how to maintain or reform their shared basic structure. This second desideratum speaks against any criterion that, like the principle of utility, is too difficult to apply and hence too easily abused. Rawls seeks the morally best *public* criterion of social justice.

His central idea is to answer this moral question through a prudential one: morally best is that public criterion of justice which prospective citizens would choose on prudential grounds. The criterion and the basic structures based on it should be as good as possible for the persons living under them; nothing else need be considered. This central thesis is, of course, itself a moral claim—to be developed and examined in what follows.

Citizen's interests and preferences vary and are shaped by the actual basic structure of their society. For his prudential question to have a determinate answer, Rawls needs therefore a vantage point that attains some independence from the status quo and also ensures agreement. This vantage point is the original position—an imagined deliberation among 'parties' who, acting in the interest of prospective citizens, are to agree on a public criterion of justice without knowing (due to a 'veil of ignorance') the distinguishing features (creeds, values, tastes, desires, and endowments) of their clients or even the natural and historical context of their clients' society.

To have grounds for deliberation, the parties need some information about the interests of their clients. Rawls makes them assume that all clients have three interests, which he portrays as closely connected to their role as citizens in a democratic society (and hence as not biased toward any particular religious, philosophical, or ethical world-view or way of life). Rawls calls these the three higher-order interests, suggesting both that they are interests in the content and fulfillment of other interests (like second-order desires are desires about desires) and also that they are deep, stable, and normally decisive. These interests are (a) to develop and exercise a sense of justice, which involves a sincere allegiance to some conception of justice (whose content remains unspecified so as not to prejudge the parties' decision), (b) to develop and exercise the capacity to form, to pursue, and rationally to revise a conception of the good, and (c) to protect and advance one's particular conception of the good (Rawls 1993, pp. 19, 74). The main question in the original position is then: which social order—consisting of a public criterion of justice and of the basic structures this criterion would actually bring forth in various alternative contexts—affords the best prospects for higher-order interest fulfillment?

Rawls makes the dramatic claim that the parties would, because of their severely limited information, make their choice pursuant to the maximin rule, seeking to optimize the worst social position that the public acceptance of their criterion might generate. They would examine candidate criteria of justice, asking of each how badly off, in terms of the three higher-order interests, persons might come to be in societies in which it is the accepted public criterion of justice. And they would prefer the criterion that promises the higher floor (*max*imum *min*imorum), even if it would also lead to a much lower ceiling or lower average.

Rawls argues that the parties would then choose a criterion of justice formulated in terms of certain social primary goods, such as rights and liberties, income and wealth. Access to these all-purpose means is not only a good proxy for, but also much easier to measure than, higher-order interest fulfillment, which enhances the criterion's capacity to foster agreement on institutional design. Rawls claims then that the parties would choose these two principles as the public criterion (Rawls 1993, pp. 5f):

> *First principle*. 'Each person has an equal claim to a fully adequate scheme of equal basic rights and liberties, which scheme is compatible with the same scheme for all; and in this scheme the equal political liberties, and only those liberties, are to be guaranteed their fair value.'
> *Second principle*. 'Social and economic inequalities are to satisfy two conditions: first, they are to be attached to positions and offices open to all under conditions of fair

equality of opportunity [the opportunity principle]; and second, they are to be to the greatest benefit of the least advantaged members of society [the difference principle].'

The first principle is to have lexical priority over the second and, within the second, the opportunity principle is to have lexical priority over the difference principle (Rawls 1971, pp. 302f). 'Lexical' is short for 'lexicographical' and thus invokes how words are arranged alphabetically, giving priority to the first letter over the second, to the second over the third, and so on. Rawls conceives priorities among principles accordingly: in the comparison of alternative feasible basic structures, a superiority in terms of a lexically prior principle overrides any inferiority in terms of lexically subordinate ones.

The proposed public criterion of justice requires, then, that a society's basic structure be arranged so as to secure, above all, the basic liberties. These include the political liberties, freedom of thought and liberty of conscience, freedom of association, freedom and integrity of the person (including freedom of movement and the freedom to hold personal property), and the rights and freedoms included in the rule of law. Except in the case of the political liberties, the first principle does not require that citizens have sufficient means to take full advantage of their basic liberties; the distribution of such means (e.g., income and wealth) is governed by the second principle. Yet it does require more than legal recognition: citizens must have secure access to their freedoms; attempts to disturb their enjoyment or exercise must be effectively prevented and deterred.

The second principle addresses the social and economic aspects of basic structures. The opportunity principle requires that persons have roughly equal chances of success irrespective of their initial (parental) socioeconomic position. The difference principle requires that rules affecting socioeconomic inequalities (in particular, the tax system) be designed so as to optimize the worst socioeconomic position. Existing poverty is justified if, and only if, no institutional reform decreasing or increasing inequality would raise the lowest socioeconomic position.

2. *The Bias Toward Recipient-oriented Theorizing*

While Rawls's theory has received much criticism, it has also in the last 30 years shaped the debate about justice and, most importantly, the prevailing understanding of the concept of justice. There is little awareness now of the distinctive features of, or alternatives to, the specific concept of justice employed by Rawls and his many critics and defenders.

While the word 'just' can, and often does, function as a one-place predicate, the concept of justice (like the concept of mother) essentially involves a second place: to be unjust is to be unjust to someone; A is just or unjust to B, to certain recipients.

The idea of recipients, of those who have justice claims on a particular iudicandum, invokes the questions what their claims on the iudicandum are, what these recipients have and do not have, and what they ought to have or not to have. The concept of justice essentially involves then also a third place for relevant goods and ills, broadly conceived: A is just or unjust to B by affecting whether and to what extent B has C. (As the category of conduct includes omissions, so the category of goods and ills includes the null-case of receiving nothing, being denied a good or being spared an ill.) For B to suffer an injustice, there must be goods or ills that B either has-but-should-not-have or lacks-but-should-have.

The concept of justice as explicated thus far—fundamentally a three-place concept, with frequent but derivative one-place and two-place employments—frames current discussions of justice. According to it, justice is a feature of certain iudicanda, which depends on their effects on the distribution of certain goods and ills to or among their recipients. One might call this the passive concept of justice, because it directs moral attention to those by whom justice and injustice are suffered. Employing this passive concept, one will focus on a iudicandum's effects on its recipients—specifically on its impact on what these recipients are able to have or to be (relative to what they ought to be able to have or to be). One will consider a iudicandum just in proportion to its impact on the moral quality of the distribution of relevant goods and ills among its recipients: To be just is to promote good distributions. The passive concept thus leads easily to a conception of justice as distributional; and much of the current justice literature is indeed about how to code and rank distributions.

This framing of the debate may well be a remnant of long-dominant consequentialist, especially utilitarian, theorizing (Bentham, Mill, Sidgwick), which Rawls has superficially done so much to displace. The central consequentialist idea is that subjects, conduct, or social rules should be assessed solely by their effects on how well the world goes. Most current theorizing about justice involves the closely related thought that the justice of subjects, conduct, or social rules should be assessed by their effects on the moral quality of the overall distribution of goods and ills among the iudicandum's recipients. In both cases, the interest in outcomes is indirect. How well the world goes is of little practical interest in itself, but can be of great practical interest if one judges the moral quality of subjects, conduct, or social rules by their impact on how well the world goes. Similarly, the moral quality of overall distributions is of little practical interest in itself, but can be of great practical interest if one judges the justice of subjects, conduct, or social rules by their impact on the moral quality of distributions.

Does it make sense to take distributions as the most basic iudicanda and then to judge the justice of subjects, conduct, or social rules by their distributional effects? With respect to subjects and their conduct, this mode of assessment is widely rejected. Among the timeworn staples of ethics classes are gruesome organ redistribution stories designed to elicit the response that it is not true that subjects and conduct that aim at or produce the best overall distributions are always just. Abstractly considered, a situation in which everyone has at least one eye and one kidney is surely morally better than (an otherwise similar) one in which some, through no fault of their own, have no functioning eye or kidney while many others have two. But redistributive conduct and subjects aiming at such an abstractly better distribution are nevertheless considered gravely unjust.

With respect to subjects and their conduct, cases of this sort may be used to draw the conclusion that we ought to distinguish between treating recipients justly and promoting a good distribution among recipients and, more generally, between how subjects treat their recipients and what impact they have on them. The moral significance of this distinction can be illustrated with matched doing/allowing scenarios such as the following: in Scenario One, Art has two functioning kidneys and Sue has none; we must decide whether to give one of Art's kidneys to Sue. In Scenario Two, Art has one functioning kidney and Sue has none; we must decide whether to give a donated kidney to Art or to Sue. (Other things are presumed equal across scenarios, with both Art and Sue urgently wanting the kidney in question.) In terms of their distributional effects, the two decisions are on a par: in each scenario, we decide whether the final distribution of kidneys will be 2:0 or 1:1; and a decision in Sue's favor is then in both scenarios equally promoting of a good distribution. Intuitively, however, the scenarios differ dramatically: a decision for Sue treats Art unjustly in One but not in Two and a decision for Art treats Sue unjustly in Two but not in One.

With respect to social rules, a similar distinction seems called for, and for similar reasons. Just social rules for allocating donated kidneys favor those who, through no fault of their own, have no functioning kidney over those who have one, and thereby promote a better distribution of kidneys. But just social rules do not mandate the forced redistribution of kidneys from those who have two to those who have none, though doing so would likewise promote a better distribution of kidneys. Once again, treating recipients justly does not boil down to promoting the best distribution—what matters is how social rules treat their recipients, not merely what their effects on them are.

This distinction has been remarkably neglected in current work on social justice. It is not surprising that it plays no role in consequentialist theorizing, which is committed to the view that social rules should be judged by their effects on the overall outcome, irrespective of how they produce these effects. Remarkable is that Rawls' theory, which he bills as a deontological alternative, likewise makes the justice of social rules depend exclusively on the overall distribution they tend to produce. Rawls assigns no moral relevance to *how* basic structures affect the overall distribution of goods and ills. And he is followed in this by most of his critics.

At least this decision is clearly built into the centerpiece of Rawls's theory: 'the persons in the original position try to acknowledge principles which advance their systems of ends as far as possible. They do this by attempting to win for themselves the highest index of primary social goods, since this enables them to promote their conception of the good most effectively whatever it turns out to be. The parties … strive for as high an absolute score as possible' (Rawls 1971, p. 144). By judging social orders in this purely recipient-oriented way, Rawls ensures from the start that they are judged exclusively by their 'output' in terms of what overall distributions they generate among their participants—without regard to how they may bring it about that particular social goods or ills end up with particular persons. While Rawls differs from utilitarians in regard to how distributions should be coded and assessed—fulfillment of higher-order interests rather than happiness, maximin rather than sum-ranking or averaging—he shares with them the purely recipient-oriented mode of theorizing about justice.

Consistently followed, this approach should lead Rawls to embrace strong compensation requirements with regard to natural handicaps. It is evident that the extent to which a person's higher-order interests (especially the third) are fulfilled depends not merely on her share of social goods but also on her natural endowments. Someone genetically predisposed toward good health, cheerfulness, intelligence, and good looks is better able to advance her conception of the good than someone genetically predisposed toward sickliness, melancholy, low intelligence, and ugliness. How, if at all, would the parties take account of this fact? Even leaving aside genetic modifications, the parties can still raise the floor of higher-order interest fulfillment by formulating a criterion of justice that takes account of the natural distribution—by requiring basic structures to favor the naturally disfavored in the distribution of social goods and ills insofar as doing so raises the floor (by ensuring that no one is very badly off in terms of both natural and social goods).

These considerations notwithstanding, Rawls claims that his parties would adopt a criterion of justice that assesses each basic structure solely on the basis of the distribution of social primary goods it produces: 'a hypothetical initial arrangement in which all the social primary goods are equally distributed … provides a benchmark for judging improvements' (Rawls 1971, p. 62). The two principles do not take into

account natural primary goods, such as 'health and vigor, intelligence and imagination' (Rawls 1971, p. 62): 'The natural distribution is neither just nor unjust' (Rawls 1971, p. 102).

How might one react to Rawls' apparent inconsistency? First, one might reject and revise his exclusive emphasis on the distribution of social goods and ills. In this vein Amartya Sen has argued that, since natural differences among persons evidently affect their quality of life, we should focus on the distribution not of social primary goods but of capabilities. How badly off someone is depends on her access to being well-nourished, adequately clothed and sheltered, etc., which, in turn, depends not merely on her income, but also on her physiology as well as on the climate and culture she confronts. To this critique, Rawls has responded that he had, for purposes of a first approximation, chosen to leave severe natural handicaps and disabilities aside and that the remaining natural disadvantages—Sen had mentioned differential caloric and textile needs—are so minor that their accommodation within a criterion of justice is not worth the cost in terms of increased complexity and consequent divisiveness. But this response is unconvincing: even ordinary natural handicaps—such as ugliness or a tendency toward melancholy and depression—can be quite devastating. And even if severe natural handicaps of mind and body can be ignored in a first approximation, they cannot be left aside in the final version of a theory that is to serve as a public standard by reference to which citizens shape and reform their society's basic structure.

Second, one might defend Rawls by arguing that natural inequalities are of little importance to a person's true quality of life: her ability to fulfill her higher-order interests. This response is also unpromising. Innate mental disabilities, resulting in low intelligence or an inability to concentrate, can surely undermine a person's capacity to understand and apply a conception of justice as well as her capacity to form, to revise, and rationally to pursue a conception of the good. Such disabilities, and genetically based ugliness and melancholy as well, surely also affect profoundly a person's success in advancing her particular conception of the good.

Following Rawls' proposed criterion of justice at the expense of his purely recipient-oriented machinery for deriving this criterion, one might thirdly argue that the distribution of natural goods and ills, however important to persons, is irrelevant to the assessment of basic structures, which should be based exclusively on the distribution of social goods and ills each generates: the task of social rules is to do justice to, or to treat justly, all those whose lives are regulated by this order. This requires a just allocation of the benefits and burdens of social cooperation, not promotion of the best attainable distribution of all (social and natural) goods and ills that may be relevant to higher-order interest fulfillment or quality of life. Natural inequalities precede social rules, so to speak, as persons already have their genetic endowments and handicaps when they enter society. A just basic structure should not then make the naturally favored subsidize the naturally disfavored any more than a just parent or administrator or civil judge should seek to allocate benefits and burdens under her control so as to even out natural inequalities. This view faces the difficulty of drawing precisely enough the distinction between social and natural inequalities, to which it gives so much moral significance. It is not clear how one can, without considerable arbitrariness, measure the extent to which a given disease or inequality in earning power is due to genetic and to social factors. Taken strictly, this view would moreover lead to the controversial conclusion that there is nothing unjust about a society that has a just economic system but then leaves the allocation of medical care (as well as of the means of mitigating melancholy, homeliness, low native intelligence, etc.) entirely to the market.

3. *Toward a More Adequate Theory*

A fourth option is to develop a conception of social justice that neither (like the two principles) ignores natural goods and ills nor (as the original position would suggest) takes account of them on a par with social goods and ills. The key idea is that a criterion of social justice must be sensitive not merely to the intrinsic features of goods and ills (such as their kind, magnitude, and frequency), which make them relevant to the recipients' quality of life, but also to an extrinsic feature, namely to the way in which their distribution is affected by social rules. Such a criterion must take account of—and its application thus requires information about—the particular relation between social rules and human quality of life, which may affect whether some institutionally avoidable shortfall is an injustice at all and, if so, how great an injustice it is.

The intuitive moral significance of this relational feature can be shown by distinguishing, in a preliminary way, six ways in which a social order may affect the goods and ills of its recipients. The following illustration uses six different scenarios, arranged in order of their intuitive moral significance, in which, due to social rules, certain innocent persons are avoidably deprived of some vital nutrients V (the vitamins contained in fresh fruit, say). First-class shortfalls are officially mandated, paradigmatically by the law (legal restrictions prevent certain persons from buying foodstuffs containing V). Second-class shortfalls arise from legally authorized conduct of private subjects (sellers of foodstuffs containing V lawfully refuse to sell to certain persons). Third-class shortfalls are foreseeably engendered through the uncoordinated conduct of subjects under rules that do not specifically mention them (certain persons, suffering severe poverty within an ill-conceived economic order, cannot afford to buy foodstuffs containing V). Fourth-class

shortfalls arise from private conduct that is legally prohibited but generally tolerated (sellers of foodstuffs containing V illegally refuse to sell to certain persons, but enforcement is lax and penalties are mild). Fifth-class shortfalls arise from natural factors whose effects social rules avoidably leave unmitigated (certain persons are unable to metabolize V due to a treatable genetic defect but are not receiving the treatment that would correct their handicap). Sixth-class shortfalls, finally, arise from self-caused factors whose effects social rules avoidably leave unmitigated (certain persons are unable to metabolize V due to a treatable self-caused disease—brought on, perhaps, by their maintaining a long-term smoking habit in full knowledge of the medical dangers associated therewith—and are not receiving the treatment that would correct their ailment).

Even without all necessary qualifications and refinements, this list makes clear that it is highly relevant to the justice of social rules *how* they affect the distribution of goods and ills, that it is no more true of social rules than of subjects and conduct that they are just if and insofar as they promote a good overall distribution. How can the moral significance of this relational feature be explained? Social rules are not merely imposed on people (the 'recipients'), but also imposed by people. Purely recipient-oriented theorizing ignores these imposers of social rules; and the passive concept of justice has no place for them. Once the assessment of social rules takes account of both recipients and imposers, the sought explanation is at hand: social rules that cause harms by mandating them are more unjust than social rules that engender (equally frequent and severe) harms through overly mild penalties and lax enforcement, because they reflect a different attitude on the part of their imposers. The first injustice is close to the negative-duty end of the spectrum (bringing harm about), while the second injustice is closer to the positive-duty end (letting harm happen).

This hypothesis also explains why justice does not require social rules that mandate beatings whenever the total number of beatings is thereby reduced—and why it may (*pace* Rawls 1971, Chap. 4) oppose official restrictions of basic liberties which, by making other such liberties more secure, enhance citizens' freedom overall. Rawls must count official and private threats to basic liberties on a par: from the prudential perspective of prospective citizens, it is no worse for one's basic liberties to be threatened by laws or government agents than for them to be equally threatened by zealots, criminals, or drunk drivers (cp. Rawls 1971, p. 242). Here Rawls collides with the widely held belief that official violations are morally more significant, so that, for example, a society should not allow its government to restrict the basic liberties of (some) citizens whenever doing so will prevent greater threats to basic liberties by private actors. 'Reforms' that weaken constraints on policing or introduce lower standards of evidence or disproportionate punishments (e.g., the death penalty for recidivist drunk drivers) are not thought to accord with justice merely because risks to citizens are reduced on balance.

This diagnosis suggests that a genuine alternative to purely recipient-oriented theorizing can be facilitated by developing a more active concept of justice, one that includes a fourth essential place for (what one might call) the agents of justice, for those who have or share moral responsibility for the justice or injustice of the iudicandum. Pursuant to this alternative concept, the injustice of any iudicandum presupposes some agent(s), D, responsible for its injustice or for making it (more) just. Calling this the active concept of justice alludes to its diverting some attention from those who suffer justice and injustice to those who produce them.

While the passive concept easily leads to a conception of justice as distributional, the active concept suggests a conception of justice as relational, as involving a relation between particular agents and recipients mediated through a iudicandum. By drawing attention to what we owe one another (see Scanlon 1999), to each agent's specific responsibilities for particular iudicanda and, through them, to their particular recipients, the active concept leads away from the idea that a concern for the justice of a iudicandum is simply a concern for its promoting a good distribution among its recipients. Rather than tie justice to an outcome and thus view it as something that obtains to a greater or lesser extent (what would justice be like, what ought recipients to be able to have or to be?), the active concept presents justice as something that is done to a greater or lesser extent: by particular agents, through a iudicandum, to particular recipients.

To conclude, unjust subjects, conduct, and social rules involve victims unjustly harmed by them. But it does not follow that the magnitude of the injustice is a function of the magnitude of these harms. It may also depend on how these harms are produced. The active concept of justice invites sensitivity to such relational factors. In regard to social rules, such sensitivity can take the form of a scalar version of the familiar distinction between negative and positive duties. Such a scale is needed to weight the harms rules produce by the way in which they produce them (mandate, authorize, engender, …). A similar such scale is needed to gauge the degree to which different agents contribute to imposing unjust rules. Moral responsibility for the justice of some iudicandum may vary from agent to agent. So there may be competition among iudicanda—one may have responsibilities with regard to achieving and maintaining the justice of several iudicanda and one may then have to decide how much of an effort one ought to make with regard to each. These issues concerning responsibilities and their prioritization are crucial for giving justice a determinate role in the real world. And they tend to be

overlooked from the start, or grossly oversimplified through a generic duty to promote just iudicanda, when the topic is approached in terms of the concept of passive justice.

Justice: Political

Political justice is a term whose meaning varies according to the different aspects of justice that it is used to highlight. This article discusses four different ways in which the term is used: (a) to characterize the principles that govern a distinctly political sphere of distributive justice; (b) to point to a distinctly political way of arriving at principles of distributive justice; (c) to describe the departures from the ordinary forms of criminal justice that are required by political trials and war crime tribunals; and (d) to characterize the distinctive forms of justice that emerge within political as opposed to other forms of community. After looking at each of these different ways of talking about political justice, the article concludes by exploring some of the controversies that emerge from the tensions among them.

1. Political Justice

1.1 Political Justice as a Sphere of Distributive Justice

The simplest and most familiar way of talking about political justice is as a particular sphere of distributive justice (Walzer 1983, Chap. 13). Justice is most frequently described as a set of principles that guide the distribution of goods within a community. As a sphere of distributive justice, political justice refers to the principles by which distinctly political goods, such as citizenship, voting rights, and access to political office, are distributed. Debates about these principles, with their clash of democratic, meritocratic, and aristocratic arguments, are a familiar feature of everyday political life as well as the history of political thought, so they do not need much elaboration here.

1.2 Political Justice as a Source of Distributive Principles

This way of talking about political justice is much less familiar, at least beyond the walls of the academy. John Rawls, the author of the influential book, *A Theory of Justice* (1971), has popularized it within the academic community. A political conception of justice, according to Rawls, is one in which shared principles of distributive justice are derived from the agreement of rational people who find themselves in a common political situation or culture, rather than from what Rawls calls 'comprehensive' claims about human nature, rationality or well-being. Political justice, in Rawls' sense, is contrasted with metaphysical justice or philosophic justice rather than with principles of justice that govern the distribution of goods in other spheres of life, such as the economy, the family, or civil society. Rawls argues, in particular, that rational and truly impartial participants in a democratic public culture would respond to the challenges of a pluralistic society by choosing the two principles of justice that he defended *A Theory of Justice*. Rawls developed this conception of political justice in order to defend his theory of justice against complaints that it rested upon untenable assumptions about human nature and rationality (Rawls 1985, 1993). It has become popular among some scholars

who welcome it as a way of philosophizing about justice without metaphysics. There is, however, a great deal of controversy about whether Rawls can reach his substantive conclusions successfully without invoking the kind of assumptions about human nature and rationality that he declares off-limits to a 'political' theory of justice.

1.3 Political Justice as Extralegal Procedures of Criminal Justice

A third way of talking about political justice focuses on the exercise of justice in criminal trials. It refers to those difficult cases in which extraordinary circumstances make it impossible to follow the ordinary norms of legal procedure that are designed to shield criminal justice from partisan political beliefs and passions. Such cases include, most prominently, the trials of political leaders for acts that they committed in previous regimes and of members of defeated nations for acts that its members committed in war (Kirchheimer 1961, Shklar 1986). In political trials or war crime tribunals many well-known and generally respected norms of criminal procedure, such as judgment by neutral third parties and the prohibition against retroactive legislation, are hard, if not impossible, to follow. As a result, these exercises of justice look questionable from a purely legal point of view, the imposition of the political preferences of the powerful rather than an application of the rule of law.

The need for this particular conception of political justice has been questioned from two opposing perspectives. On the one hand, many scholars believe that we can extend the familiar norms of the rule of law even into the controversial arena of political trials and war crime tribunals. On the other hand, other scholars believe that the distinction between political and ordinary cases, or between politics and law, is a myth. They argue that all criminal cases are, in effect, political because rule of law norms invariably subordinate legal judgments to partisan political goals and opinions.

1.4 Political Justice as Communal Practice

A fourth and final way of talking about political justice treats it as the distinctive way in which judgments about right and wrong are made and enforced within political communities. Political justice, in this sense, is contrasted with domestic justice or imperial justice, i.e., with the way in which justice is practiced in communities that lack the conceptions of citizenship and sharing of power that are usually associated with the idea of political community. The classic model for this version of political justice can be found in Book 5 of Aristotle's *Nicomachean Ethics*. Aristotle argues there that we need to distinguish the form of justice that develops among those who take turns in ruling and being ruled, i.e., among members of a political community, from the forms that develop among members of families or subjects of large empires. He goes on to argue that in political communities justice takes two different forms: conventional right, which concerns judgments about matters—such as which side of the road we should drive on—where we are looking for agreement rather than an intrinsically correct standard of justice; and natural right, which concerns judgments about matters—such as how to punish murder—where we debate about intrinsically correct standards (Yack 1993, Chap. 5). Understood in this way, political justice represents a way of exercising power rather than one aspect of distributive justice.

2. Comparisons and Controversies

These four ways of talking about political justice are logically compatible with each other. In practice, however, there are some tensions among them, tensions that inspire interesting controversies in contemporary debates about justice.

The most interesting of these tensions is the difference between the first two conceptions of political justice described above, each of which treats political justice as a component of distributive justice and the last two conceptions, each of which treats it as something more than distributive justice. In most theories the 'normal model' of justice (Shklar 1990), is a distributive model, a set of rules and principles governing the distribution of goods within a particular community. The third and fourth conceptions of political justice discussed above, however, challenge this normal, distributive model of justice in a way that the first two conceptions do not. For if you believe that there is a realm of criminal justice in which political judgments about the good of communities should take precedence over pre-existing rules and procedures, then you are treating justice as something more than the distribution of goods according to the impartial application of generally recognized rules and principles.

And if you believe that political justice concerns a distinctly political way of exercising power to further the good of a community, then distributive models of justice look like attempts to de-politicize the exercise of justice, attempts to hide the assertion of power that accompanies every attempt to impose standards of justice upon a community.

Viewed from the perspective of the third and fourth conceptions of political justice outlined above, the Rawlsian conception is strikingly *apolitical*. Rawls may start out from our shared political condition, what he calls 'the fact of pluralism.' But in order to deal with this situation he asks us to *imagine* how rational and truly impartial participants in a shared democratic public culture would choose to order the

basic institutions of their society. As a result, there are no politics, at least as politics are ordinarily understood, in Rawls' conception of political justice: no competition for power, no efforts at persuasion or co-optation, no tests of our ability to use power wisely. Politics, as ordinarily understood, are subordinated to a set of principles of justice in Rawls' conception of political justice.

But viewed from the perspective of Rawlsian and other 'normal' models of justice, there is strikingly little *justice* in conceptions of political justice that treat justice as more than the application of a body of pre-existing rules and principles. For making justice depend on the partial and contestable judgments that inform the exercise of political power takes away the determinacy that most theorists associate with the concept of justice. Without stable standards equally available to all, how, they ask, can we use justice to settle our conflicts and establish social order? There may well be, from their point of view, a sphere of activity in which the exercise of power cannot be guided by pre-existing rules and principles. But in that sphere we go beyond the reach of justice and have to call on other virtues, such as prudence, benevolence, or courage, to guide us.

Where does this controversy leave us with regard to the concept of political justice? The first conception of political justice, as a particular sphere of distributive justice, is relatively uncontroversial. As long as political rights and privileges are distributed within a community, there will always be debate about the best way to do so. Such debates continue today, most often among various versions of democratic and meritocratic principles of distributive justice.

The other three conceptions of political justice are, in contrast, quite controversial, as we have seen. All three conceptions grow out of the loss of the sense that we can derive the content and legitimacy of our standards of justice from a set of principles sanctioned by God or nature. But Rawls responds to that loss by trying to show how human beings confronted by a common political situation can construct such a set of principles for themselves without invoking higher authority. And those who employ the last two conceptions of political justice respond by insisting that we must acknowledge and accept the partial and uncertain use of power that inevitably accompanies the exercise of justice in political life. The theoretical difficulties that years of criticism have identified in Rawls' attempts to justify his two principles of justice raise serious doubts about his conception of political justice. But the lack of determinacy and stability in the opposing conceptions of political justice raise very legitimate concerns about our ability to use them to maintain a decent political order. Until these concerns are met by a more systematic and convincing theory, these conceptions of political justice seem unlikely to replace distributive models as the mainstream approach to theorizing about justice.

Justice: Social Psychological Perspectives

1. Definition and Subject-matter of Social Psychological Discussion of Justice

Justice means that people get what they are entitled to, or deserve, on the basis of who they are and what they have done. Although clear in abstract terms, this definition leaves undecided what exactly particular people are entitled to get. Similarly, the basic rule of distributive justice, that people have the right to be equally treated as others who are alike them, leaves unsettled the criteria according to which the likeness of people should be assessed and the kind of treatment that the people should get. Justice can be unambiguously defined only on an abstract level. The abstract definition is open to multiple translations into concrete terms. For that reason, it is likely that different people or groups differ in their justice judgments of given conditions or circumstances. Even if views of justice are socially shared, this does not change the basically subjective nature of judgments of justice and injustice.

In contrast to other scientific disciplines studying justice, social psychology does not take a normative approach. It deals with justice in a descriptive rather than a prescriptive way. The aim is not to define what is just and unjust, and how justice can be achieved. The

focus on the contrary is on the subjective sense of justice and injustice and its impact on human action and judgment. Social psychologists study what people regard as just and unjust under given circumstances, how people deal with the concept of justice, how they react to situations that they regard as unjust, and under which circumstances, and why, people care about justice.

2. *Distributive Justice: Early Beginnings and Development of the Field*

The social psychological discussion of justice originated from relative deprivation research (Stouffer et al. 1949, Runciman 1966) and Homans' (1961) propositions about distributive justice. Although in slightly different terms, all these writings proposed that people evaluate outcomes they receive relative to some kind of comparison standard rather than in absolute terms. The comparison standards define the quality of outcome people expect to get based on the outcomes that other people receive. The evaluation of one and the same outcome differs depending upon its position relative to the comparison standard used. If the outcome is equal to the comparison standard it will be experienced as satisfying and appropriate, if it is lower it will be experienced as dissatisfying and inappropriate.

An important step in the development of the field was the research and theorizing by Adams (1965) on affective, cognitive and behavioral consequences of perceived inequity. Similar to Homans, the author suggested that people consider what they contribute to an interaction or relationship (i.e., their inputs) and what they get in return (i.e., their outcomes). They compare the ratio of their own outcomes and inputs with the outcome–input ratio of others and expect the ratios to be equal. If the outcome–input ratios of a person and the comparison other do not match, people experience inequity. Inequity is an aversive state of distress that motivates people to restore equity either 'actually' by behavioral means or 'psychologically' by cognitive reconstruction. Interestingly, equity theory claims that this holds equally for people who are worse off and those who are better off than the comparison other. Adams used the equity model to explain workers' reactions to under- and overpayment at work. Walster et al. (1978) developed equity theory as a general theory of social justice and applied it to various different kinds of social interactions and relationships.

Another important impetus came from the just world hypothesis (see Lerner 1980). According to this view, people have a basic desire to believe in a just world in which people get what they deserve. This basic desire leads people to act, or engage in cognitive distortion, in order to maintain or re-establish the belief that the world around them is just.

Early social psychological conceptualizations of justice focused on one particular form, namely *distributive justice*, i.e., the justice of the distribution of outcomes or resources. In addition, the early conceptualizations concentrated on one particular principle of distributive justice, the equity or contribution principle. This principle prescribes that people's outcomes should be proportional to their inputs, and the outcome-input ratios of different people should be equal. The narrow focus of early theory and research was later extended in several respects. Within the domain of distributive justice, alternative conceptualizations proposed the existence of multiple justice norms, the most prominent being the equality principle (to each the same), the contribution or equity principle (to each according to his contributions), and the need principle (to each according to his needs). The multi-principle approaches to distributive justice assume that different distribution rules are regarded as just, and serve as principles of action and evaluation, under different conditions (see Deutsch 1975, Mikula 1980). One of the decisive conditions is the basic orientation of the respective social system or group. According to this view, the equality principle predominates in groups with solidarity orientation, the equity or contribution principle within production oriented groups, and the need principle in groups with caring orientation. Empirical studies in this tradition of research were designed to identify situational and personal conditions that determine which distribution principles are used and regarded as just (see Törnblom 1992).

3. *Procedural Justice*

Further developments in the field extended the focus and considered additional forms of justice. Justice judgments do not only refer to the way in which outcomes are distributed, but also to the decision-making procedures by which the distributions are arrived at, i.e., *procedural justice*. The social psychological study of procedural justice was stimulated by the work of Thibaut and Walker (1975). These authors studied people's responses to different third-party procedures of conflict resolution. They found that people regard procedures that provide them with control of the decision-making process, and the decision itself, to be fairer. In addition, they found that the perceived fairness of the procedures shaped people's satisfaction with their outcomes. Subsequent research studied particular features of procedures that contribute to the perception of procedural justice and injustice, and the consequences of these perceptions (see Lind and Tyler 1988, Tyler et al. 1997).

Justice researchers identified a variety of procedural elements that contribute to perceived fairness of procedures. For instance, Leventhal (1980) proposed that procedures will be regarded just if they ensure:

consistent treatment across persons and over time, utilization of accurate information, suppression of personal biases of decision makers, existence of appeal mechanisms by which wrong decisions can be corrected, representation of the affected parties in the decision-making process, and compatibility with fundamental moral and ethical values. Empirical evidence suggests that three procedural features are particularly relevant to the perception of procedural justice: the opportunity for participation of the parties concerned, decision makers' accounting for the decisions made, and treatment of concerned parties with dignity and respect. People consider procedures that allow them to participate in the decision-making process and express their opinions and views ('voice') to be fairer. Interestingly, this seems to occur even when the expressed opinion does not influence the final decision, as long as the respective parties feel that their views have been seriously considered. In addition, people regard decisions more fair if the decision-making authorities explain and account for their decisions. This gives the impression of neutrality and increases people's trust in the authorities. Finally, people regard procedures more fair when the authorities treat them with dignity and respect. Taken together, people seem to be concerned both about structural aspects of the decision procedures and social aspects, i.e., the enactment of the procedures.

Perceived procedural justice has a variety of positive consequences. Procedural justice promotes people's acceptance of decisions, their long-term adherence to agreements, and their willingness to cooperate with groups they belong to. Perceived procedural justice also enhances the perceived legitimacy of civil authorities, institutions and rules, and people's willingness to defer to authorities and their decisions. Finally, perceived procedural justice improves people's satisfaction with the outcomes they receive. Strikingly, these positive consequences result even if the decision procedures lead to unfavorable outcomes for the persons concerned.

4. *Reactions to Injustice*

Social psychological theory and research distinguished three major types of responding to injustice: actual restoration of justice by behavioral means, psychological or cognitive restoration of justice by changing the interpretation of the situation, and nonacting or resignation (see Tyler et al. 1997). People may prefer cognitive over behavioral reactions to injustice for various reasons. People who caused injustice, and people who are advantaged unfairly, may be inclined to justify the given situation to avoid the need for compensation or restitution and to protect a positive self-image. People who are disadvantaged unfairly may be motivated to deny being victims of injustice in order to protect their self-esteem. In addition, they may come to the conclusion that they themselves are responsible for their own fate. They may also view their negative situation as a result of a legitimate process and thus not regard it as unjust. Finally, they may perceive their situation as normal and appropriate because they compare themselves predominantly with similar others who share the disadvantage. People also seem to be inclined to regard 'what is' as 'what ought to be.' Another important reason why people may not behaviorally react to injustice is that they feel powerless and have resigned to their fate.

Behavioral reactions to injustice include attempts to restore justice either in the form of seeking compensation or retaliating against the responsible agent, or leaving the unjust relationship or group. The likelihood of behavioral reactions of the former type increases when people see a chance of improving the situation, and when they assume that the situation would not change without any action. In addition, perceived personal benefits and costs will influence whether people react behaviorally or not. However, the intensity of feelings of injustice seems to be the most relevant factor. People with strong feelings of injustice are more likely to react behaviorally to injustice independently of the costs involved and the likelihood of success. Behavioral reactions to injustice can occur as individual-level responses and collective or group-level responses. Collective reactions are more likely when the injustice is perceived as a collective rather than an individual issue.

5. *Subjectivity, Divergent Views of Justice, and Social Conflict*

The subjective nature of justice judgments makes it plausible that different people or groups differ in their assessments of given situations. Divergent evaluations and interpretations are particularly likely among people who hold different perspectives or roles in relation to a perceived injustice (Mikula et al. 1998, Tyler et al. 1997, Walster et al. 1978). Three particularly relevant perspectives are the perspective of those who suffer from the injustice (i.e., the 'victim'), the perspective of those who caused the situation in question (i.e., the 'actor' or 'perpetrator'), and the perspective of people who perceive the critical situation without being personally affected (i.e., the 'observer'). Actors typically tend to regard their own behavior as appropriate and just, and to attribute any negative behavior on their part to external circumstances. Victims and observers are more likely to regard the same behavior as unjust, and attribute responsibility and blame to the actor. Similarly, majorities and minorities sometimes disagree about what constitutes a fair decision-making procedure in political settings.

Divergent views about what is just and unjust can evoke social conflicts. The notion of justice can be

helpful for, but also detrimental to, the limitation and resolution of social conflicts (Mikula and Wenzel 2000). To be helpful, the conflicting parties have to reach a shared view of the situation and their entitlements or to recognize the existence of differing but equally legitimate views of justice. Rigid ideas about what is just, and the firm conviction that the own view is the only true and right one, contribute to the escalation of social conflicts. Conflicting parties may even exclude each other from the moral community within which moral values and rules of justice apply. In this case, justice loses any conflict resolving function.

6. *Why Do People Care About Justice?*

The question of why people care about justice received different answers in different social psychological theories. One group of theorists assume that people are concerned about justice because it serves their self-interest of maximizing their outcomes in the long run. For instance, equity theorists (Walster et al. 1978) proposed that social systems develop rules of justice, and induce members to follow these rules, because this can maximize collective outcomes. People expect others to follow the rules and follow the same rules themselves as long as it is in their interest to do so. Early theorizing on procedural justice (Thibaut and Walker 1975) argued in a similar way. People care about fair procedures, and regard procedures that give them control over outcomes to be fairer, because they help them to maximize their outcomes in the long run. The relational or group-value model of procedural justice (Lind and Tyler 1988, Tyler and Lind 1992) provides an alternative perspective. According to this theory, people are concerned about their position in groups. They use experiences with their treatment by authorities as a source of information about their position. The evidence that they are treated justly indicates that they are regarded as valuable and worthy members of the group. This has positive implications for their self-esteem and self-worth. While providing different explanations of people's caring about justice, due to instrumental concerns about outcomes versus relational concerns about group status, both groups of theorists regard justice as a means rather than an end in itself. Other authors criticize that these views do not capture the essential feature of justice as a moral ought. Without denying that justice may be used as an instrumental means, they argue that justice often is an end in itself. People are motivated intrinsically to behave justly, and sometimes act in ways which are not in line with self-interested motives and maximizing own outcomes. Future justice research will have to consider, and try to integrate, the different theoretical positions and analyze the conditions which stimulate the two manifestations of justice concerns in people's conduct and thinking.

7. *Areas of Social Justice Research*

Social justice research expanded into many different areas of social life: work organizations, legal institutions, educational settings, civil institutions, social policy and economics, gender issues, environmental issues, international conflicts, family issues, close personal relationships, and coping with life crisis and victimization. People's perceptions of justice and their reactions to injustice in work organizations have been one of the main areas of social justice research from the very beginnings of equity theory. The rapid growth of this line of research has led some authors to use the generic term 'organizational justice' (see Cropanzano and Greenberg 1997). Empirical evidence shows that the perception of distributive justice shapes people's satisfaction with the outcomes they receive, work performance, absenteeism, and turnover. The perception of procedural justice influences workers' organizational citizenship behaviors and reactions to a variety of organizational measures such as personnel selection procedures, performance evaluations, layoff decisions, strategic organizational planning and change, and workplace drug screening.

8. *Concluding Remarks*

Social psychological research has substantiated impressively that people care about justice and proved that justice judgments influence human conduct and thinking. Justice matters on the interpersonal level, the intergroup level, and the societal level, even though differences exist with respect to the justice principles that are used in evaluations of justice and injustice, the perception of personal and collective injustice, and the conditions that lead to personal level and group level reactions to perceived injustice (Tyler and Smith 1998). Some authors argue that moral values and rules of justice apply only within a limited range of social relationships. People are less concerned about justice with respect to people who are outside their own social group or category. People can be excluded from the moral community within which moral values and rules of justice apply because they are dissimilar or different or because they are perceived as competitors or enemies.

Juvenile Justice: International Law Perspectives

Since the 1980s there has been a quiet revolution spreading through the world of child criminal justice. It has spread globally as far as Australia (Young Offenders Act (1993)) and New Zealand (Children, Young Persons and their Family Act 1989) in the South Pacific, Canada (Young Offenders Act 1985, as amended), and Costa Rica in the Americas, Ghana, South Africa (Constitution of South Africa 1996) and Uganda in Africa (Child Statute 1996).

The catalyst for this reform is the United Nations Convention on the Rights of the Child 1989—the first global treaty protecting children's rights (see Van Bueren 1998a). The Convention on the Rights of the Child enshrines the full range of civil, political, economic, social, and cultural rights. It stresses a holistic approach to children's rights—all rights are indivisible and related. This has important implications for child criminal justice, as it implies that all rights must be considered for children in the criminal justice system, from the right to freedom of expression to the right to the highest attainable standard of health.

Freedom of expression, protected in Articles 12 and 13 of the Convention, envisages that children must be consulted in all decisions which affect them. This includes the planning of child criminal justice policy from prevention through detention policies and conditions. Indeed, Sri Lanka was specifically criticized by the Committee for not taking children's views into account.

The Convention on the rights of the child focuses states' attention on children as victims of crime, an aspect of criminal justice that, given the demonization of children in some countries, is often overlooked. Article 39 obliges all States Parties to take appropriate measures to promote 'physical and psychological recovery and social reintegration' for child victims of abuse, neglect, torture, cruel, inhuman and degrading treatment, and punishment. Such recovery and reintegration services ought to occur in an environment which fosters the health, self-respect, and dignity of the child.

The principle of nondiscrimination under Article 2 is also applicable to the child criminal justice system. In particular, the committee has noted discrimination against socially and economically disadvantaged children. In relation to Bolivia, the UN Committee on the Rights of the Child recommended that alternatives to institutional care for economically and socially disadvantaged children should be created.

As a human rights treaty, the Convention removes the debate about child criminal justice from the bitter sphere of party politics and places the discussions and campaigns firmly in the arena of legal commitments, which a country is required to implement. In the 191 countries bound by the Convention, the provisions of child criminal justice are removed from party politics but are used by campaigners to help shape the political debate, particularly when drafting bills of rights and children's statutes.

In addition, there are three sets of rules adopted by the global community which provide greater detail on the daily operation of child criminal justice. These

rules are the United Nations Standard Minimum Rules for the Administration of Juvenile Justice 1985 (Beijing Rules), United National Rules for the Protection of Juveniles Deprived of their Liberty 1990, and United National Guidelines for the Prevention of Juvenile Delinquency 1990 (Riyadh Guidelines). These, together with the United Nations Guidelines for Action on Children in the Criminal Justice System 1997, and the United Nations Declaration of Basic Principles of Justice for victims of Crime and Abuse of Power 1985, provide a comprehensive framework of child criminal justice. The texts are reproduced in van Bueren (1988b).

The provisions in the Convention on the Rights of the Child, together with the provisions in the international instruments, have resulted from experience-gathering and reflection over several decades on the best ways to protect children's rights.

States from different regions are also bound by regional treaties, which include principles on child criminal justice. These embrace the European Convention on Human Rights 1950, the American Convention on Human Rights 1969, and the African Charter on the Rights and Welfare of the Child 1990.

1. *Children, not Juveniles*

We have begun to shift away from using the term 'juvenile.' The United Nations Programme of Action does not concern 'juvenile justice' but rather 'children in the criminal justice system.' If, as Rorty and others argue, experience is shaped by language (Truth and Progress 1988), then the adoption and use of the term 'juvenile justice' by an number of English-speaking jurisdictions also has to be queried.

Because of international legal developments, the time has come to question the rationale behind describing a young person in conflict with the law as a juvenile offender, while a person under 18 in need of state protection is described in terms of child welfare. The only acceptable justification for retaining the distinction between juveniles and children is that juvenility sometimes includes those over the age of 18, and some states wish to extend additional levels of protection to this age group. However, this can be done without retaining two separate terminologies for those under 18.

The use of an inappropriate judgmental layer makes it harder to argue against the more punitive suggestions being made in the American Counter Reformation. Distinguishing between adult and under-18-year-old offenders resulted from differences in approach between the civil and the criminal legal systems in relation to children. However, as the international laws on children make clear, all of the special protections apply to children under the age of 18 in the justice system, regardless of whether the field is civil or criminal. In international law, the special protections attach because of childhood, and childhood is defined solely with regard to age.

2. *The Benefits of Using a Human Rights Approach*

The international laws on child criminal justice also act as powerful but peaceful catalysts for change. The Convention on the Rights of the Child takes the argument beyond questioning who should have priority—children or society. The international law is clear—the best interests of the child dictate that children have priority; by prioritizing children, society benefits. According to Riyadh Guideline 1.4, child criminal justice 'should be conceived as an integral part of the national development process of each country.' It is no longer permissible under international law to place child criminal justice at 'the bottom of the pile' of resource allocation. States are under an immediate legal duty to ensure that children's civil, economic, social, and cultural rights in child criminal justice are fully protected. This can only be done if sufficient resources are allocated for all stages of the justice system, not just in courts but also in prevention and detention. A well-resourced child criminal justice system operating in accordance with international law should not be regarded as a drain on national resources. Indeed, it should reduce the risk of reoffending.

The Convention calls for the establishment of a child-oriented system which recognizes the child as the holder of rights and freedoms. The Convention stresses the need for all actions in child criminal justice to be guided by Article 5, which provides that the best interests of the child should be the primary consideration. Indeed, the United Nations Committee on the Rights of the Child, the body entrusted with implementing the Convention, criticized Mongolia because Mongolian legislation ranked the recovery and reintegration of children as only the third goal behind the protection of society and the punishment of the child.

One of the attractions of the international law on child criminal justice is that it requires a psychological shift for society. International law now merges what were once the punishment and rehabilitation functions of juvenile justice with the service provision and protections of child welfare. The trend implies that much of child criminal justice should be governed by the same principles as child protection. The unified child rights approach is the same for the civil and the criminal justice fields. Some states, such as Uganda, have one children's statute governing both areas of justice. It is also reflected in the return, albeit with modification, of indigenous values and approaches, for example, Family Group Conferencing, developed

from Maori traditions in New Zealand, places child criminal justice within the family unit. This is a very different approach from punitive penalties for parenting.

The international laws on child criminal justice have also been used by states when drafting their constitutions. The 1996 South African Constitution has adopted verbatim provisions from the Convention on the Rights of the Child in relation to detention. Hence, the international laws on child criminal justice have helped to inspire legislative reform and innovative and creative thinking. Those campaigning for legislative reform have not only been adults. In June 1985, the National Street Children's Movement was established and held its first Street Children's Congress in Brasilia, with over 500 street and working children taking part (see Rizzini et al. 1993). It attracted much media attention and the children were articulate in denouncing the State Foundation for the Welfare of Minors (FUNABEM), and institutional and police violence against them in the criminal justice system. They demanded urgent reforms.

The Movement began to give the children a more positive public image. Two constitutional amendments, inspired by the Convention on the Rights of the Child, were proposed, and supported by petitions signed by 1,300,000 children and 200,000 voters. These proposals became the Brazilian Constitution's Chapter on the Rights of Children and Adolescents 1988. Children were also consulted on the provisions in what became the Children and Adolescent Act, Hence the mobilization of different sections of society is seen as indispensable to raising public awareness and participation about child criminal justice issues.

Change has not only occurred through popular participation. In some countries, the courts have reacted to campaigns for improving child criminal justice. In India, a case was brought to the Supreme Court by a social worker and freelance journalist, to remedy the appalling conditions in which children were held in jail (*Sheela Barse v. Union of India*). The Supreme Court of India directed that every district and session judge should visit the district jail at least once every two months and, in the course of the visit, consider the conditions of children in prison and draw the attention of their High Court and the administration to penal conditions. The Court also directed the State Legal Aid Boards to make legal advice available to children detained in prison awaiting trial on criminal charges (Rizzini et al. 1993, p. 599).

The Court referred to an order made on 12 July 1986 relating to children with disabilities, and destitute and abandoned children. It directed the Director General of All India Radio to give publicity seeking the cooperation of nongovernmental organizations and social services in the reintegration and recovery of these children. The Court remonstrated that these children should not be in jail, but should be given adequate medical treatment and receive training.

The Court also suggested that, rather than each state having its own Children's Act, it would be desirable to have national parliamentary legislation. Just as the Inter-American Commission on Human Rights was concerned about the different standards prevailing in child criminal justice in American states, so the Indian Supreme Court was concerned about the different standards found in Indian states.

The court also ruled that the petitioner could visit jails, borstals and all child criminal justice accommodation institutions in all parts of India. The Supreme Court proclaimed, '[t]he petitioner need not be looked upon as an adversary. She had in fact volunteered to do what the State should have done' (Rizzini et al 1993 p. 600). The Court saw the petitioner as helping it fulfil its goal in protecting children's rights.

Similarly, the South African Constitutional Court in Hugo upheld President Mandela's decree that all mothers in prison on 10 May 1994 with children under the age of 12 years should benefit from a remission of sentences. In other words, rather than have children in prison with their mothers, or children left abandoned outside prison without their mothers, the best interests of the child dictated that mothers should be released. The Constitutional Court, in upholding Mandela's decree, took into account that the release of mothers would help prevent abandonment and poverty of children whose mothers were incarcerated.

The President also decreed the release of two other groups: prisoners with disabilities, and young people.

There is still a very long way to go, but the Convention on the Rights of the Child has operated as a very effective catalyst in protecting the rights of children in the justice system.

K

Kant, Immanuel (1724–1804)

'The character of a true philosopher is such that the philosopher does nothing other than to exercise his natural powers and capacities—this namely through the searching investigation of critique.' This claim cannot be put more humbly—it is the very claim which guided Kant on his way to the *Critique of Pure Reason* and effected a 'revolution in style of thought' which continues until this day. According to Kant, this exercise and development of the best human powers deserves the title of philosophy only then, however, if such activity emanates from independent thinking: 'my philosophy must be grounded in my own self, and not in the understanding of others.' Philosophy cannot merely serve the satisfaction of individual curiosity, but rather should be related to the 'interests of humanity.' At the outset of his critical career, Kant wrote that he would deem himself 'more useless than a common laborer' if he couldn't believe that philosophy would contribute to 'the establishment of the rights of humanity.'

Kant was born on April 22, 1724 in Königsberg into a family of manual laborers of very little means. His schooling took place in the strict spirit of Pietism. At the age of 16, Kant began his studies at the university of his native city, financing himself in part by giving private lessons and playing at the billiard table. The breadth of his subjects of study—mathematics, natural science, theology, philosophy, and Latin—was later to be reflected in the wide spectrum of Kant's fields of inquiry. Initially, his interest in modern physics was particularly strong; he viewed Newton's *Philosophiae naturalis Principia mathematica* as the paradigm of rigorous science.

Kant's first academic publication, *Thoughts on the True Estimation of Living Forces* (1747), owes its importance above all to its central claim, which is very much indicative of Kant's later philosophy. Here the 24-year-old attempts to settle a dispute between Cartesians and Leibnizians by proposing a mediating position relative to the point of view of each party. Kant exclaimed: 'I have already drawn up the path which I would like to follow. I shall set upon it, and … nothing should prevent me from pursuing it further.' Having lost the basis of his financial support through the death of his father, Kant left the university in 1746 in order to earn a living as private tutor in various families. During this time, Kant had occasion to pursue several extensive studies in natural science, the results of which he published anonymously in 1755 under the title *Universal Natural History and Theory of the Heavens*. Here, both the birth of the cosmos and solar systems, as well as the development of the earth up until the appearance of life and the rational animal, man, are deduced solely from physical laws. In positing the creation of heavenly bodies out of rotating nebula, Kant anticipated Laplace's theory; and the insight that spiral nebula are actually very distant galaxies secured Kant a sure place in the history of astronomy. In the year 1755, Kant returned to the university. Having attained a doctoral degree with a meditation 'On Fire' (*De igne*), he earned his *venia legendi* with a postdoctoral treatise on 'First Principles of Metaphysical Cognition.' In this work Kant marked out that field of problems with which he was to occupy himself for his entire life. Even the so-called 'transcendental philosophy' of the critical period remains connected to the 'first principles,' in that it poses the question after the 'conditions of the possibility' of our knowledge. Although these 'conditions of possibility' are no longer located in a divine understanding—later, Kant came to understand them as the functional conditions of human understanding and in this respect as *a priori*—they nevertheless continue to be the object of metaphysics.

For Kant, all scientific knowledge is metaphysical insofar as it requires us to go, by means of concepts, beyond purely empirical experience. This is always the case in those passages where Kant speaks of knowledge in general, of 'world' and 'reality,' of morality, beauty, or history. Understood in this sense, transcendental philosophy is a 'metaphysics of metaphysics.' Moses Mendelssohn's famous statement that Kant was a 'Crush-All' of metaphysics should therefore not be so construed, as if all metaphysics had been discredited by critique. Actually, Kant disabled only the claims of a theorational and empirist metaphysics, while setting 'critical' standards which all scientific metaphysics must be able to satisfy.

In the over 25-year period between Kant's postdoctoral thesis of 1755 and the publication of *Critique of Pure Reason* in 1781, Kant wrote several works concerning the foundation of theoretical and practical metaphysics. He also experimented with empirically designed procedures, and began to show a certain affinity for skeptical methods—an affinity which was to prove lasting. Two works from this period give us the impression that Kant might have considered abandoning metaphysics altogether: the elegantly parleying *Observations on the Feeling of the*

Beautiful and the Sublime (1764) and the satirical *Dreams of a Spirit-seer* (1766). Kant's appearance of having an antimetaphysical stance must have been strengthened for his contemporaries when, having completed yet another obligatory dissertation 'On the Form and Principles of the Sensible and Intelligible World' (*De mundi sensibilis atque intelligibilis forma et principiis*) in 1770, Kant published nothing worthy of mention for 11 years. In retrospect, we can recognize the approach of critical thought in this second dissertation: space and time are introduced as human forms of intuition which do not belong to things as understanding apprehends them. At this point, however, Kant still thought human understanding capable of a kind of cognition which could apprehend the nature of things as a divine understanding might.

The continuing 'critical' insights of the following years forced Kant to renounce the claim that we are able to know the nature of things. From a human perspective, nothing can be said about how 'things-in-themselves' are constituted. At this point in Kant's philosophical development, such 'things-in-themselves' as a divine understanding might be able to know can no longer serve us as the idea of a substance which could provide a basis for the things we can know. It does not even make sense to pose the question concerning the reality of 'things-in-themselves,' for they are mere concepts—we do not even know if anything corresponds to them. As such, the 'thing-in-itself' is simply an expression of our own limitation. The 'thing-in-itself' may serve as a limiting concept, however, in order to prevent us from deeming human knowledge absolutely certain. Even the pure concepts of understanding and reason do not have access to absolute truth.

Kant by no means contests the possibility of knowledge; he is not an agnostic on this count. Rather, he emphasizes the relativity of human knowledge: every insight, even in the objective natural sciences, is functionally relative to human cognitive capacities. We perceive reality in the manner in which it 'appears' to us. Every objective perception is dependent on the sensible intuition in space and time, and remains in this respect limited to experience. But renouncing experience leads either to analytical judgements, which only express what is already contained in concepts, or it misleads us to speculation, in which all certainty is lost. Yet the speculative thinking of pure reason is not sterile. Under conditions of disciplined self-critique, pure reason may contribute to the guidance and ordering of empirical knowledge (its 'regulative function'), it can ward off dogmatic claims (its 'critical function'), and it can set practical goals in those areas where certain knowledge is not attainable anyway. In this last case, pure reason becomes 'practical reason.'

The *Critique of Pure Reason* (1781), in which Kant systematically developed these insights, initially received little attention. The second edition (1787), elucidated by the Prolegomena (1783) and expanded by the *Grounding for the Metaphysics of Morals* and the *Metaphysical Foundations of Natural Science*, gave rise to a sea change, the likes of which philosophy had seldom seen. Kant's experimental-philosophical proposal for the foundation of the results of human knowledge proceeded no longer from the character of the object, but rather from the conditions of the subject—an innovation which came to be understood as a revolution in science. The 'cardinal propositions' of human knowledge cannot be extracted from 'things-in-themselves,' but rather have their fundaments in our very acts of cognition, and only become the fundament of nature *qua* 'appearance' through human activity. This went very well with the heightened self-confidence of the Enlightenment. The critique of reason declares man originator of his world—without contradicting the results of natural science or questioning the traditional claims of the belief in divine origins. At the same time, the delimitation of knowledge by means of critique serves to assign belief a genuine place. God and world, freedom and the person come to be interpreted as concepts of pure reason; they do not denote any object, but are imperative for the conceptual self-determination of the individual.

This attempt to ground human procedural capacities *a priori* had consequences for practical action; Kant showed these in the *Critique of Practical Reason* (1788). In ethics, too, the cardinal propositions are not grounded in the world, but are the product of our own capacities. It is not possible to speak of any pre-existing 'good' or 'evil' in the world: one must seek the origin of these terms solely in the human will. Insofar as this will conceives itself as a rational one, it determines by itself what is to count as morally good. The principle of the will is therefore that of self-determination (autonomy) according to the principle of practical reason in the will itself. So long as we acknowledge a commitment to this principle—and we have already done so when we ask ourselves what we 'should' do—we understand ourselves as free and autonomous. In this way, we have the possibility to orient the principles of our action (maxims) on rational insight and submit them to the general self-jurisdiction of reason, which consists in the categorical imperative. Like the categorical elements of the perception of nature, the categorical imperative does not emanate from external authority but from man's own conception of himself as a rational being.

No new virtues are made compulsory in Kant's critical refoundation of ethics. Instead, principles from Platonic, Aristotelian, and Stoicist ethics are made subordinate to specific criteria of reason. In the last analysis, the emancipated individual alone must determine these criteria. Justification of behavior through one's own insight (and therefore through one's own reason), which first came into philosophical consciousness through Socrates, ascends to its full conceptual conclusion here. The autonomy of ethical

self-determination aspired to since antiquity, while being defined over and against empirical explanation, thereby gains a pointedly individual expression. The 'categorical imperative' has meaning only in relation to the 'maxims' or 'subjective principles' of the individual. It is to be noted that justification always refers only to the 'form' or conceptual part of a moral judgement. The concept alone is meaningless without content or 'material,' however, and this is also the case in ethics.

There are therefore always certain 'preferences' involved in that 'material' which must be adduced to every moral judgement and hence to every moral act. Feelings and passions belong to the moral world. Thus, there must be some feeling which gives impetus to moral action—Kant calls it the 'feeling of reverence.' He is careful not to conflate the necessary motivation of acting with its justification; as in Plato, justification may only proceed from rational insight. Solely by means of this kind of insight can man experience himself as free.

Kant's third critique, the *Critique of Judgement* (1790), contains in Part 1 a grounding of aesthetics, once again departing from human standards alone. Aesthetic judgement is the expression of a harmony of cognitive powers which stimulate the individual pleasurably: whenever sensibility and reason come together and mutually intensify one another, an aesthetic experience is possible. Aesthetic experience also expresses itself in a 'judgement' in which the individual, existing in unrestricted subjectivity, communicates himself to others. Kant frees aesthetic judgement from all claims of scientific truth, moral valuation, and purely sensible satisfaction. In aesthetic experience, everything depends on one's own self-autonomous ('heautonomous') judgement. This faculty of judgement binds all sensible and mental powers together in itself and is capable of producing its own pleasure. What is more, it demands expression among those who are like-minded. Hence the faculty of judgement does not at all isolate the individual, but is the very thing which brings him into a conscious relation with those who are congenial to him.

In Part 2 of the *Critique of Judgement* Kant draws up a theory of living nature. The individual constantly judges nature in analogy to his own experience as an active being. An organism is perceived in accordance with its functional purpose, 'as if' a rational and end-oriented will were operating within it—a will which the individual is admittedly only acquainted with through himself. Kant's theory of the organism attempts to grasp the dynamic complex unity of living beings. In so doing, he draws upon the principle of causation whenever this is possible. In this vein, Kant establishes the definition that the parts of the organism 'join one another in the unity of the Whole by virtue of being mutually the cause and effect of one another's form.' Indeed, a living product of nature stands in itself 'reciprocally as cause and effect.' Kant thereby made the way for a theory of 'self-organization' which found much attention in the twentieth century, in biology as well as in physics and sociology. The third critique contains the most important impulses for the following generation of German philosophers, particularly for Schelling and Hegel. These philosophers sought to overcome the subjective limitation of aesthetic and teleological judgements emphasized by Kant within the framework of an extensive objectivity of nature or of mind.

Once he had completed his critical works, the elderly Kant went about the business of drawing systematic consequences for particular areas of research. He only managed this, however, in the domain of practical action. Against the resistance of the Prussian Censor, Kant showed these consequences for religious belief (*Religion Within the Limits of Reason Alone*, 1793) and published in 1796/7 the *Metaphysics of Morals*, containing not only a 'doctrine of virtue' for self-responsible action but also doctrines of law and state. Together with the brief essay *Perpetual Peace*, this work exercised direct influence on the political opinions of Kant's contemporaries.

Kant put the productivity of his principle of critical justification to the test in numerous smaller writings on political philosophy and the philosophy of history, also concerning the concept of mankind or the relation among the sciences. Though he added no new model to the pre-existing political constructions of his time, he did develop a new principle of legitimization for political rule under the auspices of a conception of law and the idea of international treaty. He showed how, under general conditions of law, morality, and politics are connected through the medium of the principle of publicity without being derived from one another. He probably was the first to see that the action of states is not only to be justified with regard to the obligations to its own citizens, but is rather to be measured by 'cosmopolitan' standards which require international protection. Where once was the primarily religiously motivated idea of a Christian and European peace order, Kant placed the concept of an international peace order founded upon legal institutions—a concept upon which was drawn in the foundation of the League of Nations in the twentieth century.

Kant's theory of world peace was an innovation in political theory. It was based upon a historically and economically well-founded diagnosis of the state of mankind on the verge of the complete colonialization of the earth. There is no longer a single political entity on the globe which is independent from the political events in any other given part of the world. Because the surface of the earth offers only limited space, people can no longer make way for one another. War, the historical importance of which Kant recognized, can therefore no longer be a means for political ends. The French Revolution had shown that a people's claim to freedom is capable by itself of causing overdue changes in law. Hence Kant arrived at a compre-

hensive conception of the right, of morality and politics on the basis of 'human rights.' These rights, which guarantee freedom and equality for all, are to be made binding within states by means of a republican and representative constitution, and are to be secured among different states through a system of treaties. A stop is put to colonial politics by 'world citizens' rights'; at the same time, each individual citizen has the basic right to humane treatment, even in states other than his own. The individual states remain intact as indispensable units of social self-determination, but they are compelled by the dynamics of self-binding law to make internal reforms and to rely upon a federal alliance in their external relations. In his brief treatise on *Perpetual Peace*, Kant sketched a theory of politics appropriate to modern conditions of action through the combination of juridical, moral, rhetorical, and power-political elements.

Kant was prevented from completing his system of natural philosophy by numerous obligations which resulted from the broad public debate over his works. Inspired by the French Revolution, Germany experienced a euphoric decade of critique before the turn of the eighteenth century. Kant was thus exposed not only to a growing following, but also to a rapidly formed and primarily religiously motivated polemic. He gave proof of his literary ability in his equally polemical responses to this polemic. It is an ability which, in Kant's main works of critique, only reveals itself to those who have penetrated the difficult coherence of his thought.

In 1796 Kant ceased to teach and in 1801, at the age of 77, retired. His physical strength, already weak, deteriorated rapidly thereafter. Kant could hardly influence the edition of his lectures on anthropology, pedagogy, logic, and geography which were prepared by his students. Nevertheless, he continued working on the yet incomplete philosophy of nature. In doing so, Kant returned once again to the premises of his epistemological critique and conceived a unity of man and nature which bears a remarkable resemblance to the systems of Schelling and Hegel. While writing, Kant's strength suddenly failed him. The speculative notes break off with increasing regularity, and comments on everyday incidents are interspersed among Kant's notes. These writings, which today are collected and published under the title *Opus postumum*, document the way in which Kant's body gradually failed his mind.

Kant's final years were marked by a deterioration of physical and mental powers which was nevertheless born with dignity. On February 12, 1804 Kant died of old age in his city of birth. Despite numerous offers from other universities, Kant never left Königsberg. Yet he always took an active interest in world events, and kept company with businessmen, administration officials, and officers. He knew the travel literature of his time so well that one might think he had been to Java, America, or London himself. He was an enthusiastic supporter of the ideas of the French Revolution, both in the daily society gathered at his table and in public. In Kant's main *œuvre* of critique as well as in his wide-ranging biological, social, and political interests, one driving incentive of Kant's philosophy is manifest: the exploration of the possibilities and boundaries of man.

In his lectures on logic Kant often summarized the 'cosmopolitan importance' of philosophy in four central questions: (a) 'What can I know?' (b) 'What should I do?' (c) 'What may I hope for?' (d) 'What is man?' To the first question, Kant added by way of explanation, 'answer *metaphysics*; to the second, *morality* answers; to the third, *religion*; and to the fourth, *anthropology*.' The true meaning of this catalogue of questions is only recognized then when Kant adds that the last question encompasses all the others. In conclusion Kant writes that one could basically count metaphysics, morality, and religion to anthropology, 'since the first three questions are related to the last.' Thus Critical Philosophy appears to be, above all, a comprehensive inventory of the best human faculties—and these are the faculties of reason.

Kantian Ethics and Politics

Kantian ethics judges an action as morally good if it is done autonomously out of duty and its maxim could be the foundation of a general law. Neither the purpose nor the outcome of an action have any impact on its moral value. This is why Kantian ethics is normally seen as contrary to any type of consequentialist ethics. Politics, according to Kant, has always to be strictly under the rule of law as it works to achieve the happiness of the people as an end of its own. Implementing the rule of law also in international politics, Kant hopes that international relations will move slowly toward eternal peace. (Because it is not in all cases clear whether Kant means 'right' or 'law,' and because he sometimes even seems to make use of the double meaning of the German word *Recht*, it is more appropriate to use the word 'right' instead of 'law' from now on, as Mary Gregor does in her translation; Kant 1996.)

Kant draws a clear distinction between the fields of morality and legality. Hence, it is possible to discuss these topics separately, without denying the important connections that are due to the common origin of their key principles in (practical) reason (cf. e.g., Kersting 1993, 175ff).

1. *Ethics of Duty—Ethics of Autonomy*

Although, as with any other label, it is an oversimplification to reduce Kantian ethics either to an ethics of autonomy or to a mere ethics of duty, it might help in finding an initial approach to say that somehow it is both. The close connection between these two central concepts will be clarified later. However, they both signify that Kant does not develop an eudaimomian or any type of consequentialist ethics. Kant does not think that happiness is unimportant, as we will see later. But he deliberately rejects ancient eudaimonian ethics as a possible foundation for morality, and centers his postcritical works on moral philosophy around the concepts of duty, autonomy, and moral law (Forschner 1993, Wike 1994). Simplifying again, it seems helpful to characterize Kantian ethics within three steps, more or less identifying each with one of the central Kantian works on moral philosophy.

1.1 *Extracting and Vindicating the Categorical Imperative: The Groundwork of the Metaphysics of Morals* (*GMM*)

In his first larger postcritical work on ethics, starting from the statement that nothing can be called good without restrictions except a good will, Kant shows that a will is good if and only if it acts autonomously out of duty and according to the famous categorical imperative (CI). Everything other than a good will may be used with bad intentions. Even some of the virtues can be held by immoral people as the 'coolness of a scoundrel' proves to us (Kant 1996, p. 50). By saying that lack of success does not diminish the moral value of good will 'as something that has its full worth in itself' *as long as good will acts 'with its greatest efforts'* (Kant 1996, p. 50), Kant immediately answers some of the most tenacious objections to his ethics.

The main topic of the GMM is an attempt to clarify the relations between duty, autonomy, and the law of morals. First, he shows that the concept of duty is the best way to explain what is meant by a good will; particularly, how the moral worth of an action does not lie in its expected effect but in the principle of volition. An action is morally good if it is not only done in *conformity with duty* but *from duty* (Kant 1996, p. 53). Duty is defined as 'the necessity of an action from respect for law' (Kant 1996, p. 55) (according to the principle that I ought to act in such a way that my maxim could become a universal law) and respect is defined as a feeling that is 'not received by means of influence' but 'selfwrought by means of a rational concept and therefore specifically different from all feelings … that can be reduced to inclination or fear' (Kant 1996, p. 56). In Kant's view, the question of whether our maxims could become a universal law provides us, 'inexperienced in the course of the world' as we are, with an easy test of whether the maxim of our volition is morally good. This is what 'common human reason' has 'always before its eyes and uses as the norm for its appraisals,' although it 'admittedly does not think so abstractly in a universal form' (Kant 1996, p. 58). It is important to notice Kant's regard for common human reason and the morality of the common people, which is, according to his own testimony, due to the influence of Rousseau (Schneewind 1998, 487ff., Kant 1902, ff. XX, 44). Kant does not see the CI 'act only in accordance with that maxim through which you can at the same time will that it become a universal law' (Kant 1996, p. 73), as an invention of philosophers, but as a precise and short formula of how ordinary people think about morality. However, what he claims is that, until now, no philosopher has found a clear and precise description of what common reason thinks about ethics.

Nevertheless, common human reason might indeed find some difficulties in the abstractness of this account, just as philosophers until now. This can be seen from the comment of Friedrich Schiller who felt immoral because he loved his friends from inclination and not from duty. Hence, it should be mentioned that actions in conformity with duty that are motivated by inclination are not immoral. We just have no means to judge whether they are moral. Kant does, however, distrust inclination which he characterizes in the *Critique of Practical Reason* (*CPrR*) as 'blind and servile, whether it is kindly or not' (Kant 1996, p. 235).

On the other hand, as Kant explains in the outset of the second part of his *Groundwork*, we never really know whether we, or anybody else, acts from duty. If we look closely enough at all empirical actions, even at those 'from love of humankind' that are generally in conformity with duty, we 'come upon the dear self, which is always turning up' (Kant 1996, p. 62). Therefore, we require an 'isolated metaphysics of morals' that is made for all rational beings. Thus, there are the two results: (a) that morality is something for rational beings and (b) that a will is a good will not from love of mankind or any other inclination but from its accordance with the moral law. With good will reason itself becomes practical.

An ongoing subject that is discussed several times in this and in the later works is the relation of happiness to morality. Kant constantly argues that morality cannot be based on any principle about happiness. He has different reasons for saying this. First, because instinct is a much better guide to happiness than reason, it would have been an unnecessary and useless effort of nature to provide us with reason if it were for the sake of happiness. While this argument has been criticized for its obscure 'naturalism,' one may in fact agree with the view that happiness is a natural aim for rational beings, so it is useless to set the pursuit of happiness as a norm. According to another argument 'it is a misfortune that the concept of fortune is such an indeterminate concept that, although every human being wishes to attain this, he can still never say determinately and consistently with himself what he really wishes and wills' (Kant 1996, p. 70). Furthermore, because it is very difficult to predict the result of an action, it would be very difficult to decide whether it is right or wrong, whereas, in Kant's view, it is very easy to know how the categorical imperative handles this. However, it is important to notice that morality and happiness are by no means necessarily in conflict. They are just logically independent, insofar as happiness is the most general term for an object of the will, i.e., for the matter of the will, while the will's moral goodness is due to its form (*CPrR*, Kant 1996, p. 160). It is even a moral duty to preserve one's own happiness just to avoid the temptation to act immorally out of poverty or envy.

The rejection of happiness as the basic moral end in itself leads Kant to the characterization of the CI as the one and only unconditionally valid imperative. In contrast to the imperatives of skill and prudence (prudence teaches us how to achieve happiness), there is no external end that justifies the categorical imperative. Another result is the special status of *rational* beings as ends in themselves. Kant's hypothetical construction of a 'kingdom of ends' (*Reich der Zwecke*), which is somehow included in the concept of every rational being, may be the best tool to show how closely duty, autonomy, and the moral law are interrelated in his moral philosophy. In the kingdom of ends, every rational being, including God, i.e., every person, is seen as a lawgiver of the moral law. This is the reason why they are autonomous. Every finite rational being has the duty to follow this law. Every rational being is an end in itself and thus benefits from the moral law. Because of its deeply egalitarian character, obviously influenced by the Rousseauist view of the *volonté générale*, it might be better to follow Mary Gregor's suggestion for an alternative translation of *Reich der Zwecke* by 'commonwealth of ends' (Kant 1996, p. 83, on the 'moral force of reciprocity,' cf. Korsgaard 1996, 194f.). In the discussion of the few last decades on animal and medical ethics, the question has been raised whether the circle of those who benefit from the moral law should be expanded to beings that are not rational or only potentially rational.

Due to the inordinate reliance on the *Groundwork* in the attempt to clarify Kant's moral philosophy, the charges of formality and emptiness have been laid against Kant. An integral reading of his works shows, however, that this charge is misplaced. It even becomes clear that it would be misleading to label Kant a 'rule ethicist.' True, maxims can be tested as to their universality, but on the ground of maxims alone it is not always possible to decide what to do in a particular situation. Kant is perfectly aware of this, as his stressing of the importance of the faculty of practical judgment and his casuistical questions in the *Doctrine of Virtues* (*DV*) in the *Metaphysics of Morals* make clear. Before we deal with these issues, we must look at why the CI is valid or why we should be moral, in Kant's words, *how* the categorical imperative is possible (cf. Guyer 1998). Although Kant's main thrust on this issue is to be found in the *CPrR*, it is worth seeing how he deals with the question in the *Groundwork*.

1.2 The Moral Law, Free Will, and the Highest Good: The Critique of Practical Reason

In the third part of the *Groundwork* that points to a critique of pure practical reason, Kant himself poses the question: 'But why, then, ought I to subject myself to this principle and do so simply as a rational being, thus also subjecting to it all other beings endowed with reason?' (Kant 1996, p. 96). Here he answers this question by removing a 'kind of circle' (Kant 1996,

p. 97, Schönecker 1998). It seems that, on the one hand, we must be free from causal determination to be subject to the moral law and on the other hand, we must declare that we are subject to the moral law because we are free. However, freedom, i.e. autonomy, consists of the self-constraint of the will through the moral law.

Kant finds his solution by making the distinction between two 'standpoints.' In one, we are in the world of senses, having only cognition of appearances, never cognition of things in themselves. In the other, we are, especially in a practical context, members of the world of understanding (Kant 1996, p. 98). However, 'as a rational being, and thus as a being belonging to the intelligible world, the human being can never think of the causality of his own will otherwise than under the idea of freedom' (Kant 1996, p. 99) and this means submitting to the moral law. However, Kant admits that we can never explain *how* pure reason becomes practical (Kant 1996, p. 104). This seems to be the problem of his moral philosophy in general: either the 'good will' through which pure reason becomes practical is in the intelligible world of understanding. Then it is difficult to understand how it can be *my* will. Or it is *my* will, and then it is difficult to see how it can be completely separated from all my emotional attitudes. To talk of two standpoints does not help much while there can be no explanation of their inter-relationship.

The close connection between the freedom of will and the rule of the moral law—the first is what makes the law hold, the second what makes freedom known to us (*CPrR*, Kant 1996, p. 140)—is one of the main topics of the *CPrR* where Kant maintains several times that, with moral law, we have in practical contexts as a reality what could in theoretical philosophy only be proved to be not impossible in the solution of his 'third antinomy' in the *Critique of Pure Reason* (Kant 1902, ff. III, 366ff., cf. Wood 1999, 172ff., Ertl 1998).

In a comment in Sect. 7 of the chapter on the principles of pure practical reason, he explains the fundamental law of pure practical reason, i.e., the CI, as a 'fact of pure reason' (Kant 1996, 164f.) that is not empirically found. Although it is not quite clear what is meant by this cryptic formula, which is repeated several times within the *CPrR* and other Kantian works, sometimes with slight variations, it appears not to mean that something is revealed to pure reason or to us by pure reason but rather that the use of pure reason in practical contexts implies that we are under obligation by moral law.

Because happiness is the natural object of desire of human beings, i.e., of all rational and finite beings, whereas the moral law rules the formal structure of the will, happiness, like any other material content, cannot be the incentive for moral law. Kant explicitly rejects the moral relevance of any distinction between higher and lower pleasures. Nevertheless, Kant tries to reconcile the human wish for happiness with his concept of morality in his theory of the 'highest good' where he finds in the doctrine of Christianity (in contrast to the teachings of the Epicureans and the Stoics (Kant 1996, 241ff.)) a chance to give to those who are worthy of happiness the 'hope of some day participating in happiness to the degree that we have been intent upon not being unworthy of it' (Kant 1996, p. 244). To support this hope, he proposes in his doctrine of postulates not only the freedom of will but also the immortality of our soul that continues its way towards perfection even after our death and the existence of an almighty god who can and will give deserved rewards to those who lived in conformity with moral law. Perhaps one cannot be sure that a *postulated* god can give *real* hope to everybody and an incentive to follow the moral law. Perhaps, instead, some may find this incentive in the hope for glory or in the hope to contribute to the moral improvement of the world or in something similar.

1.3 Living the Categorical Imperative: The Doctrine of Virtues

In the *Doctrine of Virtues* (*DV*) of his late masterpiece *The Metaphysics of Morals*, Kant deals with the different types of duties that cannot be ruled by outer laws—duties of man concerning himself and his perfection and duties concerning the happiness of others. In the *DV* it becomes clear that for Kant there are obligatory ends for human beings: this indicates that his moral philosophy, which is surely not a variation of consequentialism, is not a pure *Gesinnungsethik* either, i.e., the outcome of an action does matter, although it is not always in our hands what this outcome might be. To be sure, that does not mean that the moral quality of an action is determined by anything else other than the quality of the motivation and the universality of the maxim in question. This includes the idea, however, that the agent must do everything he or she can to make morality (in the form of moral actions) a reality in the world. Because we have a duty to follow the CI, we have a duty to pursue our own perfection and the happiness of others. We also have duties toward ourselves. These are due, again, to our 'double existence' in the world of appearances and the intelligible world. We have duties toward ourselves as rational beings, i.e., toward the humanity in us (§ 3, Kant 1996, p. 544).

A second important achievement of the *DV* compared to earlier works is the casuistic element that demonstrates how Kant's ethics might be applied, at least in some cases. There are also considerations on the use of judgement (*Urteilskraft*) in the *CPrR* (Kant 1996, 194ff.). But here, 'the rule of judgment under laws or pure practical reason is this: ask yourself whether, if the action you propose were to take part, you could indeed regard it as possible through your will' (*CPrR*, Kant 1996, p. 196, on moral judgment see Herman

1993). In his later work, however, Kant uses the humanity formula, i.e., our duty to respect the moral law and our duty to respect every man as an end in himself to deal with particular subjects. Among these questions and subjects are suicide—that is to be seen as 'debasing humanity in one's person' and therefore morally forbidden (§ 6, Kant 1996, p. 546), as well as 'defiling oneself by lust' (Kant 1996, 548ff.), avarice (Kant 1996, 555ff.) and servility, 'self-esteem is a duty of the human being to himself' (§ 11, Kant 1996, 558), and also duties like beneficence and gratitude (Kant 1996, 571ff.) and vices like envy and malice (Kant 1996, 576ff.). He also deals with friendship (Kant 1996, 584ff.). Particularly in the 'casuistical questions' that are added in different places, one can find that Kant's views on these subjects are somehow strict. However, they are much more diversified than might be expected after reading the *Groundwork* and even the *CPrR*. Nevertheless, a remaining problem appears to be that Kant supplies no guidelines on how to interpret the moral law in 'hard cases.' This is partly due to his view that a law court, which he often uses as a metaphor for the internal judgment of the conscience (*DV* § 13; Kant 1996, p. 560) must *apply* the law via imputation, not *interpret* it, i.e., the court has to decide whether this individual case falls under the law, not to explain what the law means. This seems to have been a common view of eighteenth century continental legal theory. On the other hand, Kant may be the first philosopher who recognized that to apply a rule we need a faculty of its own, which he called the faculty of judgment, a discovery that is sometimes attributed to Wittgenstein's reflections in rule-following.

2. *Right and Politics*

According to Kant, any ethically acceptable politics has to take place under the rule of right. It is the duty of 'moral politicians' who are opposed to hypocritical 'political moralists' to do their best to bring constitutions of states and political relations between states 'into conformity with natural right, which stands before us as a model in the idea of reason' Toward Perpetual Peace, TEP, Kant 1996, p. 340). Nevertheless, there is an aim of politics on its own, i.e., the happiness of the citizen (TEP, Kant 1996, p. 351)—something that might be surprising to some of Kant's critics. Pivotal to Kant's legal and political philosophy is, therefore, first his treatment of right and how to determine its realm and, second, his hope on historical development towards peace and republican government. The key engine for bringing about legal progress is the public use of reason (Toward Perpetual Peace, TEP, Kant 1996, p. 351).

2.1 *Right as Compatibility of Freedom*

Defining right in the *Introduction to the Doctrine of Right* (*DR*) of his *Metaphysics of Morals* as the condition for the compatibility of one person's outer freedom with that of the other (Kant 1996, p. 387), Kant gives an account of every human being's innate right of freedom as 'independence from being constrained by any other's choice' (Kant 1996, p. 393). In fact, according to Kant, 'right is connected with an authorization to use coercion' (Kant 1996, p. 388) as long as this coercion is opposed to a wrongful 'hindrance to freedom in accordance with universal laws' and so is understood as 'a hindering of a hindrance to freedom' (Kant 1996, p. 388). 'Strict right' that is 'not mingled with anything ethical' can even 'be represented as the possibility of a fully reciprocal use of coercion that is consistent with everyone's freedom in accordance with universal laws' (Kant 1996, 388f.). The strict reciprocity of rightful coercion shows how crucial the egalitarian element is in Kant's legal philosophy, together with the emphasis on freedom from any other's arbitrary coercion.

Kant's doctrine of right begins with private right 'concerning what is externally mine or yours in general.' There have been vehement discussions within the few last decades about whether the fact that private right is treated before public right together with Kant's view that there is possession already in the state of nature (§ 9, Kant 1996, 409f.) justify looking at Kant as a possessive individualist (Saage 1994, Zotta 2000) or whether one should stress his statement that this possession is only provisional and 'conclusive possession' is possible 'only on a law of a common will' (§ 9, Kant 1996, p. 410), such that Rousseauist and therefore egalitarian parts would gain more weight. Anyway, Kant rejects Locke's founding of property on work, because work is something 'accidental' to the land that cannot decide whose property it is (§§ 15, 17), and bases provisional possession on first occupation, conclusive possession on the common will (cf. Williams 1983, p. 94, cf. Kersting 1993, 337ff.). Perhaps one might say that although Kant's primary concern is with individual freedom—according to his definition of right—he nevertheless has a sense for public welfare and distributive justice (Rosen 1993).

Because in the state of nature property and any right are insecure 'however well disposed … human beings may be' (§ 44, Kant 1996, p. 456), we have the moral and legal duty to enter a state of public right (§ 42). What Kant describes in his *DR* is 'the state in idea' that 'serves as a norm for every actual union into a commonwealth' (§ 45, Kant 1996, p. 457). Kant clearly prefers a republic with division of powers that is the only alternative to despotism and 'any true republic is and can only be a system representing the people' (DR § 52, Kant 1996, p. 481) which is obviously incompatible with the absolutist and feudalist systems of his times. Therefore, there is another discussion on whether he really rejects every resistance against unjust regimes so bluntly as it looks like in the published works (DR § 49 A, Kant 1996, 463f., Of the Common Saying: That May Be Correct in Theory, but is of no Use in Practice,

OCS, Kant 1996, p. 303) or whether there might be some more or less hidden hints that he sees it in a more nuanced manner (Beck 1993, Westphal 1992). Anyway, it seems to be clear that Kant prefers reform of the constitution (Goyard-Fabre 1996, 217f.) and for this he claims again and again the transcendental principle of publicity, of freedom of the pen (OCS, Kant 1996, p. 302).

According to an interesting and attractive interpretation, Kant accepts the political systems of his time—and perhaps he would do the same with those of our time—mainly because they provide us with the possibility of a change toward more just societies that are closer to the state in the idea (Brandt 1982, Kersting 1993). But this change has to be done by the sovereign via reform and not by the people via revolution (DR § 49 A, Kant 1996, p. 465). As we have to accept the state of affairs in the distribution of property at least provisionally for being able to enter a civil state with distributive justice (DR § 41), we have to accept the actually existing legality for being able to transform it by rightful means until it comes close to a true republic. On an international level, we have to accept large parts of the actual distribution of power for being able to approach eternal peace via a commonwealth of free republics. The common tool for this treatment of nonperfect social situations is the permissive law that allows us to live in circumstances that are contrary to the principles of right as long as a quick change by means of right is impossible and as long as there is a serious effort to improve the state of affairs.

2.2 Toward Eternal Peace

One of the most influential and effective elements in Kant's political philosophy might be his proposal of an international legal order that could be able to guarantee eternal peace that is not only 'a suspension of hostilities' (TEP, Kant 1996, p. 317). There had been considerations how to realize a peaceful world through a council of the sovereigns like the *Projet pour rendre la paix perpétuelle en Europe* of the Abbé St. Pierre. What Kant does—again under the influence of Rousseau—is to connect the international order with the inner structure of the state. His first 'definitive article for perpetual peace' therefore says that 'the civil constitution of every state shall be republican' (TEP, Kant 1996, p. 322) and the second that 'the right of nations shall be based on a federalism of free states' (Kant 1996, p. 325). This 'surrogate' for a world-republic—which seems to be unachievable under current conditions—provides a way to maintain the sovereignty of the participating states with the rule of right, the only alternative to the unacceptable rule of war, 'right cannot be decided by war and its favorable outcome' (Kant 1996, 327f.).

On the other hand, Kant is not a categorical pacifist. He accepts that wars had played an important role in the development of mankind (*Idee zu einer allgemeinen Geschichte in weltbürgerlicher Absicht*, Kant 1902, ff., VIII, 24ff.), and he would prefer the warlike state of nature to a repressive world monarchy (TEP, Kant 1996, p. 336). He is not an unrealistic dreamer who expects world peace within a short time. Anyway, as Doyle (Doyle 1986) and others have shown, it was not an unrealistic assumption that democratically governed states tend much less to bellicose behavior than others. Kant rather thinks, or hopes, that with the help of the 'great artist nature' (*die große Künstlerin Natur*, TEP, Kant 1996, p. 331), human societies will move slowly but steadily towards the federation of free republics guaranteeing eternal peace. Kant's idea seems to be that even immoral actions ultimately lead to an improvement of the legal order without discharging the culprit of his responsibility, however. Somehow behind the back of the agents who are looking for their personal advantage, the artist nature works in a way like Smith's 'invisible hand' towards this federalism of republics that might even turn into a world republic. Anyway, this historical development prepares conditions under which persons may act morally much more easily than it is for them now in a situation that is closer to the state of nature.

Kant does not consider this 'mechanism of nature' (ib.) as a natural law. Rather it is a projection of practical reason, a hope we must have because we have a duty to move toward eternal peace. Elsewhere, Kant says, if we can't prove that a development will take place but can't prove the contrary either, a need of reason (*Vernunftbedürfnis*) gives us the right to expect what seems more rational (Kant 1902, ff. VIII, Kleingeld 1995, p. 94).

Key, Valdimir Orlando (1908–63)

1. Biographical Summary

Valdimir Orlando Key, Jr. was born in Austin, Texas on 13 March 1908. He spent his childhood in the very small West Texas town of Lamesa, later obtaining a BA from the University of Texas at Austin in 1929, and an MA degree at the same institution in 1930. V. O. Key, Jr. then moved to the University of Chicago—then perhaps the premier institution for studying American politics in the United States—and received his doctorate there in 1934. His early professional years were devoted to teaching and, later, to work in Washington for the Social Science Research Council and, subsequently, as part of the technical staff of the National Resources Planning Board during the heyday of the New Deal. Further Washington experience came his way during World War II with a three-year stint at the US Bureau of the Budget (now the Office of Management and Budget). His academic career took him first to Johns Hopkins University and thence to Yale and Harvard Universities, the latter from 1951 until his untimely death in Cambridge, Massachusetts, on 4 October 1963. The long-standing illness to which he eventually succumbed did not prevent him from moving to the very front rank of American political scientists of his generation. The reasons for this fame—a reputational survey of 1965 by A. Somit and J. Tanenhaus placed him then in a clear first position—will be concisely discussed below.

2. Scientific Contribution

As a Southerner, and at a time when the South was far more a region apart from the rest of the American polity than it is now, Key proved the ideal scholar to provide a comprehensive description and analysis of the South's *apartheid* political order, and its massive influence on national politics, very shortly before its demise. This study, *Southern Politics in State and Nation* (1949), provided a detailed portrait of politics in each on the eleven former Confederate States at the time of writing, as well as analyses of the region's influence on congressional politics; and—an important contribution in its own right—an extended summary statement on the nature and consequences of one-party systems for the representation of public opinion through elections. The craftsmanship is meticulous and innovative, with a mixture of 'thick description' of persons and forces at work based on extensive interviewing, along with the skilful deployment of charts and maps based upon aggregate returns from referenda and primary and general-election returns. More than half a century later, *Southern Politics* still repays the reader's attention.

Quite a lot of Key's basic approaches to the study of American politics, and his personal value commitments, can be found in these pages. First, and obviously, lies the exceptional historic and contemporary importance of 'sectionalism' (major regional differences based on economy, political subculture and experience) in the study of American politics. This point is worth stressing, since with the advent of national scientific surveys of American voters and their behavior in and after the 1960s, this dimension strikingly faded from view in Americanist political science for a protracted period. Secondly, *Southern Politics* underscored the importance of history and

historical experience in shaping the confines of today's electoral politics. It is thus perfectly appropriate to view Tennessee politics in the 1940s (and later) in light of the polar oppositions that were displayed in a June 1861 referendum on the state's secession from the Union. This concern to cite present reality in its developmental context was also, however, to run counter to mainstream preoccupations within political science, as the quest for 'scientific regularities' variously led to embracing concepts and models derived from social psychology or economics coming to the fore.

Finally, Key's democratic value commitments, which informed his entire published output across his professional lifetime, are presented in clear view in this magisterial work. Several points about how these views were expressed deserve mention here. Key made no pretension to 'grand theory,' and imported no elaborate conceptual schemes from great Europeans such as Marx or Weber (see *Marx, Karl (1818–89)*; *Weber, Max (1864–1920)*). Like many in his and a somewhat earlier generation of American political scientists, his intellectual focus was American to the core, and concentrated on the gap between the democratic promise embedded in the national political culture on one hand, and real-world antidemocratic practices and realities on the other. These latter obviously abounded in the Southern politics he studied, and this gap represented the chief analytic problematic of his lifetime. As he demonstrated in great detail, in the kind of disorganized and exclusionist politics of his South the have-mores profited and the have-lesses lost out as a matter of empirical fact.

At the same time, Key's was a mind which was strikingly subtle and nuanced. Not for him were the sledgehammer blows of Beard (1913), or other notable writers in the American Progressive tradition. Rather, he very carefully spelled out the structure of a given state of political affairs, equally carefully pointed out the vastness of the gap between ideals and empirical reality, and invited his readers to reflect on this gap and how it might be overcome. He was an optimist about the extent this could be accomplished in time—as scholars shaped by the political crises of the 1960s and 1970s often were not. Thus, his hopes for his native region rested to a significant degree on the longer-term effects of industrialization and urbanization on its society and politics. In retrospect, these hopes were to be realized, though only in the context—he was no prophet, after all—of a massive federal intervention in the 1960s, the 'Second Reconstruction,' fuelled by the civil-rights revolution; and, not least, by the USA's foreign-policy requirements in a postcolonial world.

His later major studies displayed his awareness that there were other impediments to the realization of his ideal, the expansion of the electorate's effective role in politics through the instrument of party competition and political choice. In *American State Politics* (1956), Key devoted his attention to several of these impediments: the impact of direct primaries and other regulations of party activities on party organization, including the multiplication of uncontested seats in legislative bodies; what he calls the 'lottery of the long ballot,' i.e., the separate election of a wide range of state office-holders; and the shifting of major state elections away from coincidence with presidential elections and 'national tides' to off years, where, incidentally, voter turnout is nearly always substantially smaller than in presidential years. Key was clearly concerned about the implications of such developments for the integrity of parties as vehicles for individual and collective choice at elections. As Table 1 below shows on just one of these dimensions, his forebodings have been more than amply realized in the long generation since his death.

Table 1
Insulation effects: states having at least some gubernatorial elections coinciding with presidential elections, 1936–2000

Year	No. of states	Total no. of US reps. in these states	Total US reps. in these states (%)
1936	35	313	72.0
1956*	29	225	51.7
1984	13	58	13.3
2000	11	52	12.0

* Year of publication of *American State Politics*

In his last years, V. O. Key increasingly devoted his attention to the challenges he saw in the development of survey research, both academic and applied. This was to issue in two works, *Public Opinion and American Democracy* (1961) and—posthumously—*The Responsible Electorate* (1966), and a number of articles where criticism was perhaps more pointed. He was vigorously opposed to political-science approaches that appeared to eliminate politics from their analytic schemes. He was alarmed by the potential for manipulating the public that was already (if by today's standards dimly) visible in applied 'market research' by candidates and their media and polling staffs. For, in his view, public opinion ultimately was an 'echo chamber'; and the quality of its output was heavily dependent upon the input provided by political elites and their consultants. Finally, he was convinced that the survey-research portrait of voters as in the main know-nothings (or know-very-littles) drastically underestimated voters' practical political intelligence and capacity for purposive, rational pursuit of political choice in accordance with their interests. On one major point raised in *The Responsible Electorate*—the distinction between interelection 'switchers' and self-identified partisan independents—his view was later to receive substantial confirmation in a 1981 study of panel surveys by Morris Fiorina (1981). In any

event, Key's last work made its own real contribution to the subsequent explosion of 'issue-voting' studies and, eventually, to a much more sophisticated and politically-centered survey-research enterprise.

3. *Assessment of Key's Professional Impact and Current Importance*

As the consummate professional that he was, V. O. Key devoted himself to the well-being and improvement of the political-science profession in countless ways. One example, at a time when statistical knowledge within the profession was still pretty much at a primitive level, was his little 1954 volume, *A Primer of Statistics for Political Scientists*. Another was his textbook, *Politics, Parties and Pressure Groups* (Crowell, NY, 1942–1964), which was far the best in its field and extended his teaching to generations of students. He sought to expand the frontiers of knowledge, not only through these and other works, but through myriad contacts with his peers and service to such organizations as the Social Science Research Council and the American Political Science Association.

It may be said that, for two decades or so after his death, Key remained more revered than followed by the political-science mainstream. His was always a sterling example of outstanding craftsmanship in specifying and executing important research projects that provided new insights into the American electoral process; of an enormous mastery of the data of American politics past and present; and a most exceptional capacity to break new ground by using it in novel ways. At the same time, regionalism and history largely fell out of mainstream concerns; his older South rapidly became, or seemed to become, a museum piece; and for a long time, analysis of aggregate election data seemed to be under W. S. Robinson's 1950 ban on the uses of ecological correlation. Since then, as problematics and professional interests have shifted somewhat, regionalism and historical depth in the explanation of current states of affairs have seen a notable comeback, and a whole field, American Political Development, has emerged into view. At the same time, ecological regression has emerged as a valuable estimation technique for analyzing voter transitions, e.g., during the critical realignment of the 1850s.

In a real sense, Key's work is more significant today than it seemed to be for some years after his death. Nowhere is this more true than in one major area of research by political scientists and historians alike: the study of critical realignment as a major change process across the span of American electoral, and more broadly political, history. As of 1991 (the last formal count), more than 500 books and articles had been devoted to this subject. While some historians had recognized qualitatively the exceptional turning-point significance of such elections as 1800, 1828, 1860, 1896, and 1932. Key was the first to provide an examination of this as an empirically specifiable problem in his truly seminal 1955 article, 'A theory of critical elections' (1955). It is noteworthy that Key never saw fit to explore the subject further, and one can doubt that he would find the elaboration of models in this field always to his taste. But his was the pathbreaking innovation that truly founded a vast research enterprise that is still underway, and has also attracted the attention of non-American researchers as well (Pierre Martin, 2000).

Keynes, John Maynard (1883–1946)

John Maynard Keynes was the most influential economist of the twentieth century. He invented, almost single-handedly, a new branch of economics, macroeconomics, or the theory of what determines output as a whole, as contrasted with microeconomics which studies the forces determining the composition

of a *given* output. He did so in order to destroy the implicit assumption of 'classical' economics that a competitive market economy would always ensure full employment; and thus to justify government intervention to maintain full employment. The task seemed the more urgent in the wake of the Great Depression of 1929–1933. The result was *The General Theory of Employment, Interest and Money* (hereafter GT), whose publication in 1936 is conventionally taken to be the start of the Keynesian Revolution. Its main policy fruit was the commitment, till the mid-1970s, by most Western governments, to maintain high and stable levels of employment in their countries. The lack of secure microfoundations for Keynesian macrotheory, as well as the somewhat contentious implications of that theory for the role of governments, has continued to make Keynesian economics controversial; while economic historians have disputed the contribution of Keynesian policy to the 'golden age' of global prosperity running from the 1950s to the early 1970s.

1. *His Life*

John Maynard Keynes was born at 6 Harvey Road, Cambridge, England on June 5, 1883 into an academic family. He was the eldest son of John Neville Keynes, a logician and economist, and Florence Ada Brown, the daughter of a Congregational divine. He had an outstandingly successful school career at Eton College which was followed by an equally glittering undergraduate one at King's College, Cambridge, where he gained a first-class honours degree in Mathematics, wrote papers on the medieval theologian Peter Abelard and the Conservative political philosopher Edmund Burke, and became President of the Cambridge Union and the University Liberal Club. Of crucial importance to his intellectual and moral formation was his election, in 1902, to the Cambridge Apostles, an exclusive 'conversation' society, where he fell under the influence of the philosopher G. E. Moore, and which brought him the friendship of Lytton Strachey. Moore's *Principia Ethica* remained his 'religion under the surface' for the rest of his life. It taught that the highest forms of civilized life were friendship, aesthetic enjoyments, and the pursuit of truth.

In 1906 Keynes was placed second in the Civil Service Examination, his worst marks being in economics, which he had studied briefly under Alfred Marshall (see *Marshall, Alfred (1842–1924)*). After two years in the India Office, in which he wrote a thesis on probability in his spare time, he started lecturing on monetary economics at Cambridge; in 1909, his thesis won him a fellowship at King's College, which remained his academic home for the rest of his life. His membership of the Bloomsbury Group, a commune of Cambridge-connected writers and painters who lived in the Bloomsbury district of London, dates from the start of his friendship with the painter Duncan Grant, Lyttton Strachey's cousin, in 1908. In 1913 he published his first book, *Indian Currency and Finance*, and served on the Royal Commission on Indian Finance and Currency.

Keynes helped to avert the collapse of the gold standard in the banking crisis of August 1914 which accompanied the outbreak of the first world war. From January 1915 to June 1919 he was a temporary civil servant at the Treasury, showing a notable ability to apply economic theory to the practical problems of war finance. He was against military conscription, and would have been a conscientious objector had his Treasury work not exempted him from military service. When Lloyd George succeeded Asquith as Prime Minister, Keynes (in January 1917) became head of the Treasury's new 'A' Division, set up to manage external finance. He helped to build up the system of Allied purchases in external markets, while chafing at Britain's growing dependence on American loans and the failure to arrange a compromise peace. Keynes was chief Treasury representative at the Paris Peace Conference in 1919, where he tried unavailingly to limit Germany's bill for reparations, and to promote an American loan for the reconstruction of Europe. His resignation from the Treasury on June 5, 1919 was followed by the publication, in December, of *The Economic Consequences of the Peace*, the book which first brought him international fame. A bitter polemic, informed by both moral passion and economic argument, against the Allied policy of trying to extort from Germany an indemnity which it could not pay, it reflected his revulsion against Lloyd George's leadership in both war and peace, and his fears for the future of European civilisation. Unless the Versailles Treaty were drastically revised, 'vengeance, I dare predict, will not limp' (Keynes 1919, p. 170)

Between the wars, Keynes's life was divided between Cambridge, London, and East Sussex. He was a spectacularly successful investment Bursar of King's College, and despite some major reverses, made about $400,000 for himself over his lifetime—worth $12m. today—out of which he financed a fine collection of pictures and rare books and the building of the Cambridge Arts Theatre in 1935. In London, where he rented a house at 46 Gordon Square, he was, at various times, on the Boards of five investment and insurance companies, the chief one being the National Mutual Life Assurance Company, which he chaired from 1921 to 1937. Between 1923 and 1931 he was chief proprietor and chairman of the Board of the weekly journal, the *Nation and Athenaeum*, contributing regular articles on financial and economic topics. (He remained chairman of the Board of the *New Statesman and Athenaeum* when the two journals merged in 1931.) Between 1911 and 1945, he edited the *Economic Journal*. In the 1920s his ideas on economic policy permeated Whitehall through monthly meet-

ings of the Tuesday Club, a dining club started by his friend and stockbroker, Oswald Falk. In the 1930s, he sought to influence policy through his membership of the Prime Minister's Economic Advisory Council. In 1925, he took the lease of Tilton, a farmhouse in East Sussex, next door to Charleston, where Duncan Grant lived with the painter Vanessa Bell. This move coincided with his marriage to the Russian ballerina, Lydia Lopokova, who gave his life the emotional stability it had previously lacked, and which provided the necessary background for sustained intellectual effort.

In the 1920s, the postwar European inflations, succeeded in Britain by heavy unemployment, formed the background to his two theoretical books *A Tract on Monetary Reform* (1923) and *A Treatise on Money* (1930) which dealt with the causes and consequences of monetary instability, and their remedies. These theoretical exercises were punctuated by two notable polemical pamphlets *'The Economic Consequences of Mr. Churchill'* (1925) and *'Can Lloyd George Do It?'* (1929), written with Hubert Henderson. The first attacked Churchill's decision, as Chancellor of the Exchequer, to put the pound back on the gold standard at an overvalued exchange rate against the dollar; the second was a plea for a large public-works program. Reconciled to Lloyd George in 1926, Keynes attempted to provide the Liberal Party with a social philosophy of the 'middle way' between individualism and state socialism, suitable for an inflexible industrial structure. Regulation of demand, he would later write, was the only way to maintain capitalism in conditions of freedom (Keynes 1936, p. 381, 1940, p. 123).

The Great Depression of 1929–1932, together with technical flaws in *A Treatise on Money*, took Keynes back to the theoretical drawing board. What now seemed to be needed was not an explanation of Britain's 'special problem' of persisting unemployment, but an explanation of how aggregate output could collapse, labor remain unused, and global depression persist in a world in which resources remained scarce. From the autumn of 1931 to the summer of 1935, Keynes worked on a new book of theory, initially entitled '*The Monetary Theory of Production*.' He was helped not just by older economists like Ralph Hawtrey and Dennis Robertson, but by Roy Harrod and a 'Cambridge Circus' of young disciples led by Richard Kahn. There was just one major pamphlet in these years, '*The Means to Prosperity*,' written in June 1933. On a trip to the United States in 1934 to study the New Deal first-hand, he wrote: 'Here, not in Moscow, is the economic laboratory of the world.'

The GT, published in February 1936, tried to demonstrate both that 'underemployment equilibrium' was logically possible, and how monetary manipulation by the central bank combined with an extensive 'socialisation' of investment could maintain full employment. The first proposition, in particular, divided the economics profession, since it rejected the 'classical' thesis of a self-equilibrating economy. The publication of the GT confirmed the breach between Keynes and Dennis Robertson and Hubert Henderson, his chief collaborators in the 1920s; at the same time it marked the birth of a 'Keynesian school' of economics led by Richard Kahn and Joan Robinson (see *Robinson, Joan (1903–83)*) at Cambridge, Roy Harrod and James Meade at Oxford, and Nicholas Kaldor at the London School of Economics. In the United States, the GT supplied the younger generation of (mainly Harvard-trained) economists with a theoretical rationale for the New Deal. Keynes himself joined in the fierce controversies which his book generated, even though he was severely incapacitated, from May 1937 to March 1939, with heart disease. As another European war, and with it, the return to deficit-financed full employment became increasingly likely, Keynes sought to win acceptance for his Revolution by showing how the managment of aggregate demand to avert depression could just as easily be used to contain inflation in a war economy.

The upshot was his pamphlet '*How to Pay for the War*' (1940), which won the approval of his arch critic Friedrich Hayek (see *Hayek, Friedrich A von (1899–1996)*), and whose logic influenced Kingsley Wood's war budget of 1941. Restored to a semblance of health by his doctor, Janos Plesch, Keynes himself returned to the Treasury in August 1940 as unpaid adviser to the Chancellor of the Exchequer, and remained its dominating force for the rest of his life. Elevated to the House of Lords as Baron Keynes of Tilton, his influence was felt in the Beveridge Report on Social Security in 1942, and in the Employment White Paper of 1944 which pledged the government to maintain a 'high and stable level of employment' after the war. In 1942, Keynes became chairman of the Council for the Encouragement of Music and the Arts (CEMA), a wartime innovation which, transformed into the Arts Council of Great Britain shortly before he died, inaugurated permanent state patronage of the arts.

The American demand that, in return for Lend-Lease, Britain scrap its imperial preference system after the war, inspired Keynes to his last great constructive effort, his plan for an International Clearing Union (1942). This was designed to shift balance-of-payments adjustment from debtor to creditor countries, so as to avoid the externally-generated deflationary shocks which had spread depression under the gold standard. The Bretton Woods Agreement of 1944, which set up a system of fixed, but adjustable exchange-rates and two new institutions, the International Monetary Fund and the International Bank for Reconstruction and Development, fell short of Keynes's hopes. The abrupt US cancellation of Lend-Lease in August 1945 led him to undertake the fifth of his six Treasury missions to the United States to secure an American grant or interest-

free loan of $5bn. Forced to accept a semi-commercial loan for an amount far less than he had requested, Keynes gave a brilliant defence of his policy in his last speech to the House of Lords on December 7, 1945.

On April 21, 1946, worn out by his labors, he suffered a fatal heart attack at Tilton, a little short of his 63rd birthday. In an imposing memorial service at Westminster Abbey, Clement Attlee, the prime minster, headed a list of mourners drawn from all walks of life.

2. *Major Contributions*

Keynes's main contributions to economics can be grouped under three heads: the theory of deep economic fluctuations; the theory of effective demand; and the technique of stabilization policy based on the second.

2.1 *The Theory of Economic Fluctuations*

This cannot be wholly understood apart from Keynes's distinctive theory of probability. In his *A Treatise on Probability* (1921), his main contention was that probability is not statistical, but is a logical relationship between the premise and conclusion of an argument which fell short of demonstrative proof. Like Frank Knight (who however used a statistical theory of probability), Keynes distinguished between risk, or situations when agents can form probabilities and thus insure against loss, and uncertainty, when 'there is no scientific basis on which to form any calculable probability.' He wrote in 1937: 'Thus the fact that our knowledge of the future is fluctuating, vague and uncertain, renders wealth a peculiarly unsuitable subject for the methods of the classical economic theory' (Keynes 1937, p. 113). This may be contrasted with the modern mainstream view that agents maximise with known probability distributions, so that market-clearing models are the most appropriate for analyzing economic behavior. Keynes himself identified as a tacit axiom of the classical theory of the self-regulating economy that 'at any given time facts and expectations were … given in a definite and calculable form' (Keynes 1937, p. 112).

Keynes's theoretical work in the 1920s is devoted to unpackaging the Quantity Theory of Money (QTM) which ruled out, by assumption, the possibility that monetary disturbances can have 'real' effects on the economy. This might be true in the long-run, Keynes remarked acidly, 'but in the long-run we are all dead' (Keynes 1923, p. 65). Keynes used the quantity of money *equation* to show that changes in the quantity of money can unsettle business expectations and the distribution of income, thereby causing short-run fluctuations in the level of business activity. In doing so, he emphasised the use of money as a 'store of value' or hedge against uncertainty, and the distinction between fixed and flexible prices. Thus in the *Tract on Monetary Reform* he wrote: 'The *fact* of falling prices injures entrepreneurs; consequently the *fear* of falling prices causes them to protect themselves by curtailing their operations' (i.e., adding to their cash balances) (Keynes 1923, p. 34). In the *Treatise on Money*, he argued that the disturbing effects of money can arise not just from inflationary or deflationary policies, but from *autonomous* changes in business sentiment. Much of the *Treatise* is devoted to analyzing the consequences of short-run changes in the 'propensity to hoard' or 'velocity of circulation,' which Keynes identifies, by means of his 'Fundamental Equations,' with the emergence of windfall profits and losses, and a disequilibrium between saving and investment. Keynes shows how disequilibrium prices produce an oscillation of boom and slump round a (notional) full-employment equilibrium. But such equilibrium is achieved accidentally, in the absence of appropriate monetary policy.

The chief theoretical point which emerges from these two works is the instability in what Keynes would later call the liquidity-preference schedule. His claim was that, in a variety of situations readily encountered in economic life, hoarding money or savings can yield superior utility to investing them, and that this, combined with 'sticky' wage and price contracts, can explain quite prolonged lapses from full employment. His contribution up to1930 was largely a summation of the monetary theories of Irving Fisher (see *Fisher, Irving (1867–1947)*) and Knut Wicksell, and is properly regarded as a contribution to the theory of economic fluctuations, with increased emphasis on volatile expectations. Like Fisher, Keynes advocated a monetary policy of keeping domestic prices stable; this might be incompatible with adherence to the international gold standard, an institution which Keynes dismissed as a 'barbarous relic' (Keynes 1923, p. 138).

2.2 *The Theory of Effective Demand*

Keynes's revolutionary contribution to economics lies not in his theory of business fluctuations but in his theory of how aggregate output is determined. This is the subject matter of his GT. The QTM was a theory of the price level, when the levels of output and employment were explained in real, nonmonetary terms. Following a suggestion from Ralph Hawtrey, Keynes agreed in 1930 that 'it will probably be difficult in the future to prevent monetary theory and the theory of short-period supply from running together' (Keynes 1930, p. 146). This was the start of macroeconomics.

The core of the GT is the theory of effective demand. It tells how, when something happens to reduce aggregate demand, aggregate supply and aggregate

demand are reconciled, not through falls in the price-level of output, but by a reduction in its quantity. It is a short-period theory: prices adjust only after, and as a result of, the fall in output and employment, and even then not completely. In the short-run, the volume of output in an economy is determined by the money demand for that output. The GT is the theory of what determines the level of money demand for output.

In Keynes's notation $Y = C + I$. This tautology simply means that National Income (Y?) is equal to the sum of the expenditure on National Output, divided into consumption spending (C) and investment spending (I). Consumption expenditure is governed by Keynes's 'consumption function,' based on the 'psychological law' that consumption (and therefore saving, which is Y-C) is a stable fraction of total income, and that the marginal propensity to consume is less than unity. In a progressive economy the gap beween consumpion and production must be filled by investment if full employment is to be maintained. The amount of investment is determined by the relationship between what the investment is expected to yield over its lifetime ('the marginal efficiency of capital') and the cost of borrowing the money needed to finance it (the rate of interest). Both are subject to uncertain expectations. Consumption is the stable element in demand; investment the volatile element. Thus, what the community wishes to save may at a particular moment exceed what businessmen want to invest. The revolutionary claim of the GT is that when this happens, the divergent plans are brought into equality by a reduction in the level of income (output). Moreover, if the consumption function is known, it is possible to show, by a mathematical formula (Kahn's multiplier), by how much the community's income or alternatively employment must change to reconcile divergent saving and investment plans. The novelty of Keynes's treatment, as compared not just with the older theory, but his own *Treatise on Money*, was to demonstrate that an economy might be in equilibrium, with saving equal to investment, and aggregate demand equal to aggregate supply, at less than full employment.

Critics fastened on the most contentious feature of the new doctrine, the theory of 'under-employment equilibrium.' They denied that this was a genuine equilibrium; it was a disequilibrium state, frozen by the assumption that certain prices were fixed. Flexible interest rates and wage rates would always ensure the desired level of employment, whatever was happening to aggregate demand.

Keynes could have defended his position by saying that his fixed-price assumptions were realistic but he set out to expose the logical flaws underlying the implicit classical price-adjustment story. He denied, first of all, that the interest rate was, or could be, determined in the market for saving and investment, since the quantity of saving depends on the level of current income. This was the basis of his view that it is changes in income that equilibrate saving and investment plans. In place of the classical theory of interest, he offered his liquidity-preference theory of interest, which makes interest the price for giving up cash. The greater the liquidity-preference of wealth-holders, the higher the yield they will demand for switching from cash into bonds or other securities. Insofar as the rate of interest *does* move in response to a fall in investment demand, it will be in the wrong direction, since the 'same circumstances which lead to pessmistic views about future yields (of capital assets) are apt to increase the propensity to hoard' (Keynes 1937, p. 118).

As far as wage flexibility is concerned, Keynes agreed with the orthodox view that the *real* wage is inversely related to the quantity of employment, but denied that real wages are determined in the labor market by money-wage bargains, since an all-round reduction in money-wages might, by reducing the general price level, leave the real wage unaffected. The effect of a 'flexible wages policy' thus depended entirely on its impact on the components of aggregate demand-consumption and investment—which might well be unfavorable.

Keynes conceded that, in time, the decline in employment (or money-wage rates) would, by decreasing the amount of money required to satisfy the business demand, lower the rate of interest required to satisfy the 'propensity to hoard' (Keynes 1937, p. 118); he also thought that, after a slump, a shortage of capital goods would develop which would revive profit expectations'. (Keynes 1936, pp. 317–18). In short, a slump might eventually bring about the price adjustments which according to the classical economists were supposed to prevent the slump from occurring. He doubted, though, whether even longer-run forces would ensure a gravitational pull towards full employment. 'We oscillate,' he wrote, 'round an intermediate position, appreciably below full employment and appreciably above the minimum employment a decline below which would endanger life' (Keynes 1936, p. 254).

Despite nonacceptance by the leading economists of key elements in Keynes's macroeconomic model (Dennis Robertson, in particular, made a damaging attack on his theory of interest), critics were driven to argue for their positions within the analytical framework Keynes had set up. Macroeconomic analysis became part of the economists' tool kit, even if Keynes's own conclusions were rejected.

2.3 Stabilization Technique

Keynes's three main theoretical books were all aimed at providing justifications for conscious attempts to stabilize output and employment at a high level. The quest for output stabilization led directly to the development of National Income and Expenditure

Accounts, to enable governments to estimate the size of the 'output' gap—the gap between what the economy was producing and what it could produce at full employment (or, in later refinement, what it could produce when it was growing to trend)—which needed to be plugged by extra spending. Keynes also insisted that the aggregate demand and supply framework of the GT could be used to work out how much spending needed to be withdrawn from an economy to prevent inflation if aggregate demand exceeded aggregate supply.

In principle, stabilization policy can be either monetary or fiscal, or some combination of both. In practice, Keynes rejected the monetary route to managing demand. He did not deny that investment was interest-elastic. But he thought that interest-rate changes, produced by varying the quantity of bank credit, were too slow-moving in their effects on investment; and he was worried that if interest rates were raised to check a boom it would be difficult to bring them down to check a slump, since the expectation of falling rates would increase the 'propensity to hoard.' So he advocated a policy of permanently cheap money, to be buttressed by capital controls and 'under-funding' of the National Debt. This left fiscal policy as the main instrument for preventing both slumps and inflationary booms. Keynes's fiscal philosophy must be distinguished from Keynesian fiscal policy as understood (and sometimes practiced) after his death. It was based on a sharp distinction between the government's 'ordinary' or current-account budget and what he called the 'capital' budget, made up not just of government spending on capital projects but the economy's total investment. The government's ordinary budget should be balanced at all times, with a surplus earmarked for debt repayment in 'normal' times. It was the task of the capital budget to balance the 'national accounts.' Keynes believed that a great deal of investment was already 'socialized,' that is, subject to public policy even if it was technically private. As he put it in 1943: 'If two-thirds or three quarters of total investment is carried out or can be influenced by public or semi-public bodies, a long-term programme of a stable character should be capable of reducing the range of fluctuation to much narrower limits than formerly…If this is successful it should not be too difficult to offset small fluctuations by expediting or retarding some items in this long-term programme' (Keynes 1943, p. 322).

Finally, Keynes attached only minor importance to exchange-rate adjustments. His Clearing Union Plan (1942) provided for fixed, but adjustable rates, and this was a feature of the Bretton Woods Agreement (1944). Keynes's attitude—like that of most economists of his day—was governed by price-elasticity pessimism. He preferred countries to use, if necessary, capital controls to protect their balance of payments in the framework of a monetary regime of fixed exchange rates, low tariffs, and automatic creditor lending through international institutions.

Keynes was not an ivory-tower theorist. His theorizing was controlled by real world events. His own investment experience enabled him to identify the 'speculative' motive for holding money; his sense of political fragility led him to concentrate on the economics of stabilization; his civil service experience enabled him to turn theories into workable plans. His economic theorizing was less directly, but still importantly, controlled by his philosophical beliefs, particularly by his conception of the good life and of the conditions of just exchange.

3. *The Legacy*

Economics was transformed by its encounter with Keynes. Macroeconomics became for many years a dominant part of the subject; macroeconomic forecasting the main tool of government policy. However, Keynes's doctrines never won universal acceptance, and key aspects of his theoretical and policy legacy have been challenged. The debated issues can be grouped under four heads.

3.1 *Acceptance of Keynes's Theory*

What Keynes bequeathed was not the same as what was accepted. The first theoretical breach came with demonstrations by Pigou (1942) and by Modigliani (1944) that the Keynesian slogan 'quantities adjust, not prices' was true only if money wages were rigid. This became the basis of the 'neoclassical synthesis,' which grafted Keynesian macroeconomics on to classical theory, but left the rigidities unexplained. Milton Friedman's counter-attack was both methodological and theoretical. On the one hand, he argued that it was not acceptable to posit *ad hoc* supply and demand functions. Second, his own application of neoclassical standards of method to Keynes's aggregate equations—seen in his permanent income hypothesis (1957), the stable demand for money function (1956, 1963), and the theory of the 'natural rate' of unemployment (1968)—undermined the case for Keynesian stabilization policy. Economies were more cylically stable than Keynes had supposed; multipliers were small, or nonexistent; government manipulation of aggregate demand had no permanent 'real' effects, but only raised the inflation rate. These 'policy ineffectiveness' propositions were to be hardened still further by the 'rational expectations' school of Robert Lucas and Thomas Sargent. The tendency of Friedman's critique (popularly called 'monetarism') was to reinsert an updated version of the Quantity Theory of Money into the heart of macroeconomics. It revived the pre-Keynesian notion (adumbrated by Keynes himself in the *Tract on*

Monetary Reform) that the most important macroeconomic function of governments was to keep stable the purchasing power of money.

3.2 Acceptance of Keynesian Policy

Contrary to widespread mythology, this was patchy. Both the British government and the US Administration committed themselves to targetting 'high' levels of employment, but it is often asserted that US policy only became Keynesian in the early, and German policy in the late, 1960s, and that both Keynesian episodes were fairly brief. Much of this discussion begs the question of what one means by 'Keynesian' policy. Running a budget deficit is no more a sign of Keynesian virtue than is running a budget surplus in boom conditions anti-Keynesian. An alternative argument is that Keynes's influence was exerted not so much through national policies as through the US willingness to provide the rest of the world with reserves and liquidity. However, this likewise begs the question of how 'Keynesian' this willingness was.

3.3 The Impact of Policy on Events

For a long time, the canonical view was that Keynesian demand-management policies and Keynesian-inspired institutions (the Bretton Woods system) were mainly responsible for the uniquely successful employment and growth performance of most countries in the 1950s and 1960s. Today most of the credit for the 'golden age' is given to opportunities for 'catching up' with American technology, recession-proof military spending by the US, and high levels of 'social' spending.

In the 1950s and 1960s it was common to argue that Keynesian policy helped to save capitalism by removing the scourge of mass unemployment. (In Marxist terms, it legitimized the capitalist order.) By the 1970s it was being argued that it endangered the long-run survival of capitalism by producing rising inflation, an expanding public sector, and increasingly draconian wage and price controls.

3.4 The Current Debate Over Keynesian Economics

According to the monetarist-cum-rational expectations schools, Keynesian economics failed the predictive test: it led to inflation, still worse 'stagflation.' In the 1970s, Keynesian policies were attacked for ignoring the existence of a 'natural' rate of unemployment, and (by the Virginia or Public Choice school) for assuming that politicians wanted to maximize the collective social welfare, rather than their own individual utilities. Taken together, these two attacks offered a forceful argument against the use of discretionary fiscal and monetary policy to balance economies.

The use of models of economies with nominal rigidities is still general, but whether these rigidities are to be taken as given is much more questioned than in 1950s and 1960s. The dominant 'supply side revolution' of the 1980s chiefly was concerned to dissolve rigidities seen as institutional by deregulating labor markets. Against this, the 'new Keynesians' explained how sticky prices are rational because of transactions and information costs, and how shocks to demand can destroy both physical and human capital. These explanations seemed both to strengthen and weaken the case for Keynesian macroeconomic policy. On the one hand, they gave renewed intellectual respectability to stabilization policy. On the other hand, by explicitly introducing inflation into their analyses, they conceded the existence of a rate of unemployment (the so-called NAIRU or Non-Inflation Accelerating Rate of Unemployment) below which unemployment could not be pushed by manipulating demand. Finally, against the mainstream profession's use of Bayesian statistics and decision theory to model agents' behavior, a minority school of 'Post-Keynesians' continues to assert the fundamental nature of Keynes's attack on the rationality axiom.

An interim judgment on the Keynesian Revolution would be that the main body of classical economics was too well-entrenched to be overthrown by the frontal assault he mounted. The notion that uncertainty was at the heart, rather than at the financial margins, of economic processes, proved too subversive of the science economics claims to be, to be acceptable. Most economists would say today of Keynes what Marshall said of Jevons: 'His success was aided even by his faults … he led many to think he was correcting great errors; whereas he was really only adding important explanations.' Whether this will be the final verdict is still questionable.

Keynesianism and State Interventionism

Keynesianism, whatever its variants, assigns to the State the responsibility to regularly intervene in the operation of the economy so as to maintain its performance at a high level of employment and growth (Hall 1989). Keynesianism believes in the effectiveness of this intervention. From Keynes' analysis of the preference for liquidity and the economic crisis of the 1930s it has retained a definite skepticism concerning the effectiveness of monetary policy. Investment and consumption are held to be little affected by interest rates; it therefore suffices to have a monetary policy that maintains interest rates at a sufficiently low level. On the other hand, Keynesianism stresses countercyclical management of overall demand by means of fiscal and budget policies: financing expenditures by public borrowing in case of recession; seeking a budget surplus to hold down inflation in the rising phase of the cycle. Fiscal constraint can be relaxed to finance welfare programs. This is a decisive change with respect to classical economics that deemed a balanced budget to be the highest priority. The Keynesian stimulus works via a sort of self-fulfilling prophecy concerning investment and demand. Prewar policy held to the contrary that the modest means available to the government was a guarantee for democracy, allowing it to stand up to populist excesses and to unlimited demands from special-interest groups.

Keynes would have been hostile to Keynesianism. In all likelihood he would have espoused, although in different terms, the criticism expressed by Friedman (1968) and Lucas (1976) towards the Keynesians' conception of State intervention in the economy. But this criticism, albeit radical (and essentially well taken), is aimed less at the principle than at the modalities of an effective State intervention. Keynesianism, for all its '*naïveté*,' has managed to make this intervention accepted. This is the paradox that ensures a long life for intellectual and political debate about Keynes' writings. This contribution is divided into three sections: a history of the reception encountered by Keynesian ideas: criticism of these ideas, and the relevance of Keynes today.

1. *The Reception of Keynesian Ideas*

Keynesianism was not born with Keynes. Hicks (1937) notably formalized the IS-LM curves that jointly determine the global income and the rate of interest, via the relations between investment, savings, demand and supply of money. Samuelson (1948) provided the analytical frameworks of macroeconomic policy. Put briefly, the synthesis thus established, neoclassical in spirit, resituates Keynes' work in the conventional framework of market equilibrium. It eliminates the role of agents' expectations, which was decisive for Keynes (as well as eliminating the role of the 'state of confidence'), and replaces it with a mechanistic vision of the economy that is reduced to a few global parameters. Phillips (1958) then added the curve linking wage increases, rising prices and the unemployment rate. The development of national accounting and statistical apparatus provided the basis for econometric modeling. Little by little economists, following in this respect the theory of economic policy elaborated by Tinbergen (and drawing politicians and political discourse in their wake), came to espouse the use of macroeconomic models for the quantitative evaluation of State policy. Keynesian policy is funda-

mentally a policy designed to fine-tune short-term fluctuations in the economy. If short-term forecasts given by a model are accurate, then the long-term evaluation of the effects of a policy is presumed to be reliable. The long-term outcome is engendered by a carefully constructed chain of short-term periods. Keynes thought, on the contrary, that the agents' view of the long term had a direct effect on their current behavior.

From the 1930s to the 1950s the reception of Keynesian ideas spread through three channels: the influence of professional economists' expertise on political decision making (seeking new explanations for the economic crisis); new demands formulated by political parties (themselves conditioned by previous experience); and the capacity of Keynesian ideas to spawn broad political coalitions. The configuration of history fostered the convergence of these three channels: the heritage of the war economy (when the 'young' Keynesians had demonstrated the effectiveness of State organization and intervention); the needs of reconstruction (which called for a high level of public investment), and the expansion of social policies aimed at achieving full employment. In the light of the prewar risk of confrontation between the labor agenda (leading to nationalization of the means of production) and that of capitalism (*laissez-faire* liberalism), Keynesianism offered a compromise. Full employment and sustained growth could be achieved in a capitalist economy through the judicious use of macroeconomic management (without interfering with the management prerogatives of private capital). Labor could see full employment guaranteed, and capital could continue to control investment.

But in order for Keynesian policy to be effective two structural conditions were necessary: a system of appropriate institutions; and a common language and beliefs shared among the actors in the economy. These conditions were fulfilled to various degrees depending on the country—more highly developed in Great Britain and France though differently, than in the United States or Germany. The State must be linked to the actors by a set of institutions that structure the flow of information and resources. These institutions ensure a common assessment of the economic situation and provide security for anticipations (notably via property rights and contract law). A relationship of confidence between the central bank, the State, and financial markets is crucial for the financing of public debt and establishing regulation of the banking system. At the same time, shared views of the expected and legitimate role of the State must spread throughout the economy and society. This 'conventional' foundation creates the state of confidence enabling each actor to constitute favorable anticipations (of demand and investment). The combination of these anticipations is self-fulfilling of the forecast projected by the macroeconomic model; it allows State intervention to attain its goals. This double system of institutions and shared conventions paradoxically ensures the effectiveness of Keynesian policy. Without this system, Keynesian policy is nothing. This is what the Keynesians forgot. They consequently come to believe in the State as a *deus ex machina*. In neglecting the question of expectations they left the way open for the school of rational anticipations. The return in force of market economics and neo-classical rationality was the outcome.

2. *Criticism of Keynesianism*

A series of attacks, some old (Hayek, Buchanan) and others recent or renewed (Friedman, Lucas, Sargent), converged in the late 1960s and early 1970s, leading to a collapse of Keynesianism.

Hayek and Buchanan had paved the way, one by rejecting any sort of validity for macroeconomics in itself, the other by demolishing the myth of the State as an enlightened despot. Keynesianism opens the floodgates of inflation by facilitating uncontrolled creation of credit. Then come wage and price control policies that eliminate inflation at the cost of much higher unemployment than that which would have resulted under a stable currency regime (Hayek). Economics can be seen as a science that gives people greater control over their environment, but it has no command over politics. Governments are more interested in collecting the maximum number of votes than in pursuing the public good (Buchanan).

The Phillips relationship had given Keynesian policy its missing link: that of setting wages. Fine tuning efforts could focus on the inflation/unemployment dilemma: how much unemployment is needed to ensure price stability? The stagflation of the 1970s (high unemployment and high inflation occurring simultaneously) was its downfall. Friedman reintroduced anticipations. He showed that the trade-off between inflation and unemployment is only temporary: it stems from inflation that is not anticipated by agents. Eventually unemployment returns to its natural rate, which is determined by structural socio-economic characteristics, but at the price of higher inflation. Discretionary monetary policy cannot durably stabilize either interest rates or unemployment at low levels. Keynesians situate themselves in a world where everyone anticipates that prices will remain stable, and where this anticipation persists no matter what happens to prices and wages. This world has vanished. Friedman updated his 1948 program: replacing a discretionary monetary policy with public adoption by the monetary authorities of a set rule. In the present instance this means: setting a growth target for the money supply (using a specified monetary aggregate); avoiding sudden changes, not overreacting to events. In 1948 this 'monetarist' framework had received no attention. Economists had adopted the highly flattering position of 'advisor' to the managers

of the economy (and thereby justifying the development of their profession). The contrast between the massive unemployment of the Great Depression and the success of the post-war economy had persuaded the economy's managers of the efficacy of systematic State intervention. 'Friedmanian' rules are now widely followed by monetary authorities (like the Federal Reserve Bank or the European Central Bank).

Lucas's criticism was aimed at the use of macroeconometric models. The theory of economic policy (Tinbergen 1952) underlying this use is invalidated by the fact that actors adapt their rules of decision to modifications in economic policy. The variables controlling economic policy are thus endogenous to the system; the structure of the models varies with economic policy. No reliable projection of future behavior and trends can be obtained by extrapolation of series and correlation with the past. In order for a change in the rules to have a chance of being effective (i.e., leading to foreseeable trends) it must be publicly debated and understood by the actors in the economy. Once again, despite a few pockets of resistance, this criticism ultimately dealt a fatal blow to substantive macroeconomics 'defined by itself to be the body of expertise … devoted to the development and refinement of forecasting and policy evaluation methods' (Lucas 1980, p. 250). This discipline failed to foresee the return of economic growth at the dawn of the twenty-first century. But this has not prevented the teaching of macroeconomics to continue in academia.

Now that the din of the dogmatic battles has ceased, a more balanced assessment is possible. The structuring role of the anticipations of agents is now recognized. They introduce an irreducible element of unpredictability. What counts in the dynamics of the economy is action and coordination. Economic policy must abandon the aim of influencing the course of events by substantial and discretionary means. Its field of action relates to the rules that serve as the framework of reference for private forecasts and actions. At bottom, for these rules to be effective they must be debated and made public. They leave room for interpretation in action and for innovation. They provide a framework that can be publicly revised and adjusted in keeping with the results obtained. This does not imply, however, an absence of concern for joblessness and full employment, but rather a clearer consciousness of the properties of various policy instruments and how they complement each other. The unemployment rate can no longer be a direct target of economic policy. Measuring an unemployment rate under full employment is meaningless. Firms and employers have many options other than unemployment at their disposal for adjusting to fluctuation in the demand for products and to the outlook for innovation. Satisfactory allocation of social risks is the task of welfare economics. Providing a framework of stability and security that safeguards the anticipations and terms of agreements concluded–this should be the essence of economic policy (Lucas 1976). But can this modest objective satisfy the body of professional economists, who are much more numerous than in the past and permanently accustomed to the comforts and remuneration of policy expertise?

3. *The Relevance of Keynes Today*

Keynesianism is dead, but what of the writings of Keynes himself? In his ferocious criticism of Tinbergen in 1939 Keynes already expressed the arguments that were later expanded by Lucas (who did so without making any reference to the writings of Keynes). This criticism originates in Keynes's *Treatise on Probability* (1921). As early as this work he understood that the problem is a double one, that of measurement and that of 'passing from statistical description to inductive generalisation' (Keynes 1939, p. 566). If all causal factors must be measurable for economic policy to be subjected to statistical tests and forecasting, 'it withdraws from the operation of the method (of Tinbergen) all those economic problems where political, social and psychological factors, including such things as government policy, the progress of invention and the state of expectation, may be significant' (1939, p. 561). Keynes was likewise prudent concerning the arithmetic of the multiplier. Lastly, for Keynes the prime target of monetary policy was the value that actors accord to the conventions that they follow on financial markets. It is the state of confidence that is important, and not directly interest rates and unemployment.

'Neo-Keynesians' have counter-attacked. They integrated into the Keynesian scheme rational anticipations and the possibility of exogenous shocks and of constraints on individual supplies and demands. But in so doing they remain open to these criticisms of Keynes. And by insisting on the rigidity of costs, their recommendation of wage flexibility paradoxically converges with that of liberals attached to the idea of reducing the natural unemployment rate. The 'post-Keynesians' (Davidson 1991) insist on the radical and non-probabilistic uncertainty that surrounds the decision-making of economic agents. They thus move closer to the institutional (and not solely political) content of Keynes' message. They attempt to express his relevance to the current context. This uncertainty stems from an instability in the overall trajectory of the economy. Institutions must be created to construct a 'corridor' that restricts the range of directions that actions can take. Following Keynes' intuition on inference and probability, it should probably be added that institutions allow people to make judgement and inference on situations of action which are well-founded and secure.

It is time to leave behind the paralysis of opposing schools and dogmatic assumptions (in particular regarding States vs. the market, or the nature of the

market, or rationality). Too often a worthwhile idea is rejected, on the pretext that it comes from the opposing school. Little by little a macroeconomics of rules is expanding in which government of the economy by the State is permissible (a posthumous victory for Keynesianism). But, as thought Keynes, this government must be limited in scope and in ambition (Skidelsky 1999). The dynamics of the economy are above all the result of the actions, anticipation and coordination of the actors. These actors are diverse in terms of their identities, their means and ends (and in the relationship they establish between means and ends). The knowledge they have acquired of their terrain renders their action irreplaceable in a context of uncertainty. A framework of democratically debated, stable and foreseeable rules seems necessary for the implementation of collectively effective actions. But the debate is shifting to the status of these rules (are they prescriptive rules, or guidelines open to interpretation in action?) and to the status of macroeconomic variables (objectives, constraints, or simple by-products of market activity?).

Kimura, Motoo (1924–94)

Motoo Kimura was Japan's foremost population and evolutionary geneticist. He is best known for his neutral theory of molecular evolution, which asserts that the great majority of evolutionary changes at the DNA level are driven by mutation and random survival of mutant genes, rather than by natural selection. He was also a major contributor to the mathematical theory of evolution and population genetics.

1. Life

Motoo Kimura was born on November 13, 1924, in Okazaki, Japan. Early in his life he was fascinated by plants and had a deep interest in their structure. He also displayed an early talent for mathematics. He was admitted to the National High School in Nagoya in 1942. Here, thanks to a knowledgeable and sympathetic teacher, he studied the chromosomes of lilies. This institution also provided his first contact with biometry, and he realized for the first time that he could use his mathematical skills to study biological problems. In 1944 he was admitted to the Kyoto Imperial University.

Normally Kimura would have enrolled in the Faculty of Agriculture to study with the internationally respected geneticist, Hitoshi Kihara. But agriculture students were being called into military service, while botany students were not. So, on Kihara's advice, Kimura enrolled in the Faculty of Science. By the time of his graduation the war was over, and he joined Kihara who encouraged his study of mathematical problems. During this time, Kimura had no specific duties and took the opportunity on his own to read systematically in mathematical genetics. His mathematics, formidable as it sometimes seems, was mainly self-taught. Life in wartime Japan was miserable, and remained so for some time afterward. Kimura was able to supplement a sparse physical and intellectual diet by visiting his cousin, a quantum physicist who lived in the suburbs and could supply both food and scientific talk. Kimura hoped for a theory of population genetics comparable to that of physics.

In 1949, he joined the staff of the National Institute of Genetics in Mishima, and retained this position for the rest of his life. Thanks to help from some American geneticists studying the effects of the atomic bomb in Hiroshima, he was able to obtain support for graduate study in the USA. After a year at Iowa State College Kimura transferred to the University of Wisconsin in 1954 as the author's student. This also provided an opportunity for daily association with America's most eminent population geneticist, Sewall Wright, who had recently moved to the University of Wisconsin.

Except for his graduate years and several short periods abroad, Kimura spent the remainder of his life in the National Institute of Genetics in Mishima, Japan. Late in his life, he developed amyotrophic lateral sclerosis and died on his 70th birthday, November 13, 1994.

2. *Major Contributions*

Kimura's scientific life can be divided into two periods. The first began while he was still a student and continued until 1968. During this time he made major contributions to the mathematical theory of population genetics. In 1968, he introduced his neutral theory of molecular evolution. Although he never stopped making theoretical contributions, his major efforts from this time on were devoted to further developments and defense of the neutral theory.

The mathematical theory of evolution had its heyday in the period roughly from 1920 to 1950. It was almost completely dominated by three men, R. A. Fisher and J. B. S. Haldane in England, UK and Sewall Wright in the US. Kimura became the logical successor. Much of Kimura's work utilized the stochastic equations of the Russian mathematician, A. Kolmogrov. Kimura showed a remarkable inventiveness in solving these difficult equations and applying them creatively to significant evolutionary problems.

Among the problems that Kimura solved are: the probability that a new mutant gene will ultimately spread through the population; the number of generations required for this process; if the mutation is lost, the number of generations it persists before loss; the number of individuals that carry a mutation during the time until it is fixed or lost; and the average age of a mutant gene segregating in a population.

At the same time he contributed to many other areas of population genetics theory. These included: a comparison of inbreeding systems, showing that systems minimizing the immediate increase in homozygosity are not the best in the long run; a further development of Fisher's 'fundamental theorem of natural selection' with more explicit treatment of gene interactions; a new and influential model of population structure, the 'stepping stone' model, in which migrants are restricted to neighboring colonies; the efficiency of rank-order selection in changing gene frequencies and removing deleterious mutations from the population.

By 1968 the subject of molecular evolution was in a period of rapid development, which still continues. This was the year of Kimura's bombshell. He argued that the great majority of amino acid and nucleic acid changes are selectively neutral. Instead of natural selection as the main directive force, these changes occur by mutation and whether they persist or are lost is a matter of chance. Remarkably, Kimura's early work on stochastic processes turned out to be preadapted for the study of molecular evolution. He had a set of ready-made tools available, and he proceeded to exploit them with great vigor.

The neutral theory made a number of qualitative and quantitative predictions. Among these was that molecular changes occur at a rate independent of structural and physiological changes; Kimura noted that sharks, whose external form has hardly changed in an enormous time period, have as much molecular variation as rapidly evolving animal species, such as mammals. There were a number of similar predictions. One of the simplest and most remarkable is that the rate of neutral gene substitution in the population is equal to the rate of mutation of this gene per individual. This has permitted predictions of evolutionary rates; departures from these predictions provide evidence for natural selection. Rates that are slower than the neutral expectation can be attributed to 'selective constraint;' that is, the amino acids in this region are so specifically fitted to their function that any replacement doesn't work as well. Thus, essentially all mutations are harmful and are removed by natural selection (sometimes called purifying selection). Several proteins, for example some histones, are in this category. Any change in the molecular structure is harmful. In contrast, regions that evolve faster than the neutral rate are attributed to positive selection. An appreciable number of the mutations are beneficial. One of the best understood examples is the DNA region governing tissue transplants.

The neutral theory has provided a rational basis for the idea of a 'molecular clock' guiding the rate of evolution. The rough constancy of the mutation rates for comparable genes in different organisms—in particular that they are much more stable than the forces of selection—has led to the clock assumption becoming the basis for construction of phylogenetic trees, a field of great activity as molecular data are increasingly used.

At first, Kimura's theory was rejected out of hand by most evolutionists. But gradually, over the years, it has come to be widely accepted. It is now realized that a great deal of the DNA of higher organisms has no known function and that the actual genes constitute a small part of the DNA. At present it is accepted that most nucleic acid substitutions follow the neutral paradigm. As for amino acid changes, the jury is still

out. Clearly some changes follow neutral kinetics, others clearly are selected, and the proportions are yet to be sorted out.

3. An Assessment

Let it be said at the outset that Kimura's work has had its greatest impact on evolution theory rather than on the social and behavioral sciences. His work is very general and is applicable to the whole living world, of which that of greatest interest to social scientists, human evolution, and human behavioural evolution in particular, are only a part. Molecular evolution has yet to make the impact on human behavioral evolution that it is certain to make one day.

Kimura's greatest contribution has been to impose a stochastic viewpoint on the study of evolution. Beneath surface regularities (and irregularities) of form and function are a multitude of molecular changes, governed by the laws of chance. At present, research in behavioral genetics and evolution is based mainly on deterministic theory. Problems such as separating genetic from environmental effects are usually studied by such means as observing adopted children or identical twins reared apart, and the techniques are usually those derived from analysis of variance. But as evolutionary and population genetics theory becomes further developed and richer, and as the molecular basis of behavioral traits (including those in humans) are better understood, stochastic aspects will play an increasingly important role.

The study of natural selection and adaptation has long had difficulty in formulating clearly testable and falsifiable hypotheses. This has been particularly evident in the abundance of 'just so' stories; because we can think of a plausible reason for a structure or function doesn't necessarily mean that it arose for this reason (although it often has). One attribute of the neutral theory is that it can provide a null hypothesis for testing causes of evolutionary changes. For example, as mentioned above, the neutral theory makes a simple evolutionary rate prediction, against which departures can be measured. Thus far, this kind of reasoning has been used mainly for genes with physiological functions, but as the molecular basis of behavioral changes becomes better understood this kind of analysis will be increasingly applicable.

During his lifetime, Motoo Kimura received virtually every honor for which an evolutionary geneticist is eligible. In addition to numerous honors both in Japan and elsewhere, he was a foreign member of the United States National Academy of Sciences, the Royal Society of London, and the Chevalier de L'Ordre National du Mérite in France. He received honorary doctorates from the Universities of Chicago and Wisconsin.

Kimura's lasting impact is twofold. The first, best appreciated by population geneticists, is his enrichment of population genetic and evolutionary theory, especially as these are influenced by stochastic processes. The second, appreciated by a much larger audience, is his discovery of the enormous role that random processes play in molecular evolution. Kimura never denied the importance of Darwinian natural selection as the main evolutionary force shaping form and function, but beneath this, he emphasized, is an enormous play of random changes at the molecular level. In addition to Darwin's 'survival of the fittest,' he added the slogan, 'survival of the luckiest.'

Kindling, Neural Basis of

The epilepsies are a heterogeneous group of chronic brain disorders characterized by an enhanced susceptibility to spontaneous, recurrent seizures due to the excessive activation of neuronal networks. In recent years a number of widely diverse causes of epilepsy have been identified, including specific gene mutations, developmental defects, and acquired metabolic and structural abnormalities. For example, a mutation in a subunit of the nicotinic acetylcholine receptor is the basis of autosomal dominant nocturnal epilepsy, while other types of epilepsy have been linked to calcium channel defects (Clark and Wilson 1999). Abnormal brain development resulting in dysplasias and other cortical malformations may also lead to epilepsy (Guerrini et al. 1999). At almost any age, injury to the brain due to stroke, trauma, infection, tumors, as well as the adverse effects of alcohol and other neurotoxic substances may be epileptogenic. Despite this diversity, the multiple causes of epilepsy share at least one key feature i.e., they all produce long-lasting changes in neuronal physiology that result in recurrent spontaneous electrical discharges. Identifying the mechanism(s) of epileptogenesis will there-

fore lead to a more thorough understanding of brain function and contribute to the development of more effective pharmacologic treatments for epilepsy. While the underlying cellular processes responsible for the epileptic state remain unknown, a great deal of progress has been made in delineating the critical events associated with seizure induction and propagation, as well as epileptogenesis, primarily through the use of animal models. In this regard, the kindling model of epilepsy has played a dominant role.

1. *Definition of Kindling*

In 1967 Goddard demonstrated that daily administration of a subconvulsant electrical stimulus in rats caused a long-lasting change in brain function characterized by the subsequent development of generalized motor seizures. Since this initial report, electrically induced kindling in the mammalian brain has been one of the most widely employed methods to produce recurrent seizures both *in vivo* and *in vitro*. During the initial stages of kindling the inciting electrical stimulus usually produces no overt changes in behavior or electrical activity as measured by an electroencephalogram (EEG) (McNamara et al. 1992). However, with successive stimuli there is associated EEG evidence of hyperexcitability in the form of an after-discharge. Initially, the electrical seizure activity is unaccompanied by behavioral seizures. However, with continued periodic stimulation the duration of the afterdischarge increases along with the development of behavioral seizures. The behavioral stages of kindled seizures in rats can be classified according to the following classes: class 1, facial clonus; class 2, head nodding; class 3, contralateral forelimb clonus; class 4, rearing; class 5, rearing and falling. Once a class 5 seizure is reached, the subject is considered to be fully kindled. In this state, seizures can be elicited by low-level electrical stimulation even after a prolonged stimulus-free interval, indicating that kindling induces permanent alterations in neuronal physiology. Importantly, elicitation of an afterdischarge is required for kindling to occur. In addition to electrical stimulation, after-discharges can be produced by carbachol or other convulsant agents, as well as alcohol, which are used in models of chemical kindling.

2. *Kindling Properties*

Experimental evidence has demonstrated that different brain regions have varying capacities to develop kindled seizures (Sato et al. 1990). The regions most susceptible to kindling include limbic structures such as the hippocampus, amygdala, and piriform cortex, as well as certain areas of neocortex (Sato et al. 1990, McNamara et al. 1992). Interestingly, there is substantial overlap between epilepsy-prone regions in the rodent brain and those in humans, lending further support to the validity of using kindling models to study epileptogenesis in humans. However, it is important to point out that there are variations between kindling models. In this regard, there are clear differences between the electrophysiological and behavioral features following neocortical stimulation and those following stimulation of limbic structures, such as the hippocampus or amygdala (McNamara et al. 1992). For example, in contrast to amygdala kindling, the afterdischarge produced by stimulation of anterior frontal neocortex may be accompanied by behavioral changes at the outset. The behavioral features, however, are less pronounced than with limbic stimulation. Additionally, seizures evoked by stimulating frontal neocortex are relatively brief when compared to amygdala- or hippocampal-evoked seizures. Although not well understood, these differences may eventually be found to have clinical relevance in terms of modulating the responses to pharmacologic treatment.

The epileptogenic potential of a specific brain region appears to be closely correlated with the rate of kindling i.e., the amount of stimulation required to elicit a class 5 seizure (Sato et al. 1990). Thus, both the amygdala and piriform cortex require the least number of stimulations to reach the kindled state, while hippocampal kindling occurs relatively slowly. Evidence has suggested that increased kindling efficacy, particularly in the amygdala/piriform cortex region, may be related to strong connections with motor and other forebrain systems, as well as the presence of highly reactive neurons with pacemaker-like properties (Sato et al. 1990).

3. *Kindling Induces Changes in Gene Expression and Cellular Morphology*

Investigations employing the compound, 2-deoxyglucose, which labels metabolically active brain regions, have been performed in kindled animals. The results of these studies indicate that the regional pattern of activation following electrical stimulation appears to be stage-dependent i.e., during stages characterized by partial seizures the amygdala and piriform cortex are metabolically labeled, while other areas are subsequently recruited following further stimulation (Ackermann et al. 1986). Activation of brainstem structures such as the substantia nigra has also been reported in kindled animals. Regional increases in metabolic activity in the kindled brain can be correlated with the induction of molecular markers such as the immediate early gene, c-fos (Dragunow and Robertson 1987).

Immediate early genes encode transcription factors that are thought to play critical roles in regulating long-term changes in neuronal function and structure (Sheng and Greenberg 1990). These alterations are likely important in normal brain functions such as

learning and memory, as well as pathological conditions such as epilepsy (Sheng and Greenberg 1990). Transient activation of the c-fos gene has been demonstrated in both the hippocampus and piriform cortex of kindled animals (Dragunow and Robertson 1987, Dragunow et al. 1988, Simonato et al. 1991). Moreover, the spatial and temporal patterns of expression of c-fos and other immediate early genes, such as c-jun and NGFI-A, may undergo complex changes following a single afterdischarge (Simonato et al. 1991). These findings suggest that the transcriptional targets of Fos protein and other immediate early gene products may be critical effectors of the long-term modifications in neuronal function that are associated with kindling.

In addition to immediate early genes, kindling-induced alterations in the expression of growth factors, neuropeptides, and other proteins have been documented (Perlin et al. 1993, Kopp et al. 1999). Increased activity of calcium binding proteins has also been demonstrated in the dentate gyrus of kindled animals, suggesting that intracellular calcium may be an important modulator of epileptogenesis. Increased intracellular calcium associated with oxidative stress may lead to free radical formation and neuronal injury in some kindling paradigms (Rauca et al. 1999).

Kindling-induced effects have also been connected with morphological changes in neurons and astrocytes. Although the contribution of astrocytes and other glial elements needs to be clarified, both astrocyte proliferation and activation have been observed in the hippocampus and amygdala/piriform cortex of kindled rats (Sato et al. 1990, Adams et al. 1998). Studies in knockout mice suggest that the astroglial glutamate transporter may play a role in defining the duration of kindled seizures (Watanabe et al. 1999). Timm staining, a histochemical technique that is widely employed to evaluate synaptic reorganization following neuronal injury in the central nervous system (CNS), has been used in kindling studies (Sutula et al. 1988). An increase in the density of Timm-positive granules in the dentate gyrus of kindled rats supports the notion that mossy fiber collaterals terminate back on their cells of origin and thereby enhance the reactivity of the hippocampus (Sutula et al. 1988). In addition, the compelling results of ultrastructural studies have revealed kindling-induced changes in both the number and type of synaptic terminals, providing a possible anatomical basis for the long-lasting alterations in synaptic function (Geinisman et al. 1992).

4. *Excitatory Neurotransmission and Kindling*

A discussion of the neural basis of kindling would not be complete without addressing the role of exctitatory and inhibitory synaptic transmission. It is widely held that epileptogenic mechanisms are associated with alterations in the balance between excitatory and inhibitory synaptic functions in the CNS. Excitatory neurotransmission in the mammalian CNS is primarily due to the activation of glutamate receptors (Michaelis 1998). Although the molecular biology of glutamate receptors is beyond the scope of this entry, it is important to recognize that glutamate receptors are commonly classified on the basis of pharmacological profiles into ionotropic i.e., *N*-methyl-D-aspartate (NMDA), α-amino-3-hydroxy-5-methyl-4-isoazole propionate (AMPA), and kainic acid (KA) subtypes, as well as ligand-gated metabotropic receptors (Michaelis 1998). Each type of glutamate receptor is formed by an assembly of several subunits (i.e., NMDA receptors have five subunits), all of which have been cloned, sequenced, and functionally characterized. As expected, specific combinations of subunits can assemble into functional glutamate receptors with distinctive physiological and pharmacological properties (Michaelis 1998). Several features distinguish NMDA receptors from the other subtypes of glutamate receptors. These include a voltage-dependent Mg^{2+} block of the ion channel that is relieved by depolarization, sensitivity to glycine, and, most importantly, the ability to allow entry of Ca^{2+}, which is itself a key modulator of neuronal excitability (McBain and Mayer 1994).

Among the classes of glutamate receptors, the activation of NMDA receptors appears to play the most prominent role in modulating long-term alterations in synaptic function in the nervous system, a process that is referred to as synaptic plasticity (Mody 1999). NMDA receptor activation has been documented in the kindled state, and changes in specific channel properties have been proposed to form the underlying basis of enhanced NMDA function after kindling (Mody 1999). Among the NMDA receptor-related alterations that have been reported with kindling are prolonged channel opening, increased channel phosphorylation, enhanced agonist potency, and alterations in the Mg^{2+} block (Mody 1999). Evidence has also indicated that such alterations may last for up to one month or longer. In contrast, other studies have demonstrated either no changes in the expression of NMDA subunits, or minimal changes in the binding of L-[^{3}H]glutamate to NMDA receptors after electrical or chemical kindling (Ekonomou and Angelatou 1999, Mody 1999). Additional evidence supporting a prominent role for NMDA receptor activation in the development of kindling is provided by studies employing NMDA antagonists. NMDA receptor antagonists such as aminophosphonovaleric acid (AP5), and channel blockers such as MK-801, are highly effective at inhibiting kindling development (McNamara et al. 1988, McNamara et al. 1992). For reasons that are at present poorly understood, these same antagonists are relatively weak suppressors of seizures in previously kindled animals.

5. *Inhibitory Neurotransmission and Kindling*

As ligand-gated $GABA_A$ receptors are responsible for most of the inhibitory neurotransmission in the mammalian brain, it is reasonable to surmise that repression of GABAergic synaptic inhibition may promote seizure development and kindling. Analogous to glutamate receptors, $GABA_A$ receptors are composed of different subunits that assemble into functional channels that regulate Cl^- ion conductance, ligand affinity, and sensitivity to modulators (Luddens et al. 1995). Although a decrease in synaptic inhibition may lead to increased neuronal excitation, the role of altered GABAergic synaptic transmission in the development of epilepsy remains controversial. Changes in the expression of $GABA_A$ receptor subunit proteins, as well as increased sensitivity of channels to modulation by Zn^{2+} have been demonstrated (Mody 1999). However, both enhanced GABA binding as well as an increase in the number of $GABA_A$ receptors have been reported in the kindled hippocampus (Mody 1999), consistent with increased synaptic inhibition.

Taken together, the results of these and other studies suggest that kindling induces alterations in glutamatergic or GABAergic synaptic functions characterized by effects on either intrinsic channel properties or synapse topology, respectively. Thus, altered synaptic excitation is primarily due to changes in the physiological properties of NMDA receptor channels, while changes in synaptic inhibition are due to alterations in $GABA_A$ receptor numbers, subunit composition, and ligand affinity. Whether epileptogenesis is associated with an imbalance between glutamatergic and GABAergic functions, however, remains to be determined.

6. *Relevance of Kindling to Human Epilepsy*

Because of the strong correlation with long-term alterations in brain function the kindling model is highly relevant to the study of chronic epilepsy in humans. In this regard, it is important to recognize that the permanent changes produced by periodic subconvulsant stimuli distinguish kindling from other seizure models i.e., electroshock or the administration of compounds such as pentylenetetrazol, in which single seizures are produced in an otherwise normal brain. This has important ramifications for pharmacotherapy, as agents that may be effective anticonvulsants in single seizure models may not prevent kindling-induced seizures. One example is the NMDA receptor channel blocker, MK-801, which inhibits electroshock-induced but not kindled seizures (McNamara et al. 1988). In addition, a distinction must also be made between drugs that are anticonvulsant and those that are antiepileptogenic. Accordingly, compounds such as MK-801 may be more effective at inhibiting the development of kindling (i.e., antiepileptogenic) rather than kindled seizures (anticonvulsant), while other drugs such as carbamazepine may block kindled seizures but not kindling development (Sato et al. 1990). Further, drugs that have both antiepileptogenic and anticonvulsant properties (i.e., valproic acid) may provide greater therapeutic efficacy against epilepsy. It is therefore important to include the kindling model in drug-screening programs aimed at identifying antiepileptogenic compounds for use in humans.

Additional similarities to human epilepsies provide further rationale supporting the use of the kindling model to study human epileptogenesis. Many of the behavioral and electroencephalographic features of kindled seizures in rodents bear a striking resemblance to those of temporal lobe epilepsy in humans. Surprisingly, attempts to produce complete kindling (i.e., class 5 seizures) in nonhuman primates have met with limited success. Although class 4 and class 5 seizures can be elicited in baboons, experimental evidence has suggested that there may be strain-dependent differences in the susceptibility of nonhuman primates to kindling (Sato et al. 1990). Nonetheless, the ability to induce kindling in nonhuman primates supports the idea that a kindling-like mechanism plays an important role in the development of epilepsy in humans. In addition, several groups have reported the development of recurrent seizures in patients who have received repeated periodic electrical stimulation to the brain for the treatment of either schizophrenia or chronic pain (Sato et al. 1990). These observations lend strong support to the idea that kindling does occur in humans.

If the kindling pathway is a critical component in human epileptogenesis, then the identification of pathophysiological conditions that may promote kindling becomes increasingly important. There is accumulating evidence suggesting that a focal brain injury may lead to increased neuronal excitability and repetitive discharges that, under certain circumstances, may kindle surrounding structures. In addition, it has been recently proposed that hippocampal damage due to febrile seizures in early childhood may lead to focal neuronal hyperexcitability resulting in the development of temporal lobe epilepsy (Chen et al. 1999). This idea is supported by investigations using glutamate analogues such as kainic acid (KA). Selective neuronal degeneration following KA treatment results in sprouting of hippocampal granule cell axons and formation of recurrent excitatory synapses that may result in abnormal repetitive discharges and a kindling-like process (Routbort et al. 1999).

7. *Summary*

Kindling is a phenomenon that is characterized by a progressive and long-lasting increase in seizure susceptibility, or epileptogenesis, resulting from the administration of periodic subconvulsant electrical or

chemical stimuli. The electrophysiological and behavioral features of kindling have been well defined and may vary with brain region. Limbic and specific neocortical regions have the greatest potential for kindling. Kindling-induced brain activation is associated with altered gene and protein expression in neurons and glia, as well as morphological changes that contribute to long-lasting modifications in neuronal structure and function. Additionally, changes in both excitatory glutamatergic and inhibitory GABAergic synaptic neurotransmission have been demonstrated in the kindled brain. Similarities between the kindling model and human epilepsies provide further justification for using kindling to study epileptogenesis in humans. Recent evidence suggests that a kindling-like process may lead to the development of epilepsy following a focal injury to the brain. A more thorough delineation of the cellular and molecular events underlying kindling will therefore provide a greater understanding of epileptogenesis in the human brain, and could lead to the development of more effective antiepileptic treatments.

Kinship in Anthropology

Studies in kinship, and the related institutions of marriage and the family, have until recently been central to anthropological investigation and debate.

The problem of handling the topic of kinship cross-culturally is the key to understanding the historical development of a large majority of anthropology's central analytic concepts, theories, and methods. Deliberations over the puzzles of kinship and marriage gave rise to the discipline's most sophisticated technical and theoretical elaborations, and its most virulent, ever-present controversies. It was also assumed to be the area of technical competence, the most demanding of rigor in thought, through which anthropology could best defend its scientific respectability. As a result, kinship was that aspect of social life that became the linchpin for the unfolding of all the grand paradigms of thought within anthropology, whether it be Morgan's narrative of evolutionism (1871), Malinowski's functionalism (1930), Radcliffe-Brown's structural-functionalism (1952), or Lévi-Strauss' structuralism (1969). As Fox (1967) could still comment, 'kinship is to anthropology what logic is to philosophy or the nude is to art; it is the basic discipline of the subject.' The situation has, however, changed.

Nowadays at least two major questions can be asked. First, why did anthropologists predominantly prioritize kinship over politics, economics, and religion? Second, why lately have they shown a decided *lack of interest* in kinship, or rather in 'kinship' as it was conceived traditionally within anthropology? The answers will take us to problems in the major presuppositions underlying anthropology's highly valued analytic constructs of kinship and society. Although it has been the case that kinship from the start has always been the object of strident debate, it is only since the 1960s that the legitimacy of the topic itself began to be queried. In more recent years the process of doubting has accelerated due to very basic epistemic shifts within anthropology in the wake of feminism and other modes of disciplinary self-inspection about its claims to knowledge. One prevalent conclusion forthcoming from such transformations is that much of received kinship theory is no longer seen as justifiable.

1. *The Narrative of Kinship*

1.1 *Law and Order by Another Name*

The primary puzzle for the anthropologist throughout the first half of the twentieth century was how to explain the maintenance of order within the 'simple societies' of far-flung regions where anthropologists conducted their research. Such societies lacked the basic law and order organizing institutions of Western society. They had no government to speak of, no marketplace as we know it, and no law courts, police, or armies. It was clear that they did not compartmentalize their social life into the distinct and separate institutions that we recognize as kinship, economics, politics, and religion. Anthropologists found instead that these peoples used the *idiom of kinship* to frame most of their activities, including those with political, economic, and religious intent. Analytically, the step from this insight was to view kinship to be the major institution of 'tribal' societies, and the kinship tie to be the one that compelled all others in social relations. Kinship, as the strongest of social bonds, became seen as the basis through which 'primitive' societies maintained order; it was through kinship ties that people created relations of social solidarity. Thus, 'social structure,' that is, those rules regulating the kinship, marriage, and residential institutions of a people that endow social role and identity, and which, therefore, perpetuate societal relationships, became anthropology's proper object of inquiry (e.g., see Radcliffe-Brown 1965). Everything else, a society's morals, law, etiquette, religion, politics, and education, was to be studied as but an aspect of social structure (Radcliffe-Brown 1965), or in other words its kinship system.

The emphasis anthropologists placed upon the problem of 'societal order' cannot be stressed too much. As Firth comments, the perception of order was fundamental to their investigation (Firth 1961). An underlying concern was over what could replace the authority of government in 'simple' societies, and the answer was to view kinship as having this coercive power. In other words, it was the kinship system that came to be understood as playing the same official function among 'primitive' peoples as government does in western societies. The reasoning leading to such a conclusion is circular, for kinship as a system became defined as the primary source for the rules and regulations that provided for order and continuity within 'native' society. It was presumed that the status, role, rights, duties, and obligations of a person in a 'simple society' were forthcoming from and ascribed by the person's place within the kinship system. The primary societal organization of these societies was then understood to be 'kinship-based,' and it was the 'kinship polity' (see Fortes 1969) forthcoming from either patrilineality or matrilineality that was the key concern. The slippage was simple: we have government, while they have the politics of kinship.

The evolutionist agenda underpinning such kinship theory is obvious, despite the Functionalists' claim to the contrary. It was a bias that assumed that the history of humankind's social development discloses a progression that moved from a reliance upon the natural facts of kinship, and the cultural elaboration of them, to a Western style of development that increasingly compartmentalizes the societal institutional ordering of kinship, economics, politics, and religion in such a way that kinship eventually becomes deprioritized. Anthropology's main object for study has been modern Europe's alien other, all those 'primitive' peoples attached to worlds marked as an uncivilized part of nature to be transcended and dominated by modern civilization. In large part

anthropology's technical vocabulary has denoted primitivism, and 'kinship' is no exception. First of all, the institution of kinship, more than any of the other primary domains of society, was understood to be the one most closely linked to the natural in human activities: while kinship can modify nature, it cannot transcend it. As Schneider (1984) argues, an axiom critical to kinship theory has been that the social and cultural attributes of kinship are derivative of the biological relations of reproduction. Thus, if all those alien societies studied by anthropologists were kinship-based, and if for their people the idiom of kinship took priority over economics, politics, and religion, their primitive status was further confirmed.

1.2 The Plot Thickens: The Distinction between the Domestic and the Jural

The 'law and order' thrust of traditional kinship studies, which equated the kinship system (of 'primitives') to 'society' itself, also came to include the critical distinction between the 'domestic' and 'jural' domains of kinship. The realm of the domestic was composed of relations of filiation between parents and children; it was the domain of the hearth, the family, the husband, his wife, and his children. In Fortes' terms (1969), it was the domain where the 'axiom of amity' reigned. In contrast, within the 'jural' domain the everyday relations of amity and filiation were for the most part irrelevant, for the principles of descent and lineage ruled its membership and provided the backbone for its jural structures of dominance and subordination. It was the jural domain that comprised the polity and, thus, provided society with its order and continuity. The prescriptions and regulations of the kinship polity (composed of its 'corporate descent groups') were what ruled and constrained 'primitive' people. A man's jural status, rights, and obligations within society were in essence provided by his place within the lineage of his birth. Genealogy determined one's political status, and one's rights to land and other entitlements.

Given the above narrative of the place of kinship in 'native' societies, we can understand that the received wisdom of kinship theory until as late as the 1970s was that unilineal descent systems were necessary as a sticking plaster of 'primitive' societal order—despite increasing evidence to the contrary. As Radcliffe-Brown (1965) asserts, 'unilineal institutions in some form, are almost, if not entirely, a necessity in any ordered social system.' Even Lévi-Strauss, in his major critique of descent theory in kinship studies, finds the existence of unilineal descent essential to the logic of his model of elementary structures of marriage exchange. He says that this is because the social cohesion of elementary systems of kinship that are premised on the notion of groups of men exchanging wives requires a rule of descent, for the groups themselves must be defined by such a 'stable' rule of descent (Lévi-Strauss 1969). One should be aware, however, that Lévi-Strauss began his formidable attack upon the prevalent view of 'descent as societal order' in 1949, and that his stress upon alliance over descent as the salient ordering principle of 'primitive society' did not become part of mainstream debate until the 1960s (e.g., Leach 1961, Needham 1964), but also see the earlier debate between Radcliffe-Brown (1953) and Dumont (1953). The concern of Lévi-Strauss, it is to be noted, was with creating a minimal model of society by showing the ways in which kinship groups were integrated through rules of marriage exchange, that is, he wished to demonstrate how classifications of kinship and marriage logically provided a broader level of societal integration than that achieved through rules of descent alone.

The rather chauvinistic reductionism of the structural functionalist and structuralist grand paradigms of society and societal ordering, where society itself was to be equated with male structures of order and control, took another couple of generations to unveil and unravel.

2. The Question of Definitional Rigor

2.1 Kinship, Descent, and Marriage

In itself, a fuller ethnographic record began steadily to undermine many of the major analytic constructs of kinship and societal order, particularly the idea that 'primitive society' was universally based upon exogamous, corporate, land-holding, unilineal descent group structures. By the 1950s and 1960s reports of field research especially from the Pacific on kinship systems that were not premised on a unitary rule of unilineal descent but upon cognatic, bilineal, ambilineal, or double descent principles became legion (cf. Bohannan and Middleton 1968). The debate over the unitary view of unilineal descent basically was closed by the influential article by Scheffler (1966), who was able to demonstrate through the ethnography by then at hand that notions of descent were used among different peoples, and by the same people, toward highly varied ends, and not necessarily toward that of corporate group structure.

By the 1970s, for instance, through the ethnography from Amazonia that began to enter mainstream debates on kinship and marriage, it became clear that the notion of descent itself could hardly be declared a universal principle of 'primitive' social ordering, for there were peoples who did not recognize a principle of descent as relevant for any social or political purpose (e.g., see Rivière 1969, Overing 1975). Even kinship and marriage as analytical constructs *per se* came also under attack, especially the notion of achieving any type of unitary view of either (but also, see Leach's

(1961) earlier hacheting of these sacred constructs of societal ordering). We find Needham (1971) announcing flamboyantly that 'there is no such thing as kinship, and it follows that there can be no such thing as kinship theory!' He was referring to 'minimal' definitions of kinship when framed in the context of genealogically reckoned jural rights, such as their allocation and transmission from one generation to the next. Cross-culturally, the ethnographic evidence could not uphold a totalizing view that assumed a predictable relationship between the cultural constructs of kinship and its classification, social roles, rights, and obligations, and the allocation of individuals to particular types of social groups. It was this unitary package of kinship as part and parcel of particular politico-jural orders that earlier anthropology had indeed upheld.

Even more courageous for the times are Rivière's (1971) queries into the analytic concept of marriage. He argues against any jural definition of marriage, and suggests instead that the institution of marriage first be viewed structurally, as one of many relationships conceived possible between men and women. It was his reading of the ethnographic literature that anthropologists had been defining institutions cross culturally as 'marriage' when the said institutions in fact had 'no feature in common other than that they are concerned with the conceptual roles of male and female' (Rivière 1971). In other words, to understand what marriage is for any given people the question of the cultural construction of gender relationships must be understood, rather than the jural relations between groups of men that entail their exchange of women.

It is significant that Rivière's fieldwork experience had been with indigenous peoples of Amazonia, for whom anything approaching a 'jural' relationship usually would be stretching the point, as too would lineages and descent-group ordering as normally discussed in the literature. It was as difficult to find corporate land holding groups among Amazonian people, as the elders who might rule them. There were no *groups* of men forming ties of alliance through the exchange of their women. Instead, ties of marriage, which moreover were highly salient to Amazonian constructs of sociality, were linked to a principle of cognation and not descent. As a consequence the contributions of Amazonian specialists, in line with Dumont's (1957) reading of marriage alliance in India, played a major part in the later reinterpretation and unraveling of both alliance theory as first formulated by Lévi-Strauss and descent theory as formulated by Fortes and Radcliffe-Brown.

2.2 The Structural Analysis of Kinship Terminologies: The Power of the Paradigm

It is by now obvious that we cannot achieve an analytic definition of the construct of kinship and related institutions that would be both universally adequate and at the same time respectful of indigenous understandings and knowledge. In short, anthropology cannot, even if it wished, arrive at a universal definition of kinship. Part of the dilemma is of course linguistic, insofar as most of the important analytic terms of anthropology have not only been highly abstract but also continued to carry the complex historical baggage of western thought and practice. Terms such as society, community, family, kinship, descent, lineage, or structure, function, and system, are to be used at the peril of totally eluding another people's understanding of what they are doing socially—which, one would think, is the very *raison d'etre* of the anthropological task. As anthropology slowly came to realize, any 'definitional rigor' to be achieved through the use of any of these terms is well-nigh impossible. Such constructs tend to sit within particular and forceful paradigms of social order, and therefore carry all the litter of such grand narratives. Structural functionalism was followed by structuralism, and the structural analysis of kinship terminologies was a particularly obvious case of a paradigm so powerful that its highly reductive results killed for the time being the possibility of interesting further advances being made in kinship theory, the very area where anthropology was once so creative and rich in debate.

The overwhelming allure of structural analyses of kinship can be ascribed to the power of their methods which wed anthropology to advances in modern linguistics, a field considered to have become the most scientific of the human sciences. The methods and models of formal analysis were so enlightening of previously misunderstood structures that they gave promise to a mathematical rigor and definitional clarity that would transform anthropology into a 'true science.' Their initial success was so stupendous (e.g., see Lounsbury 1968) that they made seeming child's play of previous attempts to provide order to the complicated structures of many 'native' kin terminologies. Anthropologists were taught to be more rigorous in discerning the logical differences between systems. Such sophistication in method was greatly needed in anthropology, and for its example we can be only grateful.

However, as Overing (1987) has noted, the method became confused with world view. The logic of the method through sleight of hand became equated to the logic of terminological use, and thus also with indigenous thought. As a result, we arrived once more at the 'universal' to what Schneider so aptly derides as the anthropological 'Doctrine of the Genealogical Unity of Mankind' (Schneider 1984) or the genealogical meaning of kinship terms. Kinship is, everywhere, first and foremost about genealogical relatedness (see especially, Scheffler 1978), a resoundingly uninteresting conclusion to come in the wake of such dazzling structuralist performances. It

was also a judgment that was highly suspect. It appears that the method itself allowed for no other interpretation because the meanings of terms were made to fit not only the domain of logic, but also western commonsense notions about what kinship is. The demand itself of formal analysis for logical rigor reduces the number of its elements that account for meaning to very few: affinity as well as consanguinity can be allowed, but not the further complications of what such notions possibly mean from the indigenous point of view. It was the niggling doubt over this issue (where are all the people?) that drove many anthropologists away from the technical chore of analyzing kinship logics. As Campbell (1985) remarks, the very abstract level at which structural analysis operates is about the tenth remove from anything going on in daily practice and thought.

The more recent formal analyses of kinship terminologies in the hands of scholars such as Héritier (1981) move in the more promising direction of not assuming indigenous meaning. The aim instead is to specify the structural possibilities of a given classificatory system that in turn frame or limit the choices made in reality. In short, the exercise is no longer directed toward the task of uncovering hidden layers of meaning, but to explore the interplay between structure and the semantics of actual use.

3. *Is There Hope for Kinship?*

Schneider (1984) advises anthropologists not only to stop looking for 'kinship' but also all the other metacultural categories of economics, politics, and religion which, together with kinship, form a quartet of societal domains embedded in European culture and have been willy-nilly incorporated into the European social scientist's analytic schemes. While we can heartily agree with Schneider's full blown rampage against the anthropological treatment of the topic of kinship, such concordance does not entail the dismissal of the study of those social relationships, and their classifications, that were once, more or less, subsumed under the label of 'kinship.' People do bear children, and there is a social framework through which they do so, and through which these children are raised to become adult members of human social groups. The members of these social groups follow particular practices in the course of which relationships that are highly significant for them are developed, as too are very interesting ways of thinking about them. With all this we can agree. The overriding question still remains—how do we understand and translate such practices, relationships, and ways of thinking?

Happily, since the 1980s, anthropologists have developed a myriad of ways to approach subjects that formerly would have been classified under the general rubric of 'kinship.' While nowadays the topic of something called 'kinship' does not loom large in the literature, such issues as 'self,' 'agency,' 'gender,' and the life of values and affect, do. The topics of personhood, emotions, and aesthetics are much more likely to take their place in the titles of doctoral theses than those of kinship, affinity, and jural rules. Thus, we see that the 'technical' language of anthropology has been transformed in the wake of the shifts of attention away from something we once called the 'jural-political domain,' with its contrast to something we labeled 'the domestic group,' and equally removed from the notions of social structure and prescriptive behavior, and those of rights and obligations. In their place, idioms of equality and inequality are now being explored, and such values as nurture, sharing, generosity, and those of peace and violence. The stress is upon ambiguity, flux, the personal everyday, and a multiplicity of voices, rather than upon grand structures of mind and society and societal rules and regulations. The emphasis tends to be upon context and the performative, and not underlying and hidden rules of practice and thought. Such shifts in direction have often been undertaken in a spirit of rebellion, by feminists but also many others, against the ethnocentrisms underpinning the grand narratives of anthropology. The gain has been that anthropologists are presenting very different pictures, certainly in their richness, from those of yesterday of the ways other people view, act, and experience the world of the social. These depictions in themselves are further enlightening of the previous 'sins' of reduction, prejudice, and ethnocentrism.

3.1 *The Impact of Gender Studies*

It has made all the difference to the ethnographic endeavor to include the subject of women and especially women's voices. In the process we have time and again discovered a rich symbolic world that demands an understanding of the interplay of men and women, and their respective knowledge, that makes travesty of the simplistic 'male only' models of yesteryear. It is only by understanding both male and female (often complementary or conflicting) perspectives that gender relations among another people can begin to be comprehended. As gender studies progressed, it became absolutely clear that the authoritative voice of the ethnographer was insufficient, as too that of the male 'informant' (not a designation that we can use today!). Nor can we speak from the perspective of a generic female, for there is no such thing. There is ever a plurality of voices, a seemingly helter-skelter chiming that provides, significantly, fertile layers of evaluative contextualization, the recognition of which has in the end changed our anthropological visions of culture and society.

All those kinship structures through which men established important relationships with each other through the exchange of their muted women, which

became the model of 'society'; all those 'political' roles and statuses through which men who controlled the political domain came to be the knowledge-holders of their culture—these were the topics that once were recognized as primary anthropological concerns. From the 1970s onwards, once women were inserted firmly within the context of 'establishment' discourse in anthropology, the consequence was a true 'Kuhnian' shift of paradigm. The epistemological and methodological foundations of the discipline were indeed shaken when females, fifty percent of the world's population, finally entered the picture. Thus, the 'question of women' did play a large part in upsetting established ways of thinking and practice in anthropology, and not least in regard to the topic of kinship.

One major contribution of the early writings on gender was to make anthropology clearly aware of its exclusion of women as a topic for study, and how such oversight was, moreover, linked to the male bias of dominant theoretical and methodological assumptions of the discipline, and beyond that to major strands of western thought in which anthropology played its part. In *Women, Culture & Society*, its authors show how women, like men, transculturally 'are social actors whose goals and strategies are intrinsic to the process of social life' (Rosaldo and Lamphere 1974), and that 'even in situations of overt sex role asymmetry women have a good deal more power than conventional theorists have assumed (Rosaldo and Lamphere 1974). It became quickly obvious that major presuppositions and procedures of the discipline needed to be reconsidered radically in order to include the agency of women. In other words, studies of social life and its organization needed to include women as actors and speakers and not as mere passive, muted objects of men. It slowly came to be seen that women as well as men played a major role in the creation of social ties of community life.

There is by now a large amount of ethnography telling of indigenous peoples among whom the women, both ideologically and in practice, control their own labor, and the products of it (see much of the contemporary literature on Amazonia). Likewise, values—and the structures of equality and inequality linked to them—may not be so straightforward, but ambiguous, as among the Hagen of New Guinea where there is constant play between egalitarian and hierarchical principles (e.g., Strathern 1988). There are also now many ethnographic examples showing that the quality of the relations between the genders may well be subject to perspective, where females have a very different view from males of the strength of their respective roles and participation within the social life of the community (e.g., Keesing 1987). This stress in studies of gender upon the critical importance of presenting perspective and thus allowing for the 'authorship of many' has led to energetic debate over the epistemological foundations of anthropology, which in turn has transformed the question, the topics, and the methodology of the discipline—and in the end its own self image as having the right of authorial privilege.

3.2 Kinship by Another Name? Networks of Relationships and Personal Kind Terms

We find that Schneider and Needham, as pioneers in the deconstructing of key concepts of kinship theory, were merely tapping the surface of a modernist creation for which the very notion of kinship was but one aspect of a multifracteled edifice filled with assumptions about society and the social order, that in turn were tied to networks of ideas about the relation of the family to other societal institutions, and the relationship between the sexes, the private and the public, the dominant and the subordinate, all of which were implicated further by presuppositions about the nature of human existence, and its progress, which in addition were premised upon ontological notions of the priority of reason over the emotions, and so it continued through an enormous number of other dualisms and bundles of relations pertinent to the western imagery of society and the world, and the elements of which they were comprised. Our notion of kinship carried with it the interarticulations of this entire structure.

The interesting lesson that has been learned more recently through changing the types of questions anthropologists' ask is that other people's views of the social relationships of everyday life are as enmeshed as our own within wider networks of meaning. They also include ontological presuppositions about the nature of human existence and capabilities for sociality that are linked to bundles of relationships and arrays of ideas about the world that are as complex as our own. How do we then understand these other sets of linkages, so unlike our own? That has become a primary question. The quest for understanding their interconnections has in part required the unpeeling of our presuppositions about reproductory and biological processes, parenting, the nature of the material world, and the interconnections of all of these things to what we call Society (cf. Strathern 1992).

Overing (1985) has suggested that to understand better the complexity of indigenous social thought, we should change the label of what we have been calling 'kinship terms' to 'personal kind terms.' This involves a radical switch in perspective that concomitantly raises the conceptual status of these terms to one more closely aligned to the indigenous view and practice. As with many of our own constructs of 'natural kinds,' 'personal kind terms' are also highly abstract, philosophically important concepts that defy unitary definition. They share the openendedness and elusiveness that is typical of all abstract terms that comprise complex relational properties. The difference is that

personal kind terms do not refer to the world of nature, which is the western domain of competence, but to qualities of personal relationships, the area that indigenous people have opted for theoretical elaboration (cf. Horton 1979). We have reduced their personal kind terms to our own very weak language of kinship, one that speaks of 'consanguinity,' 'affinity,' 'social category,' and 'amity,' which is often a bad mistake. These terms, as used in everyday life, can have metaphysical weight that goes well beyond our western notions of a 'biological' relationship or one through marriage. Moreover, the quality of the relationship they demonstrate, as, for instance, one of nurturing, teaching, treachery, competition, or predation, may override a more 'physical' kind of relating. Will this man or woman work tranquilly with me, or have predatory designs that will make me ill?

Certainly in Amazonian ethnography, the emphasis today in investigations of peoples' use of relationship terminologies is often upon the metaphysical and/or moral loading of the classifications (e.g., Teixero-Pinto 1997, Viveiros de Castro 1992, Overing 1985). For instance, Kidd writes about the Enxet of Paraguay that:

> Their understanding of why they act as they do centres on their concept of the *waxok*, an aspect of the self that is both intensely private and inherently social. They insist that their social behaviour—both appropriate and inappropriate—can be explained by the physical—or metaphysical—state of the *waxok*. Furthermore, because the *waxok* is also the centre of cognition, people can also consciously transform it so as to enable themselves to act in either a self-centred or other-regarding manner. It is an explanation that, I believe, we should take seriously if we want to understand indigenous social life and it is one that finds its root in the practice of child-raising, in the creation of 'good/beautiful' people who have been taught not only how to think but how to feel. It is this *waxok*-centred combination of thinking and feeling that enables the Enxet to act appropriately and which, ultimately, guides them as they strive to generate sociality and engender tranquillity (Kidd 1999).

The peoples of Amazonia have been difficult for anthropologists to believe, and to an interesting extent still are (cf. Overing 1999). For many of these people the personal ties of parenting, nurturing, sharing, and pooling are not premised primarily on a notion of 'biological linkage' or a 'linkage through blood,' or membership within a jural group, but which instead are generated over time through consistent and processual action. As such, the personal quality of a relationship as made manifest through everyday practice is paramount to its classification. In other words, the ongoing quality of a relationship (as in the 'growing' of a child by a parent and child, the mutual care of brothers, or sisters, or of any other personal relation) may have generative value in a material sense that goes far beyond the minimal possibilities that are endowed through the act of sex (e.g., Gow 1991). For sure, the personal kind terms that are here being applied to their nearest and dearest, and to those further afield, are about reproductory possibilities, but it is not 'reproduction' in the sense that the anthropologist imagined it in traditional kinship theory.

4. *Kinship is Alive and Well!*

In fact, we can say that kinship studies are as alive and well as always in anthropology, in that the personal relationships and activities of parenting, nurturing, and the processes of generating and gendering of bodies into social adulthood hold center attention. Such studies are, however, unrecognizable as pertaining to the kinship theory of yesteryear. A similar reorientation of concentration is as clear in Melanesian studies as in those of Amazonia (e.g., Strathern 1988) where personal relationships are discussed through categories very different from the former ones of prescriptive rule, roles and statuses, and social structure, and where the talk instead, as among Amazonianists, is upon the indigenous understandings of such matters as gender distinctions, the contents of the self and the mastery of them, and the construction of human bodies; it is about indigenous ambiguities over the nature of personhood and the various possibilities of agency in this world and others, and the elaborate relation of these issues to indigenous practice, the life of affect, and their metaphysics. In other words, a dialogue is being created between us, the anthropologists, and them, the peoples of New Guinea or Amazonia, over what it means to be human in this world, or female humans, male humans, or betwixt and between? What does it mean to be social beings in this world? How do we go about attaining this state? If for other people the western grand distinctions between society and nature do not hold, what other possibilities of an interesting kind are there? These are very different questions from those asked in mainstream anthropology in the 1970s and 1980s.

Kinship Terminology

Kinship terminology forms the most complex, orderly, and cross-culturally variable, part of a language's vocabulary. These characteristics make it central to semantics (Sect. 1). At the same time the use of kinship terms as address terms brings in considerations of footing, which can detach the logic of address usage from that of referential use, necessitating more contextual accounts of kin term use (Sect. 2).

Kinship terminologies often reflect the culturally patterned ordering of social categories of descent, marriage, and alliance, and this has ensured their enduring interest to anthropologists (see *Kinship in Anthropology*). It is now clear that the diversity of kinship systems around the world boils down to a restricted set of variants on a few basic types. These typologies of kinship systems are discussed in Sect. 3.

1. Semantics of Kin Terms

The challenges posed by kin terms can be illustrated by comparing English and Marri-Ngarr, an Australian language (Scheffler 1978). Fig. 1 illustrates the Marri-Ngarr system schematically, while Table 1 lists the full set of denotata for selected terms. In analyzing kinship, we distinguish *kin terms*, which are emic (language-internal) categories, from etic (universally discriminable) *kin types*, the set of denotata a particular term includes. Thus the English kin term 'uncle' includes (at least) the kin types father's brother (FB) and mother's brother (MB). Other abbreviations we will use are C (child), S (son), D (daughter), H (husband), W (wife), Z (sister), m (man speaker), w (woman speaker), e (elder), y (younger).

To avoid clutter, many kin types known by the same kin term are omitted from Fig. 1. For example, in Marri-Ngarr same-sex siblings always receive the same

Figure 1
Marri-Ngarr kinship system (source: Falkenberg 1962, p. 39)

kin term: F and FB are both known by *it:a*; but only the first is given in Fig. 1, though both are listed in Table 1. Further, since a FB is equivalent to a F, his sons are equivalent to father's sons, in other words to brothers, meaning that this type of cousin (FBS) also falls into the 'brother' category, *ngauwe*.

The first dimension on which these systems differ, then, is that Marri-Ngarr but not English is 'classificatory'—by using certain principles of extension, it extends indefinitely outwards to encompass the entire social universe. A corollary is that the distinction between consanguineal (or 'blood') and affinal relatives (related by marriage) is hard to maintain, since any potential in-law is already related as a blood relative: the rule favoring marriage to certain cousins (FZC) means that a man's FZH who, as in English, is a type of uncle (*kaka*), is at the same time a potential father-in-law. In English, on the other hand, kin terms take in only a fraction of the social universe, and in general consanguineal and affinal terms are distinct.

The second striking difference is in how the denotational space is carved up. We focus on just one of the many differences that exist. Both languages have four terms to cover parents and their siblings, but in English father and mother, who are 'lineal' relatives lying directly on the descent line, are distinguished from the 'collateral' relatives uncle and aunt, which take in any siblings of parents, whether same sex or opposite sex. However, in Marri-Ngarr, parents' same-sex (*parallel*) siblings—FB and MZ—are known by the same term as the parents themselves, in contrast to parents' opposite-sex (or cross-) siblings, who receive distinct terms (Fig. 2).

The cross vs. parallel distinction, although irrelevant to English, pervades the Marri-Ngarr system. The distinction between 'cross-aunts' and 'cross-uncles' (*ngaia* and *kaka*), related to one's parents by an opposite-sex sibling link, and 'parallel' aunts and uncles (*kela* and *it:a*) is the key to understanding how 'cousins' get divided into two categories: cross-cousins (*manggen* if female, *do'goli* if male)—children of cross-aunts and cross-uncles and therefore potential spouses—vs. parallel cousins, the children of one's parallel aunts and uncles, who are treated as siblings and are not possible marriage partners. The cross vs. parallel distinction is reflected in kinship terminologies around the world and there are good social reasons for its importance. If membership in social groupings is passed down a patrilineage or matrilineage, then you are in the same group as your parallel relatives but in a different group from your cross-relatives.

The complexity and cross-linguistic variability of kin terms makes them a fertile testing ground for theories of semantics. During the structuralist semantics period of the 1950s and 1960s a common approach was to represent meanings as clusters of abstract features, a technique known as *componential analysis* (see D'Andrade 1995 for a recent evaluation). The appeal of these analyses lay in their economical use of small numbers of components which combine to generate large numbers of terms, and in the way in which particular terms with wide reference could be defined through the use of abstract components which range over a large class of kin types.

Burling (1970) illustrates the application of componential analysis to Njamal, whose kinship system closely resembles the Marri-Ngarr system above. The Njamal term *mama*, for instance, which takes in a comparable range of kin types to the Marri-Ngarr *it:a*,

Table 1
Full set of denotata for selected Marri-Ngarr kin terms

	Term	Gloss	Primary denotata	Other denotata	English translation equivalents
1	*tjan'angga*	Parallel grandkin	FF, MM	FFB, FFZ, MMB, MMZ, FMBW, MFZH, mSC, wDC, ZDC, BSC, HZCC, WBDC	Grandfather, grandmother, great uncle, great aunt, grandson, granddaughter, great nephew, great niece
2	*it:a*	Father	F	FB, FFBS, FMZS, MMBS, MFZS, WMB	Uncle, second cousin once removed, mother-in-law's brother
2a	*it:a il:ingeri*	Wife's mother's brother	WMB		Mother-in-law's brother
3	*ngaia*	father's sister	FZ	FFBD, FMZD, MMBD, MFZD, MBW, WM	Aunt, second cousin once removed, mother-in-law
3a	*ngaia il:ingeri*	Wife's mother	WM		Mother-in-law
4	*kela*	mother	M	MZ, MMZD, FMBD, FFZD, FBW, WFZ	Mother, second cousin once removed, father-in-law's sister
5	*kaka*	Mother's brother	MB	MFBS, MMZS, FMBS, FFZS, FZH, WF	Uncle, second cousin once removed, father-in-law
5a	*kaka boi*	Wife's father	WF		Father-in-law
6	*ngauwe*	Brother	B	S of (3), (5)	Brother, cousin, second cousin
7	*ngaka*	Sister	Z	D of (3), (5)	Sister, cousin, second cousin
8	*manggen*	Female cross-cousin	MBD, FZD	D of (4), (6), WZ, BW, HZ	Cousin, sister-in-law
9	*do'goli*	Male cross-cousin	MBS, FZS	S of (4), (6), HB, WB, ZH	Cousin, brother-in-law

aunt		*mother*	*father*	*uncle*	
FZ	MZ	M	F	FB	MB
ngaia	*kela*		*it:a*		*kaka*

Figure 2
Parent and uncle/aunt terms in English and Marri-Ngarr

is defined as G^{+1} $M^{e}S^{m}$, i.e., as a relative in the first ascending generation who is male and belongs to the same patrimoiety as ego. (Patrimoieties divide Njamal society into two halves, with membership in each patrimoiety inherited from one's father; marriage must be with a member of the opposite patrimoiety, which means that, for example, your mother and her brother will be in the opposite patrimoiety to you.) Abstract features such as 'same/opposite patrimoiety' enable the analyst to account for the wide denotational range of such terms as Njamal *mama* or Marri-Ngarr *it:a*.

However, componential analysis of kin terms has been attacked from a number of quarters. Kay (1975) points out that the use of semantically uninterpreted features without a predicate-argument structure removes kin terms from standard logical relations such as entailment, and obscures the fact that kin terms are two-place predicates (and in many languages kin terms are actually verbs—see Evans 2000). He proposes an alternative logic-based system of representation.

From another angle, Wierzbicka (1986) attacks the hidden circularity of using terms such as 'ascending generation' to define a word such as *mama* without mentioning 'father,' since 'ascending generation' can only be defined with respect to parenthood. She proposes a definition of 'father' which refers outside the kin domain, drawing on his role as begetter (at least for English and Njamal). By allowing the analyst to spell out the relevant cultural components in the definition, this approach has the advantage of showing exactly how a concept such as 'father' may vary across cultures—for example, is the father the begetter, or merely the man married to the woman at time of giving birth to the child? Non-kin primitives are also useful in predicting metaphorical extensions of kin terms, such as the use of 'father' to mean 'priest' (Kronenfeld et al. 1985).

An attack from a third direction came from extensionist approaches (Lounsbury 1964, Scheffler 1978), which heralded a paradigm shift away from 'categorical' theories of meaning, which hold that concepts can be defined satisfactorily in terms of necessary and sufficient conditions applying equally to all members, toward prototype theories which allow for varying degrees of membership from focal to peripheral. For example not all 'uncles' in English are equally good exemplars—all speakers will agree that MB and FB should be included, while for FZH and MZH speakers may disagree, and some will prefer hedging expressions such as 'sort of an uncle' or 'uncle by marriage.' MB and FB are therefore *focal* members of the uncle category, while FZH and MZH are *peripheral* members.

Scheffler still uses componential analysis for focal category members: the primary denotatum of Marri-Ngarr *it:a*, F, is defined as K.L.G1.+.♂ i.e., parallel lineal male kin of first ascending generation. However, to get the remaining members of the category, he employs various *extension rules*. For example, a *same-sex sibling merging rule*, which places same-sex siblings in the same category, extends *it:a* from F to FB. Half a dozen extension rules, chained together if necessary, can generate all the extensions in column 5 from the primary denotata given in column 4 of Fig. 1.

2. *Kin Terms in Interpersonal Context*

So far we have been maintaining a traditional idealization, stemming from the use of the 'genealogical method,' which has long been used to elicit kin terms while obtaining genealogies: one asks how the informant addresses and is addressed by each person in the genealogy (Barnard and Good 1984). In fieldwork this method is a necessary step in obtaining an initial set of terms, but it has the drawback of examining kin terms in isolation from their actual use, thus bracketing out the contributions of politeness, conversational footing, and discourse goals to usage (Zeitlyn 1993). In Ungarinyin, for example, which normally distinguishes even- and odd-numbered generations, some terms are extended to take in all generations in a lineage when discussing patrilineal clan estates (Rumsey 1981). Within the functionalist program in linguistics, which sees language structure as resulting from the pressures of actual use, context holds the key to understanding changes in the system itself.

Once kinship terms get used in address, further factors come into play. Often languages have distinct kin terms for address ('Dad!)' and reference ('My father was wise'), although the line may be hard to draw. For reasons of politeness, kin terms often have a wider range when used as address terms, extending to nonkin, as with Indonesian (*i*)*bu* 'mother,' which in address may extend to older females more generally (then dropping the first syllable).

With its long documented heritage, Chinese offers an unparalleled opportunity to trace how address and reference terms change over time. Kryukov (1998) shows how certain innovations start among address terms, later spreading to reference terms. In the Book of Song (first millennium BC), both father and his

siblings were referred to by the general term *fu*, but in address the distinct term *shufu* could be used for FyB. By mid-millennium, however, *shufu* also appears as a reference term. This is typical of how, because they respond to interpersonal context, address terms are usually the more dynamic segment of the kinship system, giving them a special importance for understanding how kinship terminologies change.

Address, however, is not the only way interpersonal context impacts on kinship terms. As mentioned, kin terms are fundamentally two-place predicates, and in many languages there is obligatory marking of the reference point or *anchor* by a possessor suffix: for example, Dalabon *bulu-ngan* 'father-my.' In languages such as English, by contrast, the anchor is typically implicit and must be recovered by pragmatic inference. Speakers often have the choice of whether to take themselves, the hearer, or some third person as anchor. According to context, the English word 'Mum' can be interpreted with an anchor that is first-person (e.g., said by a child to an adult), second-person (e.g., said by an adult to a child), or third-person (e.g., said by a child-care worker taking the child's perspective).

In all these examples the kinship predicate is calculated with respect to just one anchor. However, kinship terms may also make two anchors simultaneously explicit in special 'trirelational' systems, such as the Mayali terms known as Gun-dembui: alongside basic terms like *garrard*, 'mother,' are terms such *al-garrng*, 'the one who is your mother and my daughter,' and its converse *al-doingu*, 'the one who is your daughter and my mother.' See Merlan (1989) for discussion of a similar system in Jawoyn.

The ability to take another's perspective is a hallmark of mature 'social intelligence,' and studies of how speakers manipulate the choice of anchor have important implications for the development of social cognition. Concomitantly, the need constantly to shift away from an egocentric viewpoint in reckoning kinship makes it a difficult semantic field for children to master. Piagetian-style studies of how children acquire kin terms have examined the development of relational abilities (Danziger 1957, Luong 1986).

3. *Typologies of Kinship*

The systematic comparison of kinship terminologies around the world, begun with Morgan's *Systems of Consanguinity and Affinity of the Human Family* (1871), has made kinship vocabulary the most widely sampled and analyzed semantic field, leading to the finding that 'the thousands of systems of kinship terminology in human societies around the world are but variants of a limited number of different types' (Godelier et al. 1998, p. 5).

Consider sibling terminologies. Nerlove and Romney (1967) examined 245 languages for the patterning of terms across the eight logical kin types given by the product of *sex of ego* × *sex of referent* × *relative age*. Common patterns are the use of a single term ('sibling') for all eight kin types, and the division into two terms based on sex of referent (as in English 'brother' vs. 'sister'). Strikingly, they found that of the 4,140 logically possible types only 10 were attested in more than one language of the sample.

The dominant typologies of kinship terminology take the patterning of parent/aunt/uncle terms to be the best predictive feature of the rest of the system. The relevant patterns are illustrated in Table 2, which gives the three commonest type-terms used in the literature.

While the first four types are each widely attested, the fifth, although logically possible, is unattested, presumably because it would require a disjunctive definition (F *or* MB), whereas the extended categories in the other types allow one to find a common factor (e.g., 'male relative of one's patriline' for the Iroquois type). Here the systematic absence is probably attributable to cognitive rather than social causes, since disjunctive categories are widely dispreferred (Greenberg 1980, Hage 1997).

The central role of parent/uncle/aunt terms in typologies of kinship follows from their part in regulating marriage possibilities. The commonest type of marriage partner among relatives is some type of cousin, and the figuring of cousin relationships depends in turn on the classification of parents' siblings.

The Dravidian system is a widely cited example of the relation between kin terms and marriage rules, since it is widely associated with exchange of spouses between descent groups, in the form of reciprocal cross-cousin marriage (i.e., between FZC and MBC), as in southern India (Trautmann 1981). If a man marries his cross-cousin (e.g., FZC), then his cross-uncle is simultaneously his father-in-law, and in fact the terminological equation of these two kin types is widespread in Dravidian terminologies.

This example shows how choices made in one part of the system—here parent/uncle/aunt terms—predict what choices will be made elsewhere. The development of implicational statements—cross-linguistically robust logical relations between one linguistic feature and another—is a central concern of linguistic typology, and one can revisit typologies of kinship in these terms, testing out formulations such as 'if a language distinguishes parallel and cross-cousins, it will distinguish parallel and cross-uncles.'

Characterizing possible kinship systems by suites of implicational statements rather than simply by idealized types has the advantage that, although in 'type cases' large numbers of features co-occur, this is not always the case. First, not all kinship systems display full type consistency. For example, there is a natural correlation between a bifurcate merging pattern in the first ascending generation and a parallel versus cross-cousin distinction in ego's generation. But not all languages display this: Pitjantjatjara has a bifurcate merging pattern (F = FB ≠ MB; M = MZ ≠ FZ) but

Table 2
Major typologies of kinship system, based on father/uncle term

			Morgan	Lowie/Kirchhoff	Murdock
F	FB	MB	Classificatory	Generational	Hawaiian
F	FB	MB	Classificatory	Bifurcate merging	Iroquois (including Dravidian, Kariera)
F	FB	MB	Descriptive	Bifurcate collateral	Sudanese
F	FB	MB	Descriptive	Lineal	Eskimo
F	FB	MB	(Not named)	(Not named)	Not attested

Source: adapted from Trautmann 1981, p. 84.

does not distinguish cross-cousins from parallel cousins or siblings (Scheffler 1978). In terms of the typology in Table 2, we would have to say that Pitjantjatjara is 'Iroquois' in the first ascending generation, but 'Hawaiian' in ego's generation. A comprehensive typology thus needs to allow for many parameters to be varied independently, rather than assuming they always co-occur; the sorts of extension rule outlined in Sect. 1, being logically independent, allow this.

Second, the types given in Table 2 are too crude. Murdock (1949), extending his focus into other generations, recognized a further two types, Crow and Omaha, based on cross-generational mergings (e.g., Crow: FZ = FZD = FZDD). The basic types also neglect the affects of relative age of the father's sibling, yet| Gui, for example, treats FyB as a type of F while lumping FeB and MB with FF (Ono 1997). The most detailed explorations of differences between systems supposedly of the same type have concerned bifurcate merging systems. In Kariera systems, for example, spouses in the ascending generation always differ in crossness, whereas in most Dravidian systems they do not (Viveiros de Castro 1998).

All kinship systems employ a limited series of kin terms for a potentially infinite set of kin types. But although the number of attested systems way exceeds the classic fourfold or sixfold typologies of Lowie and Murdock, it is nonetheless striking that most logically possible systems are not found. While extensionist approaches manage to parametrize this patterned diversity by not requiring groups of characteristics to go together, they do not make explicit the implicational relationships between one type of extension and another—here we need to bring in tools developed by linguistic typologists. Only by combining these approaches will we solve the puzzle of how human beings, despite being evolutionarily equipped for diversity in their constructions of social categories, repeatedly come up with similar solutions, due to a tangling of cognitive and social factors that we have yet to unpick.

Klein, Melanie (1882–1960)

Within psychoanalysis worldwide, Melanie Klein has had more impact than any other psychoanalyst besides Freud. Her wide-ranging contributions not only reshaped psychoanalytic understandings of mental life; they also have fundamental import for social scientific understandings of human action and the creation of meaning. That Klein is indisputably the most important psychoanalyst after Freud also points to the unusual prominence and participation of women in psychoanalysis from almost the beginning (see Chodorow 2000).

Born in Vienna on March 30, 1882, Melanie Reizes Klein moved to Budapest in 1910, where she began to read Freud. She entered analysis and analytic training under Freud's colleague Sandor Ferenczi (on Klein's biography, see Grosskurth 1986, and Segal 1979). She moved to Berlin in 1921, joining the Berlin Psychoanalytic Society and entering analysis with Karl Abraham. Her first formal work as a child analyst began in Berlin. At the invitation of Ernest Jones, Klein visited London in 1925 to lecture on child analysis, and she subsequently moved to England in 1926. Until her death in London on September 22, 1960, she was an active clinician, a leading and innovative child analyst, and a prolific writer who had many followers and colleagues.

Understanding Melanie Klein's life requires an understanding of the history of psychoanalysis. Klein had no direct contact with Freud, but was trained and supported by Ferenczi, Abraham, and Jones, the leaders of the main psychoanalytic centers outside of Vienna and Freud's most important colleagues. These several centers allowed more possibility for independence of thought and action than Vienna itself. While Klein was pioneering the practice and theory of child analysis in Berlin and London in the 1920s, Anna Freud was engaged in a parallel project, based on somewhat different understandings and methods, in Vienna. After Freud developed cancer in 1923, he came to depend almost entirely on his daughter as both professional heiress and personal companion and caretaker. Klein's theory, technique, and stature as a child analyst directly challenged Anna Freud's primacy in this same arena, and Freud was drawn to support his daughter. Thus, even as Klein considered herself the true theoretical heir to Freud, her work from the outset was strongly contested by Anna Freud and her father.

As a result of the Anschluss of March, 1938, in which Hitler, with the approval of many Austrians, seized and incorporated Austria into Nazi Germany, the Freuds moved to London, thereby setting the stage for a confrontation and theoretical and organizational sharpening of differences. Freud died in 1939, but the followers of Anna Freud and those of Melanie Klein in London spent the latter war years in 'Controversial Discussions' (King and Steiner 1991), with an 'Independent' Group holding a middle ground and developing its own theories. Debate posed Klein's espousal of Freud's late instinct theory, with its focus on aggression, her theories of early infant development, her advocacy of the analysis of very young children, and her insistence that the analysis of children (and adults) should begin immediately from interpretation of unconscious fantasy, against Anna Freud's focus on ego defenses and ego functions, her following of the traditional structural and libidinal phase theories, and her advocacy of analyzing from the most surface layer of defense rather than from the deepest layer of unconscious fantasy. The result of the 'Controversial Discussions' was a settling in of a Kleinian Group, led by Klein until her death and still an active force in British psychoanalysis (Spillius 1988 includes writings on theory and technique by Klein's students and later colleagues).

Since the 1940s, no psychoanalytic center has developed without grappling with Klein. Kleinians continue to be central to British psychoanalysis, and Kleinian thinking has shaped psychoanalysis throughout Latin America. Kleinian ideas were initially anathema in the USA, where emigre analysts were closely allied with Anna Freud, but since the 1980s, Kleinian thinking has become widely influential. In Europe too, psychoanalytic theory grapples with, accepts, or challenges Klein.

Kleinian theory is a complex, intertwined whole resting on several foundations (see Klein 1975). This account focuses on Kleinian theory rather than on Klein's founding contributions to child analysis and psychoanalytic clinical technique. As a psychoanalyst, Klein like Freud begins from the discovery and

investigation of the dynamic unconscious, the postulate that conscious thinking only expresses a small fraction of what goes on in the human mind. The beginning datum of Kleinian theory is the psychic reality, or internal reality, of what Klein called 'unconscious fantasy.' The dynamic unconscious consists of repressed or split off fantasies that have a powerful effect in shaping conscious life, feeling, and behavior. Unconscious fantasy operates from the very beginning of life and consists of affect-laden stories or proto-stories about the self, the body, and one's relation to others. These stories are not linguistic or narrative, but are forms of implicit knowing and being that portray in direct, unmediated, affectively charged ways, a mental picture of an inner world of self and others. Klein described how this internal reality is created and its constituent effects on all bodily experience, interpersonal relations, and social and cultural experience (for an extended reading of Klein along these lines, see Chodorow 1999b). It is an 'object-relations theory,' picturing the self, or ego, in relation to others, or objects. Klein's method of play analysis and work with very young children led her to a 'developmental theory' based on changes in prevalent unconscious fantasies. The management of anxiety about 'aggression' in self and others is a central goal of most unconscious fantasy.

Although Freud discussed the ego's relations to its objects and the effects of the object upon the ego—for instance, in his claim that the ego contains a history of object choices—Klein is considered the original object-relations theorist. For Klein, the ego is object-related from birth, all drives are directed towards objects rather than toward gratification and release, and all psychological life revolves around internal pictures of the ego in relation to its objects. Objects are both external—actual people like mother, father, or analyst with whom the self interacts—and internal, parts of the outside world that are unconsciously experienced as within the self. Objects in this 'internal world' may be 'part-objects'—an aspect of another, a body part of another, like the mother's breast or a fantasy of her inside organs—or 'whole objects'—others in all their different aspects. Psychic life especially consists in the building of an internal world through what the ego does psychologically with objects, using such mechanisms as 'splitting,' 'projection,' and 'introjection.' Through these processes, internal and external realities are continuously recreated in relation to one another.

Whereas for Freud, repression of unacceptable thoughts and feelings is the key defense, for Klein, splitting, introjection, and projection are the central defenses. Klein's developmental account revolves around the uses of these defensive processes. In the 'paranoid-schizoid position,' the self and the earliest internal objects—initially the mother's breast, and throughout life, objects that represent the breast—are psychically experienced as either all good or all bad. The ego's goals are to keep bad and good parts of the self and object separate. The ego attempts to preserve its own goodness by keeping good, or loved, objects within, and ejecting and rejecting bad, or hated, objects. 'Projective identification' then leads the ego to feel that the object, now containing bad parts of the self, is persecutory. To control the now persecutory objects, they may be reintrojected, in turn bringing hatred back into the self, which projects badness back into the object. And so on. Split-off good feelings and parts of the self may also be defensively projected into the object, so that the self can feel protected and loved. 'Persecutory anxiety'—the fear of being attacked by bad objects or of annihilation of the self—is the dominant anxiety of the paranoid-schizoid position and leads to the spiral of splitting, projection, and introjection that characterize it. The paranoid-schizoid position is paranoid because of the fear of attack it contains and schizoid because it is based on separating different aspects of the self and the other.

When the child reaches the 'depressive position,' he or she recognizes people as whole objects and painfully realizes that an attack on the bad object is also an attack on the good one, since they are one and the same. Guilt arises, along with the desire to make 'reparation.' Reparation is one root of creativity throughout life as well as of the desire to parent and take care of others. 'Depressive anxiety'—the fear that one will damage the good object—is the characteristic anxiety of the depressive position. Unlike Freud's libidinal stage theory, Klein's theory of positions is not a stage theory in which the achievement of the depressive position involves the giving up of the paranoid-schizoid. All people who have reached the depressive position continue throughout life to move between the two positions.

A complex inner world of self and objects constitutes unconscious fantasy and is the basis of 'transference.' For Klein, transference is not just the putting of early feelings about a parent onto the analyst but a total way of being in the world. Although it is mainly investigated in analysis, transference gives meaning to and animates all experience. It functions as an internal prism through which the world is perceived, becomes subjectively meaningful, and is an object of action. Klein, and especially later Kleinians, also show how forms of thinking themselves transferentially express psychic structure and psychic fantasy, for example, whether a patient can make connections among thoughts, can keep anxiety-laden ideas in mind or must split them off and evacuate them, can keep ideas whole or must destroy or fragment them, can take in ideas from the analyst, can symbolize generatively, and other similar processes.

For Klein, the most anxiety-laden and intolerable unconscious fantasies concern aggression. Klein holds to the later Freudian dual-drive theory, rejected by many analysts, of the life and death instincts. The death instinct constitutes a threat of annihilation or fragmentation from within, creating basic existential

anxiety from the beginning of life. The basic wish of the psyche is to get rid of this threat, leading to the projection that creates the first bad object. Persecutory anxiety thus arises originally as a direct response to the internal threat of destruction from within and thereafter also in response to the aggression that has been through projective identification put into objects. The paranoid-schizoid and depressive positions are both organized largely in response to anxieties generated by these fears of annihilation, aggression, and hatred that emerge from self and object.

A major manifestation of the death instinct is found in envy, which Klein describes as the most toxic emotion. Klein discovered the importance of envy in patients' attempts to destroy and dismantle the help offered by the analyst. Envy originates in the perception that the other possesses and enjoys something good and desirable—originally imaged as the creativity, fullness, and bounty of the maternal breast. The envious impulse is to spoil or destroy that goodness. Envy is felt especially virulently against those who appear not to be envious, those who can enjoy creativity and happiness in others. The envious cannot feel gratitude or serenity, and in fact envy is perhaps the least tolerable of emotions, because its goal is to destroy or spoil not that which is bad, but that which is good. Envy is manifested in attempts to destroy the offerings of parents, of teachers, of analysts, of any whom seem contented and happy. In literature, Iago represents envy in its purest form.

Although she did not explore these implications herself, Klein's work has profound implications for social science (see e.g., Chodorow 1999b). Klein's account of unconscious fantasy and transference challenges the sociological assumption that the material or structural reality of politics, society, and culture come first and create or determine human life. By documenting how people create the subjective meaning of the world from within, through the dynamics of unconscious fantasy, and how perception, action, and thought result from a transferential shaping that has real effects, Kleinian theory demonstrates that action in the external world is not only taken through the conscious, rational assessment of options, nor is it determined through structural or material constraints. Action is as much a result of an internal, psychologically created picture as of society or culture, and meanings are as much created psychodynamically through affectively-charged fantasy as they are culturally presented.

Splitting, projection, and introjection are psychological mechanisms that characterize many social processes. Many of the major political events, crises, and controversies of our time can only be fully understood if the operation of rage, splitting, projection, and introjection is taken into account (see Chodorow 1998). For example, political and cultural demonization of the enemy is psychologically based on projection and introjection, in which all good resides in the nation, the ethnos, the group, or the political party, and all bad resides in those who are not part of this group. Splitting bad from good, and containing all good within the self while putting all bad into the other, underpins all virulent racism, nationalism, ethnic conflict, and attempts at ethnic cleansing or genocide. Splitting may also be used to ward off elements in the self that are threatening because they are too attractive. Thus, misogyny and homophobia express splitting, projection, and denial, in this case of misogynist and homophobic men's feminine identifications or desires for other men—attractions and desires that are too anxiety-laden to be contained within the self. Finally, Klein describes the great envy of women's creative insides and the psychic threat of images of the mother who contains everything good and powerful—babies, milk, the father's penis, and the ability to give and take life. Such images of maternal power and the mother's body help to explain the psychological intensity of abortion politics and perhaps the extreme violence of a few anti-abortion activists (for a brief overview of Kleinian theory in relation to gender, see Chodorow 1999a).

Kleinian theory is therefore a basis both of a theory of psychoanalytic treatment and a description of how the human mind develops and operates. It describes how people create themselves and give the world subjective meaning. It explains motivations for action and perception. It is thus an essential component of all investigations of society, politics, and culture.

Knowledge Activation in Text Comprehension and Problem Solving, Psychology of

In order to successfully comprehend written discourse, readers must have the necessary resources to manage the vast amounts of information that continually become available during reading. Ultimately, this means that at some point in the comprehension process this information must be reduced and organized into a coherent representation, one that reflects the intended meaning of the writer. Two major components of the comprehension process are those involved in the activation of the knowledge necessary for comprehension and those involved in the integration of that information. Although they are not necessarily discrete components, many current theories do treat them as such (e.g., Ericsson and Kintsch 1995, Kintsch 1988a, 1998b, Myers and O'Brien 1998, O'Brien and Myers 1999). The focus of this article will be on the current state of knowledge concerning the activation component.

One of the earliest and still most influential models of the comprehension process was developed by Kintsch and van Dijk (1978). According to this model, text is processed over a series of cycles. On each cycle, a small portion of the text is transformed into a set of propositions that are connected in working memory on the basis of argument overlap. Once connected, a subset of these propositions is held over in working memory in order to provide possible connections for the set of propositions input on the next cycle. As long as each set of input propositions can be connected to those currently in working memory, the text is considered locally coherent and comprehension proceeds smoothly. If, however, there are no readily available connections in working memory, the reader searches the long-term memory portion of the representation in order to find a proposition that provides a connection. Once found, that proposition is returned to active memory and the connection is made.

Many of these assumptions concerning when and if readers search memory, as well as what information is readily available to the reader, set the stage for our current theories and understanding of the knowledge activation component of the comprehension process. For example, many studies (e.g., Dell et al. 1983) have demonstrated that when a reader experiences a local coherence break, a search of long-term memory does indeed take place. Inactive portions of the representation are reactivated, providing connections that facilitate the re-establishment of local coherence. However, we are still grappling with the conditions under which this knowledge activation process occurs, and whether the activation process is active or passive.

For a brief period of time, these issues were best captured by contrasting the minimalist (e.g., McKoon and Ratcliff 1992) and constructionist (e.g., Graesser et al. 1994) views of how a reader gains access to earlier portions of a discourse, as well as information from general world knowledge. In the original paper presenting the minimalist view, McKoon and Ratcliff argued that the amount of information available to the reader was quite limited—primarily the immediately preceding one or two sentences. As long as this 'readily available' information allowed the reader to maintain local coherence, no further search or activation processes were necessary, nor would they occur. In contrast, Graesser et al. argued that the reader was motivated by the 'search after meaning' principle. A critical assumption of this principle was that readers were not satisfied with maintaining local coherence; they also sought to maintain global coherence. Maintaining global coherence involves the activation and integration of relevant information from earlier portions of the episodic memory representation of the text, as well as knowledge-based relations derived from general world knowledge.

Consistent with the constructionist view, there have been several demonstrations that information presented earlier in a text may be available even when a text is locally coherent. For example, Albrecht and O'Brien (1993) presented participants with passages containing a description of a particular characteristic of a protagonist (e.g., 'Mary was a strict vegetarian'). Following several sentences that served to background the characteristic, participants were presented with a target sentence in which the protagonist engaged in an action that was locally coherent but contradicted the earlier-described characteristic (e.g., 'Mary ordered a cheeseburger and fries'). Reading times on this target sentence were inflated when contrasted against appropriate controls. This indicated that, although not necessary for local coherence, the backgrounded characteristic was reactivated and disrupted the comprehension process.

In response to these kinds of findings, McKoon and colleagues proposed the memory-based text processing view (e.g., McKoon and Ratcliff 1995). According to this view, concepts currently in working memory make contact with other concepts processed earlier, as well as related concepts from general world knowledge through a fast-acting, passive resonance process (e.g., Ratcliff 1978). The primary difference between this view and the earlier minimalist view was refined as a result of the definition of 'readily available' to now include easy access to vast amounts of related information without the need to invoke any sort of strategic search processes on the part of the reader. With respect to the constructionist view, this passive activation component is an uncontroversial bottom-up component of the full comprehension process. Inclusion and acknowledgment of this component have muted much of the debate between the two contrasting views and shifted the focus toward a combined attempt to assess the kinds of information that are likely to be readily available to a reader. This

bottom-up view of the activation component is shared by several prominent theories of memory activation during reading (e.g., Ericsson and Kintsch 1995, Goldman and Varma 1995, Kintsch 1988a, 1998b, Myers and O'Brien 1998).

It is easiest to explain the strongest assumptions of the memory-based text processing view within the context of the resonance model proposed by Myers and O'Brien (1998). It is important to note that the model is limited to processes and factors governing only the (re)activation of concepts and propositions during reading. Other models do extend this process to how that information is evaluated and ultimately integrated into the evolving text representation, most notably Kintsch's (1998b) Construction-Integration (C-I) model and Goldman and Varma's (1995) CAPS-CI model. The resonance model is based on the assumption that concepts and propositions derived from the sentence currently being processed, or information residing in working memory as a result of reading earlier portions of text, serve as signals to all of memory. The intensity of those signals may depend on the degree of attention given to the text elements they reflect but the process initiated by the signals is not under the control of the reader; it is both passive and dumb. As in many models of memory (e.g., Ratcliff 1978), Myers and O'Brien assume that this process is one in which concepts and propositions in the discourse representation and in the reader's knowledge base resonate as a function of the degree of match to the input. This match depends on the featural overlap among concepts, and on the argument overlap of propositions. Memory elements that are contacted by the initial signal in turn signal to other memory elements. During this resonance process, activation builds and when the process stabilizes, the most active elements enter working memory.

There are two critical features of the resonance process. First, it is continual; a signal is constantly being sent to all of memory, not just when triggered by a coherence break. What is resonating in long-term memory changes constantly with each change in the content of working memory. More important, the resonance process is dumb. Any information that resonates sufficiently is returned to active memory independent of whether that information will ultimately facilitate or hinder comprehension. Note that Kintsch's (1998b) C-I model has the same assumption; because the construction (or reactivation) phase is both passive and dumb, it is quite possible that the output of the construction phase will be incoherent, and possibly contradictory.

This bottom-up view of knowledge activation eliminates the distinction between local and global coherence. Because most information related to any current input into working memory automatically resonates and is reactivated in response to that input, the reader simply needs to monitor the coherence of the information that is in working memory. By definition this will involve not only recently read information, but also related information from earlier portions of the text, as well as related information from general world knowledge.

There is mounting evidence that this knowledge activation is indeed passive and dumb. Several studies have shown that inactive portions of memory are activated and become part of the integration process, even when that information contradicts and/or disrupts comprehension (e.g., O'Brien et al. 1998). Even stronger evidence exists in studies in which information that is related—in terms of featural overlap—but irrelevant becomes active and disrupts comprehension. For example, Cook et al. (1998) found that if a narrative described a secondary character as a vegetarian (e.g., Joan), a later reference to the primary character (e.g., Mary) eating a hamburger resulted in the reactivation of the vegetarian characteristics assigned to the secondary character. It is difficult to explain these types of findings in terms of a reader actively searching memory for relevant information. But these types of findings become obvious predictions for comprehension models that include a passive activation component.

In many earlier models of knowledge activation there was an order in which the episodic memory trace and general world knowledge were activated. Kintsch and van Dijk (1978) assumed that the episodic memory trace was activated first, whereas van Dijk and Kintsch (1983) assumed that general world knowledge was activated first. Current models (e.g., Kintsch's 1998b C-I model) now routinely assume that both sources of knowledge are activated in parallel—an assumption that must be made if knowledge activation is passive. In earlier work examining knowledge activation, researchers often examined activation of the episodic memory trace while holding general world knowledge constant (e.g., O'Brien 1987) or vice versa, holding the episodic memory trace constant while varying general world knowledge (e.g., Spilich et al. 1979). Because most models now assume that the two sources are activated in parallel, pressure is mounting to examine the interaction of these two knowledge sources. The most promising work in this area is that of Kintsch and his colleagues' use of Latent Semantic Analysis (LSA, see the special issues of *Discourse Processes*, 1998, **25** devoted to LSA). LSA is a method for assessing the impact of general world knowledge on the comprehension process. It involves the building of large, but simple, associative networks of word meanings. This is done by measuring co-occurrences of words in large text corpora. The mechanism for activation is consistent with Kintsch's C-I model (i.e., passive). LSA has proven quite successful in accounting for several cognitive phenomena including word recognition, sentence-word priming, and text comprehension. It is very exciting and promising that a simple associative network can go so far in accounting for the impact of general knowledge activation on the

comprehension process. However, although computationally it provides a good fit to data, its value as a representational theory may be limited (see Perfetti 1998). Nevertheless, it provides an excellent starting point for considering the interaction of the two sources of knowledge activation.

The activation and instantiation of inferences, either necessary or elaborative, plays a crucial role in the comprehension process. Clearly, before any sort of inferential information can be incorporated into an evolving representation of a text, it must be activated (see Kintsch 1998b, for an excellent discussion of the distinction between activation and instantiation, p. 189). It must also be validated against general world knowledge (Singer and Halldorson 1996). By definition this means knowledge-based relations not explicitly stated in the text but already present in general world knowledge must be activated. Two critical questions are. What information is activated? And how does activation occur? Within the memory-based text processing view, any concept that is semantically related to what is currently being read should be passively and automatically activated. This makes a vast amount of information quickly and readily available (e.g., Ericsson and Kintsch 1995), some of it useful to the reader, some of it not. Currently this account of the initial knowledge activation phase can account for the majority of results showing activation of information that ultimately plays a role in inference generation (e.g., Murray et al. 1993). However, there is also evidence that some inferences require a slower-acting conscious process (e.g., Calvo et al. 1999). The memory-based text processing view cannot account for these sorts of active generation processes. The question of active vs. passive inferences remains an open and important issue for future research.

The issues and principles raised in knowledge activation in text comprehension also apply to issues in problem solving. Within Ericsson and Kintsch's (1995) model of long-term working memory, activation of the knowledge necessary for problem solving is initially guided by the textual input. Automatic activation processes enrich explicitly stated information. This activation links information in working memory to large, pre-existing structures in long-term memory. The result is a large expansion of the information that is readily available to be used in problem solving. This is an important first step in understanding problem solving processes. However, beyond the initial activation stage, the issues in problem solving become enormously complex and messy. Problem solving is typically assumed to involve complex, conscious, resource demanding operations. Other than in situations involving well-practiced experts, those operations that can, or will, be utilized are difficult to constrain, and as a consequence are difficult to predict (see Kintsch 1998b).

The primary goal of models consistent with the memory-based text processing view is to explain as much of the overall comprehension process as possible without invoking strategic processes on the part of the reader. These models are incomplete because they typically lack a full specification of the mechanisms for evaluating and integrating the large amount of information they assume to be readily available to the reader. Some of those mechanisms are well specified in the top-down components of current constructionist models. Any complete model of the comprehension process will have to include many of the components identified in the memory-based text processing models as well as many of the top-down components identified in constructionist models. The current state of the field of text comprehension has clearly identified these two ends of the comprehension continuum. Future work that begins to identify the gray area between these two end points is likely to prove the most informative to a complete theory of the comprehension process.

Knowledge, Anthropology of

1. *First Approaches: The Late Nineteenth and Early Twentieth Centuries*

Most nineteenth century formulations of the problem of knowledge focused on what entire social groups shared. These formulations also implicitly or explicitly assumed an evolutionary schema of social development from 'elementary' to more complex societies, a notion as common to Charles Darwin as it was to Karl Marx. Thus William Robertson Smith (1972), a Biblical scholar whose work profoundly influenced later sociologists and anthropologists, including Émile Durkheim and E. E. Evans-Pritchard, saw a close relationship between the stage of development of a social group and the nature of its intellectual, religious, and moral life. For example, Smith argued that to understand the message of the prophet Ezekiel, the social organization of his time had to be delineated, together with the cosmology and modes of thought contemporary with it. If Ezekiel's prophetic message was found to be different from that of Samuel, Smith argued, it is not because of any contradiction in the Bible but because Samuel addressed himself to groups and situations at different stages of human development.

This dual sense of evolution in history and in the complexity of social forms was basic to Émile Durkheim's *Elementary Forms of the Religious Life* (1915) and his *Primitive Classification* (1963), co-authored with his nephew, Marcel Mauss. Durkheim's goal was to study the most 'elementary' societal forms in order to discern the basic social elements out of which ideas of time, space, causality, category, and person are constructed. Using the example of Australian aborigines, which he considered the best documented 'elementary' society, Durkheim argued that religious thought, like all forms of thought, derived from collective social action.

Durkheim sought to synthesize the two major prior approaches to categories of thought, the 'apriorist' and the 'empiricist'. The apriorist approach, exemplified by Immanuel Kant, viewed categories of thought as immanent in the human mind. The empiricist approach, exemplified by John Locke, saw these categories of thought as derived from experience, with individuals independently constructing similar perspectives. Mediating between these two approaches, Durkheim argued that categories of understanding were neither innate nor derived from individual experiences. Instead, they were the product of a 'collective consciousness' created and sustained through shared ritual action. This social basis of knowledge and categorization applied as much to the classification of objects and the natural world as it did to religious thought, at least in 'elementary' societies.

For Durkheim, the notion of the 'collective consciousness' ('conscience collective') joined assumptions of the fundamental faculties of the human mind with the creation of collective representations. Durkheim's argument was elegant but in synthesizing the main currents of European social philosophy, he was unable to demonstrate the primacy of the social in 'causing' forms of classification. At the least, his argument suggested an analogy between the social order and forms of knowledge, and his psychological assumptions concerning collective representations were quickly superceded. Nonetheless, his work profoundly influenced successive generations of anthropologists interested in the ethnographic representation of cosmologies and religious beliefs and their relation to the social order.

2. *The Ethnography of Knowledge*

An example of how the work of Robertson Smith and Durkheim influenced ethnographic writing in the first

half of this century is E. E. Evans-Pritchard's study of the Nuer of the southern Sudan (1940). Evans-Pritchard cites neither of these predecessors in his text, although their influence is evident in the structure of his argument. He depicted the Nuer as a cattle-herding people with a simple material life and minimal social and political differentiation, highly dependent on their local environment and seasonal migrations. Evans-Pritchard described these in detail, indicating how ecological conditions shaped Nuer social life and cosmology, or ideas of religion, causality, and the order of things. He showed how the structure of Nuer lineages, age-grades, and political units corresponded to their ideas of time, space, and political relationships.

Like Durkheim, Evans-Pritchard allowed readers to infer that Nuer categories and classifications derived from the structure of their social and political life. As with Durkheim, however, all Evans-Pritchard demonstrated was common schemas or homologies of form among a 'traditional' social structure, ideas of time and space, and cosmology.

The anthropological tradition represented by Evans-Pritchard remained dominant through the mid-twentieth century, inspiring other work on cosmology and social structure in other African societies, including John Middleton on the Lugbara and Godfrey Lienhardt on the Dinka.

The roots of Durkheim's influence continued well beyond mid-century and could be seen in the work of anthropologists such as Edmund Leach and Mary Douglas (1966). Such studies suggest the extent to which people go to maintain or distinguish conceptual kinds and boundaries among animals, plants, genders, foods, peoples, and types of activity. Claude Lévi-Strauss (1966) also focused on the forms of classification implicit in both the kinship structures and in the myths of 'elementary' societies, exploring similarities across cultural traditions that suggested common 'structures' in myths, for example, akin to those studied by structural linguists. Lévi-Strauss's work encouraged a focus on how analogies are made between different cultural domains.

Some anthropologists, such as Maurice Godelier (1986), sought to join Durkheimian concerns with categories and classification to a Marxist-inspired linking of ideas of knowledge to modes of production. As with Durkheim's work, however, the emphasis in these studies remained primarily in the classificatory schema implicit in systems of knowledge and in analogies between symbolic representations and material/economic life rather than in how people created, imposed, and altered, ways of knowing.

3. *Psychology and Anthropology*

Until the 1920s, the lines between psychology and anthropology significantly overlapped. It was often psychologists more than anthropologists who engaged in comparative work across societies and explored the extent to which humans thought alike. Some anthropologists argued that human intellectual and cognitive processes were essentially similar and varied only on the level of evolution of their culture. Others, such as the French philosopher, Lucien Lévy-Bruhl, argued that there was a great divide between the pre-rational and 'primitive' forms of thought and the 'rational' thought of modern societies. Lévy-Bruhl's argument had a strong resonance in French colonial lobbies, and was even offered to explain the presumed inability of the Muslim societies of North Africa to abandon social forms and beliefs supposedly inadaptive to the colonial, modern world.

After the 1920s, however, there was an increasing separation between psychological and anthropological approaches to cognition and knowledge. Psychologists more than anthropologists explored issues of cognition, the capacity and processes by which individuals learn, classify, and make associations and analogies. Psychologists thus focused on how the brain is 'hard-wired' for certain thought processes, including the ability to learn languages. Anthropologists dealt more with culturally learned forms of knowledge and classification. Only a few anthropologists, such as Gregory Bateson (1972), continued to envision a common ground between the two disciplines.

As Dan Sperber (1985) noted, anthropological work always had two dimensions. Some anthropologists have been more interested in the interpretation and analysis of particular cultural and social groups. Others have been more concerned with the cultural abilities and dispositions of humankind in general. Studies in cognitive anthropology, as the latter focus became known, underscored this distinction. These were the anthropologists most inclined to explore the link with psychology. The 1960s again brought scholars from the two disciplines into close collaboration. In one key study, for example, color perceptions, a domain that anthropologists previously assumed to be culturally transmitted, became recognized as having a more limited range of variation than was initially supposed, suggesting underlying cognitive principles (Berlin and Kay 1969).

The focus of the Durkheimian tradition of the anthropology of knowledge was always in the 'outer' frame of knowledge—how classificatory schemes for understanding society and the world related to the social order. The work of the cognitive anthropologists studied the order internal to particular schemes of knowledge—such as botany, color, disease types, firewood, and kinship and relationship systems. Michael Cole (1996) called this renewed collaboration between anthropologists and psychologists the 'second psychology,' in which the two disciplines explored the frontier between culture and 'mind' in understanding cognitive development, the acquisition of literacy and

numeracy, and language acquisition. In this vein, Holland and Quinn (1987), for example, use the term 'schema' to refer to standard learned patterns of activity, such as 'going to the post office,' by which members of a society learn cultural patterns and habits to accomplish routine tasks, freeing individuals to focus instead on less predictable situations.

4. *Intellectuals*

Another component of the anthropology of knowledge is the role of intellectuals in society and the social production of knowledge. Until recent decades, anthropologists were primarily concerned with those bodies of cultural knowledge shared by all members of a society. Anthropologists such as Radin (1957) in American anthropology and Griaule (1965) in the French tradition portrayed intellectuals as possessing an especially intense awareness of the sacred center of their society and an ability to reflect and explain its categories of knowledge. A classic essay by Victor Turner (1967) on the knowledge and character of one of his principal informants on Ndembu symbolism, comparing him to an 'Oxford don' also broke from an earlier tradition in which individual producers of knowledge were subsumed in larger collectivities.

An influential approach to defining intellectuals in relation to theories of modernization and modernity was Edward Shils (1972). For him, intellectuals were those imputed with an 'innate need' to understand and articulate ideas and concepts that are more general and profound than those faced in practical, everyday concerns. For Shils, all intellectual work originally arose from religious occupations, but religious orientations in modern times have attracted a diminishing share of the creative capacities of an elite oriented toward more 'modern' concerns. Shils's approach assumed that not all knowledge was equally shared, and it also encouraged anthropologists and other scholars to think of varied types of intellectuals and their relation to the different political and social contexts in which knowledge is produced and valued. Whether they were called intellectuals or entrepreneurs, anthropologists shifted their focus away from discerning classificatory categories and cosmologies and toward the economic and political contexts in which knowledge is produced and shaped.

In this shift to understanding knowledge and its social distribution as process and as historically rooted, the strategies used for comprehending 'elementary' societies—to invoke Émile Durkheim's term—were adapted to depict ideas of knowledge in advanced, 'complex' ones. Thus Pierre Bourdieu compared the cognitive style implicitly learned at the Sorbonne to that transmitted by Bororo elders in the Brazilian Amazon. For Bourdieu, the verbal maneuvers learned by students preparing for the *leçon* at the Sorbonne furnished a model for the 'right' mode of intellectual activity in the French context as much as the dualistic spatial layout of Bororo villages embodied Bororo cosmology as interpreted by dominant elders. The dualistic method of the *leçon*, which establishes a traditional 'two views' on any subject, is subsequently applied to discussion of a wide range of intellectual problems, to the exclusion of alternative, less culturally valued approaches.

5. *Knowledge and Power*

Bourdieu's work on education, social class, and knowledge in the 1960s linked together several long-standing themes in the anthropology of knowledge, but also indicated a shift from earlier concerns with categorization to the practice of creating and distributing knowledge. Bourdieu, like Bloch (1985), Fardon (1985), Godelier (1986), and others, related knowledge and social classifications to the distribution and control of resources. In the specific case of education in France, Bourdieu depicted how the style and forms of knowledge of French higher education converted social classifications into school ones, relating mastery of the 'symbolic classifications' and habits of thought of formal schooling to both class and social capital.

The theme of the historical problem of change in dominant ideologies of higher education and how these ideologies were related to the conflicting interests of class and social groups in complex societies was raised at the beginning of the century. Durkheim's (1977) neglected lectures on the evolution of higher education in France is a case in point. It was only by the 1970s, however, that such ideas rose to the forefront of anthropological thought. Studies such as Bourdieu's on higher education in France, and others on themes such as the internal logic and changing social context of Islamic ideas of knowledge (Eickelman 1985) and the process by which dominant ideas of religion and tradition shifted in Indonesia (Hefner 1985) joined the long-standing anthropological concern with tacit knowledge in religious experience with how social actors derive meaning from public symbolism and continually shape and renew bodies of knowledge in differing social and historical circumstances.

Fredrik Barth's (1987) account of local variations in the cultural traditions of the Ok of highland New Guinea illustrates both the shift to understanding how people produce and use knowledge, and the erosion of the earlier distinction elementary and complex societies. The Ok use their ritual occasions to create and alter systems of knowledge as much as seminars and innovative lectures accomplish the same objective in contemporary European societies. Departing from earlier accounts such as Evans-Pritchard on the Nuer, Barth emphasized the processes of thought and innovation at work within a system of knowledge, producing multiple variations and developments.

Approaches such as Barth's also had profound implications for the idea of culture. Rather than viewing culture implicitly as internally homogeneous, shared, and sharply bounded, culture instead is conceived as a perpetually interactive social organization of communication in which individuals reproduce and alter representations and symbols. Knowledge is thus produced in the enactment of the 'regulated improvisations' (Bourdieu 1977) by which people express thoughts, organize, and interpret social action. Social practice in specific historical contexts thus produces 'objective' structures (economic and power relations) that in turn produce cognitive and affective dispositions of the social world common to members of given social groups or classes.

Current trends in the anthropology of knowledge thus encompass two related concerns. One builds on new collaborations between anthropology and psychology, exploring new ways of relating public and institutionalized cultural expression to cognition and mental representations (Shore 1996). The other focuses on the social production of knowledge and its relation to power, value, communications, and control. The earlier concern with the values, cosmology, and ways of knowing that are, common to all people in a given society, has given way to how ideas and innovation are communicated in more bounded and explicit fields of knowledge. Such studies include the diffusion of knowledge and ideas in Silicon Valley, the genome project and in biogenetic engineering, and the implications of new communications media on ideas of religious and political authority. The processes by which change is embodied in implicit shared ideas of gender and sexuality, and authority and responsibility, also forms a component of current concerns in the anthropology of knowledge.

Knowledge, Education, and Skills, Geography of

Knowledge, professional skills, inventiveness, competence, creativity, technological capabilities, and educational achievement have never been evenly distributed in populated space. Apart from everyday

routine information and common sense, most forms of knowledge and skills display large spatial disparities. Since knowledge is regarded as a key factor for competitiveness, development and modernization, a geographical perspective is required to analyze and to explain the spatial structures, processes, and disparities involved in the creation, adoption, distribution, and application of knowledge and skills.

1. Spatial Concentration of Knowledge and Skills

1.1 Diffusion of Knowledge and Information

New knowledge (whether in the form of technologies or social values) is created in particular places and contexts and through interaction within space. The speed at which new knowledge and information diffuses over space depends on the type of knowledge, the institution within which the new knowledge is produced, the interest of the producer (inventor) to share his or her knowledge, the previous knowledge necessary to understand the contents of new information, the availability of technology necessary for the production and application of knowledge, and the inclination to accept the knowledge.

The first type of knowledge and information which is most quickly distributed in space is the kind of 'public news' which is easily understood by almost everyone, which does not require previous knowledge or expensive technology, and whose free distribution is in the provider's best interests. This type of information and knowledge is highly mobile, can be spread around the globe in seconds and is easily available by telecommunication.

The second type of knowledge and information is more complex and cannot readily be used even by those who have access to it if these constituencies lack the previous knowledge, experience or training necessary to recognize, understand and evaluate the contents of the information. This type of knowledge can only be transferred from one person to another if the receiver's training, skills or capability are broadly equivalent to that of the sender. Previous knowledge necessary to understand an information may consist of knowledge of a foreign language or of a specialized scientific discipline. The third type of knowledge and information is kept secret by its producer in order to gain an economic, political, scientific or military advantage.

These three forms of knowledge and information vary in the degree of their spatial concentration and in the speed of their diffusion. Only the first type of information, which is the least important for economic competitiveness and innovation, is (theoretically) ubiquitously available, assuming all places have the technical equipment and all people an equivalent inclination to receive the message. The second type displays a much higher spatial concentration in a few centers or areas, and often circulates only between the upper levels of the urban hierarchy (Hägerstrand 1966, Törnqvist 1968, 1970, Pred 1973). The third type has the highest degree of spatial concentration. The term 'spatial concentration' does not imply a tight, everlasting linkage to a certain place but rather a conglomeration of functions that may change its location over time.

1.2 Center and Periphery as Spatial Representation of Power and Knowledge

Terms such as power, authority, dominance, and control are only applicable in the framework of asymmetric social relations. Asymmetric social relations manifest themselves spatially, both in the horizontal and in the vertical dimension. Due to the importance of spatiality in the construction and representation of difference, social structures and social relations are often described spatially by terms such as center, core, periphery, marginality, outsider, top, bottom, segregation or distance. In spatial representation knowledge and power regularly take an elevated or central position. Dependent positions with low status are at the margin.

A center is a point of reference, orientation, and authority. It is the nodal point (field) of interaction and communication whence the elements of a social or spatial system are ruled, coordinated, and controlled (Strassoldo 1980). It collects and distributes resources, sets the rules, norms, and standards for the members of the system; it controls, legitimates, and accumulates knowledge (Latour 1987); it provides a conspicuous public platform from which ideas emanate; it constructs realities and creates memories and identities. The center is the place where the highest levels of authority, power, decision making and knowledge are located. Most of the work places located at the periphery are lowly skilled and are the site of lowly paid routine activities coordinated and controlled by external decision makers. The antagonism between core and periphery is a spatial representation of an uneven distribution of power and knowledge.

Why do power and knowledge so frequently build coalitions and why do they seek proximity to each other? Both instrumental power (the capacity to make others do our will and the ability to control, regulate and dominate), and association power, i.e. the power to do things by acting in concert or using institutional mediation (Agnew 1999), have to rely on experts, scientists, academics and 'think tanks' to achieve and sustain their position. They also need representatives of spiritual knowledge (priests, intellectuals, artists, ideologues) who share their norms and values and legitimate their power. It is in the interest of power to bind knowledge into networks of assent (Agnew 1999). On the other hand, both scientific knowledge (ex-

pertise) and spiritual knowledge seek proximity to (political) power for various reasons. First, centrality is the spatial manifestation of authority, importance, and prestige. Authority fascinates most experts and intellectuals, they want to be concerned with the essential in existence, and strive for influence and recognition. Second, network-centrality determines access to valued resources and information unavailable to those at the margin. Third, experts, scientists, and artists in many cases have to prove their usefulness to power in order to secure their privileges and the resources they need for their work. Fourth, proximity to power may also increase the opportunities to influence important decision-makers. Close spatial proximity between power and knowledge seems to be indispensable. Even intellectuals (dissidents) opposing those in power have to operate in centers in order to get access to communication networks and to obtain response in the media. Decision makers, professionals, experts, artists, and intellectuals striving for prestige, influence, and success, sooner or later find their place of work in one of the centers or will create for themselves a new center in their chosen field.

Work places of important decision-makers, highly skilled specialists, and high-technology industries show a strong tendency toward spatial concentration, whereas lowly skilled routine activities in production and administration show a trend towards dispersion and decentralization. The main characteristic of peripheries is that they constantly loose the largest part of their highly educated to the centers.

Knowledge is rooted in people, but it is also embodied in technologies, products, services, management performance and institutions of schooling, education and training. The broad range of research topics is paralleled by the large variety of theoretical approaches that the geography of knowledge, education, and skills has to apply. The following chapter presents one example, namely theoretical approaches explaining the spatial concentration of work places for top-level decision-makers, intellectuals, and highly skilled specialists. Work places present important settings and contexts for a great variety of actions.

2. *Theoretical Approaches to Explain the Spatial Concentration of Knowledge*

2.1 *Organization Theory*

For an organization the production and acquisition of new knowledge and the ability to learn, adapt and reorganize itself are the best means to cope with uncertainty. The acquisition of new knowledge and new information is no guarantee for successful decisions and actions but it increases, at least for a certain time, transparency, predictability, and efficiency while sustaining flexibility and competitiveness and enhancing survival chances in an uncertain environment. According to this approach, it is not the 'fittest' that survive but those who constantly acquire new knowledge, skills and information and are therefore able to adapt quickly to new situations and to cope with new challenges. 'It is evolution through learning that clearly dominates and accounts for the major variations in human social behavior' (McClintock 1988, p. 60). There is no doubt that incompetence, ignorance, and lack of experience are the main factors leading to the collapse of social systems and the decline of centers. The question of how much incompetence, ignorance or lack of skills a given social system can afford depends primarily on the intensity of competition, on the uncertainty of the environment, and on the available resources of the system.

As centers and peripheries are socially constructed and as space is a product of relations and interactions, both the status and the locations of centers and peripheries change over time. In spatially *mobile* social systems, such as nomadic tribes or armies in war, centers constantly change their location in space. Most social systems, however, are spatially rooted and change the location of their centers and peripheries only gradually. Large and complex social systems show a hierarchy of centers. The definition of a place as center or periphery and its ranking in the hierarchy vary with the spatial scale; a center at the micro-scale may be defined as periphery on a macro-scale.

Since an organization can only compensate for a certain amount of incompetence for any extended period of time, it acts in its own interest when it fills the key positions of information processing, decision making, planning, coordination, and control with highly skilled, educated, and experienced persons. In particular, those positions and subsystems that are constantly confronted with uncertainty and whose decisions have long-lasting consequences for the entire system require highly developed skills, knowledge, and experience. In social systems, knowledge, skills, and experience are a value-adding source and have the same function as redundancy in technical systems. They reduce uncertainty and enhance survival chances.

In a dynamic and competitive society, the acquisition of knowledge and skills is an ongoing process that is never finished. Much of our knowledge is transitory and looses its value after a certain time. In a competitive society, it is not knowledge itself that counts, but the possession of prior, specialized, unique, better or rare knowledge that justifies the role of experts and advisers, that makes knowledge attractive to those in power. Advisers, counselors, experts, priests, and intellectuals derive their power from their claim to know *better* or *earlier* than the majority of people, from their ability to reduce the complexity of knowledge and to make knowledge useful. In a dynamic and competitive society, the skills and knowledge needed for the key functions of a system striving

for success (survival) will always be scarce and expensive commodities.

The first crucial question is where to locate scarce knowledge and skills within a social system's structure of decision making. In bureaucratic systems and in systems confronted with low degrees of uncertainty, decision-making, problem-solving, research, development, and planning will shift to the upper levels of the system's hierarchy and consequently the lower levels will be characterized by routine activities and work places for those with lower skills. In systems confronted with a dynamic and complex environment and dealing with constantly changing, unpredictable, one-time transactions, decentralization of competence and authority within the system is more effective. For a more detailed discussion of various types of organizations, environments and means of coordination see Mintzberg (1979).

The second question is where to locate scarce knowledge and skills spatially. Routine activities for which there are plans, rules, and regulations call for lower skills and less face-to-face contacts with other organizations. They are predominantly regulated and coordinated by indirect contacts such as letters or telecommunication. Therefore, they can be situated in a great number of smaller cities or even rural areas, as long as the traditional location factors such as transportation and wage costs make it feasible. The harder it is for decisions to be governed by guidelines, plans, regulations or so-called hard information and the greater the uncertainty about the future, the more necessary it is to have frequent and spontaneous face-to-face contacts with knowledgeable and well-informed decision-makers and highly skilled specialists of other organizations. The needs of the highest management levels for face-to-face contacts and valuable networks can only be fulfilled in a few large centers offering a large diversity and density of knowledgeable specialists and prominent decision-makers.

Trustful relations and frequent face-to-face contacts to leading decision makers in government, research, finance, consulting, media or industry offer access to early knowledge about important tendencies and innovations and provide the top positions of an organization with crucial information, thus facilitating their quick response and adaptation to new situations and developments.

2.2 Symbol Orientated Approach

The spatial distribution of work places for the highly and lowly skilled, for the powerful and powerless cannot be fully explained by functional arguments. Distributions are also influenced by the symbolic meaning of places. A place can be a symbol for prestige, reliability, credit-worthiness, and power. Another address only short distance away may suggest danger, poverty, failure or crime. The terms center (core) and periphery have a strong symbolic meaning. A center is associated with social attributes such as power, authority, dominance, prestige, control, and influence. The term periphery symbolizes dependency, marginality, backwardness, lower skills, lower prestige, weakness and subordination.

It is not only the functional and spatial division of labor that creates centers and peripheries. Anthropology, social psychology and the history of religions also offer a large number of ritualistic constructions of centers. In many religions, the center is a sacred place where the gods revealed themselves or where the connection with the gods was initiated. In early civilizations, the magicians, sages, and priests were assembled at the symbolic center of power or represented themselves as the center of the social system. Their claim to have a connection with gods or with the ancestors or to represent god's will on earth gave them a central position in their social system. Such ritualistic constructions of centers are also to be found in modern societies. In many cases centers claim pre-eminence with regard to knowledge and competence. It is not only the functional significance, but also the symbolic and psychological meaning of the terms center, core, heart, and top that attracts intellectuals and other successful knowledge producers.

2.3 Conflict Theory

Knowledge and information are not uncontested. Places of knowledge production compete with each other, newly fabricated knowledge may disrupt or destroy existing values, memories, and belief systems, and is not appreciated everywhere.

Knowledge can be used as a means to discipline, control, regulate, exclude, and manipulate. Production and distribution of knowledge and information are often associated with censorship, forgery, and propaganda. Many national memories, historical 'realities', social statistics, and 'truths' are socially constructed according to the interests of dominant groups and contested by other groups. Those in power have always tried to exercise tight control over institutions of knowledge production and information distribution, fortunately with limited success. The shamans, magicians, and priests of earlier centuries tried to ensure their monopoly of holy knowledge. A number of European universities were established not to improve knowledge and culture, but to strengthen the political power of the rulers, to generate an élite cadre or to erect an 'intellectual fortress' against unwanted influences.

The representations of the culture, history, and geography of colonies by imperial powers (Said 1978, Gregory 1998) are perfect examples of the assertion that culture (knowledge) underwrites power and power elaborates culture (knowledge). After the in-

troduction of compulsory schooling by the nation state schools, universities, and academies were constantly used by the central authority to enforce the 'universal' knowledge of those in power against the 'particular' knowledge and narratives of minorities. Since the school was considered an important instrument in the socialization process of the younger generation and of immigrants, its mission included consolidating the nation state by assimilating ethnic minorities, by supporting ideological and political propaganda, by transmitting historical narratives, and by creating national identities. The construction of belief systems, the legitimation of new knowledge, the creation of a regional or national identity, as well as the production, distribution, control, and suppression of information, is guided and controlled by the 'centers of calculus' (Latour 1987). The use of knowledge as a means to discipline and control, the fact that the spatial diffusion of knowledge may be accompanied with disjunction, contestation, opposition and debate, and the contest between various forms of knowledge, have contributed to the spatial concentration and separation of knowledge.

3. *Early Roots, Research Topics, and Possible Future Directions for the Geography of Knowledge, Education, and Skills*

3.1 *Early Roots and History*

The difficulties in measuring various types of knowledge across space may have contributed to the fact that empirical studies for a long time focused rather on educational achievement and school systems than on knowledge itself. The study of the relation between knowledge and action, of creative milieus or of the role of indigenous and religious knowledge started much later.

The historical roots of a 'geography of knowledge, education, and skills' can be traced back to the first decades of nineteenth century. Some of the negative consequences of the industrial revolution such as poverty, child labor, crime, alcoholism, and a lack of decent housing aroused an interest in moral statistics, first in France and Great Britain, and later in other countries. Many nineteenth century social reformers believed that poverty, crime, and alcoholism were caused by ignorance and a lack of moral education. They therefore studied social and spatial disparities of illiteracy, the provision and quality of schools, the skills and salaries of teachers, the availability of books in households, and the educational attainment of children.

France was the first country comprehensively to study regional differences in illiteracy. The main sources were the examinations of military recruits and marriage registers (Furet and Ozouf 1977, Heffernan 1989). In 1826, Charles Dupin gave a lecture about the interrelation between the population's educational achievement and economic well being. In 1827, he published the *Carte figurative de l'instruction populaire de la France*. This map demonstrated large regional disparities in educational attainment between northern and southern France (reprint in Meusburger 1998, p. 193). The tables added to this map compared the educational attainment, the number of patents for inventions, and the membership in the *Académie Française* with various economic indicators suggesting a correlation between educational achievement and economic performance.

In Britain, a number of *Statistical Societies* and *Friendly Societies* emerged in the 1830s and 1840s to study the living conditions and social situation of the poor and to foster social reform. Literacy was again a main concern of these studies. In 1849, J. Fletcher published a map showing 'Ignorance in England and Wales' in the *Journal of the Statistical Society of London*.

Apart from occasional studies of drop out rates and truancy, of busing problems, and of the locations of schools and universities, human geography has neglected spatial disparities in knowledge, education, and research until the mid-1960s. This changed when Robert Geipel (Munich) and other geographers initiated and institutionalized a 'geography of education'. For detailed treatment of its history and development in various countries see Meusburger (1998).

3.2 *Research Topics and Possible Future Directions*

The newly emerging 'geography of knowledge, skills and education' in its early period of the 1960s and 1970s first focused on spatial diversities of school systems (size, equipment, location criteria, and catchment areas of schools and universities), on spatial patterns of expenditure on education, on the evolution of patterns of school provision, on cultural and economic effects of schools and universities, on spatial effects of educational policies and school planning concepts, on the effects of school closures, and on spatial disparities of educational achievement.

On the spatial macro-scale, indicators of educational achievement are used to describe the spatial dimension of social stratification and the spatial distribution of human resources. The educational achievement of the adult population is measured by indicators such as the proportion of illiterates, the proportion of the adult population who completed a certain level of education (e.g. proportion of university graduates) or by median school years completed. Literacy is often regarded as a precondition for the modernization process. Spatial disparities in the educational attainment and behavior of pupils (students) can be measured by indicators such as the proportion of an age group attending (a certain type of?) school, by transition rates of an age group to various types of

secondary schools and universities, by school completion rates, by the scale of dropout and truancy, the suspension rates and many other indicators.

From the 1980s onward geography studied the personnel employed at schools, universities and research institutions. This included spatial disparities of the age-structure, skills, income, gender, social, ethnic, and regional origin, careers, and regional mobility of teachers, scientists, and other knowledge workers.

Influenced by research in economy and sociology, geography started to study the spatial variations in the transition from the school system to the occupational system in the 1980s and 1990s. The main research interests dealt with the correlation between educational achievement, first positioning in the labor market and professional career, and the spatial discrepancies and balancing mechanisms between supply and demand of skilled and unskilled labor. Migration motive patterns and distances of highly and lowly educated, of skilled and unskilled persons, and the interrelationship between career and regional mobility are central issues in this research field. The 'brain drain' and the transfer of talent from peripheries to centers strongly contribute to the long-term persistence of spatial disparities at all scales.

The more recent research topics and possible future directions include issues such as: (a) spatial disparities of research input (financial, technical and human resources, infrastructures), and research output (e.g. patent density, innovation density); (b) spatial differences in the quality of schools (measured by achievement tests); (c) the necessity of adjusting curricula to local economic needs or cultural traditions; (d) the role of schools (teachers) for local cultures and local empowerment; (e) the definition and spatial delimitation of creative (innovative) milieus, regional, and international differences of high-tech competitiveness; (f) the effects of telecommunications on the spatial distribution of work places for knowledge workers; (g) the role of indigenous and religious knowledge; (h) the evolvement and long term spatial effects of scientific networks; (i) the relation between human resources, endogenous economic development and economic conduct; (?j) the role of knowledge producers in the construction of historical narratives, national memories, and regional identities; and (k) the use of knowledge or enforced ignorance as a means to discipline and control. This list of research topics is never closed and strongly depends on the region, culture and time period studied. As knowledge is 'a capacity for social action' (Stehr 1994), and as it influences the perception, evaluation, decision making and actions of individuals, and the conduct of constituencies, a knowledge-based approach can be applied to a broad range of topics in human geography.

Knowledge (Explicit and Implicit): Philosophical Aspects

Explicit knowledge is knowledge that the knower can make explicit by means of a verbal statement: 'Someone has explicit knowledge of something if a statement of it can be elicited from him by suitable enquiry or prompting' (Dummett 1991). Implicit knowledge can then be defined simply as knowledge that is not explicit. On this construal, implicit knowledge corresponds roughly to what Polanyi calls 'tacit knowing': 'we can know more than we can tell' (1967).

The distinction between explicit and implicit knowledge might seem to be connected closely to the familiar distinction (Ryle 1949) between knowledge of a proposition ('knowing that') and possession of a skill ('knowing how'). In everyday cases of 'knowing that' (such as knowing that the atomic number of lead is 82) the knower can say what it is that they know. In contrast, it is manifestly possible to have a skill (such as the ability to tie one's shoelaces) while being quite unable to give any verbal account of how the performance is achieved. So 'knowing how' may provide examples of Polanyi's 'tacit knowing.'

But implicit knowledge, as it is considered here, is closer to 'knowing that' than to 'knowing how.' In cases of implicit knowledge, a proposition or rule is known, but this is not available to the knower for verbal report. In the absence of verbal report, an attribution of implicit knowledge must be supported by other kinds of empirical evidence. But more fundamentally, we need some account of what it is for a subject to possess knowledge but to be quite unable to make it explicit (cf. Dienes and Perner 1999).

1. *Implicit Memory and Perception*

In cognitive psychology, a distinction is drawn between explicit and implicit tests of memory. Explicit memory tests 'make explicit reference to and demand conscious recollection of a specific previous experience.' But in an implicit memory test 'memory for a recent experience is inferred from facilitations of performance … that need not and frequently do not involve any conscious recollection of the prior experience' (Schacter 1989). For example, a subject might be shown a list of words and then tested in various ways. In an explicit test, the subject might be asked to say which words were on the list (recall) or might be presented with words and asked whether they appeared on the list (recognition). In an implicit test, the subject might be given a task that involves responding to words (e.g., by reading them aloud). Memory for the words on the list would be inferred from the fact that the subject reacts faster to those words than to words that were not on the list. The subject's reaction to a word that was on the list is said to be 'primed' by the earlier exposure to that word.

Intuitively, explicit tests of recall or recognition probe whether the subject still knows, in the everyday sense, which words were on the list. In contrast, implicit tests seem to provide evidence that information about which words were on the list is in some way present in the subject, perhaps in a form that can influence the subject's performance only on particular tasks. This intuitive idea that the two kinds of tests probe rather different kinds of memory, or information storage, is supported by findings that there are factors that affect performance on explicit tests and implicit tests differently (Schacter 1989). For example, extending the interval between the initial exposure to the list and the subsequent test may impair performance on an explicit test but not on an implicit test. Conversely, changing the sensory modality of presentation between initial exposure to the list and subsequent test (e.g., from auditory to visual presentation) significantly reduces priming effects in an implicit test but has little or no effect on recall and recognition in an explicit test. In addition, under some conditions performance on an implicit test has been shown to be uncorrelated with success or failure on an explicit test.

Priming effects may be observed even in the total absence of recall or recognition. When a word is initially presented with a very short exposure, and is followed by another stimulus to produce 'backward masking', the subject is quite unable to report anything about the word. But that initial presentation may still facilitate responses to the same word in a subsequent task. The results of masked priming experiments demonstrate implicit memory without explicit memory.

In cases where a subject is unable, even at the time of the first presentation, to report which word appears on the screen, we may say that perception itself is implicit rather than explicit: it is 'perception without awareness.' The influence of perceptually presented information of which the subject is unaware is also apparent in an experiment involving very brief presentations of photographs of faces that show expressions of emotions (Dimberg et al. 2000). Subjects are shown a happy, neutral, or angry face, rapidly followed by a

neutral face (to produce backward masking). They report seeing nothing before the neutral face. Yet their facial reactions, detected by measuring activity in facial muscles, are significantly different, depending on the emotional expression of the briefly presented face.

2. Knowledge and Belief

It is natural to describe these cases of implicit memory and implicit perception by saying that the tests reveal that the subject knows more than she can tell. But it is also natural to raise a query about the use of the term 'know' here. In epistemology, knowledge is usually taken to be true belief that meets some further condition involving justification of the belief or reliability of the method by which the belief is produced. The mechanisms of information gathering in perception and information storage in memory are plausibly reliable. But the notion of justification does not seem to be applicable in cases where the subject is unaware of the presence or influence of the information. So, if knowledge always involves justification, then so-called implicit knowledge does not seem to meet the requirements for knowledge. And even if knowledge is construed in a more inclusive way, there is room for doubt as to whether implicit knowledge amounts to a belief on the part of the subject.

At least three factors contribute to this doubt. One is the subject's lack of awareness. But this is not, by itself, decisive since it is possible to make sense of the notion of an unconscious belief. A second factor is that implicit knowledge seems to be limited in its influence. A belief may figure in many different ways in the subject's subsequent reasoning and planning, depending on their other beliefs and desires. But implicit knowledge that a happy face has been presented has only been shown to affect facial muscles. States of implicit knowledge do not appear to be inferentially integrated with the subject's beliefs (Stich 1978); they are, rather, inferentially isolated. However, this again is not quite decisive, since we can make sense of the idea of compartmentalized beliefs.

A third factor contributing to the doubt about the applicability of the folk psychological notion of belief is that believing requires the possession of concepts. No one can believe that penguins waddle without having some concept of penguins and of waddling. But, in at least some of the cases of implicit knowledge that we have mentioned, the subject does not need to possess the concepts that a theorist would use to characterize the information that has been gathered and stored. Thus, for example, the involuntary facial response to a happy or angry face does not seem to depend on the subject having any conceptualized grasp of the emotions of happiness or anger. A subject who lacks the concepts of happiness or anger cannot have any beliefs about happiness or anger. Yet such a subject may, it seems, be described as possessing implicit knowledge that a happy face or an angry face has been presented.

These considerations do not show that cases of implicit knowledge should never be grouped together with ordinary knowledge and belief. But examples of implicit memory and perception illustrate how, in cognitive psychology, the notion of implicit or tacit knowledge encompasses unconscious storage and processing of information whether or not this falls within the domain of the folk psychological notion of belief.

3. Preserved Implicit Knowledge in Neuropsychological Patients

Patients suffering from brain damage as a result of a stroke or head injury often show preserved implicit knowledge in the absence of explicit knowledge (Schacter et al. 1988).

Amnesic patients cannot remember recent experiences. If, for example, an amnesic patient is given a list of words to study she will perform poorly on a subsequent test of recall or recognition. But studying the list, even though it goes unremembered, may affect subsequent performance. In some cases, amnesic patients who are asked to complete three-letter sequences with the first words that come to mind, show the influence of the studied list in much the same way as happens with normal subjects (Warrington and Weiskrantz 1968). This is implicit memory in the absence of explicit memory.

Some patients are blind in a region of their visual field as a result of damage to their visual cortex. They are unable to report whether a light stimulus is present or absent in that region, to say whether a presented stimulus is, for example, an X or an O, or to discern the emotional expression on a face presented in the blind field. The patients say that they do not see the stimulus at all. Yet some of these patients, when asked to guess whether a stimulus is present or absent, or whether the stimulus is an X or an O, or whether a video clip presented in the blind field shows a happy or a fearful face, perform significantly above chance levels. This is the phenomenon of 'blindsight' (Weiskrantz 1986, de Gelder et al. 1999). It is a case of implicit perception in the absence of conscious or explicit awareness of the salient properties of the presented stimulus.

Prosopagnosic patients are unable to recognize and identify familiar faces. If, for example, a patient is asked to classify photographs as being of familiar or unfamiliar faces or to match names to faces, they perform at chance levels. Yet their autonomic affective responses (in particular, skin conductance responses) to familiar faces are significantly different from those to unfamiliar faces. A prosopagnosic patient may be unable to classify the faces of famous people according to their occupation (e.g., politician or television personality) although they can, of course, correctly assign occupations to the names of these people. But,

in some cases, presenting the face of a television personality alongside the name of a politician or vice versa interferes with the patient's performance when asked to assign an occupation to the name, just as it does in normal subjects (Young 1998). Information about the occupation of the person whose face is presented affects performance even though it is not available for verbal report.

Blindsight and other neuropsychological phenomena present challenges for both philosophical and empirical theories about consciousness. They also raise questions about the extent to which normal subjects are authoritative about the workings of their own minds. A normal subject would probably find it compelling to suppose that, when he sees the face of a television personality, his conscious recognition of the face interferes with his classification of a simultaneously presented name as that of a politician. Although this is likely to be correct, the fact that the same pattern of interference is found in patients who are unable to recognize faces raises an alternative possibility. It is at least conceivable that, contrary to what it is so compelling to suppose, the interference is produced in normal subjects in the same way as in prosopagnosic patients, by a process of which the subject is quite unaware.

4. *Implicit Learning*

Subjects may be trained to classify items as belonging or not belonging to some category by being provided with a principle or rule of classification. That is, the teacher may make the principle or rule explicit. Alternatively, subjects may be provided with a set of exemplars of the category; or they may simply be provided with feedback as to whether their classifications are correct or incorrect. On the basis of studying a set of exemplars, or after a period of training, a subject may achieve performance on the classification task that is significantly better than guessing at random. Indeed, the subject's classifications may be reliably correct. A subject who has attained a reliable level of performance may then be able to state the principle or rule of classification. In this case, even without being explicitly told the rule, the subject has gained explicit knowledge of the rule. But it may happen that the subject is quite unable to state the rule, even though his classifications reliably conform to the rule. In this case, the subject may be said to have learned the rule implicitly. The subject has achieved conformity to the rule without being able to state the rule.

Research in the area of implicit learning involves many complex issues (Berry and Dienes 1993, Shanks and St. John 1994). An experimenter may assign items to a category on the basis of a particular rule of classification, R, and may seek to discover whether a subject who has learned to make the same category assignment has arrived at explicit knowledge of the same rule. But asking the subject whether he is using rule R to make his classifications is problematic since considering that question may itself bring about a change in the subject's explicit knowledge.

Instead, the subject may simply be asked what rule they are using. But, if they do not produce a statement of rule R in response to this question, it by no means follows that the subject's classifications depend on implicit rather than explicit knowledge. One reason is that a rule that is explicitly known might not be volunteered because, for example, the subject is not entirely confident that it is correct. A second reason applies even if the subject does not have explicit knowledge of rule R. It may be possible to achieve classification performance that is significantly better than guessing at random, or even reliably correct over a large range of cases, by using explicit knowledge of some other rule.

To at least some extent, problems with the notion of implicit learning can be overcome by identifying independently well-motivated characteristics of implicit and of explicit knowledge. If a subject does not provide a statement of rule R but nevertheless makes classifications in conformity with rule R then their classification performance can be assessed in the light of these characteristics.

There is, however, a more general problem with the notion of implicit learning of a rule. So far, this has been characterized as learning to make classifications that conform to the rule, yet without explicit knowledge of the rule. We have observed some difficulties in deciding empirically whether explicit knowledge is really absent. But the more general problem is that any battery of performance that conforms to a rule inevitably conforms to more than one rule. If a subject's classification performance conforms to rule R_1 and to rule R_2 and the subject has explicit knowledge of neither rule, then the subject may be said to have implicitly learned something. But that does not settle whether the attained state of the subject should be described as implicit knowledge of R_1 or of R_2. In a case where two rules require just the same classifications, there is a question of principle whether any sense can be given to the notion of implicit knowledge of one rule rather than the other. A considerable body of research on implicit learning concerns the task of learning an artificial grammar (Reber 1989). But it is in the context of discussions of knowledge of natural language grammars that this question of principle has its original home.

5. *Tacit Knowledge of Rules*

In a famous passage, Chomsky (1965) says: 'Obviously, every speaker of a language has mastered and internalized a generative grammar that expresses his knowledge of his language. This is not to say that he is aware of the rules of the grammar or even that he can become aware of them.' Knowledge of the rules or

principles of a generative grammar is usually described as tacit knowledge and it counts as implicit knowledge according to our definition. The claim that ordinary speakers of natural languages tacitly know a grammar for their language is a core element of Chomskyan linguistics (e.g., Chomsky 1986, 1995).

Some philosophers have argued that the claim involves a conceptual confusion on the grounds that the notion of a rule of language belongs with the idea of a normative practice in which people advert to rules to justify, criticize or excuse their actions (Baker and Hacker 1984). But the notion of a tacitly known rule should be distinguished from the notion of a rule that figures in a normative practice. Once the distinction is made, there remains an important question about the relationship between the rules that are tacitly known by individual speakers and the normative practices in which those speakers participate. But that question does not indicate any conceptual incoherence in the very idea of tacit knowledge.

Other critics have urged that the ideas of tacit knowledge of rules and of unconscious information processing in general are problematic because of a deep connection between intentionality and consciousness (Searle 1990). But in response to this worry it can be said that, while there may be a connection between consciousness and the intentionality of beliefs, the states of tacit knowledge that Chomsky talks about are importantly different from belief states (Stich 1978, Davies 1989).

5.1 Quine's Challenge

Quine challenges Chomsky's introduction of the notion of tacit knowledge by making use of the distinction between behavior that conforms to a rule and behavior that is guided by a rule. A subject can behave in a way that conforms to a rule without using the rule to guide his behavior for, as Quine (1972) uses the notion of guidance: '(T)he behavior is not *guided* by the rule unless the behaver knows the rule and can state it.' Guidance requires explicit knowledge.

Chomsky's tacit knowledge is supposed to require less than explicit knowledge; but it cannot be equated with mere conformity. In fact, conformity to rules is neither necessary nor sufficient for tacit knowledge of those rules. It is not necessary, since the presence of tacit knowledge of rules does not guarantee perfect deployment of that knowledge in actual performance. It is not sufficient, since a tacit knowledge claim is not offered as a summary description of behavior but as a putative explanation of behavior. There will always be alternative sets of rules that require just the same behavior for conformity; but it is part of the idea of tacit knowledge that a speaker's actual behavior might be correctly explained in terms of tacit knowledge of one set of rules rather than the alternatives.

It is at this point that Quine (1972) poses his challenge. He insists that, if an attribution of tacit knowledge is an empirical claim that goes beyond a summary of conforming behavior, then it should be possible to indicate what kinds of evidence would count in favor of or against that empirical claim. He also insists that this evidence should involve the subject's behavior. To this latter point, it is reasonable to reply that there can be no a priori limit on the kinds of evidence that might be relevant to an empirical claim. So it is not legitimate to restrict evidence to the behavior of the very subject to whom the attribution of tacit knowledge is being made. But the more general point about evidence is a fair one.

5.2 Sketch of an Account of Tacit Knowledge

More fundamental, however, than the question of what evidence would support an attribution of tacit knowledge is the question what the correctness of such an attribution would consist in. We can sketch one answer to this fundamental question by using an example that involves not rules of syntax but very simple letter-sound rules of the kind that could be employed in reading words aloud. Suppose that one of these rules states that if a word begins with the letter 'b' then its pronunciation begins with the sound /B/. If a subject's pronunciation behavior conforms to this rule then it displays a pattern. Whenever a presented word begins with 'b,' the subject's pronunciation begins with /B/. But the transitions that concern us are not these transitions from presentation to pronunciation. Rather, we focus on transitions amongst beliefs or states of information. Whenever the subject starts out with the information that the presented word begins with 'b,' the subject ends up with the information that the word's pronunciation begins with /B/.

If these states were beliefs, then the subject's pattern of transitions from belief state to belief state would be accounted for if the subject possessed explicit knowledge of the 'b'-/B/ rule. This piece of explicit knowledge would figure as a common factor in the causal explanations of the subject's transitions from belief to belief. In contrast, there would be no such common factor if the subject had merely memorized the pronunciation of each of a large number of words beginning with 'b.' The difference between having explicit knowledge of the rule and having an independent piece of knowledge for each of the instances that fall under the rule corresponds to a difference in causal-explanatory structure.

In fact, we do not assume that the subject has beliefs about words and their pronunciations; the transitions may involve states of the kind that figure in information-processing psychology. Still less do we assume that the subject either has explicit knowledge of pronunciation rules or else has explicitly memorized the pronunciations of words. But we do make use of the idea of a common factor in the causal explanations of transitions. An attribution of tacit knowledge of the

'b'-/B/ rule can be construed as the claim that there is a single state of the subject that figures in the causal explanations of the various particular transitions that the subject makes (Evans 1981).

In general, a state of tacit knowledge is a state that figures as a common factor in causal explanations of certain transitions amongst states of information (or beliefs). Where different sets of rules require the same transitions for conformity, the attribution to a subject of tacit knowledge of a particular set of rules is made correct by the presence of a particular structure in the causal explanations of the subject's transitions (see also Davies 1987, Peacocke 1989).

Once an account of tacit knowledge in terms of causal-explanatory structure has been given, it is a relatively straightforward matter to give examples of empirical evidence that would confirm the attribution to a subject of tacit knowledge of a particular set of rules such as a grammar. Indeed, some of this evidence meets Quine's additional requirement of concerning the behavior of the subject to whom the attribution is being made. Relevant behavioral evidence could come from experimental studies of language acquisition, language perception, and language dysfunction following brain damage, while further evidence would be available from neural imaging.

6. *Explicit and Implicit Representation*

According to the basic notion of explicit knowledge introduced at the beginning of this article, explicitness is a matter of the subject being able to present information in linguistic form. It is not a matter of how the information is stored in the subject's mind or brain when it is not being called upon.

Suppose that someone knows, in the everyday sense of that term, the axioms of some theory. Provided that this knowledge can be verbally articulated it counts as explicit knowledge. Now consider some theorem that is derivable from those axioms. The person who knows the axioms may well, with some suitable enquiry and prompting, be able to see that the theorem follows from the axioms and to state it verbally. For example, someone who explicitly knows some elementary arithmetical facts may be able to work out, and to state, that 68 plus 57 equals 125. On Dummett's account, this latter piece of knowledge, even though it is computed when needed rather than being stored in memory, counts as no less explicit than the stored elementary facts from which it is derived. Indeed, it counts as explicit knowledge even before the knower works it out; for explicitness is defined in terms of the possibility of eliciting a verbal statement by enquiry or prompting. Once some propositions are classified as explicitly known, the category of explicit knowledge also includes at least some of the as-yet-undrawn consequences of those propositions.

But the terms 'explicit' and 'implicit' are also used to mark a number of distinctions that are specifically related to the storage and processing of information. Thus, Dennett introduces a quite different distinction from Dummett's when he says (1983): 'Let us have it that for information to be represented *implicitly*, we shall mean that it is *implied* logically by something that is stored explicitly.' On this different usage, the as-yet-undrawn consequences of propositions that count as explicitly stored would be classified as implicitly represented.

In fact, relative to any given notion of explicit representation or storage of information, it is possible to define a whole family of notions of implicit representation or knowledge. The members of the family differ over the inferential resources that can be used in drawing out consequences from the information that is explicitly stored. We might, for example, consider only deductive inferences that can be carried out by the person in question. Then, if a person explicitly stores elementary arithmetical facts in memory and is able to infer that $68 + 57 = 125$, this would count as implicit representation of that latter fact. Alternatively, we might allow any valid deductive inference, whether or not the person can actually carry it out. In that case, implicit representation or knowledge would outrun the possibility of eliciting from the person a verbal statement. We might go beyond deductive logic and allow methods of induction or rule extraction, with or without a restriction to methods that are available to the person in question. In that case, a person who stores in memory only facts about particulars might count as having implicit knowledge of generalizations or rules that subsume those facts.

The notion of implicit representation also depends on a prior conception of explicit storage. But there is no uniquely correct account of what explicit storage amounts to. One idea that is, however, fairly naturally associated with explicitness in the context of theories of information storage and processing is that explicitly stored information has to be accessed before it can be used. An access problem may result in a failure to use stored information that is relevant to the task in hand. A second idea that sometimes goes along with the notion of explicitness is that explicit storage involves the use of a language-like code. Putting the two ideas together, we have a picture in which explicit storage of information is a matter of linguistic inscriptions on pages that are not always easy to locate. Drawing out the consequences of explicitly stored information would then be naturally conceived as manipulating inscriptions in ways that are analogous to the formal procedures involved in the derivation of theorems from axioms in logical systems (Fodor 1987).

The notions of explicit storage and implicit representation under discussion in this section belong with mechanistic theories about the storage and processing of information. They could be applied to any information-processing systems and have no

special connection with human subjects. Even in the case of human subjects, information might be explicitly stored yet not accessible to consciousness and not available to the subject for verbal report.

A state of tacit knowledge (as sketched in Section 5) could be constituted by the explicit storage of a rule that was not accessible to consciousness. Indeed, it sometimes seems to be assumed that, within the picture of the storage and processing that we have just sketched, tacit knowledge of a rule is always embodied in a mechanism by having the rule explicitly stored. There is a clear distinction between explicitly storing information and using that information; use of stored information involves processes for accessing that information. But such access processes are not typical of the operation of connectionist networks (McClelland et al. 1986): 'Using knowledge in processing is no longer a matter of finding the relevant information in memory and bringing it to bear; it is part and parcel of the processing itself.' So, against the background of the assumption that tacit knowledge involves explicit storage, it is often said that what is distinctive of connectionist networks is that they perform cognitive tasks without having tacit knowledge of rules.

The account of tacit knowledge in terms of causal-explanatory structure certainly allows for the case of tacit knowledge that is a matter of explicit storage. But the key notion in the account is that of a common factor in causal explanations of certain transitions amongst states of information. So the account also allows for the possibility of tacit knowledge that is 'part and parcel of the processing,' and it is left open that tacit knowledge may sometimes be embodied in connectionist networks (Davies 1995).

Knowledge Representation

1. Knowledge Representation: Ideal and Reality

The fundamental conjecture of knowledge-based artificial intelligence (AI), known as the physical symbol system hypothesis (Newell and Simon 1976), posits that the cognitive processes of any broadly intelligent agent, natural or artificial, can be largely characterized in terms of a knowledge base: a transparent, symbolic representation of the agent's beliefs, intentions, and value judgments, together with reasoning processes that modify the knowledge base in rational ways, and perceptual and motor processes that connect the knowledge base to the outside world. The field of *knowledge representation* (KR) is the study of how such a knowledge base can be constructed.

The physical symbol system hypothesis requires that a knowledge base be symbolic, transparent, and modular. That is, the atomic elements of a knowledge base are symbols, each of which has an associated meaning. It is possible to identify small substructures of the knowledge base that correspond to specific beliefs, judgments, and intentions. For example, the belief that Holbein painted a portrait of Thomas More in oil might be represented in a predicate calculus formula like

$$\exists_X \text{ oil_painting}(X)$$
$$\wedge \text{ painter(holbein, } X) \wedge \text{ depicts } (X, \text{thomas_more})$$

or in a fragment of a semantic net, such as that shown in Fig. 1. Here the symbols are '$\exists$' (meaning 'there exists'), 'X' (a variable), '$\wedge$' (meaning 'and'),

Figure 1
Fragment of a semantic net

'oil_painting,' 'painter,' 'holbein,' and 'thomas_more'; the parentheses and the comma indicate the syntactic structure. (The fact that some of these symbols are English words is purely for the convenience of the human reader; the formula could just as well be notated

$$\exists_X \text{ g001}(X) \wedge \text{ g002(g003, } X), \wedge \text{ g004}(X, \text{g005})$$

if it is accepted that 'g001' denotes the property of being an oil painting, that 'g002' denotes the relation of a person painting a painting, and so on.) It should be noted that not every belief of the agent can be explicitly expressed in the knowledge base. For example, a person who knows that Holbein painted a portrait of Thomas More will also know that Holbein knew how to paint; that Thomas More was painted; that Thomas More was born before Holbein's death; and so on. Clearly it is not plausible that each of these ancillary beliefs is separately represented in the knowledge base. Rather, they are represented implicitly, in the sense that they can be derived as needed.

Of course, the construction of the broadly intelligent artificial agent described above is today just a pipe dream for the distant future. Any work aimed at achieving a working system any time soon must be much more modest in its ambitions. Within the context of such limited objectives, the problem of knowledge representation is one of finding data structures that express the knowledge needed for the particular application.

Thus broadly construed, the problem of knowledge representation would appear to be equivalent to computer programming generally. Any program, after all, uses some data structures, and incorporates some kind of knowledge. What distinguishes a data structure as interesting from the point of view of knowledge representation is that its design reflects some of the features of the broadly intelligent knowledge-based agent described above. As artificial intelligence is the study of tasks that are easy for people (or animals) to carry out but difficult to implement in a computer, so knowledge representation is the design of data structures that express knowledge that people deal with easily, but are hard to encode in a data structure.

The design of a knowledge representation can be very roughly divided into four parts

(a) *Architectural* issues involve defining general-purpose schemas for knowledge representation and procedures for reasoning with these schemas. Most of the research in knowledge representation has been addressed to architectural issues, as they are largely independent of the particular domain and application (Reichgelt 1991).

(b) *Content* issues address such questions as what is the knowledge to be represented, how should the domain be conceptualized, what are the key concepts in the domain, and what kinds of partial knowledge must be dealt with. Since content issues are always

domain-dependent, and often task-dependent, they are much less susceptible to general treatment. However, there are some domains—such as time, space, epistemic states, plans, and so on—that are so ubiquitous in intelligent reasoning, and so difficult, that it is worthwhile studying them extensively in the abstract, without reference to a particular application (Davis 1990).

(c) The *implementation* of the knowledge representation as a data structure and of the reasoning mechanisms as procedures is usually carried out in a uniform way for a given architecture; alternatively, it may be highly specialized to a particular class of problems.

(d) Finally, any knowledge representation requires an *interface*, either to user queries or to application programs such as robot control. As interface issues are entirely task-dependent, there is very little that can be said about them in general.

This article will begin (Sect. 2) by discussing some features that are desirable in a knowledge representation. It will then (Sect. 3) survey some of the important architectures in knowledge representation. Section 4 will discuss the issue of content, illustrating it with a brief discussion of representations of time. Finally, Sect. 5 will discuss two alternative approaches to knowledge representation: neural networks and digital libraries.

2. *Desiderata*

The design of a knowledge representation, whether for a broadly intelligent agent or for some limited application, will generally aim toward the following objectives:

(a) *Scope*. A comprehensive knowledge representation scheme should ideally be extensible to cover any possible object of human thought, and any humanly possible belief system.

Table 1

O'Keefe	USA	1887	1986

Of course, the designer of a KR theory need not explicitly state how the theory can express knowledge about the Parthians, the blue whale, and the Crab Nebula. But a convincing case should be made that beliefs about such things can be expressed in the representation, if necessary. A complete KR theory should explain in detail how to represent fundamental and universal subjects of human thought, such as time, space, simple physical categories, the human mind, and human relations (Davis 1990, Hayes 1979, McCarthy 1968).

A knowledge representation for a limited application should cover all relevant aspects of relevant domains.

(b) *Expressivity*. The KR scheme should be able to express the various forms of partial and incomplete knowledge that naturally arise for the desired application.

For example, a standard form of representation is a collection of tables of values, known in computer science as a 'relational database.' For example, Table 1 displays a table of paintings and a table of artists.

However, even within its narrow scope, such a representation may not achieve reasonable expressivity, because there is no way to express plausible partial states of knowledge such as:

Turner lived in the nineteenth century.

Rembrandt painted many oil paintings.

Vermeer did not make any sculptures.

The Sistine Chapel and the sculpture of David were created by the same artist.

If such partial states of knowledge are important in the application, then a more expressive language must be found.

Another example: it is tempting to represent spatial information using a representation that corresponds to a single picture of the scene (see *Computational Imagery*). This is often called *diagrammatic representation*, (Glasgow et al. 1995), though this term is used in many different conflicting ways. Such representations are easily understood and support efficient inference. However, they cannot be used to represent partial information. For instance, an agent might know that A is a mile from B and that A is a mile from C without knowing the distance from A to C. However, it is not possible for a single picture to display the distances from A to B and from A to C without committing itself to some particular distance between B and C. Therefore, unless all the program's geographic knowledge can always be expressed in a precise map, this representation will not be sufficiently expressive.

(c) *Precision*. The meaning of a knowledge representation should be unambiguous, and, as far as the nature of the subject matter allows, well defined.

(d) *Support for reasoning*. It must be possible to model the processes of reasoning involved in cognition in terms of well-defined operations over the knowledge representation. For example, as mentioned above, an agent who knows that Holbein painted a portrait of

More should be able to conclude that Holbein knew how to paint, that More was born before Holbein died, and so on.

(e) *Efficiency of reasoning*. The implementation of reasoning operations over the knowledge representation must also be efficient. Conclusions must be derived in the time that they are needed, often a matter of seconds or fractions of a second.

(f) *Learnability*. A broadly intelligent agent must be able to learn over time from experience and from instruction. Therefore, modules must exist that can learn from experience and can generalize individual cases to general rules. The knowledge representation should support such learning modules (Mitchell 1997).

(g) *Support for uncertainty*. If an agent can only use knowledge that it knows with 100 percent certainty, it will be paralyzed. Rather, an agent must be able to compare relative likelihoods, and to take action on the basis of the best information it can get. A knowledge representation should therefore support the expression of relative degrees of certainty, and reasoning modules should be able to take these degrees of certainty into account (Pearl 1988).

(h) *Robustness*. The information in a knowledge base will sometimes be simply wrong or corrupted. The effects of a single error in the knowledge base should be limited in scope.

(i) *Ease of construction*. In the best case, it may be possible to build a large knowledge base automatically or semiautomatically from existing data sets, such as conventional databases, online libraries, or collections of digitized images. If the knowledge base must be constructed by hand, then a notation that is simple and natural enough to be used by programmers with little technical expertise is clearly preferable to one that can be used only by an expert in knowledge representation. Other things being equal, the less human labor, especially expert labor, that is required to build a knowledge base, the better.

(j) *Interface*. A knowledge representation should support a suitable interface to the user or the application.

Expressivity and precision are features, both of the architecture and of the content of a knowledge base. Scope is chiefly a feature of content, though expressivity and therefore architecture do bear on scope; some domains inherently require a very expressive language. Robustness, ease of construction, and support for reasoning, for learning, and for uncertainty are primarily features of the architecture. Efficiency of reasoning depends on the implementation, which, in turn, reflects the architecture, and on the class of problems being solved.

3. Architectures

A number of KR architectures are briefly surveyed below. The particular architectures included here have been included, in part because of their importance in KR research and applications, and in part to illustrate the range of possible approaches to KR.

3.1 Logic-Based Systems

A logic-based system represents knowledge as a set of sentences in a logical language. Reasoning is implemented as inference procedures that carry out deductive proofs authorized within the logical theory (Geneserth and Nilsson 1987) (see entry *Deductive Reasoning Systems*).

A logical theory characteristically consists of three parts

(a) *A syntax*, which specifies what kinds of symbols may be used, and how they can be combined to form well-formed sentences.

(b) *A semantics*, which specifies what kinds of meanings may be attached to symbols, and how these meanings combine to form the meaning of sentences.

(c) *A proof theory*, which specifies what manipulations over sentences constitute deductive proof.

For example, first-order logic (also known as the predicate calculus) is the most widely used logic in knowledge representation. In first-order logic, there are seven kinds of symbols.

(a) *Constant* symbols represent individual entities. For example 'holbein' may represent Hans Holbein. The symbol 'ad1517' may represent the year 1517.

(b) *Predicate* symbols represent properties of relation. For example, 'painter' may represent the two-place relation of a person painting a painting. The predicate 'precedes' may represent the two-place relation of one event preceding another.

(c) *Function* symbols represent mappings. For example, 'birth_of' may represent the one-place mapping of a person to the event of his/her birth. The function 'creation_of' may represent the one-place mapping of an artifact to the event of its creation.

(d) The *Boolean operators* are '$\wedge$' meaning 'and'; '$\vee$' meaning 'or'; '$\neg$' meaning 'not'; and '$\Rightarrow$' meaning 'implies.'

(e) *Variables*, such as X, Y, Z, represent indeterminate objects.

(f) The *quantifiers* are $\forall$ meaning 'for all,' and '$\exists$' meaning 'there exists.'

(g) Finally, the grouping symbols, which serve to specify the structure of a sentence, are the comma and the open and close parentheses.

Constant, predicate, and function symbols are known as *non-logical* symbols; they may be chosen, and their meanings may be assigned, by the designer of the knowledge base. Boolean operators, quantifiers, variables, and grouping symbols are known as *logical* symbols; their meanings are fixed by the logic. The distinction is roughly analogous to the distinction between open and closed categories in linguistics, or to the distinction between identifiers and reserved words in programming languages.

The syntactic rules for first-order logic establish that these symbols can be put together to form sentences such as

(1) $\forall_{X,Y}$ painter $(X, Y) \Rightarrow$ precedes(birth_of(X), creation-of(Y))

The semantic rules establish that, given the above assignments of meanings to the symbols 'painter,' 'precedes,' 'birth_of,' and 'creation_of,' the meaning of this sentence is that the birth of a painter precedes the creation of any of his works. The proof theory establishes that, given formula (1) above and the fact, 'painter(holbein, more_portrait),' it is possible to infer

(2) precedes (birth_of(holbein), creation_of(more_portrait)),

i.e., that Holbein was born before the portrait of More was painted. Details of these rules may be found in any logic textbook (e.g., Mates 1972)

First-order logic is probably the most common foundation for a logic-based knowledge representation, but many other logics have also been applied. Some of these extend first-order logic to achieve greater expressivity. *Modal logics* define a variety of operators on sentences. For instance, given a base sentence such as 'Bill Clinton is President,' a *temporal* operator might generate the sentence 'Bill Clinton has been President,' an *epistemic* operator might generate the sentence, 'Al Gore knows that Bill Clinton is President'; a *deontic* operator might generate the sentence 'Bill Clinton ought to be President.' These operators can be combined, as in the sentence 'Al Gore should have known that Bill Clinton would be President' (Turner 1984). *Fuzzy logic* allows the use of vague terms that are hold to greater and lesser degree; for example, 'George Washington was a tall person' is reasonably true, 'Abe Lincoln was a tall person' is quite true, 'Wilt Chamberlain was a tall person' is absolutely true (Zadeh 1987). *Probabilistic logics* allow sentences to be tagged with a measure of certainty (Bacchus 1990).

Other knowledge representations have used logics less expressive than the predicate calculus in order to achieve greater efficiency in a general purpose inference engine. For instance, in the *propositional calculus*, the only logical symbols are Boolean operators, and a separate symbol must be used for each atomic proposition. Thus there is one symbol for the proposition, 'Leonardo painted the Last Supper,' another for the (false) proposition, 'Rodin painted the Last Supper,' and so on. General rules like formula (1) above can then only be stated every instance for every pair X and Y. Despite this proliferation of symbols and formulas, however, as long as the underlying domain is not too large, it is often more effective to use the propositional calculus than the predicate calculus because the best methods of inference known are much faster for the propositional calculus than the predicate calculus (Selman et al. 1992).

The chief virtues of logic-based representation are precision and modularity. The meaning of a formula in a logic-based representation is completely and exactly fixed by the logic and the meaning of the symbols included. It is independent of any other formula in the knowledge base, and any other aspect of the knowledge base. Another important virtue is that procedures for deductive inference over logic-based knowledge bases are known. These procedures characteristically generate only valid inferences and all valid inferences (in the technical jargon, they are *sound* and *complete*) and, in practice, they can often be implemented so as to find useful answers quickly.

Their chief failing is difficulty of use. Building a knowledge base in a logic-based representation inevitably requires a large investment of expert labor. Moreover, even experts in knowledge representation find the encoding of complex domains in logical languages surprisingly difficult and error-prone. Logic-based languages also tend to be fragile. In principle, any inconsistency in any part of a logical theory invalidates the entire theory; and in practice small and subtle inconsistencies in foundational parts of a logic-based knowledge base can lead to bizarre and unpredictable results.

3.2 Semantic Networks

A *semantic network* consists of labelled nodes connected by labelled arcs (Fig. 1). A node may represent an individual such as Hans Holbein or a category, such as oil paintings. An arc represents a two-place relation between nodes, such as the relation 'painter' between a work of art and a person.

The most important arcs in any semantic network are those labelled 'INST' and 'ISA.' An 'INST' link goes from an individual I to a category C and asserts that I is an instance of C. An ISA link goes from category C to category D and asserts that C is a subset of D. Implicitly, therefore, if there is a chain of ISA links from C to D, then it can be inferred that C is a subset of D. If there is an INST link from I to C and then a chain of ISA links from C to D, then it can be inferred that I is an instance of D. For instance, in Fig. 1, it can be inferred that oil paintings are works of art, and that the portrait of Thomas More is a work of art.

The central reasoning mechanism in a semantic network is *inheritance*: a node inherits all the properties of the nodes that contain it. For instance, in Fig. 1, the node 'MORE_PORTRAIT' inherits the 'MEDIUM' arc to 'OIL' from 'OIL_PAINTING'; it inherits the 'FORM' arc to '2D-IMAGE' from 'PAINTING'; it inherits the 'DEPICTS' arc to 'PERSON' from 'PORTRAIT.' In other words, the system can infer that the portrait of More is a two-dimensional image from the facts that it is a painting, and that all paintings are two-dimensional images.

The semantic network architecture, as described above, has a number of advantages. It is easy and natural to use; its meaning can be defined precisely;

Table 2
Two frames

```
frame more_portrait
inst:   oil_painting;
genre:   portrait;
depicts:   thomas-more;
shape:   rectangle (29.5 * inch, 23.7 * inch);
surface:   wood;
date:   1527;
painter:   holbein;
owner:   frick;
image:   more.gif {file with displayable image};
endframe

frame oil_painting
isa:   painting;
medium:   oil;
surface:   ⟨OR⟩ [canvas, wood];
date:   ⟨CONSTRAINT⟩ [@.painter.birth <@.date <
        = @.painter.death];
painter:   ⟨OR⟩ [⟨INSTANCE⟩ person,
           ⟨INSTANCE⟩ workshop];
owner:   ⟨OR⟩ [lost, destroyed, ⟨INSTANCE⟩ person,
         ⟨INSTANCE⟩ institution];
endframe
```

and the inheritance mechanism is easy to implement and efficient. The chief disadvantage is that it is not very expressive. Also, the apparent simplicity of the representation can end up working against precision; unless the user adheres rigorously to the specifications of use, it is very easy to construct a semantic network that looks plausible, but that uses the same notation with two completely different meanings (Woods 1975).

It is possible, and indeed common, to increase the expressivity of the very minimal architecture described above by adding additional features, such as 'meta-arcs' that connect two arcs and describe the logical relations between them (Sowa 2000). However, the more such features are added, the less simple and natural the representation becomes.

3.3 Frame-based systems

A frame represents either an individual or a category, and associates with its subject a collection of pairs of a *slot* with a corresponding *filler*. A slot is just the name of a feature of an individual. A filler of a slot for an individual is just the value of that feature; for example, the 'color' slot for 'statue of liberty' has filler 'green.' The filler of a slot for a category contains information of some kind about the fillers of the same slot for individual instances of the category. This can take many different forms; it can be a particular value, a range of values, a constraint on values, or a function that computes the value. A tag, or structure of tags, indicates which type of information is involved. For instance, in frame 'oil-painting' in Table 2, the value of the 'date' slot is a constraint asserting that the date of a painting must take place within the painter's lifetime. The '@' sign used here is a special-purpose variable meaning the particular instance of the frame. The value of the 'painter' slot must either be a particular human or a particular workshop. The value of the 'owner' slot is either a particular person or institution, or the values 'lost' or 'destroyed.' (Note: the specific syntax used here is invented, but the features are typical of frame-based systems.) As in semantic nets, frames inherit fillers through 'inst' links, which contact an individual to a category, and through 'isa' links, which connect a subcategory to a super-category. Other forms of inference in frame-based systems include computing or verifying the value of a slot using inherited procedures or constraints and categorizing a new individual as an instance of a category based on its features (Minsky 1975, Borgida et al. 1989).

Obviously, frame-based systems are in many ways similar to object-oriented programming languages; indeed, the two theories interacted strongly in their development.

The chief advantages of frame-based architectures are expressivity, flexibility, and ease of use. The chief disadvantages is lack of precision, and lack of a well-defined model of inference. The architecture provides a wealth of features and options for both representation and inference, but only a weak underlying model. Hence, in a complex case, it is difficult to predict how these features will interact, or to explain unexpected interactions, which makes debugging and updating difficult.

4. Content

The most difficult problems facing the designer of a knowledge base are those of content: What knowledge is needed for a given application, what concepts are needed, and how can the knowledge be effectively encoded in a given architecture?

For specialized knowledge-based systems, known as expert systems (see *Expert Systems in Cognitive Science* and *Expert Systems in Medicine*), the accepted procedure of encoding knowledge involves an extended collaboration between a human expert and a 'knowledge engineer.' The knowledge engineer observes the expert solving a problem, and interviews him in as great depth as possible as to how he found the solution, how his reasoning was justified, what additional factors could have led him to other conclusions, and so forth. The knowledge engineer then abstracts a system of concepts and rules, and implements a prototype reasoning program. The knowledge engineer tests the program on a collection of examples, the expert provides a critique of the behavior of the program, and the knowledge engineer uses this critique to refine and improve the program (Stefik 1995).

In encoding commonsense knowledge, a popular methodology is to begin by defining a microworld, a small, coherent domain of study. Aspects of the real world that lie outside the microworld will either be idealized away or dealt with in a coarse, *ad hoc* manner. A collection of commonsensically obvious inferences in the microworld is assembled. The researcher constructs a formal model that suffices to justify these inferences; defines symbols to express the concepts used in the inferences; and expresses the knowledge involved in the inferences in terms of these symbols in the chosen knowledge-base architecture. Over the course of time, the microworlds considered become broader in scope and richer in detail (Davis 1990, 1998).

4.1 Time

The issues involved in content may be illustrated in a discussion of representations of time, certainly the most ubiquitous domain in automated reasoning.

Ontologically, time may be taken to be discrete or continuous, to be linear or branching, to consist of points or of intervals, to be Newtonian or relativistic. Which choice is made depends on the applications being considered. For instance, in a chess-playing program, it is natural to take time to be discrete (as nothing significant happens between successive states of the board), and to be branching (to express the options available to each player at each stage). In reasoning about most physical processes, it is usually desirable to take time to be continuous, in order to describe continuous change, and linear, since no choices are being made. (Uncertainty about the future, as opposed to choices about the future, is easily accommodated in a linear theory of time.) The relativistic model of time need only be invoked if the application involves multiple observers whose relative speed is a large fraction of the speed of light.

Many different languages have been devised for time. Some of the most popular include:

(a) *Time stamps*. If a linear model of time is used, and clock times are known precisely and are important, then each event can be marked by date and clock time.

(b) *Numerical constraints on time*. If a linear model of time is used, and clock times are important but are not fully known, then a reasonable representation can use a collection of symbolic constraints between the times of events, such as 'The date of the painting of More's portrait comes after Holbein's birth and before his death.'

(c) *The situation calculus*. This theory uses a branching, discrete model of time. There are three primary types of entities: situations, which are essentially instant of time; fluents, which are proposition whose value changes over time, such as 'Clinton is President'; and actions which mediate between one situation and a successor situation. The two principal symbols are 'results(S, A),' which maps a situation S and an action A to the situation that results if A is performed in S; and 'holds(S, F)' the assertion that fluent F holds in situation S (McCarthy and Hayes 1969).

(d) *The event/interval calculus*. Another representation for time popular in KR research is based around intervals and events. There are 13 possible temporal relations between intervals; interval I may entirely precede interval J; or the end of I may coincide with the beginning of J; and so on. The interval language contains primitives to describe these 13 relations, plus the reaction, 'occurs(I, E),' meaning event E occurs in interval I (Allen 1983).

(e) *Tense logic*. This was developed in the philosophical literature to formalize the tenses of natural language. It is a modal logic, containing operators like, 'ϕ will always be true,' 'ϕ has been true at some time in the past,' and so on (van Benthem 1983).

(f) *Dynamic logic*. This representation is popular in formal theories of programming languages. It uses a discrete, branching model of time. Statements have the form 'after P has been executed, ϕ will be true' where P is a plan or a computer program.

4.2 Very Large Knowledge Bases

Several recent projects have attempted to construct knowledge bases that encode some substantial fraction of commonsense knowledge, including the wellknown *CYC* project (Lenat 1995) and the HPKB and Ontolingua projects. The architectures of these systems combine logic-based and frame-based features, and supply powerful and well-designed inference engines and user-interfaces. The associated knowledge bases are extremely large, and have been successfully applied in a number of different tasks, including natural language interpretation, and front ends to commercial databases. No systematic evaluation of the contents of these systems has been published, and the degree of success that has been attained in addressing the fundamental challenges of knowledge representation and commonsense reasoning is therefore difficult to determine.

5. Alternative Approaches

The KR architectures we have considered above, together with many other proposals of a more or less similar flavor, such as production systems, constitute what may be called the 'classical,' or (with some question begging) the 'knowledge-based' approach to AI. Knowledge representation, in this view, involves large, complex structures of symbols, defined and assembled by hand. This approach to AI essentially derives from a line of philosophical thought running from Descartes through Leibnitz, Frege, and Russell.

In the late 1980s and 1990s, however, as a result of the inherent difficulty of this line of research, and of the limited progress that has been made, this approach to AI has been challenged by two alternative methodologies: neural networks, and statistical analysis of large corpora (see *Neural Networks and Related Statistical Latent Variable Models* and *Statistical Analysis of Large Corpora*).

Neural network research (Haykin 1999) attempts to construct computational models that resemble, with greater or lesser fidelity, the structure of the brain as currently understood. These models vary greatly in detail, but, generally speaking, they consist of a fixed structure of very many, interconnected, primitive computational parts. Each such part models a single neuron. The behavior of a part is controlled by a small set of numerical parameters. In *task execution* mode, the network begins with an input state, representing the task to be accomplished, and evolves toward an output state, representing the desired behavior. In *learning* mode, the network tries to adjust the values of the control parameters so as to achieve optimal behavior during task execution.

The permanent knowledge of such a network is thus encoded in the value of the parameters that govern the neurons. This encoding is typically opaque and distributed; that is, it is not possible to say how the parameter values encode the knowledge or even to localize the knowledge to a particular part of the network. Rather, the knowledge is an emergent property of the network as a whole.

The strength of a neural network lies in the strong theory of learning that applies. Neural networks are also generally very robust; they can often survive well if some of the training data is incorrect, or if some of the components are unreliable. Scope and expressivity are characteristically much more limited than in conventional knowledge-based systems: a neural network generally carries out a small set of narrowly focused tasks.

The difficulties in constructing a neural network are very difficult from those of constructing a symbolic representation. It is not necessary, or indeed possible, to handcraft the representation to fit one's understanding of the domain. However, it is often necessary to tune the structure of the network and the learning algorithms rather carefully to fit the application. This tuning is much more an art than a science.

The statistical approach to AI involves taking very large corpora of data, and analyzing them in great depth using statistical techniques. These statistics can then be used to guide new tasks. The resulting data, as compared to the knowledge-based approach, are extremely shallow in terms of their semantic content, since the categories extracted must be easily derived from the data, but they can be immensely detailed and precise in terms of statistical relations. Moreover, techniques—such as maximum entropy analysis—exist that allow a collection of statistical indicators, each individually quite weak, to be combined effectively into strong collective evidence.

From the point of view of knowledge representation, the most interesting data corpora are online libraries of text. Libraries of pure text exist online containing billions of words; libraries of extensively annotated texts exist containing hundreds of thousands to millions of words, depending on the type of annotation. Now, in 2001, statistical methods of natural language analysis are, in general, comparable in quality to carefully hand-crafted natural language analyzers; however, they can be created for a new language or a new domain at a small fraction of the cost in human labor (Charniak 1993, Armstrong 1994).

Viewed as a knowledge representation, natural language text is, of course, unparalleled in terms of scope, expressivity, and ease of construction. (A few domains of human knowledge, interestingly, lie largely outside the scope of natural language; natural language is notoriously poor at expressing spatial knowledge or mechanical knowledge, such as how to tie a shoelace.) It is exceptionally weak in terms of precision and support for inference. Natural language constructs are constantly, massively ambiguous, and the disambiguation that human understanders carry out automatically and effortless depends, in many cases, on precisely the kinds of world knowledge whose representation has been found to be so difficult.

Knowledge Societies

The analysis of contemporary societal change toward information society or knowledge society can emphasize two different sets of variables: technological innovation and institutional transformation. If it is theoretically controversial as to how both sets may be causally interrelated—ranging from technological determinism to the social shaping of science and technology—empirical oberservation certainly benefits from focusing on both: the impact of technological change on the organizational and cultural institutions of society as well as on the enormous monetary and cultural investments of corporate and individual agencies in developing and using new knowledge. The terms 'information society' and 'knowledge society,' though overlapping in many respects, may help to distinguish these perspectives. The first relates to the pervasive influence of computer-based networks and thereby the globalization of information, communication, and control technologies. It assumes that collecting, copying, storing, transmitting, incorporating, manipulating, simulating, and managing information about every aspect of collective and individual life penetrate and shape all these aspects. The concept of 'knowledge society' emphasizes in a complementary way the problems and strategies of making sense of information. The knowledge work of researchers, experts, analysts, and users depends much on and contributes to information—but what makes this work important is its use of theories, models, scenarios, evaluation criteria, decision strategies, experimental designs, and implicit experience in order to establish bits and pieces of orientation and certainty. Orientation and certainty are needed by individual and corporate actors who face the risks of decision-making in an environment that has become complex, opaque, and rapidly changing precisely because of the infinite amount of information it contains. The instantaneous availability of ever increasing resources of information and information about information vastly increases the need to know something about its value and relevance (Earl 1996).

When the term knowledge society was coined, the path of societal development was conceived much more clearly. Fritz Machlup (1962) was the first to estimate the contribution of knowledge work to the economy; Peter Drucker (1969) developed guidelines for mastering the discontinuity brought about by information technology and knowledge work; Daniel Bell (1971, 1973) predicted the stage of postindustrial society, in which theoretical knowledge would be the new 'axial principle' of society and strategic resource of progress. A parallel line of reasoning was developed by reform Marxists in the so-called Richta report (1969) and the Japanese 'Plan for an Information Society' was presented to its government in 1972 (Masuda 1981). These followed a period of improving the empirical data base (Porat 1977), pondering the validity of concepts (Lyon 1988), and comparing different countries (Edelstein 1978).

Scholarly and public attention became steadily intensified and extended the general themes of the societal centrality of knowledge to a broad variety of fields of investigation: the reconstruction of class structure in knowledge society (Schiller 1981, Schiller and Alexandre 1992), its relation to postmodernism (Lyotard 1984, Poster 1990), globalization and world

society (Castells 1997), the spread of expert culture (Stehr and Ericson 1992, Jasanoff 1990), the relevance of intellectual capital and its impact on the reorganization of business (Beninger 1986, Stewart 1997), and the role of science in knowledge society (Gibbons 1994). Usually the term is used generically, denoting a comprehensive societal change, but with respect to the uneven distribution of conditions it may be analytically preferable to split the generic term and speak of various patterns of knowledge societies (Stehr 1994).

1. Defining the Concept of Knowledge Societies

The reality of knowledge societies might have pleased Plato as putting into practice his ideal of philosophy governing society. It could also be taken as fulfilling the predictions of Condorcet (1743–1794) and Comte (1789–1857) according to which knowledge about the (laws of the) development of society would be put in control of shaping its structure. Or else, the machinery of information and communication technology could be taken to have realized the ideas of integrative and long-range planning developed under the auspices of the OECD in the postwar period (Jantsch 1968). None of these visions has even approximately come true. Neither wisdom, nor generally valid law-like insights, nor integrative and comprehensive scenarios are relevant, but knowledge is expected to be helpful in singling out the risks of decision and action. The permanent modernization of societies leaves all actors in successive states of uncertainty, insecurity, and ambiguity. The more information resources are available for interpreting past experiences, signs of change, and options to adapt, the less likely it is that information itself condenses into reliable knowledge and patterns of orientation. Rather, actors are left alone with the choice between doing anything or nothing—except where there is an agency promising to be specialized in knowing how to read and use information.

Whether, of course, such a promise is reliable, may again be a matter of information which can perhaps be obtained by another agency specialized in watching closely the operations of other knowledge interpreters. The scope of work performed by knowledge agencies covers a broad variety of activities. In many cases knowledge operations become standardized and implemented into machinery and computer-aided systems. To this extent they operate as reliably as other technological tools. Still, there seems to exist a permanent tension between modeling and routinizing processes and structures, and their appropriate use in organizational and individual action. Changing conditions and situational specifities ensure that knowledge tools 'are not simply applied but processes to be developed' (Castells 1997, p. 32). The tension between knowledge as application of certified truth and knowledge as risky investigation of what has become and is going to become uncertain can be discussed on three different levels: industrial routinization of knowledge (Sect. 2.1); professional expertise (Sect. 2.2); and learning by designing tests and experiments (Sect 2.3).

2. The Production, Distribution, and Consumption of Knowledge

2.1 Routinization and Management of Knowledge Work

Knowledge work will always include certain features of individual creativitiy and imagination. But its integration into the institutional framework of society presupposes its transformation from craftsmanship to industry. Though the term 'industrialization of knowledge' may sound anachronistic—at least insofar as knowledge society is conceived to be postindustrial (Bell 1973)—some characteristic changes of knowledge work are similar to the transition from craftsmanship to industrial production. One of the essential nineteenth century breakthroughs of the industrial revolution was the development of a branch specialized in producing machine tools (Rosenberg 1972). The general tendency was to dis-integrate the manufacturing of all parts of a product and to specialize in the production of standardized parts of multiple use and high precision. Similarly, the industrialization of knowledge work proceeds by dis-integrating the craftsman style of manufacturing knowledge—a style that is best represented in the tradition of scientific research groups which start by collecting data from events, arranging them in information packages, and providing interpretation by theoretical models. Contemporary knowledge work transgresses the limits of this tradition. This does not imply a fundamental difference between science and knowledge work but assumes science and its institutions to become part of a new production and distribution system of knowledge. The most important step to be taken in this respect is to understand knowledge as something that can be designed, assembled, shaped, combined, controlled, and adjusted by means of knowledge instruments and that can be certified, licensed, and sold (Fuller 1992). The paradigm of such kinds of knowledge is the algorithm, the software core of all intelligent products and procedures. Algorithms are objectified know-how structures that instruct men, machines, and themselves what to do under certain conditions. In this sense, the history of computer and software industry resembles many traits of the machine tool and other hardware industries. Several authors have rightly stressed the differences between 'Fordist' mass production and 'post-Fordism,' but they overlook the structural similarity and material continuity between industrial and knowledge economies. Viewing know-

ledge as a produceable thing allows one to attach to it the juridical label of being a property. Where the boundary should be drawn between knowledge as either a collective and public or a corporate and proprietary good is highly controversial (Weil and Snapper 1989). Traditional philosophical understandings of knowledge, as well as the received view of professional work as applying disciplinary academic knowledge to single problems, are no longer applicable to most variants of knowledge work. The concept now refers to activities that can be characterized by importing, improving, combining, assessing, and testing knowledge by means of informatized machines, instruments, toolsets, networks, and media in order to produce expertise (Reich 1991). Having stressed the industrial aspects of knowledge work as they become manifest in material and immaterial knowledge machinery, it is only fair to point out the differences. The dynamics of knowledge work tend to create individualistic cognitive styles with respect to methods, problem selection and definition, and communication with partners and clients. It is hence by no means certain that different approaches will produce identical results. This, in turn, provokes a fundamental conflict for the management of knowledge work. On the one hand management must try to increase complexity by bringing together different approaches to defining problems, framing options, and designing solutions. On the other hand it is important to quickly reduce complexity by generating trust in prototypes, which can be tested and improved with selected users (Leonard-Barton 1995). If the main task of knowledge management is the organization of innovation, it does not leave untouched organizational design (Myers 1996). Bureaucracy needs to be replaced by knowledge links, flexible networks, and strategic alliances. Organizations not only have to support the idiosyncratic aspects of knowledge work, but also to turn into learning institutions, which work with visions, experiments, and assessments in order to permanently define the environment to which they want to adapt (Argyris and Schön 1996).

2.2 Facing the Unknown

There is a complementary aspect to the economic and organizational characteristics of knowledge society. Certainly, knowledge would not have become a predominant resource if it could not become transformed in marketable goods and services. It is not less true, however, that every state of knowledge opens up even more notions of what is not known. The more society relies on knowledge, the more it navigates into a dynamics of change. To understand, describe, predict, construct, and control this change becomes illusory—simply because of lack of knowledge.

This is exactly the reason why knowledge experts (Jasanoff 1990) and symbolic analysts (Reich 1991) are needed and expected to create islands of certainty to allow orientation and planning. Demand for knowledge expertise may differ in several respects: by its purposes, ranging from understanding to predicting and constructing; its form of communication, which may be more propositional or more practically embedded; and its scope of application. It may be a rather general theoretical belief system, a generalized rule, a simulation model, a special case experience, or just the solution of an urgent problem. Wherever such expertise is invested, the expectation is to obtain some certainty. But certainty does not exist only in degrees of quality ranging from absolutely valid, to reliable under certain conditions, to better than nothing. It is also exposed to a second-order knowledge about knowledge, or expertise on expertise. Every form of expertise depends on choices with respect to heuristics, methods, or data bases and could have been formulated differently. Where there are choices there are risks. But if, in turn, risks can only be reduced by additional expertise, then the net result may be a steady loss of certainty in society. Even if infinite amounts of information were accessible and could be processed by advanced knowledge technologies, the well-known problem of acting under bounded rationality would not be solved but enhanced. The constant examination and reformulation of social practices in the light of incoming information about those very practices is also conceived in Giddens' model of 'reflexive modernization' (Giddens 1990).

2.3 Knowledge and Science

It is important to relate the characteristics of knowledge society to those of science in society. While on the one hand large-scale expertise can be interpreted as spreading the methodical and theoretical potential of science to highly specialized problems and as a consequence of a job-seeking academically trained labor force (Stehr 1992), the differences between expertise and research are obvious. Research is performed in an institutionally (laboratories) and cognitively (theories) separated world, in which failures and errors are highly welcome. Everything can hypothetically and experimentally be pushed to the extreme and only in a few cases are legal and social norms violated. Society is only affected indirectly by research, namely by transforming research results into technologies or ideologies. Even if this view meets a convenient self-description of the scientific community rather than historical facts, expertise could rarely be sold as a piece of hypothetical reasoning to which those who apply it provide the testing field. Still, it is instructive to underpin the intersections of expertise and research.

While many branches of science tend to derive expert knowledge directly by extrapolating from isolated theoretical worlds to the real world (of health, education, international affairs, social structure, de-

velopment, etc.), expertise tends to not only apply certified knowledge but to do research. Consequently, knowledge society can be interpreted as being exposed to hypothetical assumptions and experiments designed by experts and analysts. While expertise effectively reduces the complexity of the real world for an observer, it inevitably contributes to increase the risks of those who decide to rely on it.

3. Critical Aspects of Knowledge Society

This ambivalent status of expert knowledge between disinterested scientific neutrality and action-oriented advice has given rise to criticism of expert culture and its 'politics of knowledge' (Cozzens and Woodhouse 1994). Another problem to be addressed in the future is the deficient quality management of expert knowledge and the inadaequacy of licensing and accreditation mechanisms. A profound cognitive aspect of criticism relates to the loss of personal experience and judgement and its substitution by mediated images, simulations, screens, and spectacles (Morley and Robins 1995) along with a new potential for ideological manipulation (Schiller 1981). The intra- as well as international boundaries between those who have or do not have technical and intellectual access to information (information rich vs. information poor) have given rise to neo-Marxian class analysis of knowledge societies (Schiller 1992). These and other controversial aspects (see Webster 1995) indicate the deep structure and far-reaching consequences of the ongoing transformation toward knowledge society.

Knowledge, Sociology of

The sociology of knowledge is a summative term for an assortment of theoretical statements and empirical studies dealing, in diverse ways, with the relationship between various processes and products of human cognition and other sociocultural factors. On the organizational map of the discipline of sociology in Europe and in the USA, the sociology of knowledge has generally occupied a marginal position, its warrant and scope sufficiently contested 'that the history of the subdiscipline … has been the history of its various definitions' (Berger and Luckmann 1966, p. 4). Focusing on manifestations of knowledge that include ideas, ideologies, scientific theories, religious and political doctrines, moral, ethical and philosophical beliefs, world views, mental categories, cultural and organizational discourses, languages, social norms, and the forms and practices of everyday knowing, sociologists of knowledge (whether self-identified or retrospectively claimed for the area by other contributors) have concerned themselves with the sociocultural consequences of this range of intellectual products and processes and, particularly, with their origins and transformations—developments that have been linked to sociohistorical contexts, material and cultural conditions, modes of production, power relationships in various forms, institutional arrangements, internal organizational processes, and a vast array of different social positions and interests. Sociologically relevant reflection on this set of issues may be periodized in four broad stages.

1. *Antecedents of the Sociology of Knowledge*

While observations about the social foundations and consequences of various cognitive products and processes have a complex history that extends back to the Greeks and forward through Renaissance figures such as Machiavelli and Francis Bacon, the modern roots of the sociology of knowledge are generally dated from the French Enlightenment of the eighteenth century, when thinkers like Helvetius, Holbach, and Voltaire turned attention to the social bases and effects of religious—as contrasted with scientific—conceptions, while Montesquieu, Rousseau, and Condorcet adumbrated the broader thesis that human consciousness is socially determined. Working in this tradition, Destutt de Tracy advocated a 'science of ideas' that would trace human thoughts to their sensory and material conditions, ultimately making possible the construction of a new morality and a perfected political order. For this science, in 1796 he coined the term 'ideology'—a neologism that his critics swiftly converted into a pejorative word for doctrinaire dreams and illusions. (For fuller treatment of this background, see Eagleton 1991, Kennedy 1978, Larrain 1979.)

In the early nineteenth century, Auguste Comte declared the evolution of modes of human thought the main topic of the new discipline of sociology, erecting the field on the Law of Three Stages, viz., the assertion 'that each of our leading conceptions—each branch of our knowledge—passes successively through three different theoretical conditions: the theological or fictitious; the metaphysical, or abstract; and the scientific, or positive' ([1830] 1975, p. 71). Substituting French positivism for German idealism, G. W. F. Hegel ([1807] 1967) likewise presented the history of society as a sequence of intellectual stages—as successively developing forms of human consciousness, dialectically progressing to a condition of absolute (genuinely scientific) knowledge.

From the mid nineteenth to the early twentieth century, these early modern anticipations of the sociology of the knowledge were elaborated in many directions, particularly in connection with the development of 'classical' sociological theory. Rejecting Hegelian idealism for historical materialism, Karl Marx conceptualized the connections between human thought and social conditions in several ways. In his most encompassing formulation, he asserted that dialectically changing 'modes of production [formed] the basis of all history' and that the 'origins and growth [of] all the different theoretical products and forms of consciousness, religion, philosophy, ethics, etc., etc.'—the idealistic superstructure—were explainable 'from that basis' (Marx and Engels [1846] 1970, pp. 57–8). Taking the social relations of production as 'the realm of real history,' Marx's early work cast this superstructure as the derivative 'realm of ideology,' using the latter term in the pejorative sense of 'illusions' and distorted 'inversions' of reality that 'veil the class struggle' and thus promote existing patterns of class domination (Marx and Engels [1846] 1970, pp. 47, 119; Marx [1852] 1963, pp. 46–7). Relatedly, Marx linked particular ideas to specific 'material interests' and held that 'the class which has the means of material production at its disposal has control … over the means of mental production,' so that 'the ideas of the ruling class are in every epoch the ruling ideas,' as these are developed by 'conceptive ideologists' perfecting the illusions that benefit their class (Marx and Engels [1846] 1970, pp. 64, 65, 99). Marx's later work, in contrast, presented ideology less as a superstructural inversion of reality than as a reflection of inversions already embedded in particular

modes of production. Characterizing capitalism itself, for example, as an 'enchanted and perverted world,' Marx held that, whatever their class interests, conceptualizers under capitalism generally 'remain more or less in the grip of the world of illusion,' a world that 'corresponds' with 'the forms of illusion in which they move about and find their daily occupations' ([1894] 1967, pp. 827–31; for discussion, see Eagleton 1991, Mepham 1979). Subsequently, many of Marx's followers overlaid this negative view of the social functions of ideology with a broader 'sense of ideology as the mental forms within which men and women fight out their social conflicts' (Eagleton 1991, p. 90). This is a tendency evident in the work of Bernstein, Lenin, and Lukacs, and in Hoare and Smith's conception of ideologies as forces that, under sociohistorical conditions that he sought to specify, can 'organize human masses, and create the terrain on which men move, acquire consciousness of their positions, struggle, etc.' ([1948–51] 1971, p. 377).

Coming from the French tradition, Emile Durkheim approached knowledge from a different angle. Extending his concern with the social bases (and functions) of such 'collective representations' as religion and morals to the 'extra-logical origin' of 'logical thought,' Durkheim argued that the 'mental operations' by which members of preliterate societies 'classify … things, events, and facts about the world into kinds and species [are] modeled on [their] form of social organization,' i.e., that 'the first logical categories were social categories; the first classes of things were classes of men, into which these things were integrated' (Durkheim and Mauss [1903] 1963, pp. 3, 4, 8, 82). Generalizing the point, Durkheim subsequently proposed that the form and the content of all the 'categories of human thought'—of the most basic 'conception[s] of time, space, cause, number, and so on,' even in their modern scientific incarnations—'depend on the way in which the collectivity is organized, upon its morphology, its religious, moral, and economic institutions, and so on' ([1912] 1995, pp.14–16). Controversial to this day, the claim proved widely influential, inspiring work by Halbwachs (1925), Granet (1934), and others.

2. *Emergence of the Sociology of Knowledge as a Specialty Area (1920 to c. 1965)*

As a specialized theory-and-research area with its own name, the sociology of knowledge originated in Weimar Germany when Max Scheler and Karl Mannheim, reacting (*inter alia*) to Marxian theories of ideology and to the cultural crisis of their own time, advocated the creation of *Wissenssoziologie*. Scheler did so as an extension of his interests in philosophy. Seeking to recognize 'the social–historical development of [even] the highest types of human knowledge' but to 'escape [from the] philosophical relativism' that had led contemporaries to deny the truth-claims of ideas 'conditioned by a historical and sociological standpoint,' he challenged Marx's thesis that one 'can "explain" th[e] ideal world from the world of real history' by asserting that 'the history of real factors'—understood as a sequence in which kinship, political, and finally economic factors successively hold centrality—'does not at all determine the positive meaning-content of works of mind, though it does hinder, release, delay, or hasten [their] development,' opening and closing 'the sluices of the spiritual stream' ([1924] 1980, pp. 41–2, 53–4; see also Frisby 1983).

Mannheim took another tack. Excepting mathematics and portions of the 'exact sciences' from his analysis, he sought to problematize the 'social conditioning' of the forms and contents of 'every product of thought'—'perceptions and interpretations,' moral concepts of 'duty, transgression, and sin,' political 'opinions, statements, [and] propositions,' and the total 'modes of thought' of different epochs, cultures, and social groups. According to Mannheim, such thought-products stand in 'multiple interconnections' with 'the structure of historical reality,' with 'the social position of given groups'—a phrase primarily denoting class position, but also including 'generations, status groups, sects, occupational groups, schools, etc.'—and with 'the historical–social situation of the intellectually active and responsible members of the group' ([1931] 1936a, pp. 56–7, 81–2, 86, [1926] 1936c, pp. 264–5, 276). In putting forth this view, Mannheim wished to call forth a wide-ranging academic field that would subject 'the relationship between thought and existence' to systematic 'empirical research' ([1931] 1936a, p. 69, [1929] 1936c, p. 264; see also 1936b), and occasionally he engaged in such research of himself, most notably in his study of German conservative thought ([1925] 1986). But Mannheim set for the sociology of knowledge an even larger agenda, borne from his belief that examination of 'the relationship between the intellectual positions held and the social position occupied' would necessarily reveal that 'every point of view'—Marxism included—'is particular to a social situation.' From this it followed, for Mannheim, that 'the thought of all parties in all epochs is of an ideological character,' where he took 'ideological' to mean 'narrow' and 'one-sided'—properties with important epistemological and political implications. By exposing the one-sidedness of all perspectives, the sociology of knowledge would lay the basis for 'a new type of objectivity,' which was the dynamic synthesis of different viewpoints, and would bring political rivals into dialogue, checking their pernicious tendency to unmask each another's ideas as mere illusions (1936a, pp. 77–85, [1929] 1936b, p. 5; for discussion, see Kettler and Meja 1995).

Mannheim's statements drew broad attention to the sociology of knowledge in Europe and the USA and set the new field on an unsteady course. In Europe, his epistemological and political views became the focus

of extensive critical discussion and made the field, for decades, largely a site of meta-theoretical controversy (Frisby 1983, pp. 174–224). In the USA, where engagement with sociology-of-knowledge type issues had long been underway (Fuhrman 1980), Mannheim's call for empirical studies had greater resonance and fueled efforts to constitute the sociology of knowledge as an specialized subdiscipline dedicated to 'fruitful empirical research,' rather than to debate over 'philosophical' questions of relativism, objectivity, and the like (quoting Wirth 1936, pp. xxi, xxvii; see also Kettler and Meja 1995, pp. 193–246).

Particularly significant here were Robert Merton's writings in the early 1940s, which sought to move the sociology of knowledge from 'speculative insight' to 'rigorous test,' by purging Mannheim's ideas of 'their epistemological impedimenta' and associating the field with a defined 'list of problems [open to] empirical investigation' ([1945] 1968a, p. 562, [1941] 1968b, p. 542). To this end, Merton elaborated a 'paradigm for the sociology of knowledge,' in which he replaced Mannheim's 'amorphous category of knowledge' with a systematic inventory of different types and aspects of 'mental productions' and then differentiated the many possible sociocultural or 'existential bases' for human thought-products ([1941] 1968a, p. 552, 1968b, pp. 514–5). Most distinctively, Merton gave prominence to the question (which he faulted his predecessors for neglecting) '*how* are mental production related to the existential basis?'—distinguishing, in reply, a wide range of possible modes of relationship, analysis of which 'promise[d] to take research in the sociology of knowledge from the plane of general imputation to that of testable empirical inquiry' ([1945] 1968b, pp. 515, 537).

This promise proved difficult to realize, however. In the course of the next twenty years, students of Merton occasionally took up the challenge—Gouldner (1965) with research on Plato's social theory as a response to the social tensions present in ancient Greece, Coser (1965) with work on the general societal and institutional conditions that favored the development of Western intellectuals. These studies joined writings by Mills ([1943] 1964) on the social roots of US pragmatism (see also Mills 1963), by Znaniecki (1940) and Shils ([1955–68] 1972) on intellectuals, by members of the Frankfurt school on the ideology of capitalist societies (see especially Marcuse 1964), and by a scattering of other scholars on a miscellany of topics (see the collection by Curtis and Petras 1970) to steer the sociology of knowledge in more empirical directions. But these remained sporadic efforts, intermixed with works offering programmatic definitions of the sociology of knowledge and further discussion of Mannheim's more philosophical concerns (see, e.g., DeGre [1939–43] 1985, Stark 1958, Wolff [1943–65] 1983). Such works continued to distance empirically oriented sociologists from the field, even as various sociology-of-knowledge type questions resurfaced in the sociology of religion, the sociology of education, the sociology of occupations and professions, the sociology of public opinion and mass communication, and the sociology of science (Coser 1968, p. 432), as well as in research by historians of science and historians of ideas (see especially Ringer 1969).

The era that began with the writings of Scheler and Mannheim and extended to the mid-1960s remains, nonetheless, the most active period in the sociology of knowledge as a specialty area, and it stamped the area with a set of basic assumptions that were common to most work in the field at the time. These included, first, the assumption of a division between sociocultural factors, on the one side, and the substantive contents of thought-products and processes, on the other, where the former factors were 'external' to the realm of knowledge, while the latter were 'internal'; second, the supposition that the 'internal' factors were easily interpretable by the sociological investigator, their meanings more-or-less transparent in the statements where they were contained; and, third, the belief that sociological explanations of knowledge chiefly involved appeals to 'external' factors at the macro-level, i.e., to societal-wide economic, political, and cultural developments, or combinations thereof (Camic and Gross 2000; see also Kuklick 1983). Traceable to the earliest beginnings of the sociology of knowledge, these assumptions as of yet met little challenge.

3. *The Specialty in Retreat (c. 1965 to c. 1985)*

For a variety of reasons, largely exogenous to the area itself, work in the sociology of knowledge as such waned significantly from the mid 1960s to the early 1980s. This was due partly to a continuation of the tendency, already evident in the pervious period, for topics that fell to the area to undergo partial incorporation into other sociological subfields. Expanding interest in the sociology of science proved especially consequential here, for in the process of focusing on scientists' career patterns and on the organizational and normative conditions that sustain scientific institutions, sociologists of science effectively denied—despite contrary suggestions in the influential work of Kuhn (1962)—that there was even much possibility for a 'sociology of the conceptual and theoretical contents of science' and related domains of knowledge (Ben-David 1971, p. 14). In the face of this challenge, Berger and Luckmann attempted to redirect the sociology of knowledge to the study of 'what is taken for granted as "knowledge" [by] the man in the street' (1966, p. 3); but it was not long before this topic was itself transplanted, in part into ethnomethodology, another subfield then on the rise (Maynard and Clayman 1991).

Compounding these developments within specialty areas were broader trends in the social sciences during this period. Most far-reaching among these was a

growing commitment to quantitative research, based increasingly on types of survey data that seemed remote from the traditional concerns of sociologists of knowledge. This trend, to be sure, coexisted with a heightening of interest in theory and in historical scholarship, but the Marxist renaissance that was then underway generally pulled this interest towards questions about the dynamics of modes of production and state apparatuses and toward debates about the role and concept of social class (and, subsequently, about gender and race). While new theories of ideology did emerge (see, in particular Althusser 1969, 1971, Therborn 1980), they did so, almost without exception, as appendages to work on class and state structures; as such, their effect was more to divert attention from, than to turn it to, examination of the sources and consequences of cognitive products and processes in their own right. In this context, little new work in the sociology of knowledge came forth, aside from reinterpretations of figures from earlier periods (see Simonds 1978) and various editions of their original writings.

4. The Contemporary Revival (c. 1985 to the Present)

Just as exogenous developments during the two preceding decades imperiled the sociology of knowledge, intellectual trends since the mid 1980s have begun to resuscitate the field. Most generally these have included: burgeoning interest in the interdisciplinary field of cultural studies, stimulated by a declining focus on Marxist structuralism and the growing influence of works on discourse and linguistic theory, post-structuralism, and post-modernism (for discussion, see McCarthy 1996); the effort within Marxism itself to transform general claims about ideology into empirical studies of discursive formations and practices (Laclau and Mouffe 1985, Thompson 1990); the move within feminist scholarship to problematize knowledge and the standpoint and social position of knowledge producers (Harding 1991, Smith 1987); the increased production of sociologically-informed studies in the history of science and intellectual history (see Shapin 1982, Toews 1987); and the redirection of the sociology of science toward the examination of the contents of scientific knowledge and the social processes shaping them (see Collins 1983). Reinforcing these broad trends has been an expansion of interest in European social theorists whose works give considerable attention to knowledge-production processes, particularly Michel Foucault and his archeological and genealogical studies of the reciprocal constitution of various knowledge systems and webs of power relations (see Prado 1995), and Pierre Bourdieu and his writings on the dynamics of intellectual and scientific fields (see Ringer 1990).

From this confluence of exogenous developments has come a renewed concern with the sociology of knowledge, a concern that is currently pulling the field in the direction of two different approaches. The first of these is the broad-constructionist approach, exemplified in programmatic statements by McCarthy (1996), Stehr and Meja (1984), and Swidler and Arditi (1994), and in studies by Griswold (1986), Lamont (1987) and Wuthnow (1989). Pointing the sociology of knowledge outward toward the contemporary sociology of culture rather than toward the study of knowledge specialists, this perspective treats 'political and religious ideologies as well as science and everyday life, cultural and organizational discourses along with formal and informal types of knowledge' (Swidler and Arditi 1994, p. 306); and while amenable to a middle-level or institutional analysis of the social sources and consequences of these various forms of knowledge, it often retains the underlying suppositions of the 1920–65 period, viz. assumptions about the division between external (sociocultural) and internal (thought-content) factors, about the transparency of internal meanings to the sociological investigator, and about the explanatory importance of macro-level external factors. Moreover, while strongly committed to empirical research, this approach has also favored reopening some of the meta-theoretical issues that occupied earlier generations (see the contributions in Stehr and Meja 1984).

In these ways, the broad-constructionist approach diverges from the recent narrow-constructionist alternative. Found in the work of Camic (1983, 1992, Camic and Xie 1994), Collins (1998), Kusch (1995) and Shapin (1994), this second approach focuses the sociology of knowledge mainly on men and women who specialize in the production of ideas and on the particular social processes by which their ideas emerge and develop—a move that, in effect, transforms the field into a sociology of ideas. This perspective has tended to reject the core assumptions of the older sociology of knowledge, building instead on scholarship that argues that sociocultural processes are as much internal to the content of ideas as they are external (Bloor 1976, Shapin 1992), that the meanings of ideas are only understandable to an investigator after careful contextual reconstruction (Skinner 1969), and that local, micro-level settings are often the main sites for the development of ideas (Geertz 1983, Whitley 1984). Like the broad-constructionist approach, this narrow-constructionist perspective presently provides a foundation for several lines of empirical research (see Camic and Gross 2000). No forecast can yet be made, however, as to which approach, if either, will rescue the sociology of knowledge from its traditionally marginal position in the discipline of sociology.

Knowledge Spaces

Knowledge spaces are combinatorial models for encoding the conceptual organization of a given body of knowledge. Their theory leads to the design of efficient algorithms for assessing the concepts acquired by an individual in the given domain. Computer software implementing such algorithms is now in use in schools and colleges (e.g., Aleks, briefly presented later). Their output is by far richer than just a crude number (e.g., 8 out of 10) or mark (e.g., B). Indeed, it describes the present state of knowledge of the individual together with advice for further progress. Thus, by its combinatorial emphasis, knowledge space theory appears as a multidimensional generalization of classical test theory. It can also be applied to other settings (for instance, system failure analysis). Probabilistic extensions of the theory are covered in the article *Markov Processes for Knowledge Spaces*, while here the basic, deterministic concepts are introduced and some applications are sketched.

1. *Organizing a Body of Knowledge*

To start with an example, suppose that a teacher wants to assess the acquired capabilities of the pupils in a classroom as regards arithmetical multiplication. A list of items will be set up, starting from a simple question such as

Item *a* $\quad 9 \times 8 = ?$

and ending with a more complicated problem such as

Item *b*
$$\begin{array}{r} 278.9 \\ \times\, 3.98 \\ \hline = \quad ? \end{array}$$

In classical practice, all items will be proposed to all pupils. The outcome of such a test boils down to a mark assigned to each pupil, which provides no other information than the number of correct answers. The performance of such a test is very poor. First, the pupils have to work on all problems (be these problems fairly easy or on the contrary out of reach for their actual competencies). Second, the marks convey a rather inaccurate description of the concepts and techniques mastered by each individual pupil.

These drawbacks are circumvented in oral testing. Here, the teacher can improve the examination procedure by taking into account answers previously collected in order to carefully select the next question to be asked. Moreover, this flexibility helps in building a more accurate description of the pupils' strengths and weaknesses. To illustrate these two points with our example, a teacher who checks that a pupil masters Item *b* will probably avoid asking Item *a* to that pupil.

On the other hand, if the pupil does not master Item b, other items will be proposed in order to diagnose which mistakes or misconceptions hamper the pupils' acquisitions. By carefully selecting each time the new item, the teacher will gradually refine a description of the concepts and techniques mastered by the pupil. Such a description can be complemented with advice for remediation and a plan for further study.

Which are the factors that potentially make oral examination superior to written testing? Notice first that our analysis assumes a decomposition of the body of knowledge under testing into elementary pieces. To make things simple, we may suppose that each such piece corresponds to an item. Then, we assume some structure on the set of all these items. Back to our example, we declare Item a to be a prerequisite for Item b. As a consequence, we take for granted the following assertion:

from a correct answer to Item b, we may surmise a correct answer to Item a (if the latter is asked).

In short: mastery of Item a is surmised from mastery of Item b. By contraposition, this rule is reformulated as

a false answer to Item a implies a false answer to Item b.

Mathematically speaking, we have a (binary) relation P on the set Q of all items. The above assertions can now be written as aPb. We call P the surmise relation on Q and assume that P is a quasi order, that is: P is reflexive (qPq holds for all q in Q) and transitive (for all $p, q, r \in Q$, pPq and qPr imply pPr). Such a relation puts severe restrictions on the possible states of knowledge.

2. Knowledge States

Given the set Q of items, we identify the state of knowledge of an individual with the subset $\mathscr{K}$ of items that this person masters; thus $\mathscr{K} \subseteq Q$. However, in view of the surmise relation P, not every subset of Q can be a state of knowledge. Indeed, if a knowledge state contains q and pPq holds, then $\mathscr{K}$ must also contain p. We illustrate this with an example where $Q = \{a, b, c, d\}$ and P is the relation depicted in Fig. 1.

Figure 1
Diagram for a surmise relation.

Subset $\{a, c\}$ is not a knowledge state since bPc holds, while $\{a, b, c\}$ is a knowledge state as can be checked. The full family $\mathscr{K}$ of knowledge states in this example is as follows:

$$\mathscr{K} = \{\varnothing, \{a\}, \{b\}, \{a, b\}, \{b, d\}, \{a, b, c\}, \{a, b, d\}, Q\}$$

where $\varnothing$ denotes the empty set. Notice $\{a, b\} \in \mathscr{K}$ and $\{b, d\} \in \mathscr{K}$, and also $\{a, b\} \cap \{b, d\} = \{b\} \in \mathscr{K}$.

This example can be used to illustrate some general properties of the family $\mathscr{K}$ of knowledge states of any surmise relation. The empty set $\varnothing$ and the whole set Q belong to $\mathscr{K}$; moreover, if $\mathscr{K}, L \in \mathscr{K}$, then $\mathscr{K} \cap L \in \mathscr{K}$ and $\mathscr{K} \cup L \in \mathscr{K}$, that is: $\mathscr{K}$ is closed under intersection and under union. It turns out that these properties characterize families of subsets deduced from surmise relations. Indeed, this is a reformulation of Birkhoff's Theorem (for infinite ground sets Q, closure under general intersection and union, not restricted to two subsets, need to be considered). We now argue that a more general setting is required.

3. Knowledge Spaces

Suppose that a student produces correct solutions to systems of linear equations in several unknowns. The examiner cannot infer from this information whether the student has mastered computation of determinants, Gauss elimination procedure, or the substitution scheme. At least one of these three methods is mastered, but which one is not clear from the student's answers. A generalization of the concept of a surmise relation is thus needed. Again, let Q be a set of items. To each item q, several subsets $C_1, C_2, \ldots, C_k$ of Q will be attached. These clauses for q represent all possible ways of acquiring the mastery of q; their number k may of course vary with q. We denote by σ the mapping associating to q the collection $\{C_1, C_2, \ldots, C_k\}$. For an example, assume $Q = \{a, b, c, d\}$ and

$$\sigma(a) = \{\{a, b, c\}, \{a, d\}\} \tag{1}$$

$$\sigma(b) = \{\{b, c\}\} \tag{2}$$

$$\sigma(c) = \{\{c\}\} \tag{3}$$

$$\sigma(d) = \{\{d\}\}. \tag{4}$$

The expression for $\sigma(a)$ thus encodes the following fact: mastery of item a implies mastery of a itself plus

(b and c) or d.

In fact, a mapping σ is another formalization of an AND/OR graph from artificial intelligence. We will now make the concept more precise by taking into consideration four axioms (satisfied by our last example).

(a) for each item q, there is at least one clause for q;

(b) for each item q and each clause C for q, we have $q \in C$;

(c) for each pair of items q, r and each clause C for q containing r, there is a clause D for r such that $D \subseteq C$;

(d) any two clauses C, C' for the same item are incomparable, i.e. neither $C \subset C'$ nor $C' \subset C$ hold.

Axiom (b) clearly generalizes the reflexivity axiom of a surmise relation, while Axiom (c) extends transitivity. Axiom (d) translates our assumption that a clause for item q encodes a minimal way of acquiring the mastery of q.

Given a surmise system σ on Q, we define a knowledge state as any subset $\mathscr{K}$ of Q satisfying:

for each item q in $\mathscr{K}$, there is a clause C for q that is contained in $\mathscr{K}$.

In the four-item example, the collection $\mathscr{K}$ of all knowledge states is as follows:

$$\mathscr{K} = \{\varnothing, \{c\}, \{d\}, \{a, d\}, \{b, c\}, \{c, d\}, \{a, b, c\}, \{a, c, d\}, \{b, c, d\}, Q\}.$$

Any surmise relation P on Q becomes a surmise system if we attach to any item q the single clause $C = \{r \in Q | rPq\}$. Notice that the knowledge states defined from P coincide with those defined from the surmise system. We have moreover a neat variant of Birkhoff's Theorem. Indeed, a family $\mathscr{K}$ of subsets of a finite set Q constitutes the collection of all knowledge states of a surmise system if and only if $\mathscr{K}$ is closed under union, and contains $\varnothing$ and Q (an infinite version of this result is presented in Doignon and Falmagne 1999). A structure $(Q, \mathscr{K})$ satisfying these two conditions is called a knowledge space.

Closure under union is not required in most practical applications. A knowledge structure $(Q, \mathscr{K})$ is a finite set Q of items together with a family $\mathscr{K}$ of subsets of Q, with $\varnothing$ and Q belonging to $\mathscr{K}$. The elements of $\mathscr{K}$ are the knowledge states.

4. *Wellgradedness*

Knowledge assessment in our context assumes that a knowledge structure $(Q, \mathscr{K})$ has been built; the goal then is to design an algorithm that determines which state in $\mathscr{K}$ represents the knowledge of a student. This algorithm will efficiently select questions to be asked, thus reducing at each step the remaining possible states. Clearly, if all answers collected truely reflect the student's knowledge, the process will end after a few steps with a precise element of $\mathscr{K}$.

In real life, things are not so simple. Answers may be biased by lucky guesses (even if the items are not of the multiple-choice type this can happen) or by careless errors (a slight flaw in computation may alter the correctness). To take these undeterministic aspects into account, a probabilistic extension of the theory was conceived (see the article *Markov Processes for Knowledge Spaces*). It relies on a combinatorial notion that we now sketch.

After some time, an assessment procedure will have proposed one state $\mathscr{K}$ from $\mathscr{K}$ as the accurate representation in the structure $(Q, \mathscr{K})$ of the student's knowledge. A further answer of the student, say to item q, may call for a modification of $\mathscr{K}$. If $q \notin \mathscr{K}$ and q is correctly answered, then $\mathscr{K} \cup \{q\}$ should become the state selected in $\mathscr{K}$—provided $\mathscr{K} \cup \{q\}$ belongs to $\mathscr{K}$. Similarly, if $q \in \mathscr{K}$ and q is incorrectly answered, then $\mathscr{K} \setminus \{q\}$ should be selected—provided it belongs to $\mathscr{K}$. We may not assume that always $\mathscr{K} \cup \{q\}$ and $\mathscr{K} \setminus \{q\}$ belong to $\mathscr{K}$, because otherwise $\mathscr{K}$ would be the collection of all subsets (which is a much too large collection for our purposes). On the other hand, the assessment procedure should be able to explore the whole collection $\mathscr{K}$ by elementary steps consisting in the addition or deletion of a single item. To state a precise definition, we use for any two subsets $\mathscr{K}$, L of Q their (symmetric-difference) distance

$$d(\mathscr{K}, L) = |\{q \in Q | q \in \mathscr{K} \setminus L \text{ or } q \in L \setminus \mathscr{K}\}|$$

which counts the number of items q in which $\mathscr{K}$ and L differ. By definition, a knowledge structure $(Q, \mathscr{K})$ is wellgraded when for any two knowledge states $\mathscr{K}$, L in $\mathscr{K}$ with $d(\mathscr{K}, L) = h$, there exists a sequence $\mathscr{K} = \mathscr{K}_0, \mathscr{K}_1, \ldots, \mathscr{K}_h = L$ of states in $\mathscr{K}$ such that $d(\mathscr{K}_j, \mathscr{K}_{j+1}) = 1$ for $j = 0, 1, \ldots, h-1$.

For $\mathscr{K}$ a state in a knowledge structure $(Q, \mathscr{K})$, we define the inner fringe and outer fringe of $\mathscr{K}$ as

$$\mathscr{K}^I = \{q \in \mathscr{K} | \mathscr{K} \setminus \{q\} \in \mathscr{K}\}, \tag{5}$$

$$\mathscr{K}^O = \{q \in Q \setminus \mathscr{K} | \mathscr{K} \cup \{q\} \in \mathscr{K}\}. \tag{6}$$

For example, if

$$\mathscr{K} = \{\varnothing, \{c\}, \{d\}, \{a, d\}, \{b, c\}, \{c, d\}, \{a, b, c\}, \{a, c, d\}, \{b, c, d\}, Q\}$$

then

$$\{a, d\}^I = \{a\} \tag{7}$$

$$\{a, d\}^O = \{c\} \tag{8}$$

In real-life applications, the outer fringe $\mathscr{K}^O$ collects those items that a student in knowledge state $\mathscr{K}$ could directly learn without any further prerequisite. This notion plays a crucial role in the design of the Aleks software.

It can be proved that a knowledge structure $(Q, \mathscr{K})$ is wellgraded if, and only if, any state in $\mathscr{K}$ is

characterized by its inner and outer fringes. The latter condition can be stated as follows: if $\mathscr{K}$, $L \in \mathscr{K}$ and $\mathscr{K}^{\mathrm{I}} \subset L$, $\mathscr{K}^{\mathrm{O}} \subset Q \backslash L$, then $\mathscr{K} = L$.

5. *Aleks*

Aleks is a software under development at Irvine, California by a team headed by Jean-Claude Falmagne (other projects with similar goals are in an earlier stage). At its completion, it will be able to assess the mathematical knowledge of pupils and students from Kindergarten to Grade 12. Presently in use in California schools and American colleges, it covers arithmetic and algebra by a batch of more than 200 items. For a user, a session typically presents about 10 items, carefully selected on the basis of previously acquired information on that particular user, and also on collected answers. At the end of the session, the student receives information on her progress and advice for faster study. Of course, the teacher is also informed of the monitoring process. Aleks is more than an assessment system, since it provides on demand the user with explanation and access to a dictionary. From experiments, it appears that students using the Aleks system progress much further in the material than students in a conventional class.

6. *Bibliographic Orientation*

The first publication on knowledge spaces was a 1985 paper by Doignon and Falmagne. The same authors published a survey book in 1999. Various applications of the theory are covered in two books edited by Albert (1994), and Albert and Lukas (1999). An evolutive and searchable bibliography is maintained by Cord Hockemeyer at the following web address:

http://wundt.kfunigraz.ac.at/hockemeyer/bibliography.html

while Aleks website is at:

http://www.aleks.com

Kohlberg, Lawrence (1927–87)

Kohlberg was born on October 25, 1927, in Yonkers, New York, the son of a Protestant mother—a well-known chemist—and a Jewish father—a successful self-made businessman with strong civic commitment and of conservative leaning. Kohlberg grew up in a liberal Jewish community. In 1945 he joined the US Merchant Marines; he then helped to smuggle East European Jewish refugees to Palestine, was seized by the British army, and was interned in Cyprus. He fled to Palestine and spent some time in a kibbutz—pondering issues of justice and violence. In 1947 he went to the University of Chicago, reading moral philosophy from Plato to Dewey, studying Locke, Mill, and Jefferson in search of a basic moral principle that might bridge disagreements—and discovered Kant's imperative: 'treat every human being as an end in himself.' He did graduate work in psychology, studying with Bettelheim, Rogers, Gewirtz, Morris, Newgarten, Havighurst, and Strauss—'the first American scientist who attempted to integrate Piaget's structural theory with Mead's symbolic interactionism' (Kohlberg 1984, p.vii).

After two years of clinical work he started research for his doctoral dissertation on the development of moral judgment that he finished in1958. From 1959 to 1961 he was assistant professor at Yale University; 1961–2 fellow at the Institute for Advanced Study in the Behavioral Sciences in Palo Alto; 1962–8 professor at the University of Chicago; 1968–87 professor at Harvard University. Having an incurable disease, on January 17, 1987 Kohlberg ended his life.

Kohlberg changed US psychology. His influence is due to intellectual brilliance, but also to an inspiring personality attracting scientists from all over the world. Kuhmerker et al.(1991) elicited personal letters from friends and colleagues describing what Kohlberg had meant for their lives. Some core characteristics emerge: Kohlberg was 'loveable'—and had 'a remarkable ability to insure this characteristic in those who worked with him…all of whom had not only a peculiarly fanatical interest in the study of moral development but also a deep personal affection for Lawrence Kohlberg, the man.' (Grimley) Kohlberg was persistent; what struck Kegan was 'that an idea can be compelling enough and an individual devoted enough for the two to spend 25 years together in a relationship as fresh and combustible today as when it began.' Kohlberg was stern—demanding extraordinary efforts of himself and of others; he 'would call another scoring workshop whenever he felt his

assistants were working less than 80 hours a week.' His commitment was contagious: 'At the Center of Moral Education there was a sense of being at the right place at the right time—that terribly new and important breakthroughs were just around the corner…that questions of social justice were on everyone's mind and we thought we had the answers—or nearly had the answers.' He was 'a visionary' who kept 'the major questions in focus.' Had it not been for him 'many of us would not have become interested in psychology at all' (Rest).

For Kohlberg the unity of moral judgment and action was not just a theoretical stipulation—it was his very personality. A colleague recalls an occasion when he had initiated a resolution against the invasion to Cambodia. When the question arose who would accompany him in handing it over in Washington:

> …the meeting became silent. Motionless. Eerily quiet. These giants of education who daily proclaimed the virtues of equality, of human rights, of democratic citizenship and had themselves just voted overwhelmingly in favor of the resolution now sat in perfect pose, looking at their shoes. Numbed and dazzled by this educational experience. I finally noticed one lone figure somewhat unkempt in attire standing next to me. Although I had met him a number of prior occasions, that was the time I really met Larry. (Sprinthall)

Kohlberg addressed important issues authentically and in an innovative way. This carried others along. Thus, Kohlberg's theory springs also from collective endeavors—initiated, inspired, and directed by Kohlberg, but advanced by his students, friends, and colleagues as well.

1. *Kohlberg's Approach*

Kohlberg's approach ran counter to the basic assumptions about the nature of human beings, of norms, and of science dominant at the time. Humans were seen as basically passive (shaped by reinforcement schedules in behaviorism, by parental authorities in psychoanalytic theories, or by the gradual unfolding of genetic endowments in maturationism) and primarily motivated by self-serving concerns (avoiding external or superego sanctions). In contrast, Kohlberg—following Piaget—viewed people as active interpreters of their world and also motivated by intrinsic concerns (for mastery, truth, or other values).

Norms were seen as externally given contingent facts. Kohlberg, instead, viewed norms as propositions raising the validity claim of rightness, that is, in need of and capable of being justified. Psychology followed a natural science epistemology: copying or explaining reality is aimed for by standardizing measurement procedures or experimentally isolating and manipulating variables. In contrast, Piagetian analyses seek to trace universal developmental changes in subjects' interactive constructions of reality; hermeneutic interviews aim at objectivity by guaranteeing not the physical identity of the stimulus, but the identity of its meaning. Kohlberg was one of the pioneers in bringing this Piagetian cognitive frame to bear on academic psychology in the USA.

Also, his interest in moral reasoning was new. Up until then, only normconforming behavior (not moral action) or moral emotions (not moral judgment) had been studied—both from an observer's point of view. Kohlberg, instead, looked at morality from a first-person perspective. And he did so with a specific—not uncontested—understanding of morality by focusing on judgment he excluded questions of moral character, of habitualized moral dispositions, of virtues. By defining morality on deontic terms he excluded questions of the good life that he left to ethics and/or to the personal domain. By identifying morality with a justice procedure he largely neglected content. By describing this procedure as 'moral musical chairs' he sketched a hypothetical role-taking procedure that remains entirely monological.

2. *Moral Development*

2.1 *The Stage Model*

Piaget had described young children's moral development as progress from a heteronomous stage (characterized by egocentrism; unilateral respect; a focus on consequences rather than on intention; an understanding of rules as objective, absolute and unalterable; a belief in immanent justice) to an autonomous morality produced by peer interaction and cognitive decentering. From his study of adolescent development Kohlberg derived a refined description of the stage model and of developmental mechanisms.

Development consists in changes in the reasoning structure justifying judgments of 'right' or 'wrong' and in the concerns motivating norm conformity. Its structural core is a widening of the sociomoral perspective. Universally, there are three levels with two 'hard' stages each. The model is based on the following assumptions:

– each stage is a structured whole that is qualitatively different from the others;

– the sequence of stages is invariant, irreversibly progressive without stage skipping;

– the stages form a hierarchy: higher stages are better differentiated and integrated structures that allow morally better solutions to dilemmas.

The stages are described as follows:

At the preconventional level (typical for most children under nine) situations are judged from a concrete individual perspective. Rules are seen to be external to the self. 'Right' is defined as obeying rules and authority, avoiding punishment, not doing physical harm (Stage 1) or as meeting one's own interests and letting others do the same (Stage 2); the reasons for doing right are to avoid punishment and to bow to

the superior power of authorities (Stage 1) or to serve one's own needs or interests (Stage 2).

At the conventional level (typical of most adults) morality is judged from a 'member of society' perspective and is identified with socially shared internalized norms. 'Right' means living up to the expectations of one's group (Stage 3) or doing one's duty in society (Stage 4); the reasons for doing right are the need to be 'good' in one's own or others' eyes and caring for others (Stage 3) or the need to maintain a good conscience by meeting defined obligations (Stage 4).

At the postconventional level (reached by few adults only) moral values are defined from a 'prior to society' perspective in terms of self-chosen universal principles. 'Right' is upholding legal contracts (Stage 5) or is defined in terms of universal ethical principles such as equality and respect for the dignity of human beings as individuals (Stage 6). The reasons for doing right are obligations to the social contract (Stage 5) or a commitment to principles that have been rationally understood and accepted as valid (Stage 6).

2.2 Tests of Moral Development

In the Moral Judgment Interview (MJI, Colby and Kohlberg 1987) hypothetical moral dilemmas are given which allow of no 'right' answer (e.g., Should a man steal a drug to save his dying wife?) Subjects are first to decide what the protagonist ought to do (uphold the law or preserve life?) and then to justify and defend this decision against moral counterarguments advanced by the interviewer who aims at eliciting the subject's highest competence level. The responses are matched to structurally similar criterion judgments listed for each stage in the scoring manual.

In the Social Reflection Measure (SRM) Gibbs et al. (1992) developed a brief interview and coding manual that can be used for younger children. Objective tests have also been developed in which subjects rank their preference for a set of standardized responses that express stage-specific considerations (Rest's Defining Issue Test, DIT, Lind's Moral Judgement Test, MUT). Preference measures produce scores that are consistently (about one stage) higher than spontaneously produced answers, yet do correlate in medium range with scores in MJI.

2.3 Mechanisms of Development

In contrast to social learning and psychoanalytic theories which assume identification or modeling as the primary developmental mechanisms, cognitive theories see development as a result of internal restructuring in response to cognitive conflict. There is experimental evidence in support of this mechanism (cf. Walker 1986). The need to reconcile conflicting views may be the reason why taking leadership roles advances moral development.

This understanding of developmental mechanisms has inspired pedagogic interventions. Classroom discussions of moral dilemma tend to produce (albeit slight) moral growth. The institutionalization of just communities, that is, structures allowing for democratic self-government, have been shown to improve the moral atmosphere of schools or prisons considerably and generate feelings of reciprocal responsibility (Higgins et al. in Kurtines and Gewirtz 1984).

2.4 Empirical Support and Criticisms of the Stage Model

2.4.1 Sequence. Age and stage have been shown to correlate in cross-sectional studies. Regression or stage skipping have rarely been found in longitudinal studies and not been induced in experimental studies designed to produce moral development (Snarey 1985, Walker 1986). Thus, the claim of a developmental sequence and of an invariant order stands.

2.4.2 Hierarchy. There is conceptual and empirical support for the claim of hierarchy. Conceptually, the stage sequence comprises an increasing universalization of perspectives (isolated individual; dyad; group; a given society; a democratically organized society; humanity at large) and an expansion of relevant concerns (negative and positive consequences to the actor; intentions; role obligations; societal institutions and legality; universal rights). Postconventional thinking makes it possible to integrate and balance these different concerns in view of universal principles of equality and respect for the individual. Empirically, subjects prefer higher and reject lower stage reasoning.

2.4.3 Universality. Kohlberg has been accused of ethnocentrism and gender bias in claiming universal validity for a stage model that was initially developed from interviews with males in the USA only. Two issues are at stake: first, is there a universal core to morality, and second, is Kohlberg's stage sequence universal? The first issue is dealt with theoretically in moral philosophy and practically in endeavors to win worldwide acceptance for human rights. The second issue sparked extensive empirical research (see *Ethnocentrism*; *Gender and Feminist Studies in Anthropology*; *Gender Differences in Personality and Social Behavior*).

The universal presence of stages 1–4 is reported in a review of 45 studies from 27 widely diverse cultures involving over 5,000 subjects. Postconventional thinking was found in urban samples only, not in traditional tribal or village societies either in Western or non-Western cultures (Snarey 1985). Principled thinking thus seems a 'metalevel' feature necessary for

adjudicating conflicts between subculture-specific norms and not required in normatively integrated and isolated cultures.

Gilligan (1982) has claimed the existence of two moralities: a rigid justice orientation more typical for males (corresponding to stage 4) and a flexible morality of care and responsibility more typical for females (corresponding to stage 3). Empirically, reviews of research involving 19,000 subjects have shown that either there are no stage differences between the sexes (Lind et al. 1987) or else they tend not to disadvantage women, or to disappear when education and employment are controlled for (Walker 1984). Conceptually, Gilligan starts from a more encompassing understanding of morality than Kohlberg by including questions about the good life. Also, there are some theoretical confusions: 'care' often is experienced as a 'duty' by women, and flexibility—if not a mere reflection of powerlessness—seems a correlate of a modern secularized moral understanding ('ethics of responsibility', Max Weber) rather than of sex membership.

2.5 Another View of Moral Development?

One core issue concerns the relationship between judgment and action. This problem has been dealt with in several ways. First, the claim was raised and empirically supported that consistency will increase with moral development (Kohlberg and Candee 1984, Blasi 1980). This makes sense given that subjects referring to self-serving concerns will be assigned to lower stages. Later, responsibility judgments (expressing the personal relevance of moral judgments, Higgins et al. 1984, Blasi 1984), and the distinction between types A (considering pragmatic concerns) and B (exclusively focusing on moral values) have been introduced (Kohlberg 1984, Colby and Kohlberg 1987). These additions are remedies to deal with the fact that individuals differ in intensity of moral commitment—as is especially clearly evidenced by Colby's and Damon's (1994) 'moral exemplars'.

A more far reaching theoretical revision, however, may be called for in view of recent studies on children's moral understanding. Turiel (1983) and Nucci and Turiel (1993) have shown that young children distinguish between moral rules (enjoying universal, unalterable, intrinsic validity) and conventional or religious rules (that depend on authorities or God and are valid only for in-group members). Nevertheless, most young children expect a wrongdoer to feel good and only gradually begin to ascribe negative emotions (Nunner-Winkler and Sodian 1988). Until about six or seven years (i.e., before self-reflexive role-taking is developed) these predict moral behavior. By about 10 years almost all children (even those low in moral motivation) say they expect a wrongdoer to feel bad. In justifying these negative emotions most children tend to refer neither to impending sanctions nor to empathic identification with the victim but to the fact that a wrong had been committed. These departures from Kohlberg's description of preconventional thinking result from differences in problems addressed and measurement procedures used: Turiel and Nucci and Lee questioned children's understanding of norm validity. Nunner-Winkler focused on the intensity and type of moral motivation. Kohlberg asked for action recommendations in moral dilemmas. Until they begin to care about morality children will guide these along prudential rather than moral considerations.

A new reading of moral development suggests itself. Universally, children acquire an early understanding of the categorical ought: they know that moral norms are intrinsically valid and motives should not be self-serving. Thus, from early on, all have a good cognitive grasp of the constitutive feature of the moral domain—its deontic character. Moral competence, however, requires more. Sociocognitive development (which constitutes the structural core of Kohlberg's stage descriptions) and the acquisition of knowledge are needed for passing judgments in more complex situations. Moral motivation is needed to translate knowledge into action. These requisites are acquired in later and differential learning processes.

3. Kohlberg's Legacy

In discussing Kohlberg's contribution, Rest (in Kuhmerker et al. 1991) notes that the stage concept may dwindle away and additional variables (e.g., content, motivation, or character) may prove of import. What will remain is Kohlberg's part in the paradigm shift from behaviorism to cognitive psychology. More specifically, what will remain is his emphasis on the cognitive side of morality; his striving for reconstructing it from a participant perspective and linking it with philosophical quests for justifiability; his insistence that intrinsic motivation exists (still an urgent claim given rational choice reductionism); his emphasis that there is more to morality than 'being friendly with your friends' (Rest). In theory and practice Kohlberg was committed to an understanding of morality that demands building just institutions and treating all human beings with equal respect.

G. Nunner-Winkler

Köhler, Wolfgang (1887–1967)

Wolfgang Felix U. Köhler, a leading German–US psychologist in the twentieth century, was born to Franz E. Köhler, a German gymnasium (high-school) teacher and his wife Wilhelmine on January 21, 1887 in Reval (today, Tallinn), Estonia, at that time a part of the Russian Empire. Köhler's experiments with apes made him internationally renowned early during his long scientific career. As a cofounder of a school called Gestalt psychology, together with Max Wertheimer (1880–1943) and Kurt Koffka (1886–1941), he became an influential scholar many years before he left Europe to join the faculty of Swarthmore College, Pennsylvania in the USA.

1. Major Events in Wolfgang Köhler's Life and Work

The development and highlights of psychology at the University of Berlin during the first decades of the twentieth century are strongly associated with the name of Wolfgang Köhler (see Table 1). Major dates and events in his life include his time in Frankfurt (the birth-place of Gestalt psychology), his research years on the island of Tenerife during World War I, his professorship in Berlin, and his emigré years in the USA (1935–67).

1.1 Köhler's Assistantship at Frankfurt's Institute of Psychology

After his graduation from high school in 1905, Köhler undertook university studies in philosophy, history, and natural science in Tübingen, Bonn, and then Berlin, where he concentrated on psychology under Carl Stumpf's (1848–1936) supervision. Besides his studies in experimental psychology, especially in psychoacoustics with Stumpf, he continued to pursue his interests in natural science and physics under Max Planck (1858–1947) and Walther Nernst (1864–1941). In his doctoral dissertation, which he finished in 1909, he combined physical acoustics with psychoacoustics. This research, published in the same year in the *Zeitschrift für Psychologie*, demonstrated his great talent as a scientist. His findings forced his teacher Carl Stumpf to revise and do further research on his own psychoacoustical theories.

As an assistant at Frankfurt's institute of psychology (1909–1913) under its director Friedrich Schumann, Köhler worked with Max Wertheimer and Kurt Koffka, who also had been trained in natural science and experimental psychology. This cooperation lead to a life-long exchange among these three men, each of them involved in the advancement of psychological theory and research. Köhler worked on the then widely-accepted '*constancy hypothesis*,' continued his psychoacoustical investigations in Frankfurt, and in his paper on '*unnoticed sensations and errors of judgment*' (1913) merged his individual line of research with that of Max Wertheimer's pioneering Gestalt work.

1.2 Köhler's Research on Tenerife

From 1913 to 1920, Köhler conducted research on the mentality of apes, chickens, and children at an

Table 1
Chronology: major events and dates in Wolfgang Köhler's life and work

1887	Born on January 21, 1887 in Reval (Tallinn), Estonia
1905–9	University studies in Tübingen, Bonn, and Berlin
1909	Doctoral dissertation thesis with Carl Stumpf at Berlin's Institute of Psychology
1909–13	Assistant at Frankfurt's Institute of Psychology; collaboration with Max Wertheimer (1880–1943) and Kurt Koffka (1886–1941)
1911	*Privatdozent* (Lecturer) at Frankfurt
1913–20	Director of the Anthropoid Station on Tenerife; first epoch-making publications on 'transposition' and 'insight' in the chimpanzee
1920	Book: Treatise on Gestalt phenomena in natural sciences (*Die physischen Gestalten in Ruhe und im stationären Zustand: Eine naturphilosophische Untersuchung*)
1921	Professor at Göttigen Founding of the journal *Psychologische Forschung* (*Psychological Research*), together with Max Wertheimer, Kurt Koffka, and others; major journal of Gestalt psychology (until 1938)
1922–35	Full professor of psychology and director of Berlin's Institute of Psychology
1925	Book: *The Mentality of Apes* (trans. from the 1921 German book)
1929	Book: *Gestalt Psychology* (later edn. 1947)
1935	Final clash with the Nazi authorities in Berlin and emigration to the USA; psychology professor at Swarthmore College until 1958
1938	Book: *The Place of Value in a World of Facts*
1944	Influential research publication on 'figural after-effects' (together with Hans Wallach)
1954–6	Perceptual research at the *Institute for the Advanced Studies* in Princeton, NJ
1958–9	President of the *American Psychological Association* (USA)
1959–67	Perceptual and psychophysiological research at Dartmouth College, New Hampshire (USA)
1967	Deceased on June 11, 1967 in Enfield, New Hampshire (USA)

anthropoid research station of the Prussian Academy of Sciences on Tenerife, Canary Islands. He began his investigations with perceptual and problem-solving tasks, demonstrating the ape's and the chicken's size constancy and their transposition of perceived stimulus relationships. He also demonstrated the chimpanzee's fabrication and use of simple 'tools.' Most famous became the success of one of his apes named Sultan in fitting together two sticks to make them long enough to reach the goal object, a banana. Köhler (1917, 1921) also did extensive work on the chimpanzees' ability to solve a problem by stacking boxes on top of each other, thus demonstrating, once again, 'insightful' animal behavior. Köhler (1920; see Table 1) expanded the Gestalt-theoretical perspective when he wrote his treatise on '*Die physischen Gestalten in Ruhe und im stationären Zustand*' ('The physical configurations at rest and in stationary states'), a book in which he aimed to integrate basic principles in psychology and physics in a new psychoneural solution to the mind-body problem (Sect. 2.1 below). He became a professor at Göttingen's psychology institute for a short time (1921) before he followed Carl Stumpf in the chair at Berlin.

1.3 Köhler's Professorship at the University of Berlin

In 1922 Köhler became full professor of philosophy and director of the Psychological Institute at the University of Berlin, where he worked together with other eminent scientists like Max Wertheimer and Kurt Lewin (1890–1947). Here the international fame of the Berlin School of Gestalt psychology grew until its peak during the early 1930s. It was during this time that the Gestalt principles of the organization of perception were published and extended to new research issues (Wertheimer 1923) like memory, cognition, motivation, and aesthetics.

During these years Köhler also lectured abroad several times, in the USA at Clark University (1925–6) and at Harvard University (1934–5), in South America in Uruguay (1930), as well as Brazil and Argentina (1932). When Köhler encountered the harassment of university scholars by the Nazi government in 1933, he fought racial discrimination and struggled against the political authorities of those days; he may have been the only psychology professor in Germany who protested in public against the totalitarian system (Henle 1978). When in 1935 his assistants were fired, he left Germany and followed his colleagues into exile in the USA.

1.4 Köhler's Emigré Years in the USA (1935–67)

In 1935 Köhler became a psychology professor at a small but prestigious undergraduate college, Swarthmore, near Philadelphia. There he continued his research, but on a smaller scale since his efforts were hampered by the absence of advanced facilities

and the lack of a doctoral program at this institution (Ash 1995, Sarris 1995).

Nevertheless, Köhler, together with his American colleagues and students, published important new findings on figural after-effects and on related perceptual phenomena; he also studied the cortical activity associated with pattern vision (Sect. 2.2 below), and wrote three further books on Gestalt psychology, all in English (Köhler 1938).

After World War II, Köhler received worldwide recognition for his life work, including several honorary doctorates from American and European universities. He was a recipient of the APA's (American Psychological Association) Distinguished Scientific Contribution Award and was elected a Member of the National Academy of Sciences. He was also named an 'honorary member' (*Ehrenbürger*) of the Free University of Berlin, where he lectured several times, first as a visiting professor. He was elected president of the APA for the 1958–9 term, an unusual honor for an emigré scientist in the USA.

2. *Köhler's Accomplishments and his Impact on Psychology*

Gestalt theory had begun after the turn of the twentieth century as a scientific revolt, first against Wilhelm Wundt's (1832–1920) ruling elementaristic ('atomistic') approach, and later opposed to John Broadus Watson's (1878–1958)—then dominant—behaviorism. It took several decades before Gestalt theory became a fully acknowledged perspective in psychology.

2.1 *Köhler's Work on Cognition, Perception, and Memory*

Cognition and 'Insight' in the Chimpanzee: Köhler's ideas about thinking were opposed strongly to those of the other schools of psychology. Some of his research was specifically directed against E. L. Thorndike's (1874–1949) influential behavioristic interpretation of learning and problem solving in animals. According to the latter view, a correct behavioral response occurs in the course of blind trial-and-error activity; on repeated trials the correct response is reinforced and thus strengthened simply by associations in an 'automatic' way (Thorndike's 'law of effect'). Köhler, in sharp contrast to that approach, argued that Thorndike's puzzle-box task did not allow any perceptual-cognitive insight into the whole procedural arrangement and thus represents no possibility of real problem solving; 'insight' requires a situation which is completely 'natural' and 'visible' to the animal (Köhler 1921).

According to Köhler (1951), problem solving is based on the organization of meaningful relations. It begins with a situation and a goal that cannot be directly reached (the so-called 'detour' problem). The process of problem solving requires a re-examination of the situationally given materials which must be 'reorganized,' quite analogously to the reversal of perceptual patterns. Köhler was criticized by his opponents for not considering the influence of past experience on problem solving. He did not deny the role of past experience in principle, but considered it of minor significance in insightful learning. This issue has still not been fully resolved today.

2.1.1 *Human perception and psychophysical theory.*

Basic to Köhler's perceptual research was the study of stimulus relationships, starting with his comparative work on transposition in apes, chickens, and children (Köhler 1917); for example, a chicken is presented with two gray samples, a darker one, *A*, and a lighter one, *B* (the positive stimulus): after successful discrimination training the chicken is tested with a new pair of samples, *B* and *C* (*C* being lighter than *B*). The majority of Köhler's hens chose *C* over *B*, thus showing relative choice behavior ('transposition'). Köhler obtained similar experimental results with his chimpanzees as subjects, using size as well as brightness as stimulus dimensions, thereby demonstrating the priority of 'structural' properties in perception and learning. From the perspective of Gestalt-theory, the effective stimulus for a given perception or perceptual choice is always relational in character; what is perceived and reacted to is fundamentally a given 'pattern,' which is conceived of as the interaction (relation) between a particular stimulus and its surround. This idea, although challenged by the behaviorist school, has been proved to be accurate, by and large; it fits with the Gestaltists' emphases on the importance of *frame of reference* in perception (cf. Sarris 1994).

Köhler's interest in the physical processes in the brain, which dates back to his years on Tenerife (or even before), generated an influential book on a special psychoneural theory of perception. This monograph (1920) dealt with the neurophysiological processing during a given experience, in an attempt to relate the laws of physics to the brain's physiochemical characteristics. It was to this end that he later directed his research on figural after-effects and so-called satiation (Köhler and Wallach 1944). His explanation offered for these much—investigated phenomena was based on the notion that direct electric currents are generated in the cortex, resulting in different active 'fields' for various perceptual phenomena (Köhler and Held 1949). However, this theory was not accepted widely by the scientific community; on the contrary, it was later refuted on both experimental and theoretical grounds in criticisms of Köhler's speculative psychophysical isomorphism.

2.1.2 *Memory and learning from a Gestalt perspective.*

Köhler expanded the Gestalt principle of perceptual and cognitive organization to the province of

memory and learning by assuming that recognition and recall are functionally another case of grouping. When a form or pattern is perceived it tends to be subsequently recognized and recalled in a well-structured, organized way; memory traces in the brain are conceived of as neurophysiological correlates of recognition and recall.

Köhler (1947) developed several criticisms of classic associationist psychology. For instance, he attacked the 'law' of association by contiguity as being merely a mechanistic principle:

> Two processes A and B happen to occur together and, whatever the nature of A and B may be, a bond is formed between them! I do not know a single law in physics or chemistry which could in this respect be compared with the law of contiguity (Köhler 1947).

Köhler argued that meaningful pairs of words are always associated more readily than are pairs of nonsense elements since the former can more easily ('naturally') be organized into a unified pattern ('Gestalt'). According to this account, recognition and recall depend on an interaction between the assumed memory traces that are relationally determined (Köhler 1951; see the reference details in Murray 1995).

2.2 *The Impact of Köhler's Work on Psychology*

Köhler's and his followers' work gradually influenced the direction and content of modern psychology. Gestalt psychology turned out to offer an important alternative to behaviorism and its related perspectives, especially in the fields of perception and cognition, since the 1960s in the twentieth century.

2.2.1 Köhler's lasting research contributions. Köhler was a research-oriented scientist aiming at an integrative and multidisciplinary development of psychology as a science. Today his research is acknowledged widely by mainstream psychology as a major contribution to the advancement of psychology as a science. His work is seen as a theoretical and experimental breakthrough in animal problem solving and in human perception and cognition. Nowadays modern psychophysical and neurobiological theory are being used to re-examine the classic Gestalt issues.

Some of the central tasks of the brain—such as figure-ground coding, perceptual organization, object identification, and the formation of object memory—concern the integration of separately coded stimulus features into coherent and meaningful object representations. These fundamental problems in explaining the basis of perception and cognition, namely the understanding of the computational or informational significance of neurobiological activity, have not been solved. Nowadays these issues are approached by the concerted efforts of different disciplines (notably, psychophysics, neurobiology, and neurocomputing).

2.2.2 Köhler on ethics and human values. Köhler also envisioned the science of psychology as an expanding area to be developed according to an ethical understanding (Köhler 1969). His analysis of values and human ethics led Köhler to reject the commonly-held assumption that values are merely subjective; on the contrary, his position offers an alternative to the relativism that seems to dominate discussions of values in science and life.

3. *Final Notes*

Köhler died on June 11, 1967, at the age of 80 at his home in Enfield, NH, USA. There has been a Wolfgang Köhler Society on Tenerife, Spain, since 1992; and the Wolfgang Köhler Memorial Lectures are organized biannually by the *Deutsche Gesellschaft für Psychologie*, Germany's national psychology association. The Wolfgang Köhler Archives are housed in the Archives of the Philosophical Society of America in Philadelphia. The complete bibliography of Köhler is published in Henle (1971).

Korea: Sociocultural Aspects

1. *Political and Institutional Contexts of the Anthropology of Korea*

The development of the English-language anthropology of Korea, a post-liberation (from Japanese colonialism in 1945) venture, must be understood in its political and institutional contexts.

In the cold war context of the ideological division of the Koreas, the representation of 'Korean' culture has been necessarily political. The anthropology of 'Korea' has been overwhelmingly the anthropology of South Korea. While the South Korean developmentalist state has depicted Koreanness to its own ends, decades of oppositional movements have contested official representations.

The recent and simultaneous academic institutionalization of the anthropology of Korea in and beyond South Korea constitutes another critical context. Importantly, sustained Western anthropological discourse on Korea does not predate the emergence of South Korean anthropological scholarship on Korea. Hence the English language anthropological portrayal of Korea reflects considerable scholarly exchange between South Korean, Korean émigré, and non-Korean anthropologists. Also, the vast majority of US anthropological dissertations on South Korea are the works of South Korean or recent émigré (South) Korean American scholars. This history aside, however, much of South Korea's anthropological history squarely reflects the Western-centered development of social cultural anthropology. Indeed, the vast majority of anthropologists in South Korea have received their Ph.D. abroad, primarily in the United States.

2. *Village Ethnography: Korean Culture/Korean Development*

In keeping with anthropological history, the early ethnography of South Korea turned to villages as exemplary of Korean culture. Many early works sought to distinguish 'Korean' culture from Chinese and Japanese culture. Indeed, anthropology and folklore in Korea often wrote against colonial discourses which denied the historical legitimacy and cultural autonomy of 'Koreanness' (Janelli 1986). In a different vein, an interest in Korean distinctiveness outside of Korea in part reflects the marginalization of Korean studies in the Western study of East Asia.

The early portrayal of Korean culture centered on several related dichotomies: elite (*yangban*, referring loosely to membership in a genealogy with office-holding ancestors) vs. popular/non-elite culture; Confucianism vs. shamanism/popular religion; and male vs. female. These dichotomies turn on understandings of the (Chinese) Confucianization of Korea (both ideologically and institutionally) over the last four centuries. The cornerstones of Confucian practice and ideology include patrilineal descent and primogeniture, structural separation and subordination of women, and text-based ritual observance, including particularly the veneration of patrilineal ancestry. It is critical to note that the early anthropology of Korea was most comfortable locating 'Korean culture' in villages organized as *yangban* patrilineages.

In the consideration of the dichotomies above there are points of considerable disagreement reflecting theoretical developments in anthropology. While some anthropologists have been comfortable in contrasting elite hegemonic Confucian culture with popular indigenous culture (e.g., Brandt 1990 (1971), Osgood 1951), others have insisted that lived reality obscures or even obviates these scholarly constructs (e.g., Chun 1984, Kendall 1985, Janelli and Janelli 1982). Nonetheless, anthropology has continued to lend considerable attention to the persistent presence of these very categories in Korean public and private discourse (see, for example, the Korean-language writings of Kwang-Kyu Lee). These discussions echo longstanding debates in anthropology: on culture (norm/prescription/ideology vs. practice/reality), social structure (organization vs. cognitive models), gender (isolated vs. integrated worlds), and history (cultural continuity vs. the invention of tradition).

A number of early post-liberation anthropological and sociological works on Korea consider village variation, foremost the distinction between *yangban*-dominated vs. non-dominated villages (or consanguineous vs. non-consanguineous villages) (see, for example, the writings of prominent Korean ethnographer Taik-Kyoo Kim). For many investigators these distinctions took on interest in relation to the apparent collapse of the old status system under the influences of land reform (1950), the Korean War,

modern education, technological transformation, changes in economic organization, and burgeoning rural exodus. This literature, however, asks very different questions of villages, looking less for cultural essences, and more to village 'development' or 'modernization' in a rapidly changing South Korea.

2.1 Korean Cultural Patterns and Tensions

Cornelius Osgood's (1951; fieldwork, 1947) brief fieldwork in occupied South Korea becomes the first post-liberation village ethnography. In an attempt to distinguish the uniqueness of Korea, Osgood examines the culture and personality of the Korean 'man'. He writes of an 'innately emotional' Korean personality strained under the strictures of Chinese Confucian formalism. Vincent Brandt's (1990 (1971); fieldwork, 1966) village ethnography seeks to reconcile village communalism and egalitarian social relations with Korea's dominant ideological system with its rigid lineage, age, and occupational hierarchies. Like Osgood, Brandt is thus interested in cultural tensions in Korea. Prescient of later works, Brandt struggles over how to portray these tensions: an 'other' ideological system that competes alongside the Chinese, Confucian elite system; practices and values that comprise a 'different level of consciousness'; the ideational vs. the behavioral; a lower-class tradition vs. the dominant one; or in terms of ideological and cultural village variance (e.g., in accordance with *yangban* concentration, and village mode of subsistence).

2.2 Questioning Dichotomies

Roger and Dawnhee Yim Janelli's (1982; fieldwork, 1973–7) ethnography of ancestor worship rejects the facile equation of Korean ancestor worship, social organization (including gender organization), and filial piety with Confucianism. Rather, the Janellis analyze ritual ideas and practice in relation to Korean social organization—reflective of, but never reducible to, Confucianism. The Janellis are particularly interested in how the dependent, passive ancestor of prestigious formal ancestor worship can be reconciled with the active and potentially hostile ancestor of domestic ancestral rites and shamanism. They correlate women's much greater interest in ancestral malevolence with their structural vulnerability in Korean patrilocal, patrilineal, and patriarchal social organization. Shamanism and ancestor worship emerge as separate and internally coherent systems, neither wholly Confucian nor anti-Confucian.

Kyung-soo Chun (1984; fieldwork, 1975–6) was similarly interested in social practice, considering reciprocity as an organizing principle in a Korean island village. He scrutinized 'community' boundaries by considering social relationships beyond kinship, thus examining 'practical' rather than ideal patterns.

Laurel Kendall's (1985; fieldwork, 1977–8) ethnography of village shamanism and women's domestic ritual employs the insights of feminist anthropology to challenge similarly the dichotomies in question here. Writing against classical anthropological portrayals of women's ritual as revenge or resistance, Kendall argues that women's ritual domains contrast with, but by no means subvert, men's practices and objectives. Kendall nonetheless analyzes women's ritual roles and practices as a window through which Korean society as a whole can be reconsidered. She highlights social features that challenge the limits of formal patrilineal organization and ideology: the house and household (*chip*) as women's space and ritual domain; women's power as matrons of autonomous households; and women's roles as the link between bilateral kinship groups.

2.3 Village Variation and 'Development'

Village variation took on two meanings in the early anthropology of Korea. First, variation allowed some anthropologists to explore gaps between 'ideal' structures and social realities; important here are writings on villages that do not feature the dominant cultural pattern or ideology of patrilineal kinship organization. Second, village variation allowed for controlled comparison of developmental outcomes. Sang-Bok Han (1977; fieldwork, 1968–9), for example, examines ecological adaptation in three fishing communities distinguished for not having permanent patrilineal kinship organization (see also the writings of rural sociologists Man-Gap Lee and Ki-hyuk Pak). Building on this legacy, Clark W. Sorensen (1988; fieldwork, 1976–7, 1983) examines peasant households' adaptation to rapid industrialization, considering transformations of farm labor, village economy, land tenure, and out-migration.

3. The Discursive Turn: The Ethnography of Social-cultural Contests and Class/Gender

As anthropology has followed the vast majority of South Koreans out of the village to urban and modern organizational venues, 'traditional' or 'Korean' culture has been revisited. In keeping with their anthropological times, this next generation of Korean ethnographies is less interested in characterizing Korean culture or considering Korean development: it is committed instead to portraying the various discursive contexts and contests in which South Koreans live and make sense of their lives. Important to this endeavor is attention to the state—particularly its nationalist and development rhetorics—as consti-

tutive of personal subjectivities and social life. It is perhaps because of South Korea's decades of political authoritarianism that Korean anthropology features the state to an extent that many other anthropologies do not. These works challenge the facile portrayal of cultural continuity (from the village to the city or modern organization), considering instead the constructed character of cultural discourses. Persistent parameters of cultural and value difference in the contemporary anthropology of Korea have been class and gender.

3.1 *The Politics of Culture*

The new generation of works pays scrupulous attention to the political-economic context of social practice and cultural life. Exemplary is Chungmoo Choi's (1995) examination of competing appropriations of shamanism and other cultural performances by both the state and oppositional groups. In a similar vein, Roger Janelli (with Dawnhee Yim) (1993; fieldwork, 1987) portrays daily company life in a major corporation in the context of corporate and state representations of 'Korean culture'. Highlighted are the ways in which company discourses distort the reality of Korean family, lineage, and village life.

A number of works situate contemporary practice in the *longue durée* of anthropologically informed cultural history. Kendall (1996), for example, sets her ethnography of marriage in South Korea in the context of the twentieth-century sweep of Korean cultural discourses of tradition and modernity, especially apt because wedding styles are often so easily labeled one or the other.

In the 1980s, a number of anthropologists turned their attention to the cultural and historical coordinates of social movements. Abelmann (1996; fieldwork, 1987–8), for example, examines the range of urban and rural actors in a farmers' movement in order to consider struggles over history and memory (see also H. M. Kim 1997 and S. K. Kim 1997 on the women's labor movement). Also noteworthy are new ways of reading cultural practices: exemplary is Seong Nae Kim's (1995) reading of the history of ideological strife in Cheju Island through the dreams of a shaman.

3.2 *Class and Gender*

Drawing on the theory and methods of anthropology's discursive turn, anthropologists of Korea have theorized the contingent, complex character of class, and its articulation with gender.

A central debate has considered how to conceptualize the hegemony of middle-/upper-class norms and values, and the counter-hegemony of working-class life and culture. Many works portray the lived reality of class in such a way that it is impossible either to romanticize unbridled class struggle on the one hand, or to consider all Koreans as dupes of hegemonic culture, on the other hand. Exemplary is Seung Kyung Kim's (1997; fieldwork, 1986–8) examination of the lives of women factory workers in an export industrial zone. This work details women's contribution to the labor movement and recognizes prevailing views that obscure these women's powerful desires for social mobility.

Understanding that class and gender are inextricable from one another, a number of anthropological studies examine the workings of class in women's lives, and women's roles in the making and social reproduction of class, asserting particularly the importance of women's work beyond the formal economy (Myung Hye Kim 1992). Anthropologists have also wrestled with how to understand the persistence of hegemonic patriarchal ideologies and social organization. In her examination of women's reproductive ideologies across class, for example, Eun Shil Kim (2001) considers the complex and subtle play of patriarchy, class dominance, and resistance (see also H. M. Kim 1997). Also important have been analyses of the discursive production of femininity and motherhood over time and across class (see also the Korean-language writings of Oakla Cho and Taek-Lim Yoon). Particularly influential have been the prolific Korean-language writings of anthropologist Haejoang Cho (2001), who has argued for the multivocality of 'traditional' cultural legacies for women (see also Soh 1991).

4. *'Korean' Ethnography into the Future*

As anthropology has come increasingly to question its objects of study, many have begun to look beyond South Korea to reconceptualize 'Korea'. Richard Grinker (1998), for example, considers South Korean cultural and political identity through South Korean state and popular representations of North Korea (see also the prescient work of Choong Soon Kim (1988) on divided families). Also noteworthy are burgeoning transnationally focused studies of Korean diasporic communities that demand reconceptualization of South Korea and the Koreas, including studies of Koreans in China and their 'return' to Korea as migrant laborers; the Korean American transnation; North Koreans in Japan; South Korean multinational corporations abroad; and global social activism concerning 'comfort women'. Given the escalating interest in the transnational production of Korean modernity, still surprisingly unexplored is Japanese colonial ethnography of Korea, as a window on both the Japanese colonial project and post-liberation anthropological knowledge. Similarly, the missionary encounter in Korea remains little studied in and beyond anthropology.

The above horizons aside, it is important to note that for the anthropology of Korea there remain many domains almost entirely unexplored ethnographically

(in English), including all levels of schooling; childhood and adolescence; Christianity and Buddhism; the military (with its universal conscription for men); sexuality; leisure (including tourism); the media; and medical systems.

Finally, it is important to note that the anthropology of Korea has become increasingly bold in asserting its contributions to general anthropological debate. The field is ever more keenly aware of the multiplicity of global processes that converge in the Koreas, and of the important anthropological issues presented by the Koreas' postcoloniality and national division.

N. Abelmann

Korsakoff's Syndrome

Organic amnesia is a syndrome, caused by specific kinds of brain damage, in which an impairment in the ability to recall and recognize recently experienced facts and personally experienced events (anterograde amnesia) is accompanied by a similar memory deficit for premorbidly encountered facts and events (retrograde amnesia). These memory deficits occur in the face of relatively preserved intelligence and ability to recall information encountered in the previous few seconds (short-term or working memory) so that the memory deficits are disproportionate to other cognitive impairments. Korsakoff's syndrome, in which memory impairment results primarily from depletion of thiamine, is an important subvariety of organic amnesia.

1. Origin of the Name 'Korsakoff's Syndrome'

Although the syndrome is named after the Russian doctor Korsakoff, earlier authors had alluded to the disorder and it was Lawson in 1878 who first gave a formal description of a disorder in which there was a severe loss of recent memory that was frequently associated with chronic alcoholism. Lawson also distinguished between cases with relatively selective

memory loss and those in whom alcohol consumption caused a progressive dementing condition, which is nowadays referred to as 'alcoholic dementia.' Between 1887 and 1891, Korsakoff then gave the classic description of a much larger series of amnesia cases, two-thirds of whom were chronic alcoholics. The other third of the cases comprised individuals with several etiologies including neoplasm, carbon-monoxide poisoning, and diabetes, as well as persistent vomiting. Korsakoff identified how the memory disorder varied in severity, and that it had a retrograde as well as an anterograde component. He also noted that patients often falsely recollected information, a disorder known as confabulation. Korsakoff further noted that the memory disorder was commonly preceded by a state of confusion, accompanied by eye movement disorders such as nystagmus, as well as gait disturbance (ataxia).

This triad of symptoms had first been described in 1881 by Wernicke, who also reported that the syndrome, which now bears his name, was associated with alcoholism. Although the syndrome is often incomplete, it is not diagnosed unless at least one of the complexes of motor symptoms is present. There has been controversy about the frequency with which the appearance of the usually chronic memory disorder is preceded by Wernicke's encephalopathy. Although the issue is not fully resolved, it is clear that in many cases of alcoholic origin, perhaps over half, Wernicke's encephalopathy is not detected prior to the onset of amnesia. Consistent with this, it is clear that many of these cases have a relatively insidious onset often lasting over a year, and that these cases are weakly associated with Wernicke's encephalopathy. In contrast, more acute onset cases frequently show the Wernicke ocular signs. Emergence of the memory deficit may be preceded by acute coma, Wernicke's encephalopathy (both of which are life threatening), or it may emerge gradually without either of these prodroma being detected. There even appear to be cases where the memory disorder is not identified in life, but is suspected retrospectively at postmortem on the basis of neuropathology and a history of alcoholism. No evidence indicates that the presence or absence of detectable Wernicke's encephalopathy affects the memory disorder or its underlying neuropathology differently. It is, however, still possible to argue that the persistent memory disorder, caused by thiamine deficiency, is always preceded by one or more episodes of Wernicke's encephalopathy, but that these episodes may often go undetected. If correct, the brain damage underlying Wernicke's encephalopathy should be found in Korsakoff's syndrome regardless of whether or not it is preceded by a detectable Wernicke's encephalopathy. This encephalopathy does not always lead to a persisting amnesia.

Although the term 'Korsakoff's syndrome' is sometimes loosely used as a synonym for amnesia, it is more correctly reserved for those cases of relative persistent amnesia which are triggered by thiamine depletion, the most prominent cause of which is chronic alcoholism. Alcoholism is not the only cause of thiamine depletion, however, and the evidence about this cause as well as other causes of thiamine depletion has only emerged gradually over the last century. Diagnosis depends on identifying clinical and neuropsychological evidence of a disorder largely confined to memory and learning in which there is a history of alcoholism or nutritional problems.

2. *Evidence for the Role of Thiamine Depletion in Organic Amnesia*

Both Wernicke's encephalopathy and amnesia can result from a range of nutritional and other disorders related to malabsorption, which include self-starvation, intravenous feeding, particularly in the presence of glucose, persistent vomiting, surgical removal of parts of the gastrointestinal tract, and various carcinomas of the alimentary canal. De Wardener and Lennox (1947) notably observed Wernicke's encephalopathy in 52 malnourished prisoners in Southeast Asia during World War II. Over 60 percent of the prisoners also developed memory loss within six to fourteen weeks of the start of captivity, often preceded by diarrhea and vomiting. This corresponds to the time it takes beriberi, which is caused by thiamine deficiency, to develop. Symptoms of other vitamin deficiencies take longer to develop. Also, as is now well known, the symptoms responded very well to thiamine treatment when this was available and could be instituted early before brain damage was irreversible. In recent years, cases of amnesia caused by malnutrition have been reported relatively rarely, although there may be under-reporting given the prevalence of anorexia. Nevertheless, Korsakoff's syndrome with a typical neuropathology has been reported to result from dieting, particularly when this is followed by high consumption of carbohydrates, which presumably overloads the already marginal thiamine stores.

A common feature of the alcoholic and nonalcoholic patients who develop the memory deficits and neuropathology typical of Korsakoff's syndrome is very probably thiamine deficiency. Not only is alcoholism often associated with poor nutrition, which causes thiamine deficiency, but alcohol directly impairs thiamine metabolism in many ways (e.g., by distruption of the gastrointestinal transport of the vitamin as well as its storage and use). Although thiamine treatment may be less effective with alcoholic than nonalcoholic cases, this could be related to incidental factors such as the patients' ages and when the treatment was introduced. Nevertheless, it is often argued that some aspects of alcoholic Korsakoff's syndrome may be related to the direct neurotoxic effects of alcohol, and that nicotinic acid deficiency

may also contribute to development of the disorder in some cases.

Korsakoff's syndrome is a rare complication of alcoholic abuse, although its frequency seems currently to show marked regional variations, as it is apparently much more frequent in Australia than in the USA and the UK. This variation could relate to differences in factors such as binge drinking or the amount of thiamine intake. However, the syndrome's rarity has led to the suggestion that it is associated with a hereditary disorder affecting the enzyme transketolase, which needs thiamine pyrophosphate (TPP), the active form of thiamine, as a cofactor. The evidence about this is conflicting, although it is likely that some kind of transketolase abnormality is related to the development of Korsakoff's syndrome. Exactly how thiamine deficiency causes the brain damage that leads to amnesia is not known. However, TPP is involved in DNA synthesis, three enzymatic reactions vital for glucose metabolism, and the production of several neurotransmitters including acetylcholine, glutamate, gamma-aminobutyric acid (GABA), noradrenaline, and serotonin. All three of the thiamine-dependent enzymes have been found to be depressed in patients with Wernicke-Korsakoff syndrome, but not in other alcoholics. Some evidence suggests that thiamine deficiency depresses oxidative glucose metabolism more severely in brain regions implicated in the syndrome, although this does not exclude the possibility that the deficiency may also disrupt specific neurotransmitters as well.

2.1 *Evidence of Neurotransmitter Abnormalities in Korsakoff's Syndrome*

No work has related glutamate and GABA abnormalities to Korsakoff's syndrome. There is, however, evidence that reduced acetylcholine turnover occurs when thiamine activity is low, and that this may also cause reduced acetylcholine production. It has also been argued that Korsakoff patients suffer a nearly 50 percent reduction of neurons in their nucleus basalis, a basal forebrain structure which contains ascending projections that use acetylcholine as a neurotransmitter. However, other Korsakoff patients have shown minimal changes in basal forebrain structures at postmortem. This relates to an important feature of the syndrome, which is that the location of brain damage is very variable across patients so presumably only some will show marked abnormalities in cholinergic neurons. Furthermore, although studies using anticholinergic drugs have shown that the anterograde amnesia of patients who have cholinergic deficiencies may be partially caused by the transmitter deficit, their retrograde amnesia cannot be. This is because anticholinergic drugs do not disrupt premorbid memory.

Five patients with alcoholic Korsakoff's syndrome have been reported to show improved memory when given a serotonin reuptake inhibitor, and a similar effect has been reported in alcohol-treated volunteers. However, the patient study needs replicating and whether a serotonergic abnormality is linked to the syndrome remains unproved. The same can be said about the possible involvement in the syndrome of a noradrenergic disorder, as the relevant evidence is conflicting. Some work has found that levels of the noradrenergic metabolite, 3 methoxy 4-hydroxy phenylglycol, were reduced in the cerebrospinal fluid of Korsakoff patients, that these levels correlated with memory test performance, and that treatment with adrenergic agonist drugs produced a small improvement in memory. However, other work has not replicated these findings and animal studies suggest that noradrenergic neurons are more concerned with the mediation of attentional and arousal processes. If the animal studies are correct, then any effects on memory must be secondary to attentional disturbances. As with cholinergic abnormalities, noradrenergic deficiencies are also a variable feature of Korsakoff's syndrome because the level of neuronal loss in the locus coeruleus is highly variable. This small brainstem nucleus is the major source of noradrenergic projections to the forebrain regions implicated in memory.

3. *The Neuropathology of the Syndrome*

Postmortem examination of patients who have died during the acute stage of Wernicke's encephalopathy, or following a relatively prolonged Korsakoff's syndrome, show a similar, although variable, pattern of lesions that is distributed in a bilaterally symmetrical fashion within the midline diencephalon, brain stem, and cerebellum. Pathology is most common in the mammillary bodies, midline thalamic nuclei such as the dorsomedial and anterior nuclei and medial pulvinar, the periventricular and periaqueductal grey, the walls of the third ventricle, the floor of the fourth ventricle, and the cerebellum. Cortical atrophy with associated neuronal loss and increased hydration, which may be particularly prominent in the frontal lobes, has also been reported in a minority of cases with the full syndrome. This atrophy is similar in alcoholic patients regardless of whether or not they have Korsakoff's syndrome. In the acute stages of the disease, gross lesions are usually small and circumscribed with nonhemorrhagic softening or, less commonly, hemorrhages, whereas in the chronic disease atrophy is prominent, but hemorrhages may not be present. Microscopic examination may be necessary to confirm the presence of Korsakoffian pathology because gross lesions are not identifiable in all patients.

The location of the pathology that underlies the triad of symptoms which Wernicke's encephalopathy comprises is not fully resolved. The ocular symptoms perhaps involve damage to the tectal area as well as to several brain stem nuclei including the oculomotor, abducens, and vestibular nuclei, whereas the ataxia

involves cerebellar damage. Identifying the location of the lesions underlying the memory deficits of Korsakoff's syndrome has proved particularly difficult because of the range and variability of the structures that may be compromised in this disorder. Also, many non-Korsakoff alcoholics have milder memory deficits. Victor and his colleagues (1989) have reported that all of their alcoholic Korsakoff cases in whom the dorsomedial thalamic nucleus was affected showed amnesia, whereas a few patients in whom this nucleus was intact, but in whom the mammillary bodies were affected, did not show clinically detectable amnesia. There is, however, good evidence from both animal and human lesion studies that damage to either the dorsomedial thalamic nucleus or the mammillary bodies is sufficient to cause some memory deficits, so, when present, damage to either of these structures is likely to be contributing to the amnesic deficit in Korsakoff's syndrome.

Korsakoff patients with an etiology of chronic alcoholism have nevertheless shown severe amnesia even when postmortem examination only found paratenial nucleus damage anterior and dorsal to the intact dorsomedial thalamic nucleus. These patients also had mammillary body damage as well as other cortical and subcortical lesions. Korsakoff patients show variable damage to structures of Papez circuit that includes demyelination of the fornix as well as atrophy of the mammillary bodies and anterior thalamus. However, damage in alcoholic Korsakoff patients compared to alcoholic Wernicke's cases with milder memory problems has only been convincingly shown to be worse in one region: the anterior thalamus. Damage to Papez circuit structures is sufficient to cause a mild amnesia. It remains unknown how severe the amnesia produced by a combination of this damage with damage to other diencephalic nuclei, such as the dorsomedial nucleus and mammillary bodies, actually is. Most probably, extradiencephalic damage also contributes to the severe amnesia found in some patients with Korsakoff's syndrome.

3.1 Neuroimaging the Brains of Korsakoff Patients in Life

Magnetic resonance imaging (MRI) has shown that, relative to healthy people, alcoholic Korsakoff patients show widening of the third ventricle, the Sylvian fissure, and frontal sulci, as well as reductions in thalamic density. The evidence is conflicting about whether these changes are greater in Korsakoff's syndrome than in non-Korsakoff alcoholic patients, although the postmortem data would suggest that it should not be. Similarly, there is conflict about whether measures of frontal and thalamic atrophy correlate with memory measures in the Korsakoff patients. This conflict may be resolved by improvement of MRI measurement techniques in the future. Resolving this issue is important because it has often been argued that frontal atrophy may contribute to the Korsakoffian memory impairment.

Functional imaging has tended to show a picture of reduced cortical activation in Korsakoff's syndrome, which, although prominent in frontal regions, extends into posterior neocortical regions, but minimally into the medial temporal regions where lesions are known to cause amnesia. One possibility is that the reduced neocortical activation does not disrupt basic processing ability, but impairs the ability of neocortical structures to store fact and event information. Further investigation needs to determine whether the extent of reduced neocortical activation correlates with memory.

4. Neuropsychology of Korsakoff's Syndrome

The degree of impairment of intelligence and other, noncognitive functions varies widely across Korsakoff patients. Patients often show impairments of visuoperceptive and visuospatial functions, which are also found in nonamnesic alcoholics and may be caused by neocortical atrophy. Korsakoff patients are also usually impaired on several tests of executive function, particularly when the ability to shift strategy is tapped. Such executive functions are believed to depend primarily on the integrity of the frontal lobes.

Immediate or working memory as tested by the ability to repeat a string of items is usually held to be intact in Korsakoff's syndrome. However, subtle span deficits have been claimed and performance on short-term forgetting tasks has been highly variable across studies. Evidence suggests that this variability may relate to the degree of frontal lobe dysfunction. Unrelatedly, the apathy and lack of insight often reported in patients may also relate to frontal lobe dysfunction.

The anterograde amnesia of Korsakoff's syndrome comprises impaired recall and recognition of recently studied facts and events. Although recognition is lost at a normal rate even over short delays, there is evidence that free recall of complex associative information is lost pathologically fast over such short delays. There is also evidence that recall of semantically related words is more impaired than equivalent recognition after short delays, and that memory for temporal and other aspects of context is more impaired than item recognition. It remains controversial whether these disproportionate deficits, which are also found in amnesics with medial temporal lobe lesions, relate to frontal dysfunction, the severity of amnesia, or both.

Like other amnesics, Korsakoff patients also often show intact implicit or unaware memory. Thus, they show normal classical conditioning when the conditioned and unconditioned stimuli overlap in time, normal acquisition and retention of perceptual, motor, and cognitive skills, and normal priming. Priming is shown when subjects respond differently to previously

shown verbal and visual stimuli, even when these are not consciously recognized. However, as with other amnesics, Korsakoff patients may show impaired priming for certain complex stimuli that were novel prior to study.

Although, like other amnesics, Korsakoff patients show normal semantic memory when this is defined as memory for factual information that was massively overlearnt premorbidly, they are impaired at learning new word definitions and public information even when given reasonable exposure over a long postmorbid time. Their retrograde amnesia is characterized by an impaired ability to recall and recognize personal and public incidents, and facts acquired as memories up to several decades prior to the clear onset of their memory disorder. Although there is typically a temporal gradient in which earlier acquired memories are less affected, amnesia usually extends back at least 25 to 30 years.

Confabulation is rare in Korsakoff's syndrome except at the initial confusional stage when spontaneous and florid confabulation may be found. Patients may make intrusional errors when retrieving autobiographical memories, but the rare, more florid confabulation that persists beyond the confusional stage probably reflects a disorganized and disinhibited retrieval of memories and their associations. This is believed to be caused by the frontal lobe dysfunction that may be severe in some Korsakoff patients. More typically, patients show a nonfluent pattern of retrieval that is characteristic of patients with frontal lobe pathology.

Retrograde and anterograde memory deficits share little variance in patients, and it has been argued that the functional deficits are relatively unrelated and that retrograde amnesia, at least for more remote premorbid memories, is mainly caused by frontal lobe dysfunction, which produces disorganization of retrieval processes. Although Korsakoff's syndrome may be associated with a more severe temporal order memory deficit than is typically found in amnesics with medial temporal lobe lesions, it is unclear whether this too may not result from Korsakoff patients' frontal lobe dysfunction. It seems most likely that a failure to consolidate certain kinds of associations lies at the heart of the anterograde amnesia found in the syndrome, and that this is mainly caused by midline diencephalic lesions.

Kraepelin, Emil (1856–1926)

1. Biographical Note

Emil Kraepelin was born on February 15, 1856 in Neustrelitz (Mecklenburg, West Pomerania, Germany). He studied medicine in Leipzig and Würzburg from 1874 until 1878. During his medical studies in Würzburg, Kraepelin worked as a guest student at the psychiatric hospital under the directorship of Franz Rinecker (1811–83). He began his professional life in 1878 working with Bernhard von Gudden (1824–86) at the District Mental Hospital in Munich, where he stayed until 1882. Kraepelin then moved to Leipzig, where he worked with Paul Flechsig (1847–1929) and Wilhelm Erb (1840–1921). He was promoted to university lecturer there in 1883.

His lifelong personal and scientific relationship with Wilhelm Wundt (1832–1920) began in Leipzig. Encouraged by Wundt, Kraepelin wrote his *Compendium of Psychiatry* in 1883, the precursor of his influential textbook *Psychiatry*, which was to be published in nine editions between 1883 and 1927. Kraepelin stayed in contact with Wundt (see *Wundt, Wilhelm Maximilian* (1832–1920)) by correspondence and paid him several visits before Wundt's death in 1920; in many of his publications he emphasized and acknowledged the importance of this relationship.

In 1884 Kraepelin married Ina Schwabe. After a short period of employment in Leubus (in Silesia) and Dresden, Kraepelin was appointed professor of psychiatry at the University of Dorpat in 1886. In 1891 he took over the chair of psychiatry at the University of Heidelberg. From 1903 until 1922 Kraepelin was ordinary professor of psychiatry in Munich where, in 1904, he opened the new building of the psychiatric hospital of the Ludwig Maximilian University, the main part of which is still in use. Despite the difficult conditions caused by World War I, Kraepelin founded the *Deutsche Forschungsanstalt für Psychiatrie* (the German Research Institute for Psychiatry) in Munich in 1917 to encourage and improve psychiatric research (Weber 1991). During his time in Munich, Kraepelin's colleagues at the university hospital and the *Forschungsanstalt* included Alois Alzheimer (1864–1915), Franz Nissl (1860–1919), Korbinian Brodmann (1868–1918), Walter Spielmeyer (1879–1935), August Paul von Wassermann (1866–1925) and Felix Plaut (1877–1940)—to mention but a few. In 1924 the *Deutsche Forschungsanstalt* was integrated into the Kaiser Wilhelm Society and became in 1945 the Max Planck Institute for Psychiatry as part of the Max Planck Society. Emil Kraepelin died in Munich on October 7, 1926.

2. *The Concept of Psychiatric Research*

Wilhelm Griesinger (1817–68) had marked the turning point in nineteenth-century psychiatry by calling for thorough clinical and pathophysiological research based on the premise that 'mental illness is a somatic illness of the brain.' But Griesinger's theory was by no means as simple as this one statement, which is so often quoted. He held clearly differentiated views on the problem of somato- and psychogenesis, although favouring the first in the case of what was later to be called 'endogenous psychoses.'

Karl Ludwig Kahlbaum (1828–99) continued the traditions of French psychopathology as represented by J. Falret and A.L.J. Bayle and developed a clinically orientated research method in the second half of the nineteenth century in Germany, taking the course of illness into special consideration. This, like Griesinger's theory, was believed to be a victory over the speculative concepts of the so-called 'romantic medicine' and even more so an argument for a critical distance to the position of the harsh and unreflected 'somaticists,' who were no less dogmatic than some of the 'psychicists.' Kahlbaum had clearly recognized the methodological differences between pathological-anatomical and clinical-psychopathological work. With 'progressive paralysis of the insane' as an example he explained the route from the 'syndrome-course unit' (*Syndrom-Verlaufs-Einheit*) to the—postulated—etiologically-based 'disease unit' (*Krankheitseinheit*).

The influence on Kraepelin of the founder of experimental psychology, Wilhelm Wundt, can hardly be overestimated. Wundt's aim was to establish psychology as a kind of natural science which relied on experimental data. He criticized the highly speculative approach of 'philosophy of nature' in the sense of Schelling and Schleiermacher, but did not agree with materialism or association psychology in the sense of Herbart either. At least in his earlier writings, Wundt favored a parallelistic point of view in the mind–body problem. Experimental research—and Wundt's ideas were obviously the most fascinating for the young Kraepelin— may successfully be used in natural sciences as well as in psychology, without ignoring the epistemological differences between the mental and the physical. Kraepelin modified Wundt's ideas by extracting what he regarded as useful for empirical research in psychiatry. That is why Wundt's psychology, viewed through the 'filter' of Kraepelin's texts, seems much more unified and straightforward than it really was. Kraepelin simplified and, so to speak, 'smoothed out' Wundt's concept, but he did not falsify it.

Emil Kraepelin was not very interested in the philosophical basis and implications of psychiatric theory and practice. His view of what (natural) science was, and what impact it had or should have on social and political developments, was, as Engstrom (1991, 1995) has shown convincingly, typical for the way natural scientists saw themselves in Germany at the turn of the last century. Despite his skeptical attitude toward theoretical considerations in psychiatry, the following major theoretical frameworks can be identified as underlying—seldom explicitly, most often very implicitly—Kraepelin's concept of psychiatry: realism, parallelism, experimental approach, naturalism.

2.1 *Realism*

In sharp contrast to the philosophical tradition of what is usually called 'German idealism,' Kraepelin, like most of his contemporaries in the field of natural sciences, believed in an independently existing 'real world' that includes other people and their healthy or disturbed mental processes. Kraepelin repeatedly pointed out that the psychiatric researcher has to

describe objectively what really exists and what 'nature presents to him'—the formulations differ, but the essence is a strictly realistic philosophy. The consequences for psychiatric nosology are evident: such realism will lead to the concept of 'natural disease entities' which exist completely independently of the researcher. The scientist describes what he finds, or—in stronger terms—describes 'given things.' His own activity in constructing scientific hypotheses or diagnostic entities is underestimated.

2.2 Parallelism

Kraepelin advocated psychophysical parallelism. Like Wilhelm Griesinger, whom he admired for his highly critical attitude toward speculative psychiatric theories, he disapproved of reductionistic materialism which identifies mental events with neurophysiological processes. Kraepelin spoke about two kinds of phenomena, somatic and psychological, which are decidedly different, but closely connected. Kraepelin defended the existence of mental phenomena against all kinds of what he, like Karl Jaspers, called 'brain mythologies.' Contrary to Wundt, however, Kraepelin, although calling himself a parallelist, did not enter the philosophical controversy about this concept. In particular, he did not critically differentiate between parallelism and interactionism and did not realize that any strictly defined parallelism makes it more than doubtful that mental life can still be regarded as an independent sphere and not just as having a one-to-one relationship with the somatic level; and this, of course, means (causal) determinism.

As a consequence of his somewhat ambivalent position in the mind–body debate, there is indeed an implicit tendency toward monism in Kraepelin's writings, particularly when considering his ideas about psychology as a natural science. It should, therefore, be emphasized that this 'monistic tendency' was definitely not a metaphysical one, but a weak version of what may be called 'methodological monism,' insofar as he decidedly favored the quantitative methods brought forward by the natural sciences (Verwey 1985).

2.3 Experimental Approach

Kraepelin argued that the psychological experiment should become a major scientific tool, not only for the understanding of disturbed mental processes, but also for the understanding of healthy mental life. Both Wundt and Kraepelin realized the difference between a physical and a psychological experiment, but the experimental design did not differ significantly in the two areas. Kraepelin seems to have considered the experimental approach a kind of guarantee for the scientific status of psychiatric research. From this it may be inferred that he rated the experimental approach higher than the mere description of clinical phenomena, although the latter method was considered to be indispensable, especially if combined with follow-up examinations. Kraepelin developed and maintained a skeptical attitude toward subjective—especially biographically-determined—aspects of mental disorders, which could not be studied experimentally.

2.4 Naturalism

In his early writings—mainly in those on forensic topics—Kraepelin clearly expressed his opinion that *a priori* ideas, freedom of the will, and unchangeable moral values do not exist. Everything is more or less dependent on the time and the specific social and cultural context in which it is used. For Kraepelin, man is nothing but a part of nature, and anything man can do is a product of this natural existence: thus Kraepelin should be seen as an exponent of the evolutionism theory (Hoff 1998). Later in his life, he became somewhat more cautious concerning these matters, but there is no reason to believe that he substantially changed his mind. This naturalistic, 'anti-metaphysical' point of view of course made Kraepelin feel sympathetic with Darwinistic and biologistic theories, although he always rejected oversimplifications such as those in the monistic theories of Ernst Haeckel (1834–1919), Jakob Moleschott (1822–93), and Ludwig Büchner (1824–99).

3. Nosology

3.1 Basic Aspects

On the clinical level, Kraepelin changed the details of his diagnostic system over and over again. On the basic level, however, his nosology showed remarkable stability over time: between the second and the ninth editions of his textbook (i.e. from 1887 to 1927) Kraepelin did not change the central postulate. He stated that the essential features of all psychotic disorders will eventually be classified in a 'natural' system, no matter which scientific method is applied: anatomy, etiology and symptomatology, if developed sufficiently, will necessarily converge in the same 'natural disease entities' (see Fig. 1).

This very strong hypothesis is limited to a certain extent in three important theoretical papers, written between 1918 and 1920: 'Ends and means of psychiatric research' ('*Ziele und Wege der psychiatrischen Forschung*'; 1918)), 'Research in the Manifestations of mental illness' ('*Die Erforschung psychischer Krankheitsformen*'; 1919) and 'Clinical Manifestations of Mental Illness' ('*Die Erscheinungsformen des Irreseins*'; 1920). In these papers Kraepelin took into account

Figure 1

contemporary arguments such as K. Birnbaum's differentiation between pathogenetic and pathoplastic factors in Mental Illness or R. Gaupp's hypothesis of the possibility of psychogenic delusion; he now acknowledged the value of defining certain syndromes as a middle course between nosologically unspecific symptoms and specific diseases. But—and this is the essential point—at no time did he abandon his postulate of underlying distinct and natural disease entities (Hoff 1994, 1995).

3.2 Clinical Aspects

Kraepelin's clinical nosology is best separated into three periods.

3.2.1 The early period, 1880–91. This period can be characterized as the search for a reliable and valid psychiatric system between clear-cut naturalistic beliefs and the methodological framework of experimental psychology in the sense of Wundt. As regards nosology, Kraepelin slowly moved away from earlier nineteenth-century concepts which he criticized as being unreliable and ill-defined from a clinical and, especially, prognostic point of view. In these years the term *'dementia praecox'* was not yet used. A group of clinically heterogeneous paranoid and hallucinatory psychoses tending to become chronic was labelled *'Wahnsinn'* (insanity) and resembled the evolutions now known as schizophrenic psychoses leading to a residual state. In addition, Kraepelin introduced *'Verrücktheit'* (madness) as a chronic psychosis with a better prognosis, that explicitly did not lead to residual states. The affective psychoses were split into the three groups: melancholia, mania, and periodical or 'circular' psychosis.

3.2.2 The middle period, 1891–1915. During these years Kraepelin's thinking reached its most systematic and influential level as far as its clinical and scientific implications are concerned: Kraepelin significantly broadened his clinical experience and self-consciously created a complete nosological system. He finalized his concept of natural disease entities as discussed above. The main clinical result of this period—first clearly proposed in the sixth edition of 1899—was the well-known dichotomy of endogenous psychoses: that is, the separation of *dementia praecox* (schizophrenia) with—as he saw it—a poor prognosis, from manic-depressive illness (bipolar disorder) with a good, or at least better, prognosis. With respect to *dementia praecox*, he supposed an organic defect as the basis of the illness, a kind of 'autointoxication,' leading to the destruction of cortical neurons. The patient's personality may promote the development of the psychotic illness, but it is not a central factor; contrary to most other nosological areas, 'degeneration' was believed to be of much less etiological importance in *dementia praecox*. 'Paraphrenia' was conceptualized as a psychosis with acute and heterogeneous clinical symptomatology, including the development of lasting deficits, but its separation from typical cases of *dementia praecox* was justified by the absence of massive disturbances of volition and by a much lesser degree of affective flattening.

In manic-depressive illness the etiology was said to be much less clear than that of *dementia praecox*. Kraepelin proposed a genetically-determined irritability of 'normal' affects, so that the psychosis itself emerged from certain predisposing 'basic states' (*Grundzustände*). The concept of degeneration was an integrative and central part of this hypothesis. In this period, Kraepelin integrated different types of circular or recurrent affective illness into the overarching concept of manic-depressive insanity (*Manisch-depressives Irresein*) (6th edition 1899).

Kraepelin's concept of paranoia was modified several times in this period. After the very broad concept of *Verrücktheit* of the early editions of *Psychiatry*, which was of restricted clinical use, he significantly narrowed it, especially in the 5th edition of 1896. Here, paranoia was defined as a severe and chronic delusional illness without constant alteration of personality and volition; the existence of abortive or benign cases was denied up to the 7th edition (1903/04). In the 8th edition (1915) this very rigid concept was broadened again, but not as much as in the early versions. Kraepelin now accepted cases with low severity and a comparably good prognosis, but he maintained the strict separation of *dementia praecox* and paranoia.

In Kraepelin's view—highly typical of the way of thinking within the theoretical framework of degeneration theory—disorders of personality resulted from a circumscript retardation of psychological development. He argued that not all patients with personality disorders reach a 'normal' or mature level of affective and cognitive functioning. Therefore, in this field, it made no sense to delineate clear-cut disease processes as in *dementia praecox* and manic-depressive psychosis.

3.2.3 The later period, 1916–26. During this final period, Kraepelin reacted to several commentaries and criticisms of his nosology, for example, A. E. Hoche's syndromatic theory and E. Kretschmer's suggestion to supplement the Kraepelinian system with a multidimensional approach. He moved towards an internal broadening of his system by reformulating his disease concept as discussed above; he combined a more differentiated view of pathogenesis and the role of individual psychological factors with a strong and unchanged position on the existence of 'natural disease entities.' Compared to this differentiation of the theoretical basis during these years, changes in clinical nosology were small.

4. *Kraepelin and Present-day Psychiatry*

Kraepelin's psychiatry became so influential during his lifetime, because it offered a pragmatical, clinical and prognosis-oriented nosology, developed by a self-confident author who focused on straightforward quantitative and naturalistic research methods. He claimed to abandon speculative aspects of psychiatry as far as was possible, although he himself did—unintentionally—'import' a number of implicit theoretical and, in part, highly speculative aspects into psychiatry.

In the decades after World War II, Kraepelinian ideas—and 'biological' concepts in general—lost much of their influence and were discussed mainly from the historical point of view. However, Kraepelin's concepts were 'rediscovered' in the 1960s and 1970s when 'biological psychiatry' became the most influential (and most self-confident) field of psychiatric research. In particular, researchers and clinicians from the English-speaking countries viewed themselves as 'Neo-Kraepelinians' (Blashfield 1984). But 'Neo-Kraepelinianism' is not a scientific theory in the strict sense. At present, it is an important and heterogeneous set of concepts, trying to create a basis for biological research in clinical psychiatry. Of course it does not just repeat Kraepelinian ideas. Central to this set of concepts is the intention to identify the biological basis—the 'natural' basis, in Kraepelin's words—of mental disorders. But these findings may well lead to a nosological system quite different from Kraepelin's, a topic which has attracted much interest at the end of the twentieth century. Many authors have postulated a 'denosologization' of psychiatric research, especially in biological studies (e.g., van Praag et al. 1987). The idea is to prevent nosological prejudices from hampering research by restricting the interpretation of data to the limits of 'classical' concepts, especially the Kraepelinian dichotomy of endogenous psychoses. There might (and will) be, these authors argue, biological findings that reveal an entirely different distribution in psychiatric patients than that expected within the framework of classical nosology. Such an approach, though modifying Kraepelinian nosology, does not stand in real contrast to his basic ideas. On the contrary, Kraepelin himself often stressed that all diagnostic criteria and categories were due to change according to the actual state of the art in psychiatric research—leaving the postulate of the existence of natural disease entities untouched.

'Neo-Kraepelinian' authors are—as was Kraepelin himself—at risk of overestimating the explanatory power of biological findings; for example, by accepting only biological criteria for nosology, and dismissing psychopathology as 'unscientific.' Nosological prejudices or dogmas do, of course, exist in psychopathological approaches as well as in biological ones, and they always severely obstruct research.

In the context of 'Neo-Kraepelinianism,' the modern operationalized diagnostic systems *ICD*-10 and *DSM-IV* should be considered. Their main impetus is to improve the reliability of psychiatric diagnoses by establishing clear diagnostic criteria. They focus on the behavioural level by means of clinical description and try to avoid interpretation of symptoms. Whereas Kraepelin's nosological system—at least implicitly—included a number of etiological hypotheses and epistemological presuppositions, operationalized diagnostic systems aim to avoid etiological considerations (a concept which is often, incorrectly, called an 'atheoretical approach'). But in spite of these theoretical differences, both Kraepelinian nosology and modern diagnostic systems run the risk of uncritically reifying their constructs called 'diagnostic entities.' This is why the authors of *DSM-IV*, for example, warn their users not to regard diagnostic categories as definite or 'natural' entities, but as conventions which need further verification. Especially in forensic psychiatry, diagnostic systems are sometimes misinterpreted as collections of natural constants, quasi-automatically leading to diminished responsibility (e.g., pathological gambling or kleptomania).

In summary, Kraepelin's psychiatry was not only highly influential in his lifetime, but gained wide acceptance toward the end of the twentieth century, as the focus of psychiatric research again shifted to biological topics. It is of crucial importance that present-day psychiatry—be it 'neo-Kraepelinian' or not—adopts a comprehensive view of Kraepelin's scientific work, embedded in a thorough knowledge of its complex conceptual history (Berrios and Hauser 1988). Otherwise, as well as benefiting from Kraepelin's ideas, psychiatry will also be restricted by their conceptual limitations.

P. Hoff

Kuhn, Thomas S. (1922–96)

1. *Life and Works*

Thomas S. Kuhn was born July 18, 1922 in Cincinnati, Ohio. He earned a Bachelor's degree (1943) in physics at Harvard University. During his graduate work in theoretical solid state physics with John H. van Vleck who later won a Nobel prize, he was introduced to the history of science by James Conant, then President of Harvard. In 1947, while preparing a course on the development of mechanics before Galileo and puzzling over passages of Aristotle's physics, he discovered something that set the agenda of his further work. When he read Aristotle with the set of contemporary physical concepts in mind, much of Aristotle's physics seemed either awfully wrong or even outright meaningless. But by changing the ascribed meaning of some of the Aristotelian key concepts (in some cases only slightly and in others more deeply), a whole new world of physics became accessible, namely that of Aristotle and his contemporaries. After completing his Ph.D. in theoretical physics in 1949, Kuhn switched entirely to the history of science where he began by applying the insights he gained through his experience of Aristotelian physics. From 1948 to 1951, he was a Junior Fellow of the Harvard Society of Fellows, and from 1951 to 1956 Assistant Professor for General Education and History of Science. From 1956 to 1964, he was a member of the faculty of the University of California at Berkeley, mainly in the History of Science Department. In 1957, he published *The Copernican Revolution: Planetary Astronomy in the Development of Western Thought*, which became a very successful textbook. Kuhn spent the year 1958–9 as a Fellow at the Center for Advanced Study of the Behavioral Sciences in Stanford where he became aware of the different patterns typical of the interactions among natural scientists on the one hand, and among social scientists on the other. The difference typically concerns a broad consensus of natural scientists with respect to the foundations of their discipline, in contrast to social scientists who typically dispute them.

This observation became very important when Kuhn wrote *The Structure of Scientific Revolutions* (*SSR*) which was published in 1962. This is the most widely read book ever published in the history and philosophy of science, and it also had a tremendous impact in the social and behavioral sciences, most of all in the sociology of science. Its key term, paradigm, is now a household word. Some of its other central concepts like normal science, paradigm shift, or incommensurability are now commonly used in a large number of diverse disciplines. However, many of the interpretations the book (or its parts) has been given were vigorously rejected by Kuhn as deep misunderstanding of what he had intended to say. By now, more than one million copies of the book have been

sold in English, and it has been translated into at least 26 languages. In 1964, Kuhn joined Princeton University as a Professor of History of Science; he was also a member of the Institute of Advanced Study from 1972 to 1979. Kuhn's historical work after *SSR* mainly concerned the genesis of quantum mechanics. *Sources for the History of Quantum Physics* (Kuhn et al. 1967) contains an inventory of relevant material including interviews with many of the contributors to quantum mechanics. *Black Body Theory and the Quantum Discontinuity, 1894–1912,* (Kuhn 1978) is a controversial narrative of the introduction of the quantum hypothesis. Some of Kuhn's papers both on the history and the philosophy of science are contained in his *The Essential Tension*, published in 1977. In 1979, he became Professor for Philosophy and History of Science at the Massachusetts Institute of Technology until he retired in 1991. From the 1980s on, Kuhn worked on a book whose final working title was *The Plurality of Worlds: An Evolutionary Theory of Scientific Development*. In this book, he tried to elucidate the foundations of scientific change by a new theory of meaning of empirical concepts, especially of taxonomic kind terms. Furthermore, he elaborated on the evolutionary metaphor for scientific development with which *SSR*'s last chapter ended. Kuhn could not finish the book due to his death on June 17, 1996, in Cambridge, MA.

2. *Kuhn's Theory of Scientific Development*

Kuhn's main subject in the philosophy of science was a developmental scheme, or a schematic description, of scientific development which primarily concerned the basic (i.e., curiosity-driven) natural sciences. The intended description is schematic in the sense that it presents scientific development as a succession of different phases whose main features are independent of the specific subject matter of the respective science. For each one of these phases a specific mode of scientific practice is characteristic. This theory was first presented in *SSR* but was later refined in various respects.

The developmental scheme that Kuhn suggests should hold with only minor variations for all basic scientific disciplines. It consists of the following. Before reaching maturity, nascent scientific fields typically are characterized by controversies between competing schools. There is no consensus among the practitioners of the emerging field. Each one of these schools has a particular view of the respective research domain, and typically these views derive from extra-scientific sources. Kuhn has called this phase of scientific development 'preparadigmatic.' The competition among the schools eventually may end when one group produces an exemplary solution to a pre-eminent research problem with two characteristics: it is sufficiently unprecedented to attract the members of the other schools, and it is sufficiently open-ended to leave enough interesting problems for further scientific work. These model solutions are called paradigms. They serve to guide research implicitly in the succeeding period called normal science. When a science has reached its first normal science phase it is said to have matured.

Normal science is characterized by a broad consensus of the practitioners of the field about fundamental questions, and consequently, by a particular mode of research. This mode of research can be described by a five-dimensional analogy to puzzle-solving where exemplars of puzzles include chess problems and crossword puzzles. The analogy concerns:

(a) The existence of regulations constraining acceptable approaches to and solutions of problems. In the case of science, these regulations are given only implicitly, namely as part and parcel of the paradigmatic solutions.

(b) The expectation of the solubility of appropriately chosen problems. In the case of science, this expectation is fed by the conviction that the appropriateness of the paradigmatic solutions extends beyond the particular problems they are solutions of.

(c) Missing intentions of fundamental innovation of the guiding regulations. In the case of science, normal science intends to exploit the cognitive potential intrinsic to the paradigmatic solutions, and does not intend to overturn them.

(d) Absence of test or confirmation of the guiding regulations. In the case of science, this is due to the fact that in normal science, failure to solve a research problem is seen as a failure of the researcher and not of those regulations that guide research. Either the research problem was not chosen well, or the researcher was unable to solve it despite its solubility.

(e) Individual motivations: to prove oneself an expert puzzle-solver. In the case of science, this is evidenced by the extremely elaborate system by which scientific achievements are rewarded (e.g. scientific prizes including the Nobel prize, honorary degrees, invited lectures, nominations, etc.).

Normal science is always confronted with anomalies, i.e., with phenomena or problems that behave contrary to the expectations supplied by the paradigm. Anomalies do not usually call the validity of the guiding regulations of normal research into question. But under special circumstances they may, and then they become 'significant anomalies.' In such cases, the practice of science changes into 'extraordinary science' or 'science in crisis.' It aims at amending or even overthrowing the yet binding regulations. Its research focuses on the significant anomalies and their context. Extraordinary science resembles prenormal science in that it tends to develop competing schools. However, it is more focused than prenormal science as all these different schools have to deal with the same set of

significant anomalies and they all want to retain as much as possible from the earlier period of normal science. If this research leads to a new theory that is accepted by the scientific community because it can lead to a new phase of normal science, a scientific revolution has occurred. Scientific revolutions in Kuhn's sense are thus 'the tradition-shattering complements to the tradition-bound activity of normal science' (Kuhn 1962). The rejection of the older theory is accompanied by a change of the problem-field and its related standards of solution, and by a corresponding change in basic scientific concepts. Some old concepts are discarded, some new ones are introduced, and some change meaning, sometimes in a subtle way. Kuhn even describes revolutions as transformations of the world in which scientific work is done, although it is not easy to make explicit and plausible what is exactly meant by this locution. Kuhn compresses these features of revolutions into the concept of 'incommensurability': a relation that holds between successive traditions of normal science. In *SSR*, the concept of incommensurability had not become entirely clear. It was, therefore, the subject of much criticism as well as misunderstanding. Most of Kuhn's philosophical work after *SSR* aims at a clarification and further explication of the concept of incommensurability.

Because of incommensurability, we must, according to Kuhn, rethink the concept of scientific progress in the natural sciences. First, scientific progress is not cumulative, due to conceptual changes during revolutions. Cumulativity implies that something that is a part of science at some point in time will, neglecting small corrections, remain a part of science forever. But the conceptual changes that occur during revolutions are much more than small corrections of the existing body of knowledge. They amount to a thorough conceptual reorganization, and typically to a changed ontological perspective. This holds in spite of the fact that very often, much of the older knowledge is retained, especially for practical applications, and that, in the case of quantitative theories, limiting relations exist between the older and the newer theory. Furthermore, Kuhn denies that scientific progress is an approach to truth. Instead of conceiving of scientific progress as a teleological process, i.e., one that is goal-directed, we should think of scientific progress in an analogous way as Darwinian evolutionary theory conceives of evolution. Darwinian evolutionary theory states that there is no goal of evolution towards which it is directed. In a similar way, in scientific development there is no 'set goal' which would be 'a permanent fixed scientific truth' that science approaches (Kuhn 1962). However, Kuhn stresses that this does not imply that there is no progress in the sciences. There is progress in the sciences, though not in the form of an increase of verisimilitude. Rather, there is progress in the form of 'an increase in articulation and specialization' of scientific knowledge (Kuhn 1962). Therefore, the widespread characterization of Kuhn's theory as entirely relativist is simply false.

There are several breaks between Kuhn's theory and the previous tradition in the philosophy of science, some of which explain the extraordinary resonance his theory found in the social and behavioral sciences. Six of them will be discussed briefly. The first is Kuhn's altered view of scientific progress that has just been mentioned. Second, this view implies the untenability of those forms of realism which assert that science at least approximately describes what is really 'out there,' independently of any observer. Instead, theories describe the world in terms of concepts that are historically contingent and which may change in the future. Third, because of this change of basic scientific concepts through revolutions, the classical conception of reductionism is also hardly tenable. In this classical conception, the redefinition of the concepts of the reduced theory by means of the concepts of the reducing theory played a key role. But if incommensurability prevails, some of the required redefinitions are impossible because of meaning shifts. Fourth, many of *SSR*'s assertions stood in marked opposition to Popper's critical rationalism. For instance, Kuhn's normal science, as seen from Popper's perspective, is bad science because it is not continuously directed towards critically testing the guiding regulations. Instead, some anomalies are not even pursued, but are ignored or even pushed aside. Alternatives to the paradigmatic framework are also typically ignored. Yet in Kuhn's view, critical evaluation of fundamental theories is restricted to the periods of extraordinary science, and even then, scientific practice is not simply an attempt to falsify theories by confronting them with basic statements about nature.

Rather, theory evaluation is a comparative procedure in which at least two theories are assessed with respect to their cognitive abilities. Thus according to Kuhn, theory falsification as described by Popper is a stereotype that does not occur in the actual history of science. A fifth consequence of Kuhn's theory is the abolishment of the idea that science is guided by the scientific method, as construed as a set of rigorous rules. This idea has dominated the understanding of modern science from its very beginning. But according to Kuhn, exemplary problem solutions guide scientific research in its normal phase. Their cognitive potential for research is not exploited by explicit (or fully explicable) rules, but rather by implicit analogies. New problems are identified in the light of solved ones, and new solutions are judged as legitimate in a like manner.

Finally, and most importantly in our context, for Kuhn the principal agents of science are communities, not individuals. In the philosophy of science tradition before Kuhn, no one questioned the identity of the principle agent of science. But armed with the distinction between individuals and communities, it is obvious that in the older tradition, the individual

scientist was taken to be the principal actor. The possibility of two scientists rationally disagreeing was not permitted, nor were there discussions about the gradual formation of scientific consensus out of disagreement, or of the development of disagreement from a previously established consensus. In other words, scientific communities were not present in the discussion at all. Science was seen as a one-person game, but for Kuhn it is, at its heart, a social enterprise. It is communities who are the ultimate evaluators of knowledge claims. It is communities who ultimately decide between competing theories and their associated modes of research, and it is communities who are seen by themselves and by others as responsible for some domain of scientific knowledge. Kuhn, therefore, repeatedly refers to the 'sociological base of my position' (for references, see Hoyningen-Huene 1993), but at the same time, he insists that this fact does not invalidate the essential epistemological component of his theory, i.e., its normative element. How is this to be understood?

Kuhn characterizes scientific communities by the values they hold. Typically, these values comprise accuracy, scope, consistency, fruitfulness, and explanatory power, among others. These values are instrumental in the evaluation of the application of theories and, partly derivatively, in the evaluation of the theories themselves. However, these communal values are not defined so sharply that each member of the community reaches exactly the same evaluation in a concrete case of application. Individuals may differ in the relative weight they attribute to these values as well as in the specific articulation of any one of them. Yet in normal science, these differences typically do not become apparent because there is a consensus about the paradigms. However, with the advent of significant anomalies, this latent difference between scientists belonging to the same community may become manifest due to different evaluations of the anomalies, resulting in dissent. The dissent may continue with respect to the different candidates proposed to resolve the crisis. A new consensus about some theory and its ability to solve outstanding problems can only emerge if, and when, (almost) all members of the community prefer it to its competitors, although their individual differences with respect to the values have not disappeared. Thus, during crisis resolution, the individual differences of the members of the community become irrelevant. It is the communal core of the values that prompts the choice of the new paradigmatic theory. Thus, the choice of the new theory is essentially an event that has to be described in sociological terms, as opposed to psychological ones. On the other hand, the normative dimension of theory choice has not disappeared. The reasons for the choice may still be normatively evaluated. Scientific values are an essential part of the reasons for choosing some theory. They are good reasons if they promote the aims of science. This is typically the case if the values in question are those values mentioned above (i.e., accuracy, fruitfulness, consistency, and the like).

3. *Kuhn's Impact on the Behavioral and Social Sciences*

Kuhn's work has been extremely widely received in the social and behavioral sciences, more than any other philosopher's work in the twentieth century. Before Kuhn, mainstream social science had adopted a picture of the natural sciences that was based mainly on logical empiricism, and many social scientists attempted to assimilate their disciplines to that picture. However, success was limited. Neither the predictive, nor the explanatory power of a natural science like physics could be achieved. In addition, methodological controversy did not cease to exist even if in some field, a particular school became dominant for some period. In this situation, the alternative view of the natural sciences that Kuhn offered also seemed to suggest, as a corollary, a different view of the social sciences. More specifically, as Kuhn had incorporated elements in his description of the natural sciences which had been barred by the earlier tradition in the name of the objectivity of science, such as group processes and the like, the difference between the natural and the social sciences seemed to have decreased. In this way, the already comparatively high interest that social scientists have in the philosophy of science, given the epistemologically insecure status of their disciplines, became even more intense in the case of Kuhn's philosophy. At least to some authors, Kuhn seemed to suggest a kind of fresh start for the social sciences.

Three general facts about the reception of Kuhn's work in the social and behavioral sciences are striking. First, the reception was by and large uncritical, and in many cases very superficial. For example, there are literally hundreds of articles in which the reference to Kuhn appears to be a purely rhetorical device, making no substantial point. Second, Kuhn's developmental model was intended to apply only to the basic disciplines in the natural sciences. Kuhn says very little about the social sciences, basically only that they are typically in the pre-paradigmatic state (Kuhn 1962, 1977). This did not prevent many social and behavioral scientists from applying parts of Kuhn's theory to different aspects of their disciplines. Third, Kuhn's ideas have been used for the most diverse purposes. On the basis of his work, even outright contradictory assertions have been made. This is partly due to the fact that Kuhn's writings, especially *SSR*, have admitted of very different interpretations, which in turn derives from the inner tensions, ambiguities, and metaphors that they contain. In particular, Kuhn's evaluation of the rationality of science appeared as highly ambivalent, and his use of the paradigm concept

seemed at times to cover just about everything with which scientists deal. Thus, Kuhn's texts appear to have a high degree of plasticity, a fact that has been subsequently deplored by their author. Only a very close and patient reading of the texts can reduce this plasticity. But on top of the plasticity of Kuhn's texts, social scientists, due to their own agendas, have been seduced to read many things into Kuhn's work. Thus, many of the claims in the literature about what Kuhn does or does not support are not really contained in Kuhn's texts.

The predominant use of Kuhn's work in the social and behavioral sciences has concerned the current status of some discipline or its history. Is the discipline still in its preparadigmatic state or does it already have a paradigm? Or put another way, is it a 'mature' science which has reached the state of normal science? Has it had paradigms in the past? Are the changes that the discipline experienced in the past Kuhnian revolutions? Is the discipline currently in a Kuhnian crisis? Or are the social sciences fundamentally different from the natural sciences in being 'multiple paradigm sciences'? As mentioned above, these questions received the most diverse answers by different authors. Elements from Kuhn's theory were used by some to defend mainstream social science, and by others to develop a critical attitude towards it, or to defend or attack alternatives. Some authors tried to show that on Kuhnian terms, a given social science is very nearly like natural science, whereas others tried to demonstrate the opposite, and so on. No consensus has been reached in any of the social or behavioral sciences about these and related questions.

Finally, that part of the reception of Kuhn's work to which it was immediately pertinent, namely the history and the sociology of science, should be discussed. Perhaps surprisingly, in the history of science proper, the reception of Kuhn's metahistorical work does not show up heavily in the literature. This may be partly due to the same reasons that Kuhn did not apply his characteristic concepts (like paradigm, normal science, etc.) in his own historical work. Historians very often try to avoid heavily theory-laden concepts when doing historical work because of the imminent distortions of what may be gleaned from the sources themselves. In addition, historians in the second half of the twentieth century have typically been quite critical about any generalizations about the course of history (such as a developmental scheme).

But in the sociology of science, Kuhn's impact has been tremendous. Pre-Kuhnian sociology of science either discussed the social structure of science or the impact of science upon society. But in contrast to other areas of sociology, the scientific content seemed to lie entirely outside the scope of sociology because of the purported objectivity of science, which precluded any direct social contingency. The most relevant sociological question asked with respect to scientific knowledge was 'what are the social conditions of a scientific community that are conducive to the production of such knowledge?' Answers to this question typically consisted in the description of a purportedly universal value system holding in scientific communities that virtually guaranteed the desired outcome of the activities of the community's members. However, with the advent of Kuhn's work, this view was challenged in various respects. The production of scientific knowledge now seemed not at all determined by time-independent, universal methodological rules. Instead of binding rules, research is guided by values which only influence, but do not determine scientific behavior. Such values are influenced by group-specific and even idiosyncratic factors. In other words, scientific knowledge now indeed seemed socially contingent, which licenses and even appears to demand, sociological analysis. Various schools developed analytical tools for this purpose, and a great many case studies of contemporary and past science were performed. Typically, the content of science was now seen as the result of negotiations among scientists in which human interests of a personal or political nature, or power relations, played an important, and sometimes even decisive, role. Due to an intense debate within sociology and interventions mainly from philosophers, these positions showed rapid development that continues today. It should be noted, however, that despite all of the changes in these positions, Kuhn himself remained extremely skeptical towards them. In his view, the epistemological dimension of scientific knowledge, i.e., the possibility of its normative evaluation, must be an essential part of an integrated image of science, but it had been entirely dismissed by the sociology of science (Kuhn 1991, 1992).

Kula Ring, Anthropology of

First set out in detail in Malinowski's classic *Argonauts of the Western Pacific* (1922), the 'kula ring'—a translocal, long distance exchange network connecting islands off the southeast coast of Papua New Guinea (Fig. 1)—has become a classic ethnographic reference point for the study of non-Western exchange practices. Yet apart from more limited work by Fortune (1932), Roheim (1950) and Belshaw (1955), field research yielding significant publications on kula was not carried out again after Malinowski until the 1970s (see Leach and Leach 1983). This article explains key features of kula, updating Malinowski's account where necessary on the basis of the more recent work, and modifying some common over-simplifications; in conclusion, it comments briefly on anthropological approaches to kula.

1. Some Defining Features of Present-day Kula

Modern kula centers in the exchange of white (*Conus*) armshells and red (*Spondylus* or *Chama*) shell necklaces in opposite directions around the islands (Fig. 1). Only middle and upper ranked shells have personal names, but all shells are qualitatively graded. There are other kinds of kula media (see Sect. 2), but only these shells currently circle the region establishing its basic socio-geography. Kula transactors, however, should exchange directly in a limited sector with partners or potential partners in participant communities on either side of them (although illicit bypassing occurs). Working a strategic politics of influence in the inter-island world, they attempt to make names for themselves that also impact on their standing in their own community.

Transactors obtain shells of one category on visits to partners in one direction and later transact them to their own visitors from the opposite kula direction. Typically these exchange practices engage long term debt involving a year or much more between a gift and its equivalent repayment. A major transaction with multiple, additional shell exchanges pinned to its passage may go on for years. Nevertheless, less prestigous exchanges may occasionally be completed with a visitor who brings the appropriate type of shell for immediate exchange, thus avoiding the risks of default inherent in time and distance.

Although kula participants are primarily men, recent research points to the contemporary importance of women traders in the Bwanabwana region (Macintyre 1983a) and, less prominently, in some other areas such as northern Mwadau and Dobu (J. Leach in Leach and Leach 1983, p. 17); nevertheless, women participants do not usually sail on kula. This research has also revealed a crucial type of shell ownership not noted by Malinowski (but probably operative in his time) called 'kitomu' (or cognates), which is fundamental to the *modus operandi* of kula. A shell's first owner is its maker. Owners may do as they will with their kitomu shells, keeping or else alienating them to obtain high value items like pigs, magic and cash or to pay off a kula debt; the shell then becomes another person's kitomu. Alternatively one may circulate one's kitomu in kula; an equivalent return becomes, on receipt, one's kitomu, the prior shell becoming the kitomu of the equivalent's donor. Thus particular kitomu are alienated, but, apart from default, one still owns a shell as kitomu (Damon in Leach and Leach 1983, Munn 1977, 1986, Weiner 1988, 1992 cf. also Godelier 1996, p. 90–1). Kitomu shells, empty of prior obligations, provide an element of freedom in transaction that variously aids owners in the incrementation of their kula.

2. Adjustment of Some Common Oversimplifications of Kula

Following Malinowski's emphasis, a common assumption is that modern kula entails a ritual

Figure 1
The kula ring in the 1970s (from Munn 1986, p. 4)

exchange of just the two types of shell set apart as a system from trade with other non-ritual goods (see Sect. 3). But a variety of evidence indicates that such a sharp line cannot be drawn. For instance, in Bwanabwana (Fig. 1) pigs are intrinsic to kula (there called 'kune') although they obviously do not circulate around the whole ring (Macintyre 1983a, pp. 105–6). Overseas directional transactions of Gawan-built canoes can also be described as 'kula-ing' one's canoe. Armshells from southern canoe recipients become the canoe owners' kitomu; with the exchange finished, canoes are alienated from their makers (Munn 1986).

If kula media are not as exclusive as sometimes supposed, so also the circulation of the shells themselves is not exclusive to Massim islands participating in the ring: other islands make use of these shells, leaking them into and draining them out of the kula region, thus affecting kula circulation. Indeed, as Malinowski reported, a source of the necklaces (Rossel Island) is itself far south of the ring. Kula is in this sense an open not a closed system.

Neither is kula static. In its present form, it is a modern development radically affected by British colonization. One key change has been the widening of participation in kula. Formerly confined to men of influence, kula effloresced, becoming increasingly 'democratized' as endemic warfare gave way to British 'pacification' (Macintyre 1983b; Young 1983). Of course change is ongoing; for instance, in the 1990s the increased use of western boats by Bwanabwanans was reducing the southward extension of canoe transactions, thus negatively affecting Gawan acquisitions of kitomu from canoes (Damon, personal communication 1999).

At another level, change is inherent in the way individual kula paths and routing are constituted. A path of partners is initiated and maintained only through the passage of shells: without shells a path disappears. *Pace* Malinowski (1922, p. 83), partner-

ships are not necessarily 'permanent.' In a politics that entails the constant testing of trust, shifting personal relations ongoingly alter paths across the ring. Nor are routes between communities fixed. Over time kula's competitive practices can yield not just individual path alterations, but also alterations in routes. Thus by the 1970s Duau (north-east Normanby) villages no longer did much kula directly with Bwanabwana: new southern coastal villages of people from the interior had managed to insert themselves into the route (Thune in Leach and Leach 1983, p. 352).

This dynamic view of kula also illuminates non-circular aspects of its socio-geography. Although the overall routing is circular, at any given moment many paths of partners do not circle the region. A path may never attain circularity because closure can be produced only by making reliable connections via the passage of shells.

Just as kula is ongoingly subject to change, so also it is marked by variability throughout the ring. Notable are different local articulations with marital and other domestic exchanges. In Bwanabwana, kula is not sharply separable from marriage exchanges, but in the Trobriands the two are kept apart (Macintyre 1983a, Weiner in Leach and Leach 1983). Elsewhere, articulations vary. Gawan men take shells from their kula paths to give to affines for the latters' paths; shell returns ideally go back to donors and the original paths (Munn 1986). But on Vakuta, shells taken off paths for affinal recipients in return for gifts of pigs become these affines' kitomu, even though they may not be the donors' kitomu (Campbell in Leach and Leach 1983, pp. 206–7); presumably donors must find path replacements elsewhere. These sorts of local differences, among many others, have ripple affects on trans-local shell movements (cf. also Wagner 1989, p. 270, Persson 1999).

3. *Anthropological Approaches to Kula*

Serious focus upon kula first emerged within two formative studies of anthropological thinking on exchange Malinowski's (1922) first major work developing his use-oriented functionalism, and Mauss' (1950) classic essay on the gift. Basic problems posed by typical, pre-1970s kula commentaries drew on Malinowski's questionable dichotomy between kula as a ceremonial practice involving the transaction of 'useless' things and the economic trade of 'useful' things (for a brief critique see Young 1983, p. 8). The distinction between ceremonial (kula) and non-ceremonial trade was also the prototype for the later development of more complex models of economies with multiple separate 'exchange spheres' (cf. Firth 1957 p. 218).

The same Western economic dualism framed the search for some single explanatory function, or 'purpose' of kula such as 'prestige competition' (J. W. Leach in Leach and Leach 1983, pp. 5–6). In particular, it fuelled the concern with finding an economic function for kula by putting it in the service of the 'useful' commerce—for instance, as establishing 'the peace of the market' enabling utilities to circulate (Singh Uberoi 1962, p. 148; see Macintyre's 1983b critique of the association of kula with peacemaking). The period's most serious reexamination combined some of these ideas in a more broadly based structural-functional study (Singh Uberoi 1962) which viewed Trobriand kula as a sociopolitical practice periodically releasing men from internal descent group relations to establish inter-island bonds.

It is, however, Mauss's concerns that pervade contemporary kula analyses. Mauss situated kula in a theory of moral–juridical contract empowered by bonds between persons and things. His attention to the cultural symbolism and ontology of 'person-thing' relations in gift exchange (rather than simply to exchange relations between things, as in the 'exchange spheres' model) has been influential in recent exchange and kula studies. Mauss' contrast between 'archaic' gift exchange and the modern Western market-based system is also one root of current arguments involving another dualism, that of 'gift' and 'commodity' exchange. Kula figures prominently in these arguments—for instance, in Gregory's (1983) widely cited, if problematic, model of gift exchange as the transaction of 'inalienable objects' in contrast to the 'alienable objects' of commodity exchange. Yet the dynamics of kitomu (Sect. 1, 2) alone suggest the difficulties of applying this dichotomous framework to kula.

No single orientation dominates contemporary kula studies. Rather, kula has been subject to varied forms of rethinking: for example, in terms of a Marxian concern with grounding circulation in production and labor value (Damon 1980), a symbolic formulation of action, spacetime and value (Munn in Leach and Leach 1983, Munn 1986), or gendered models of power and social reproduction (Weiner 1992). Most recently Persson's (1999) detailed comparison of selected Massim societies approaches kula through the study of regional variation proposing 'a holistic perspective going beyond societies as closed entities' (Persson 1999, p. 224). Since its introduction into anthropology at the beginning of the twentieth century, kula has been a sounding board for anthropological issues, and continued to be so at the century's end.

Labor History

Labor history has a double meaning. In a narrow sense it denotes the history of social movements of wage earners, including their leaders, their organizations (e.g., mutual aid societies, trade unions, consumer, and producer cooperatives, and working-class parties), and their collective actions (petitions, strikes, boycotts, electoral campaigns, etc.). In a broad sense, labor history comprizes the history of the working classes at large, including the history of family life, demography, everyday culture, leisure activities, housing, religion, migration, and so on (see *Working Classes, History of*). In the early phases of its development as an academic discipline since the 1870s practitioners of labor history predominantly used the narrow concept.

1. Beginnings

Labor history as an academic practice came into being after the classical Wage Fund theory had become discredited. According to this theory (of which many variations have existed) there is at any point in time a fixed amount of money out of which wages can be paid; it was therefore 'plainly impossible, in any given state of capital and population, to bring about any genuine and permanent rise of wages, otherwise than in the slow course of generations' (Webb and Webb 1897, II, p. 603). Trade-union action could thus have two results. Either it would lead to a redistribution of wages from one segment of the working class to another without the total available amount increasing: 'the increased wages secured for merely absorb a larger share of the capital, leaving less to be distributed among others.' Or, trade-union action was more or less useless: 'If wages are below equilibrium, a union can raise them, thus doing what ought to be done and in time would be done by the market itself' (McCulloch 1851, pp. 50–2). In the 1870s the decline of the Wage Fund theory started with criticisms by John Stuart Mill and others.

With the decline of the Wage Fund theory trade unions and strikes came to be seen in a different light. While most scholars previously had considered trade-union activities as false in theory and pernicious or futile in practice, it now became a much more serious topic deserving careful analysis, both contemporary and historical. Pioneer efforts were, amongst others, Lujo Brentano's *On the History and Development of Gilds, and the Origins of Tradeunions* (London 1870), Richard T. Ely's *The Labor Movement in America* (New York 1886) and the *History of Trade Unionism* (London 1894) by Sidney Webb and Beatrice Webb (born Potter).

For a long time two patterns of interpretations were dominant. On the one hand there was the liberal tradition, represented by, for instance, John R. Commons and Selig Perlman in the United States, the Hammonds in Britain, or scholars like Lujo Brentano, Gerhard Schulze-Gävernitz, and others in Germany. They reconstructed the development of labor movements as the history of the civil emancipation—and consequently the integration—of the working class within capitalism.

The other 'classical' tradition was, of course, the Socialist approach in its many forms, varying from moderates to radicals, and including people like the Webbs in Britain, Edouard Dolléans in France, Eduard Bernstein and Carl Grünberg in Germany, or Edvard Bull in Norway. What these socialists had in common was their interpretation of labor history as a history of attempts to transcend capitalism—in whatever way.

Both 'classical' approaches emphasized the labor movements' institutional aspects. Classical labor history consisted of the application of the approaches, methods, formats, and styles of the traditional historiography of ideas and politics to the field of labor history. Insofar as it had addressed 'social issues,' it had been an offshoot of economics and economic history; and insofar as it had addressed the movement itself and its organizations, leaders, and ideas, it had been an offshoot of political or intellectual history. Both versions of the classical approach 'tended to produce both a model and an accepted version of history, both national and international, which ranged from an informal but not very flexible to a formal and highly inflexible orthodoxy' (Hobsbawm 1984, p. 4) I should add, however, that some authors were more or less dissident. There have always been historians who paid attention to atypical aspects, like Werner Sombart in his essays on the Italian proletariat (1895); John Le Breton Hammond and his wife Barbara Bradby in their trilogy *The Village Labourer, 1760–1832* (1911), *The Town Labourer, 1760–1832* (1917) and *The Skilled Labourer, 1760–1832* (1919), or Ivy Pinchbeck in her book on *Women Workers and the Industrial Revolution, 1750–1850* (1930).

2. Broad Interpretation

The classical approaches, whatever their precise substance, served as syntheses for large groups of labor historians. These old syntheses began to be undermined in the 1950s and the 1960s—a process that continued with even greater force in the following decades. In Britain, Asa Briggs, Eric Hobsbawm, Edward Thompson, and others tried to contextualize workers' struggles. As Hobsbawm wrote in 1964, these historians accentuated 'the working classes as such (… and) the economic and technical conditions that allowed labor movements to be effective, or which prevented them from being effective' (Hobsbawm 1964, p. vii). Somewhat later, similar trends became apparent in other countries. In the United States, Ira Berlin, David Brody, Herbert Gutmann, and David Montgomery, among others, were pioneers.

In France, where the writers of 'evenemential' (*événementiel*) labor movement history had long been opposed by the followers of the *Annales*, whose structural and serial historiography had largely 'left the people out' (to borrow Raphael Samuel's expression), some rapprochement was, especially after 1968, apparent; that was, however, such a slow process that Perrot felt the need to remark in 1979: '(In French historiography) the study of the workers' movement has polarized historians for a long time and eclipsed other problems, such as the development of the working class and its culture. However, this is changing rapidly' (Perrot 1979, p. 150). In Germany, the *Strukturgeschichte*, which was founded in the 1950s by Werner Conze and others (and which incorporated some elements from the National Socialist *Volkssoziologie*, including its focus on the 'structured totality' of the social 'order'), was modified and transformed into a modern approach combining Weberian and Marxian elements by Hans-Ulrich Wehler, Jürgen Kocka and others since the late 1960s.

Gradually, and especially since the 1960s, a broader approach to labor history has thus become widely accepted. The discipline started to incorporate studies of, for example, social mobility, migration, demography, labor processes, schooling, households, urbanization, social insurance, or sexuality. Race, ethnicity, and gender became generally accepted as essential elements of any analysis, but a full integration into mainstream historiography has not yet been accomplished.

Parallel to labor history's thematic expansion its geographical scope has widened. Labor history originated in Western Europe and North America, though there have been important contributions from other parts of the world early on. From the 1920s it became established in the Soviet Union and later in other Communist countries, and gradually struck roots in Latin America (Argentina, Brazil, and Mexico especially), Africa (especially South Africa), the Middle East, India, and Australasia. Labor history's present situation is uneven. On the one hand it has become an acknowledged and integral part of historiography in general and of social history in particular. But on the other hand, its academic conjuncture is strongly linked to political changes, like the collapse of 'socialism' in the Soviet Union and Eastern Europe, and the rise of new workers' movements in Asia.

Both thematic and geographical expansions have made labor history an extremely rich and diversified field. By now, labor history overlaps into women's history, urban history, agrarian history, cultural anthropology, folklore, social economics, history of technology, historical government theories, industrial relations, history of law, and the like. While this disciplinary expansion clearly embodies a wealth of intellectual opportunities, it also leads to a lack of orientation. Already in 1973, Thompson observed that 'The central concern of history, as a relevant humane study—to generalize and integrate and to attain a comprehension of the full social and cultural process—becomes lost' (Thompson 1973).

3. Conceptual Plurality

Labor history in the broad sense reached its peak during the 1970s when former student militants began to write their theses and books. The productivity of this generation was immense and impressive. Perhaps there will never again be written so much about labor history in so few years as at that time. Numerous substantive controversies enlivened the discipline: How should one conceptualize social classes? Are Karl Marx and Max Weber compatible? Is "labor aristocracy" a useful concept? Have 'organized' labor movements suppressed the interests of unskilled workers? How can one integrate women's history and labor history? What is the societal, cultural, and political importance of the working classes? A wide range of issues were hotly debated, in professional journals and in the general media as well.

This peak period did not last long. Most importantly, the organizing categories of the 1960s and 1970s were increasingly called into doubt, partly because they contained continuities with the founding period. Frequently the teleology of the first phase had simply been reserved. While the 'classic' labor historians had been inspired by an optimistic perspective, celebrating the emergence of mass organization and stressing the dynamics of unity and organization, the generation of the 1960s and 1970s tended to ask what had gone wrong with the movement. From a methodological point of view an 'epistemology of absence' became predominant: 'Rather than seeking to explain the presence of radically varying dispositions and practices, [labor historians] have concentrated disproportionately on explaining the absence of an expected

outcome, namely the emergence of a revolutionary class consciousness among the Western working class' (Somers 1989, p. 325).

Ever since, many labor historians regard the state of their discipline as a protracted crisis. First, the emerging paradigms of women's and ethnic history showed that there had been giant blank spots on labor history's map and that the filling in of these spots made a complete rewriting of the old narratives unavoidable. And second, the unilinear conception of class consciousness that had been dominant for a long time was questioned. 'Once it was established that class was a construction and not a predetermined consequence of structural forces, then the notion that it could be seen as the product of an autonomous culture reacting to certain political and economic circumstances ultimately had to be rethought. Class and class action, it became apparent, could work in many different and contradictory ways' (Price 1991, p. 253).

As a result of the growing uncertainty about its organizing categories, labor history is beginning to lose its character as a 'discipline.' On the one hand, the distinction with contiguous disciplines, such as women's studies, ethnic studies, anthropology, institutional economics, sociology, or social psychology, is beginning to dissolve. On the other hand, conceptual difficulties and political disappointments both have stimulated postmodern approaches, especially in the United States.

In North America and Western Europe, including Britain, the debate between labor historians is therefore dominated by a paradigmatic crisis—a crisis that, as a matter of fact, has apparently not always resulted in a strongly reduced output of the 'older generation' of labor historians, but has often caused a diminished interest among students. In Eastern Europe and the former Soviet Union, the problems are even more serious. The collapse of so-called 'socialism' has led to the almost complete demise of classical labor historiography, since the latter is with justification perceived as a constituent of the old dictatorship; generally Communist regimes used a distorted 'official' history of the national workers' movement as part of their ideology of legitimation.

At the same time, exciting new developments take place. In Latin America labor history is booming (French 2000), and in Asia it is rapidly advancing as well. After a group of Indian intellectuals had already published a series of very innovative collections of essays on the social history of the 'subaltern' classes, which focused especially on the peasants, now a generation of sophisticated labor historians has emerged in that country. Interest in labor history is increasing in several other Asian countries as well, parallel to the emergence of large groups of new wage laborers. Partly, these new labor historians grapple with the same conceptual questions as their colleagues in the rich countries, but that does not prevent their intense research activity.

4. *Core Controversies*

There seems to be four interconnected central issues dominating debates within the discipline.

4.1 *Central Categories*

The geographical and thematical broadening of labor history's scope, plus a wider time frame (which now starts to include earlier periods, roughly from the thirteenth century on) makes it necessary to rethink elementary categories, including the discipline's most central notion: labor. In the Anglo-Saxon world, this term has a double meaning. It refers simultaneously to work and to workers' movements.

Labor historians have traditionally conceived 'work' as wage labor, performed by legally free individuals in factories, mines, ports, etc., thus reflecting occupational and gendered views of classical labor movements. Implicitly not included were (a) other forms of free waged labor like domestic service, office work or voluntary military and police service; (b) unfree waged labor of indentured or otherwise bonded workers; (c) hidden wage labor, for example, through self-employment; and (d) nonwaged labor for subsistance or market purposes. Labor history's broadened perspective suggests a reconceptualization of 'work' as any human effort adding use value to goods and services; use value is understood here as 'a good or service that could sustain any activity carried on by a person other than its producer—whether or not we approve of the activity' (Tilly 1998, p. 22–3). This excludes 'purely destructive, expressive, or consumptive acts,' which might be considered as 'antiwork' (Tilly 1998, p. 23) Such a catholic approach makes it possible to overcome old fixations of an institutional or Eurocentric nature.

Traditional labor history has defined a workers' movement as 'all of the organized activity of wage earners to better their own conditions either immediately or in the more or less distant future. In all countries it has run along three lines—political, economic, and cooperative' (Commons 1932, p. 682). A broadening of the concept of 'work' and 'worker' would imply that the notion of a workers' movement has to be broadened as well, and that it should include collective survival activities of all previously excluded categories of workers, whether these are covered by political parties, trade unions, and cooperatives, or not.

4.2 *Class/Gender/Ethnicity*

The relationship between class, gender, and ethnicity has been discussed for several decades. While most labor historians originally considered 'class' as central, and 'gender' and 'ethnicity,' and 'race' as categories of a secondary nature, gradually a new consensus has grown which stresses that gender identity, race ident-

ity, and class identity have 'shaped each other' (Roediger 1993, p. 131) But despite this new understanding, the *simultaneous* historical analysis of the three identities has proved to be extremely difficult. Following Curthoys one is tempted to see a fundamental indeterminacy problem here: 'Trying to keep just two of these concepts in play has proved extremely difficult. […] But if keeping two such concepts in play is hard enough, look what happens when the third concept, be it ethnicity or class or sex, is brought seriously into play. The system, the analysis, becomes too complex to handle' (Curthoys 1991, p. 15).

4.3 Structure vs. Actor

A second fundamental indeterminacy problem has a strong influence on labor history debates as well: the relationship between the actor-oriented and the structure-oriented perspective. Classical labor history focused primarily on the agents of social changes: workers, their organizations, and leaders. More recent approaches have paid much attention to broader developments, like, for example, demographic shifts, socioeconomic structures, or governmental bureaucracies. Although few would contest that both modes of interpretation are essential for labor history, their integration is highly problematic.

Even authors who try to combine the two levels (e.g., by paying equal attention to the *longue durée* and short-term events), have to accept that they are in fact telling two separate but combined stories instead of constructing one integrated narrative. The more a scholar focuses on one aspect, the more he or she tends to lose sight of the other aspect. Elton once observed: 'Despite attempts to deny this, it [quantitative history] can effectively operate only by suppressing the individual by reducing its subject matter to a collectivity of human data in which the facts of humanity have real difficulty in surviving' (Elton 1983, pp. 118–9). The reverse could be said as well.

4.4 Great vs. Small Stories

Classical labor history interpreted the history of working classes and labor movements against the background of major long-term material and cultural changes, for example, the general process of modernization or the rise of capitalism. Since the 1970s this perspective has been challenged from at least two sides.

First, there has grown a strong tendency to critize such broad interpretative frameworks as 'centrist.' It has been argued that such a way of seeing 'positions historical phenomena either to the center or the margins of the historical process, according to their supposed role in the 'great transformation.' Against this unilinear approach, the critics juxtaposed the emphasis on experiences and processes that do not fit in general schemes. Such a 'de-centered' research strategy is expected to lead to 'a greater awareness of the uniqueness, difference, and otherness of historical phenomena, something which is rather obscured by the application of universalizing, passepartout categories (such as role, economic growth, bureaucracy)' (Medick 1987, p. 82).

Second, classical labor history has been disputed by the so-called 'linguistic turn.' This point of view claims that the backgrounds and interests of the members of a workers' movement cannot explain its development. Instead the language used by the movement's members should be considered as the driving force, as 'a complex rhetoric binding together, in a systematic way, shared premisses, analytical routines, strategic options, and programmatic demands' (Jones 1983, p. 107, cf. Scott 1988, pp. 53–67). Discourse analysis therefore replaces the study of larger material and cultural developments.

Both challenges have directed scholarly attention to previously neglected aspects of labor history. But they have also contributed to the discipline's fragmentation. If discourse is disconnected from its context and considered as 'non-referential' (Jones 1983, p. 22), or if the concept of historical master processes is contested, then labor history becomes the study of disjointed processes and texts, confirming the lack of a 'central concern' deplored by Thompson (1973). An alternative way of developing labor history further might be through maintaining the idea of master processes and of the contextual situatedness of discursive activities, but by simultaneously taking 'non-central' and linguistic aspects seriously (Kocka 1997).

5. Globalization

While the development of labor history is so problematic and uneven, in addition and in connection to this, another trend is apparent: the strong increase in the need to go beyond the national boundaries. The more we know about the history of the working classes in an increasing number of countries, the more tempting it is to place the various national developments in a broader context. Two basic reasons for that can be put forward.

In the first place, we can only discover what is specific and what is generic in our own history by looking beyond national borders. A second important reason for the crossing of national borders is that the object of the investigation is hardly concerned with these borders. Working-class formation is not neatly restricted to certain national borders, but is a process in which voluntary and forced immigration and emigration have a great influence. Dramatic developments in one country may cause turbulences in other countries; strike waves often have a transnational character; new forms of campaigning are imitated elsewhere; national labor movements communicate

with each other, learn from each other, and create international organizations.

The growing need for studies that look beyond national borders has resulted in a tremendous growth of the number of contributions to transnational labor history, which started in the 1970s. Yet the work of most labor historians is still characterized by a distinct 'methodological nationalism' which prestructures their writings, with an often rather strict separation of studies of the United States and of other countries.

Labor Markets, Labor Movements, and Gender in Developing Nations

The women's movement has made the world aware of the importance of gender in the world's labor markets. However, definitions and methods of enumeration still leave out a large section of the female work force. Even where women are included as part of the labor force they face highly segregated labor markets. Since about 1980, globalization and structural adjustment programs have negatively impacted labor movements in developing nations. However, in the process of dealing with change, international trade unions have realized the importance of organizing women workers especially in the areas of agriculture and the informal sector. These are areas of growth of the labor movement for women in the future.

1. The World's Labor Force

The world's labor force has been increasing at a fast rate in the recent decades and almost doubled between 1965 and 1995, from 1.3 billion to 2.5 billion (World Bank 1995). As Table 1 below shows, the largest labor force is in the poorest countries.

In most parts of the world, most employment is still in the nonwage, mainly agricultural sector. As Table 2 reveals, whereas employment in industrialized countries tends to be in industry or services and workers are earning a wage (USA nearly 90 percent, France 74 percent), the employment in the developing world tends to be in the nonwage sector (China 84 percent, Ghana 85 percent). So, it must be remembered that when we discuss the labor force in the developing world we are talking about a labor force that is either

predominantly self employed, in market or subsistence activities, or works in family nonpaid employment.

2. *Women and Work*

Women are part of the labor force in every country, but many aspects of the work they do are very different from men. These differences include type of work, place of work, hours of work, and even attitude towards work. Because of these differences, the work done by women is often not recognized as work, and sometimes women are undercounted in official labor force statistics. In the 1990s there was a concerted attempt from women's organizations and academics to move towards a wider definition of work which would include much of the work that women do.

Women work in fields, in factories, in offices, in mines, on waterways, much as men do, but unlike men, the household is also a major center for economic activity for women. Home-based workers, such as garment workers or leather makers, work within their homes, as do subsistence farmers and animal tenders. Women often undertake unpaid production of goods for the market as part of the family business. In addition, women usually do unpaid household work like cleaning and cooking. Government enumerators and even the women themselves often do not understand that other than unpaid housework, all other types of work should be counted as part of the market economy according to the official definitions of the 'labor force' stipulated by governments and international agencies. Because of this wide variety of work, and because of the differing perceptions of what constitutes work, women's active participation in the economy tends to remain undercounted.

Table 3
Women's percentage share of the total labor force in 1990, by region

Australia, Europe, Japan and New Zealand	39
Sub-Saharan Africa	38
Latin America and Caribbean	29
Oceania	29
South Asia	20
North Africa and West Asia	18

Source: United Nations 1995

The total number of economically active women in 1990 was estimated to be 828 million. However, women's share of the labor force, as counted in the population censuses, varies widely from region to region, as Table 3 shows.

Women's share of the labor force is higher in those countries where the majority of the labor force is in the

formal wage sector. In agricultural societies and where the informal sector is a high proportion of the labor force, women's work tends to be around the household and the family farm and hence undercounted.

> It is not easy in a population or household survey to decide whether a person is working or not, and what people are working at, particularly women in developing regions. Terms such as employment, job, work and main activity mean different things to different people. Interviewers also contribute to bias when they assume that women or children are not economically active. Persons who work for a wage or a salary are usually enumerated as economically active regardless of how the questions are phrased. The complications arise as one moves from wage and salary employment to self employment—especially in the informal sector—and to unpaid labor in a family farm or business: that is from more male-dominated to more female-dominated forms of economic activity. For example, a methodological survey in India found that 13 percent of adult women were wage or salary earners. When market oriented production was included—for example, family business, self-employment, crafts and agricultural activities—the figure rose to 32 percent. When the new ILO (International Labour Organization) standard was fully applied, 88 percent of women were found to be economically active (United Nations 1995).

Even women in the formal wage economy generally are segregated in different occupations from men. A recent cross-national study (Anker 1998) found that occupational segregation by sex is extensive in every country. Approximately one half of the workers in the world are in an occupation where one sex dominates to such an extent that the occupation could be considered a 'male' or 'female' one (an extent of more than 80 percent). In every country, female occupations generally are seen as less 'valuable' with lower pay, lower status, and fewer advancement opportunities. For example, 88 percent of managers, legislative officials, and government administrators are men. Occupations open to women are consistent with stereotypes of women. However, levels of occupational segregation vary across regions with the Asia/Pacific region having the lowest level and the Middle East/North Africa region, the highest.

3. *Globalization*

Since the 1970s, there has been dramatic growth of global trade. Markets across countries and regions are becoming increasingly linked, so those workers in even remote rural areas of developing countries are being affected increasingly by the trends in the global product and finance markets. Financial and capital flows also increased as a proportion of GDP. There has been a large increase of capital outflow from industrialized countries since 1980. Among the causes of this growth of trade are reductions in trade barriers through regional or multilateral trade agreements; rapid expansion of foreign direct investment by multinational companies; reduced barriers to international capital transfers, resulting in large flows of equity funds and other speculative investments across national borders; and diffusion of communication facilities that have dramatically increased the speed of transfers.

Since about 1980, globalization, along with structural adjustment programs, brought many changes in the structure of employment and the opportunities available. In many of the developed countries, the unskilled jobs have been transferred to the developing world, concomitant with a rise in opportunities for the skilled and professional workers at home. In Asia there was a rise in employment opportunities, wage levels, and skills, especially for younger women. However, after the 1990s economic crisis in Asia, there has been a major setback for employment. Poverty levels, which had fallen below 20 percent, have risen dramatically, to as much as 60 percent in Indonesia. Latin American countries too, had major upsets with very high inflation rates, high unemployment, and falling well-being. Countries in sub-Saharan Africa were hit the hardest with falling income per capita, high unemployment, and social unrest.

4. *Informal Sector*

The period of globalization has also seen the growth of the informal sector in all regions of the world. Since the term 'informal sector' was coined in the 1970s, it has been defined in various ways and gone in and out of favor in development circles. One dominant school of thought predicted its demise, arguing that as GDP per worker increased, the share of the work force in the formal sector would rise. However, due to slow growth, economic reforms, and/or changing patterns of production, the informal sector has grown steadily in the developing world (and in some countries of the developed world). In the 1980s and 1990s, the share of the work force in the formal sector slowed down or absolutely declined in most developing countries. It was only the rapidly growing economies of East and Southeast Asia that experienced substantial growth of formal sector employment (although the Asian economic crisis of the 1990s led to lay-offs in the formal sector and dramatic growth in the informal sector).

As an umbrella concept for economic activities that fall outside the modern and (in many countries) the agricultural sector, the informal sector has been defined in various ways. Alternative definitions emphasize the fact that informal sector activities rarely comply with official and administrative requirements; are not adequately reflected in official statistics; and are not covered by protective legislation or trade union organization. In an attempt to encompass the heterogeneity and complexity of the informal sector, the 15th International Conference of Labor Force Statisticians in 1993 adopted an international definition of the informal sector to be used in the collection

Table 4
Percentage of enumerated labor force that is in informal sector

Informal sector	La/C	Africa	Asia
Share of:			
Total employment	27	89	85
Urban employment	25	61	40–60
Poor employment	50	91	78
New jobs	54	93	NA

Source: WIEGO 1999. La/C refers to Latin America and the Caribbean

and presentation of labor force data. According to this 1993 international definition, the informal sector comprises (a) informal self-owned enterprises (with only family workers or temporary employees) and (b) informal enterprises with more permanent employees. Under this definition, whether 'informal' is restricted to nonagricultural activities, nonregistered activities, and/or enterprises of a given size is left up to individual countries. Whichever defining characteristics are adopted by individual countries, several sets of activities are particularly difficult to capture in national statistical surveys: itinerant or seasonal or temporary jobs (e.g., on construction sites or road works); secondary activities; and street vending. In addition, no matter what defining characteristics are adopted by individual countries, one set of workers is left out of the 1993 definition: subcontract workers or outworkers who work for formal firms. These limitations of official data notwithstanding, the estimated size of the informal sector is quite large, as shown in Table 4.

In India, where the official statistics are relatively good, it is estimated that the informal sector accounts for 90 percent of the total workforce and 63 percent of GDP and the household sector (of which the informal sector is the major share) accounts for 76 percent of savings (WIEGO 1999).

If home-based workers and street vendors (particularly women in these sectors) were more adequately reflected in official statistics, the size and contribution of the informal sector would be larger still. In Latin America and Asia, microstudies suggest that home-based workers (both own account and subcontract workers) account for 40–50 percent of the workforce in key export industries—textiles, garments, and footwear. In West Africa, national surveys suggest that street vendors account for more than 33 percent of the informal urban labor force and more than 30 percent of the total urban labor force.

5. *Genesis of Labor Movements*

The Labor Movement as we know it today began to emerge in Europe and the United States in the middle of the nineteenth century as a response to the massive industrialization which gave rise to a new class of the 'proletariat.' The first trade unions represented skilled male workers, and reflected their origins in earlier craft guilds. These trade unions developed support and welfare provisions (e.g., in times of unemployment) for their members and helped them find employment. Trade unions that developed later in the nineteenth century were more likely to organize all workers in the industry, particularly unskilled and general workers. This later trend was very much associated with general ideas of socialism that were strong at the time and linked to ideas of cooperation as well as trade unionism.

As industrialization came to the developing world there were spontaneous struggles by workers to organize for better work conditions. However, it was only after 1920 that the labor movement developed in the third world, most of whose countries were still under colonial rule. 1920 was momentous for the labor movement for two reasons. First, the International Labor Organisation was set up as a tripartite body with membership of National Trade Unions, Governments, and National Association of Employers, to regulate the conditions of work and provide a forum for dialogue. At the same time the newly formed USSR had followers in communist parties in most countries, who began organizing within the labor movement. The next 50 years saw the consolidation of labor movements in most developing countries along with freedom movements, which led to newly independent countries in most of Asia, Africa, and Latin America. Many of the newly independent countries included the Right of Association as a fundamental right in their Constitutions, creating a legal basis for the newly formed trade unions. Labor laws were also passed in most countries to protect the working conditions of the workers. At the same time most countries, influenced by the economic successes of the Soviet Union, instituted central economic planning and large public sector organizations. Trade unions flourished in these. At the national level in many countries, individual trade unions attempted to come together to form national federations. These federations, with their large memberships, became politically powerful in many countries. The mid-twentieth century was the heyday of the labor movement worldwide.

6. *International Labor Movements*

The labor movement has always recognized the importance of international links and trade unions in particular trades have attempted to organize across countries. For example, the IUF is one of 14 international trade secretariats that unite workers on the basis of their industry, craft, or occupation. Founded in 1920 through the merger of international federations of bakery, brewery, and meat workers, it was first known as the International Union of Food and Drink Workers. Its headquarters were located in

Zurich and membership was almost entirely European until World War II. Today the IUF represents 329 organizations in 118 countries, in all regions of the world. These organizations represent approximately 10 million workers. However, it was during the period when the trade union movement was at its height that that the major international trade union federations were formed. The International Confederation of Free Trade Unions (ICFTU) was established in 1949, with National Federations of noncommunist trade unions as its members. The World Federation of Trade Unions (WFTU), based in Moscow, was the international Federation of trade unions with a communist philosophy. In addition there were smaller international federations such as the Christian Labor Federation. Today the ICFTU represents 213 organizations in 143 countries on all five continents, with a membership of 124 million, of whom 43 million are women.

7. *Decline of the Trade Unions*

Globalization of the international economy has coincided with the decline of the power of trade unions worldwide. In the industrialized countries, the profile of production began to change. Multinational corporations moved their production into the developing countries. In these affluent nations, self-employment began to increase, employment in manufacturing and blue collar jobs declined, and service sector, professional, and white-collar employment grew. As a result, the proportion of the labor force in trade unions declined.

In developing countries, new trends began to be seen. East and South East Asia began developing at a fast pace with growing exports. The governments of these countries more or less suspended democratic functioning and with it the freedom for workers to create and join trade unions of their own choosing. In South Asia, the trade unions had always been confined to the formal sector—the private corporate and public sector enterprises—covering barely 10 percent of the workforce. As globalization and liberalization policies spread, these sectors shrank instead of expanding as had been expected, so this shrank the proportion of the national workforce unionized. In most of Africa (other than South Africa, which has had a unique history of unions being in the forefront of anti-apartheid struggles), the small trade unions, which in any case were confined to a small section of industry, were suppressed as antidemocratic forces gained the upper hand. In Latin America, countries with large industrial sectors or with large plantations had sizable unions with militant histories. However, as liberalization and globalization policies spread many of these unions were attacked. In some cases, individual unionists were killed. In the USSR and Eastern Bloc, trade unions were controlled by the State, but in many countries these unions became the vehicles for anti-government activity leading to a collapse of the USSR and change of regimes in the former socialist countries. Table 5 shows that only a small minority of workers are covered by unions in a number of regions.

Table 5
Trade union membership as a percentage of labor force in selected countries

Country	Percent
Australia	31
India	8
Kenya	9
Morocco	12
Mexico	32

Source: World Bank 1995

The reasons for decline of the labor movements have been both external and internal. One factor has been the globalization of production which led to decline of production in the countries of strong unionization, as well as the casualization of production which led to the closing of unionized factories and work going into small and contract production. A second factor has been the antilabor policies followed by governments in most developing countries. This has been most pronounced in South East Asia, Latin America, and some of the African countries.

The labor movement has been subject to a number of major internal weaknesses. Perhaps the major weakness has been the confining of the movement to large public and private enterprises. In the earlier years of development, it was optimistically believed that the economic structures of developing countries would change to become more like those of industrialized countries, i.e., with most of the workforce in manufacturing or services in the formal sector with a formal employer-employee relationship. However, instead of shrinking the informal sector has in fact expanded, and the difference in earnings, access to social security, and security of work, between the formal and informal, unionized, and nonunionized workers has grown. The labor movement was unable to reach out and organize the workers of the informal sector and as a result their own influence has continued to shrink.

8. *Women and Labor Movements*

In the early days of industrialization, when working conditions were bleak and hours were long, women were an important, though generally unskilled part of the industrial work force. However, the first trade unions were meant for skilled workers and based on a principle of exclusivity—protecting the employment of the skilled workers and keeping out unskilled. In practice, this often meant excluding women. This tradition went on until the early twentieth century

when, for example, the engineering union would not admit women to their membership, even when they made up a majority of the workforce in a factory. Male union workers also adopted the ideology of the 'family wage,' arguing that employers should pay male workers enough that they could support wives and children. Part of this ideology was that the woman belonged in the home and the man was the breadwinner.

The second wave of trade unionism started with the textile industries in England where a majority of workers were women. At the end of the nineteenth century there was a great movement to organize all workers and this is what led to the development of the general unions which organized the 'unskilled' and 'semiskilled,' including some women. However, even in this period, many women workers were excluded. Most industries and professions excluded married women and the biggest source of employment for women was still domestic service, completely unorganized. As a result of the exclusion of women from some trade unions and the fact that women were in many different forms of informal employment, in addition to trade unions there were strong women's organizations—the Women's Trade Union League and Women Workers' Federations. Some advocated women joining general unions, others favored women having their own unions.

After World War I, unions gradually dropped their ban on women members and the separate women's organizations declined. However, married women were still not usually allowed to work formally. Moreover, as the trade unions were able to get better wages and working conditions for their members the numbers of women in most unionized industries declined due to a number of reasons. First, the societal belief was that the males in the family should earn while the women were homemakers. Unions demanded a 'family wage' so that women could stay home. As wages and working conditions improved, men replaced women in the workforce. Second, protective legislation, such as limiting number of hours worked, night shifts, prohibition of entry into certain jobs, began to limit the scope of work available to women. Finally, new technologies demanded new skills for which men were able to get the training denied to women. Women's employment in modern and formal industries declined, and with it the participation of women in the trade unions.

The 1970s, however, saw the growth of a powerful world wide women's movement. This feminist movement, as it spread to developing countries, brought more skilled and educated women into the labor force. Women's employment in white-collar work began increasing, and with it women's consciousness of their own rights. In the 1980s women in the trade unions too began to voice the need for greater representation. Women began to demand more power within the trade unions and in the 1990s the international trade unions as well as trade unions at the national level began to focus on drawing more women as active members of trade unions. The ICFTU, Programme of Action for Integration of Women into Trade Union Organisations was first adopted in 1978, and updated in 1985 and 1988. The 15th World Congress in 1996 adopted resolutions on 'Equality' and 'Women and Development' calling on ICFTU and its affiliates to integrate gender perspectives into all their work, and to adopt a positive action program for women. The ICFTU reports that women's share of its affiliates is 34 percent and that women's membership has been growing in all regions in the 1990s.

However, the majority of women in developing countries are in agriculture and the informal sector. These are areas where the labor movement is still weak, and so they have not yet been integrated into labor movements.

9. *The Future of Women in Labor Movements*

Unions in developing countries have begun to recognize the importance of organizing the informal sector. However, these small unions have little or no voice at the national or international level. A number of international movements are now developing that are trying to represent women who work in the informal sector in developing nations. Among these are Home-Net, the international alliance of home-based workers, the International Alliance of Street Vendors, and the World Fisherpeople's Federation. If these alliances are examples of the future, the new labor movement will be one in which workers of all types, not just 'employees,' will be represented, and where the whole concept of work and worker will undergo a change to bring the large majority of informal sector women into the mainstream of the economy.

Labor Movements and Gender

Labor movements include trade unions and other formal organizations that seek to improve the wages and conditions of workers in industrial societies, as well as a variety of less durable social movements that share this goal. The relationship of labor movements to gender is complex and highly variable. In some times and places, labor movements have actively advanced the struggle for gender equality; in other instances, they have contributed instead to the reproduction and maintenance of gender subordination. The scholarship on the subject reflects this ambiguous legacy.

Like much of the early interdisciplinary feminist research that appeared in the 1970s and 1980s, the first wave of scholarship on the topic of gender and labor movements was largely compensatory. It sought to demonstrate that from the earliest period, all over the world, women had been actively engaged in strikes, unionizing efforts, and other collective actions intended to advance the interests of working people—even though these female contributions were nearly invisible in the literature on labor history. This work emerged alongside and was nurtured by the (then) 'new' social historians' critique of institutional labor history, as well as by the revisionist labor history and neo-Marxist sociology of the 1970s and 1980s that constructed trade unions as essentially conservative institutions (see Buhle 1990).

Challenging the conventional wisdom that women were less easily mobilized into labor movements and less active in trade unions than their male counterparts, this early scholarship recuperated the previously hidden history of women's labor struggles. It also documented the ways in which labor movements themselves had been historically—and were in the present—controlled by men, who seldom attempted to organize women, and in many cases actively excluded them from union membership. But when opportunities to mobilize and to join trade unions were available, women workers were responsive and by some accounts even more militant than men, this first wave of research showed (Kessler-Harris 1975). This perspective turned on its head the earlier view that women were a problem for labor movements, arguing instead that labor movements were problematic for women, due to institutionalized male domination. That, in turn,

raised the issue of why labor movements were male dominated. Two distinct (although not mutually exclusive) explanations emerged from the initial phase of inquiry. Both linked male domination of unions and other labor movement organizations to gender inequality in the workforce and in the wider society, but one set of commentators emphasized structural and the other cultural factors. In the structural perspective, best exemplified by Hartmann's work (1976), women's exclusion from trade unions and their subordination within labor movements was understood as a linchpin of the larger patriarchal order. In this view, male-dominated unions play an active role in maintaining and perpetuating gender inequality throughout the society, most importantly confining women to marginal, poorly remunerated forms of paid employment and at the same time reinforcing the asymmetrical gender division of unpaid domestic labor. Male workers, Hartmann and others argued, have a material interest in perpetuating their power 'as men,' and labor organizations like trade unions are a key instrument through which they pursue this interest.

The parallel, cultural explanation for the relative marginality of women to labor movements focused less on the material interests of male workers than on their cultural domination of trade unions and other labor movement institutions. It took as its starting point the notion that male and female workers, due to their contrasting social positions and their sex-segregated experience in the labor force, rely on different, gender-specific understandings of their relationships to work and to collective action focused on labor issues. In this view, labor movements have typically been linked to a specifically masculine iconography and discourse that celebrate aggressiveness and violence, and to an informal work culture rooted in exclusively masculine cultural repertoires. Women workers, to be sure, also have a rich work culture that is often sharply opposed to management, but this is organized around such concerns as family, children, and romance which are quite remote from the agendas of unions and other labor organizations (Westwood 1984). Indeed, this cultural perspective suggested, labor movements are often perceived by women workers as exclusively masculine, not only because of their militant rhetoric and overtly adversarial posture toward employers, but also because they typically operate on male cultural terrain, for example, holding union meetings at night, and in bars, so that women must compromise their respectability if they wish to attend.

These two approaches, separately or in combination, dominated the first wave of literature on gender and labor movements. They were appealing in their apparent comprehensiveness. They seemed to explain not only women's under-representation in the ranks of labor activists and among trade union members, but also their general exclusion from leadership positions in labor organizations and the scant attention paid to 'women's issues' by labor movements. Yet despite the insights these perspectives offered, they could not explain the wide range of variations in the relationship of labor movements to gender documented in the growing body of historical and sociological feminist scholarship that burgeoned in the 1970s and 1980s. As this limitation became increasingly obvious, new approaches to the subject emerged.

One of the new perspectives re-interrogated the cultural terrain that was previously viewed as separating women from male-dominated labor movements. Drawing on the concept of 'women's culture' in feminist historiography as well as on ethnographic and historical research, such scholars as Kaplan (1982) argued that 'female consciousness,' rooted in traditional domestic concerns, was not antithetical to labor movement participation but in fact could actively propel women into broad, community-based labor struggles. Other scholarship has linked women's work culture to a distinctively female style of leadership in labor organizing and to the mobilization of women workers into otherwise conventional modes of collective action, suggesting that women's culture and labor movements may not be incompatible—contrary to the earlier claims that stressed the decisively masculine cultural character of labor movements. From this apparent paradox a key question emerged, namely, under what conditions have labor movements been effective vehicles of collective action for women workers?

Not only was the presumption that the culture of labor movements and 'women's culture' are incompatible falsified, but also, the notion that the structure of labor movements was inherently male-dominated and a critical force contributing to the reproduction of patriarchy was increasingly questioned in the 1980s. Scholars began to uncover instances where male workers and labor movements dominated by them struggled on behalf of women workers and for gender equality, rather than the reverse. Indeed, sometimes male workers' gender interest in maintaining male domination has taken precedence, but in other instances men's class interest in gender equality has prevailed instead (Milkman 1987). Once again the question became: under what conditions is each of these possible outcomes likely to occur? Thus the deterministic grip of the structural and cultural explanations for male domination of labor movements and female marginality within them was increasingly loosened in favor of a more contingent approach.

Some commentators, accordingly, began to focus on variations over time in the relationship of labor movements to gender. One common line of argument constructed the shift from a craft-union dominated labor movement (which was comprised mainly of skilled workers and often excluded women and ethnic

minorities) to a more inclusive industrial union movement as the basis for a significantly more woman-friendly labor movement in many countries, even if some aspects of male domination persisted (Cook et al. 1984). Indeed, an evolutionary logic underlies much of the literature, explicitly or implicitly, according to which there is progress over time toward more gender-egalitarian and inclusive forms of labor mobilization and unionism. As the workforce has become increasingly feminized, and with the increasing challenge to gender inequality in the wider society, the claim here is that labor movements too have become increasingly open to women's participation and that their commitment to gender equality has grown (Milkman 1990).

But recent research suggests a more complex and uneven pattern of historical development. For example, Cobble (1991) has shown how 'occupational unionism' among US food service workers in the craft union era offered important opportunities for female mobilization that were later obliterated as industrial unionism became the hegemonic mode. While the unions she describes were sex-segregated, all-female groupings, such an arrangement proved to have important advantages for women workers in this particular context. For early twentieth-century waitresses, Cobble argues, 'an organizational structure based on the logic of craft, rather than being incompatible with female mobilization, provided instrumental in its creation and maintenance.' Other scholars have highlighted the effects of labor movement bureaucratization, arguing that the more diffuse, community-based organizing that is typical of the pre-institutional phase of labor movement development was more accessible to women than the later, more bureaucratic phases. In the US, for example, Frank's work (1993) shows how the broad-based labor movement that existed in Seattle in the 1920s, which included labor cooperatives, consumer boycotts, and 'union label' campaigns, offered a vehicle for women's involvement rooted in domestic and community-oriented concerns, all of which became peripheral with the later triumph of a highly bureaucratic type of 'business unionism.' More generally, recent literature documents substantial variation in the gender dynamics of labor movements and in the gender composition of labor organization memberships, intra- and internationally as well as over time. While there have been some efforts to systematically explain such variation there appears to be a strong element of historical contingency as well.

A theoretical approach that emphasizes the embeddedness of gender in social institutions, practices and culture has become increasingly influential in recent years (Scott 1988; Baron 1991). Deeply influenced by poststructuralism and postmodernist theory, feminist scholars working from this perspective excavate the ways in which gendered subjectivities are constituted both inside and outside the workplace and how these influence labor struggles. They see gender itself as an object of contestation and at the same time as a primary signifier of power relations more generally. This work has been valuable in underscoring the variable content of gender categories over time and space and the ways in which labor struggles both reflect and transform those categories.

Another focus of increased scholarly attention in recent years is the way in which gender interacts with race, ethnicity, and immigration status in the context of labor movements. The picture that emerges from the accumulated case studies is complex. Like their male counterparts, women workers often have constructed or defended exclusionary ethnic, racial, and citizenship-based boundaries within labor movements. Yet in the US, African–American women are far more likely to be union members than white women, in part because they are more often employed in unionized occupations and industries (especially in the public sector). And perhaps because today job segregation by gender tends to be even more extensive than job segregation by race, ethnicity, or citizenship, there are many examples of labor solidarity among women of diverse racial, ethnic, and national backgrounds.

In the final decades of the twentieth century, labor movements came under vigorous attack all over the world, a development that largely coincides with the global trend toward increased (although cross-nationally uneven) female labor force participation. The ironic result is that in many countries, labor movement membership has become increasingly feminized, and unions have become more concerned with gender issues and with promoting gender equality, in precisely the period in which the power and influence of labor movements have been dramatically eroded. In the US, for example, in 1999 only 14 percent of all wage and salary workers were union members (less than half the figure at the postwar peak), but the gender gap in unionization rates is lower than at any other time since records have been kept. In 1999, 16.1 percent of male and 11.4 percent of female wage and salary workers in the US were union members, compared to 24.7 and 14.6 percent respectively in 1983 (US Bureau of Labor Statistics 2000). In part as a result of its increasingly female membership, in recent years the US labor movement has embraced issues like pay equity and parental leave, and more generally has become a leading advocate of gender equality. Yet this development has had limited impact, because the overall effectiveness of the labor movement has declined so precipitously. An historically informed approach suggests the likelihood of labor movement resurgence at some future date, however, in which case it seems likely that such movements will help advance the struggle for gender equality to a greater degree than in the past.

Labor Movements, History of

'Labor movement' is a comprehensive concept of workers' organised efforts, in evolutionary or revolutionary ways, to change capitalistic societies in order to improve the economic, social, political, and cultural situation of working class people. Although based on the working class, labor movements include all kinds of socialist and some non-socialist organizations; mutual aid societies, trade unions, political parties, cultural organizations, consumers' cooperatives, and certain women's and youth organizations are the basic organizations of the labor movement.

Being a world-wide movement today, the labor movement has its roots in the first industrial revolution in Great Britain in the eighteenth century, when workers protested against developing industrial capitalism by destroying capitalists' property (Luddism). In 1812, the death penalty was introduced in Great Britain for machine breaking, and some Luddites were executed. Despite this, Luddites were active in Great Britain in the 1830s. On the European continent, machine breaking continued until the early twentieth century, even among agricultural workers. Its value as a weapon for workers in the class struggle was limited, but it was an important part of the formation of workers as a class in opposition to capitalists and the bourgeoisie.

Skilled industrial workers in Great Britain, the foremost being spinners and weavers, developed a more successful strategy in the late 1700s by starting trade unions. Unions seemed to the establishment to be a great menace, especially when they were considered to be 'contaminated' by the ideas of the French revolution. In 1815, British workers were denied the right to organize trade unions, and the class struggles of this period culminated with the Peterloo massacre in 1819. But radical political ideas were defeated all over the world, and trade unions were once again tolerated in 1824. On the European continent French and Silesian weavers also went on strike for better conditions. All over Europe and the US, workers went on strike, sometimes spontaneously, sometimes well organized; sometimes workers could achieve a wage rise or avoid a wage decrease; sometimes they could achieve or defend their right to unionize, sometimes they failed. Sometimes, striking workers not only had to fight capitalists and the police but also strike breakers, so-called 'black legs.' On some occasions skilled male workers tried to prevent capitalists from hiring female workers.

The political dimension of workers' early struggles was most obviously indicated in the French revolution in 1789, in which working-class women took part as well, but also in the European revolutions of 1830 and 1848. At the same time, socialist utopians like Henri de Saint-Simon, Charles Fourier, Robert Owen and Joseph Proudhon tried to formulate ideas of alternative societies. Even if the ideas of the Utopians were not transformed into political programs, their importance for future socialist—and feminist—thoughts should not be underestimated. The Working Men's Association in England (1835) established a comprehensive political program as a reaction to the

disappointments with the reform movement of 1830–1832. In the People's Charter (1838) secret elections, equal suffrage for men, and social reforms were demanded. A new Factory Act was introduced in 1850, which limited the industrial work time to ten hours a day and to six days a week, and the Corn Laws (grain duty) were repealed (1846). As a political program the People's Charter was succeeded in 1848 by the Communist Manifesto, which had much more far-reaching demands and had a more international perspective than the People's Charter. It argued for a take-over of the means of production by workers, and the slogan 'Proletarians of all countries, unite!' was to become a symbol for socialists for many years to come. Also, the consumers' co-operative movement, founded in Rochdale in 1844, was of more lasting importance for the working class than the chartist movement.

Being disarmed and defeated in the European revolutions of 1848, the position of the working class and the labour movements was weakened. Political activists on the continent, of which many were intellectuals, had to flee to Great Britain and the US. London became a center for European radicalism. Not much was achieved until 1863, when workers and intellectuals from some Western European countries met in London to organize a trade union and a political co-operation between workers of 'civilized' countries and to prevent the recruitment of strike breakers from the continent to England. The International Working Men's Association—the First International (FI)—was established in 1864; its most prominent members were Karl Marx, Friedrich Engels, and Michael Bakunin. At its peak the FI had 25,000 members, but differences in opinions between trade unionists and politicians about the task of the organization weakened it, as did disputes between socialists and anarchists about ideology and strategies. After the crushing of the Paris Commune in 1871 the FI faded and was finally dissolved in 1876.

Before its dissolution, the FI encouraged workers of industrialized countries to intensify trade union activities and to start national socialist parties. Skilled male workers thus organized trade unions in most European countries and in the US in the 1870s and 1880s, keeping unskilled workers as well as women out of the unions. In Great Britain these unions co-operated within the Trades Unions Congress (TUC) (1868) in the US within the American Federation of Labor, AFL (1886) and in Germany in the 'General-Kommission' (1830) (after several forerunners). Semi-skilled and unskilled male and female workers were organized or organized themselves later and usually to a lesser degree, and in some countries female workers organized women's trade unions; in Denmark the Women's Trade Union remains in 2000 as one of the biggest trade unions in the country. In several cases traveling funds (which supported individual workers in finding work elsewhere) were the origins of trade unions for skilled workers, and many workers unionized in connection with a strike. In the beginning strikes were often started spontaneously but gradually were more carefully planned.

In Great Britain the 'new unionism' challenged the older unions of skilled workers and developed a more socialistic ideology, based on class identity rather than craft, that changed the British labour movement in the 1890s. In the US unskilled workers, in 1905, organized 'One Big Union', Industrial Workers of the World. Like the Confédération Générale du Travail in France (1902), it was based on syndicalistic ideas. In Germany and the Scandinavian countries, national trade unions began to co-operate within national federations in the 1890s. At the turn of the century, 20–22 percent of all workers in Denmark and the Netherlands were organized in local and national trade unions, 10–12 percent in Great Britain, Germany, and Sweden, 6–7 percent in France, Norway, and the US, 2 percent in Australia and Italy. Not all trade unions were inspired by socialist ideas of class struggle and anti-capitalism. Several were inspired by liberalism, especially in Great Britain where trade unions had an affiliation with the Whigs. Other unions had a religious, usually catholic, affiliation, especially in Germany, the Netherlands and the Latin countries of Europe. In the US there were ethnic unions among Europeans in the early days, and among Black and Mexicans in more recent times. All unions demanded the workers' right to unionize, collective bargaining, minimum wages, limitations of the workday, and prohibition of child labour. They differed in their attitudes to strategies and political affiliations.

As was realized by the British trade unionists of the FI, trade unions should act internationally to be successful. In the late 1860s, the Amalgamated Society of Engineers had sections in the US, France and some of the British colonies. Glovers in Austria, Germany, and the Scandinavian countries had an agreement of solidarity in the early 1870s. Between 1889 and 1911, 28 International Trade Secretariats were started for international co-operation on the basis of crafts (typographers, printers, hatters, cigar makers, tobacco workers, shoe makers, glass workers, and so on). Most of the secretariats were based in Germany, a new center of industrial capitalism with many foreign labor migrants. They transferred a lot of money from the national unions to striking and/or locked-out colleagues, and tried to stop the use of blacklegs. They also tried to handle the questions of international labor migration and of Franco-German antagonism.

The international Federation of Transport Workers (1896) is the oldest international trade union remaining in existence in 2000. It started on the basis of international co-operation before national unions existed. Beginning in Copenhagen in 1901, trade union leaders from different European countries met at conferences to discuss labor issues like work time, piece work, women's work, and international labor

migration. In 1902, the International Secretariat of National Trade Union Centers was founded, having its headquarter in Berlin. From 1909, the AFL also took part in that international co-operation, and in 1912 the organization was reorganized as the International Federation of Trade Unions (IFTU).

Workers and socialist intellectuals also organized for a political struggle. While the FI had its headquarters in London, socialist parties were started in Germany in the 1860s by Ferdinand Lassalle, August Bebel, and Wilhelm Liebknecht. At a conference in Gotha in 1875, the two parties joined and formed the Sozialistische Arbeiterpartei Deutschlands (SAPD). Thereby the first nation-wide socialist political party of the world was founded, accepting a class-oriented program. The SAPD challenged the establishment in elections for Parliament, getting 9 percent of the votes in 1877. The establishment was frightened, and it tried to stop socialism by anti-socialist laws. Meanwhile, between 1874 and 1903, socialist parties were founded in all European countries; socialist parties were also founded in the US, Australia, and New Zealand. In Germany, after the abolition of the anti-socialist laws and the re-establishment of the party as Sozialdemokratische Partei Deutschlands (SPD) (1890), the socialist labor movement became a political force of increasing importance. Every large German town had important trade unions, a socialist newspaper, consumers' co-operatives, proletarian cultural associations, but Hamburg was 'No City of Socialism.' In 1914, the SPD was the largest political group in the German Parliament and the establishment was depending on it for its war policy. Trade unionists and socialists in other countries were inspired by the German development, and other socialist parties grew in importance, so much so that the parliamentarian way to socialism seemed realistic to many socialists in Western and Central Europe. This choice of strategy has been one of the most debated issues of labor history in Europe.

Britain was somewhat of an exception, but after the breakthrough of the new unionism the trade unions' connection to the Whigs was questioned. The Independent Labour Party was founded in 1893, but the Committee for National Trade Unions (1895) and the Labour Representation Committee (1900) paved the way for the Labour Party (1906). In the US, the IWW supported the Socialist Party (1901), but both organizations were pressed back by the sharp anti-socialist campaigns during World War I.

Ideologically, there were differing views regarding organizational forms among fractions and individuals within the socialist labor movements before World War I. The trade unionist strategy said that trade unions should organize political parties and control them; the British Labour Party was subsequently built based on that strategy. Many social democrats (socialists) held the opinion that trade unions should act to defend workers' rights on workplaces, while socialist parties should take part in political elections, and control the state with the help of a majority of parliamentarians. Trade unions should have great influence on the party, but not control it. Inspired by Karl Kautsky, several social democrats held a deterministic view of the development of socialism. The German and the Scandinavian labor movements were most outspoken on that idea. Leninist strategy said that the party was the avant-grade of the working class, that should bring workers' consciousness beyond trade union consciousness into class-consciousness. The idea that the party was superior to the unions in the class struggle was formulated among the Bolsheviks within the Russian social democratic party. It became the lodestar among Communists, while anarcho-syndicalists denied the value of parliamentarian activities. They argued for spontaneous and direct action, like the occupation of mills and land, and it had its stronghold in France, Spain, and Italy.

Since the dissolution of the FI in 1876, socialists from several countries had met for conferences on international labor issues. In 1889, on the anniversary of the storming of the Bastille, they met in Paris and decided to reorganize an international socialist labor movement. Even if Latin American and Asian delegates took part in the Paris conference, the Second International (SI) became a white, male, Western European dominated organization. Its main demands were the introduction of equal and universal suffrage, workers' right to unionize, and an eight hour working day, but its ultimate objective was the overthrow of capitalism. At the Paris conference, it was decided to organize May Day rallies all over the world in the memory of the Haymarket victims (Chicago 1886) and in support of the demand for an eight hour working day. Every year since 1890, the international labor movement, where and when possible, has made political demands on employers and on the state throughout the world. The hymn 'The International' has been sung by millions of demonstrating workers at the May Day rallies and at other kinds of meeting. Before World War I the manifestations were impressive, but since then they have been of fluctuating importance in the Western European democracies, while they turned into state managed events in Communist countries. In Nazi Germany, the May Day manifestations were not prohibited, but taken over by the Nazis, and in Japan the company-based trade unions have held rallies in support of 'their' company.

Saying that workers had nothing to gain from patriotism, the SI argued for proletarian internationalism and anti-militarism, and criticized imperialism. Those ideas were more or less dashed in 1914, when most German socialists supported the emperor's plea for war credits. Colleagues in the other belligerent countries took the same position, supporting the war policy. The SI also was split by different opinions on international labor migration, which complicates the idea of proletarian internationalism. The Second

International was, indeed, mostly a debating rather than a decision-making organization. World War I put an end even to that. With the outbreak of the war, also the Golden Age of Reformism ended. In the belligerent countries trade unions partly acquired a new role by mobilizing for war efforts. In the international organizations the TUC and AFL took over the dominating role that German trade unions had before the war.

World War I had vital importance for the socialist labor movement. The left wing opposed ministerial socialism, i.e., socialist members of a government dominated by liberals, as well as the party truce that most socialists accepted during the war. In 1915, representatives for the socialist opposition, mostly young people, met in Zimmerwald to protest against the war. In 1917, facing tremendous class cleavages, strikes and hunger riots, the socialist labor movement split in most countries into two parties. The Bolshevik Revolution in Russia and the failed attempts to raise revolutions in Germany, Finland, and Hungary confirmed the split, and it was made permanent in 1919, when the left-wing parties joined under Russian Bolshevik rule in the Communist International (Comintern), or the Third International. Several groups left the Comintern in 1921, after the introduction of Lenin's 21 theses and the transformation of the left-wing socialist parties into sections of the Comintern. In 1919, the social democrats (socialists) tried to reorganize the Second International, while some noncommunist left-wing parties (led by the Austrian and the French socialist parties) joined in the International Working Union of Socialist Parties (the Vienna International). In 1923 the Second International and the Vienna International merged into the Labour and Socialist International, including most of the socialist and social democratic parties in the world.

After World War I, the international trade union movement also revitalized; by 1920 about 50 percent of all workers were unionized in Austria, Belgium, Denmark, France, Germany, Great Britain, and Italy. Women workers and white-collar workers also organized gradually. The IFTU was reorganized in 1919. In 1924, it started a sub-committee on women's issues, the International Committee of Trade Union Women, but in reality women workers' rights received little attention. White-collar workers unionized, some of them by themselves in national and international trade unions, while others unionized with blue-collar workers of the same industry.

After the war, the trade union movement radicalized, for instance by claiming industrial democracy and socialization of the means of production. This radicalization made the AFL leave the IFTU. On the other hand, communist-dominated trade unions assembled into the Red International of Trade Unions in 1921, an organization that inspired strikes in noncommunist countries, and prevented strikes in the Soviet Union, where they instead became a part of the state. Syndicalistic workers in 1922 joined in the International Working Men's Association. Religious trade unions organized internationally after the war in the International Federation of Christian Trade Unions, later the World Confederation of Labor. Thus, the international labor movement was politically very split, a situation that was even more distinct after the new policy in the Soviet Union in 1928, when the communists proclaimed social democrats being 'social fascists' and their main enemies. This split was of great importance for the coming to power of fascists in Germany in 1933 and in Austria, where the Austromarxists' social experiment 'The Red Vienna' was put to an end in 1934. The whole spectrum of a split labor movement was demonstrated in the Spanish Civil War. In the US, on the other hand, semi-skilled and unskilled workers started to unionize in the Congress of Industrial Organisation (1935). US trade unions also raised some successful strikes, and in the Upper Midwest the Farmer Labor Party had some, temporary, successes in the 1930s.

The coming to power of fascism in central Europe caused two different strategies within the European labor movement. For a short time, Popular Front government in France and Spain effected important social reforms for workers, but were defeated by conservatives and fascists. In Scandinavia, the social democratic parties chose class co-operation as a new strategy, politically with farmers' parties, and with respect to industrial relations with employers (the Scandinavian model). Important social reforms were achieved in the late 1930s and after World War II. The Scandinavian countries also developed into the most unionized countries of the world, where women and white-collar workers also are highly unionized (80–85 percent at the turn of the millenium).

On the European continent, with the rise of fascism and the outbreak of World War II, the labor movements collapsed. The relations between socialists and communists sharpened even more after the Molotov–Ribbentrop pact, but towards the end of the war socialist–communist relations improved and it looked as though a united labor movement could come out of the anti fascist struggle. The postwar program of the British Labour Party attracted socialists in most industrialized, noncommunist countries. These programs were supported in elections in several countries. Important reform programs were introduced and some socialization of the means of production was done. A unified international trade union movement was reorganized in 1945, the World Federation of Trade Unions (WFTU); of important trade unions only the AFL did not join it. Capitalist and bourgeois societies seemed to be threatened in Europe, and extensive strikes challenged the social order of the US, but the Cold War put an end to that. The Red Army forced social democrats and communists in East Germany to merge into the Sozialistische Einheitspartei Deutschlands (SED). In northern, western,

and southern Europe there was once again a total split between social democrats/socialists and communists. The Soviet Union and the communist parties in the Soviet Union controlled parts of Europe, and in France and Italy founded the Cominform in 1947. In the US the Taft–Hartley law (1947) weakened the trade unions. The socialist trade unions left the WFTU in 1949 and started the anti-communist International Confederation of Free Trade Unions. The ICFTU also included the AFL, which was weakened by the Taft–Hartley law. In 1951, socialist/social-democratic parties founded the Socialist International, based on the principles of 'democratic socialism.' In the 1970s the SI added to its Euro-centrist policy more worldwide activities to counteract communist influence in the Third World, where the labor movements were mostly based amongst landless peasants.

In the Third World, the labor movement has faced enormous difficulties. Probably, activists were treated more brutally there in the twentieth century than their colleagues in Western Europe in the nineteenth century. Also, the seasonal and migratory nature of labor, and company-controlled housing counteracted unionization and political mobilization. In British colonies, however, trade unions were of some importance, even in colonial times; trade unions were organized in mining regions, in ports and at railways, and in major urban concentrations, and they took part in the liberation movement even before the 1920s. In India it was of great importance for the liberation in 1947, but since then the trade union movement has been split along both political and religious lines. After the fall of the Soviet Union, trade unions in India and in some Arab counties dominate the WFTU.

After the Soviet invasion of Hungary in 1956, some communists in Western Europe criticized Soviet communism, a criticism that accelerated after the Soviet invasion of Czechoslovakia in 1968. Inspired by the Czech communists, Euro-communism developed in the 1970s as an ideology for an independent, democratic road to socialism. In Western Europe strike activities increased in the 1960s, accelerating for a few years after 1968. In several countries, social democratic governments were the targets for this radicalization of workers and students. The social democratic labor movement was influenced and radicalized, and the social democratic and the reformed communist wings of the labor movement converged. Once again industrial democracy was demanded, but the demands gradually faded away. In some Western European countries there was political co-operation in the final 20 years of the twentieth century between social democrats (socialists) and reformed communist parties, which have cooperated in the defence of the welfare state.

The radicalization in the 1970s also meant the breakthrough of women's questions in the labor movements, partly based on a feminization of the workforce. Many women workers were employed in the public sphere with, in some respects, contradicting interests with industrial workers. Demands for equal pay for equal work were raised, women workers opposed sexual discrimination, and they politically mobilized. Most socialist parties have a minimum quota of women in party organizations and/or female candidates for parliamentary elections. Labor historians have started to focus on gender in the study of labor movements. Another consequence of postwar capitalism has been an ongoing increase of white-collar trade unions, and blue- and white-collar workers have often cooperated in trade union matters. Politically, many white-collar workers have voted for socialist/social democratic parties in Western Europe.

The labor movement, however, still has its most significant influence in Western Europe, where it focuses on questions related to the European Union. European labour movements have, however, given economic and political support to trade unions and political parties in the Third World. These relations have, however, been a little hesitating, as the labor movements in many Third-World countries have been part of the national liberation struggle. Socialist ideas, including Marxist–Leninist ideas, have been guidelines for many liberation movements, but normally they have survived only the first decade of independence. After liberation, many new rulers have tried, as was done in the Soviet Union and Communist-ruled Eastern European states, to subordinate trade unions to state policies. In Africa, however, the Congress of South African Trade Unions (COSATU) was of great and lasting importance for the overthrow of political dictatorship, as was, for instance, Solidarnosc in Poland. Today, the COSATU organize about 40 percent of all workers in South Africa, far beyond what, for instance, the AFL-CIO is capable of (15 percent).

After the fall of the Soviet Union, the communist parties of the former Soviet-controlled regions have been reformed, and have gained quite significant support in democratic elections. Trade unions have also been reformed, or new unions have started. Western colleagues have supported them a little, most of them belonging to the ICFTU.

Labor Organizations: International

> You shall not abuse a needy and destitute laborer, whether a fellow countryman or a stranger in one of the communities of your land. You must pay him his wages on the same day, before the sun sets, for he is needy and urgently depends on it; else he will cry out to the Lord against you, and you will incur guilt. *Deuteronomy*, ch. 24, v. 14, 15.

Rapid globalization succeeded the Cold War as the axis around which international labor organizations worked at the beginning of the twenty-first century. The International Labor Organization (ILO), under vigorous new leadership, sought a place at the table where the intellectual and policy architecture of the global economy is determined. The International Confederation of Trade Unions (ICFTU) and the international trade secretariats (ITSs) strengthened ties with national labor organizations to counter the power of multinational corporations that reshape the international division of labor, to influence the international institutions that provide credit to national governments, and to share in making the rules that govern trade and international investment. These bodies historically have been subordinate to the national institutions they represent; globalization may change this balance.

1. *Historical Background*

The nineteenth-century industrial revolution evoked a strong response as exploitation and social injustice grew, first in the UK and then in Europe and North America. The communitarian aspirations of Robert Owen and the reformist fervor of the Chartists was followed by more specifically class-based organizing in the 1840s and 1850s, culminating in the First International, the International Workingmen's Association (IWMA), founded in London in 1864, in which Karl Marx played a leading role. As strikes grew in number and fervor, efforts to prevent employers from importing 'blackleg' workers to break strikes strengthened international connections in Europe and the UK.

Local unions began to grow in numbers and geographic scope, reflecting the expansion of markets. Closely linked at first to socialist organizations, they developed more pragmatic activities in response to problems in the workplace. In most of Europe, the unions were created by, and were close to, socialist or social democratic movements; in the UK, by contrast, the Trades Union Congress preceded and created its political arm, the Parliamentary Labour Party.

The Chicago Haymarket affair and the prosecution of anarchists accused of the bombing strengthened efforts to build international solidarity. Major influence in the Second International, largely stimulated by Haymarket, went to socialist and social democratic parties in Germany, Austria, and Sweden, all of which sponsored newspapers, housing, theater, music, and other activities for the working class and the public. It fell victim to World War I (Windmuller 1979, pp. 3–4).

2. *The International Trade Secretariats (ITSs)*

These institutions link unions representing workers in cognate skills or sectors. The first was the Federation of Boot and Shoe Operatives, founded in1889 in Paris at the time of the first congress of the new Socialist International. By 1914, there were almost 30; they included the International Transport Federation, founded in London in 1896 by the London dockworkers, the first ITS to include semi-skilled and unskilled workers. In later years, mergers and closures reduced this number to 14 at the beginning of the twenty-first century. Except for the US mineworkers union, these were almost completely European bodies before World War I (Windmuller 1979, pp. 3–4).

Efforts to build broader international solidarity among national labor bodies separate from the socialist international began with a 1901 conference in Copenhagen organized by Scandinavian, Belgian, German, and British union leaders; the next year in Stuttgart they founded what later became the International Federation of Trade Unions (IFTU) (Van Hooten and Van Der Linden 1988, p. 11). It too fell victim to World War I, which largely ended visions of international solidarity; as Eric Hobsbawm wrote (in Van Hooten and Van Der Linden 1988, p. 11):

> For socialist leaders the outbreak of war and the collapse of their international in August 1914 were utterly traumatic … The same Welsh miners who both followed rev-

olutionary syndicalist leaders and also poured into the army as volunteers in 1914 brought their coalfield out in a solid strike in 1915, deaf to the accusation that they were being unpatriotic in doing so.

2.1 International Labor Legislation

The International Association for Labor Legislation was proposed in 1897 and formed in 1901, a 'direct forerunner of the I.L.O.' (Morse 1969, p. 7). Like its counterparts, the International Association on Unemployment, and the International Association for Social Progress, it developed model legislation designed to help governments create effective programs. Here too, World War I ended this work, though some labor unions continued to meet during the war years.

3. Between the Wars

By 1917 the American Federation of Labor (AFL), under Samuel Gompers' leadership, had established itself as the dominant national labor organization. It consisted almost completely of skill-based craft unions in a loose confederation. Efforts to organize the unskilled and semi-skilled by the Industrial Workers of the World (IWW) had been crushed by employers, unchallenged or actively supported by government at all levels. The AFL had initially resisted involvement in the war, but by 1917 it was actively involved. This brought Gompers closer to the national centers of power. In 1917 he arranged for President Woodrow Wilson to address the AFL annual convention, the first US president to do so (Larsen 1975, pp. 77–106).

In September 1918, Gompers attended the Interallied Labor Conference in London; he played a major role and was successful in sponsoring a motion in favor of full surrender by the Central Powers, against the views of some European unionists. Gompers was elected chair of the international labor commission organized to recommend measures to deal with labor questions in the peace treaty.

3.1 The AFL and Versailles

A socialist in his early years Gompers later argued that trade unions should focus on the needs of their members and eschew any broader ideological views; he once said, 'I have no quarrel with Socialists, but I have no use for their proposals.' He insisted that the commission he chaired meet in Paris, to be close to the treaty discussions, and as he said, it 'should not be held any place except Paris if we wanted to protect our deliberations from a Bolshevik stampede (Gompers 1957, p. 302).

The conference produced the basic design and purpose of the ILO, and a clause on labor rights that was included in the Versailles treaty. Efforts to revive the IFTU were less successful; the new Soviet unions wanted their own structure, as did union bodies with Catholic or Protestant denominational identities. Gompers withdrew the AFL because he saw no way to coexist with the Soviets, and because he insisted on complete autonomy for each national union body. He never wavered from the view that unions' only legitimate concern was the well-being of workers through collective bargaining.

4. The ILO Between the Wars

British delegates, impressed by the achievements of a tripartite structure of cooperation among business, labor and government in the war effort, took the initiative in incorporating tripartism into the governance of the ILO. Gompers chaired the 1919 founding conference in Washington. The Senate's refusal to ratify the Versailles treaty made it impossible, or impolitic, to propose US membership; Republican presidents in the 1920s shunned both the League of Nations and its agency, the ILO.

4.1 Early ILO History

Even without US membership, the ILO was able to move quickly and effectively. It adopted 16 conventions and 18 recommendations in its early years, dealing with the 8-hour day and the 48-hour week, protection of women and young people at work, maternity protection, and protection of maritime and agricultural workers. (Conventions are debated in two successive annual conferences before they can be adopted. When ratified by states they have the force of international law. Recommendations carry less weight.) By 1939 67 conventions and 66 recommendations had been adopted, and the tripartite governance system was firmly in place. The International Court of Justice affirmed the ILO's jurisdiction in cases brought by national governments. The ILO's program of research, utilizing experts and investigating in the field, had built a reputation for quality. As governments began to experience the potential effects of conventions, the pace of adoption slowed, testimony to the ILO's effectiveness, Membership expanded beyond the core of advanced economies to include nations in Asia, Africa, and Latin America (Morse 1969, pp. 4–23, Ghebali 1989, pp. 9–14).

4.2 US Affiliation

Reversing earlier policies, the AFL supported US membership at its conventions in 1932 and 1933.

Secretary of Labor Frances Perkins, took the lead in persuading President Roosevelt that the USA should join, and in lobbying both houses of Congress, arguing that ILO expertise could help in the design of social welfare and labor legislation, as indeed it did (Ostrower 1975, Martin 1976, pp. 427–30). The Soviet Union also affiliated in 1934, but ceased to send delegates to the annual conference after 1937, while the USA continued to participate; John G. Winant served as Assistant Director from 1935 to 1938, and as the first American Director General between 1939 and 1941.

5. *World War II, The Philadelphia Declaration and the Cold War*

Exiled to Canada during the war, the ILO convened in Philadelphia in 1994, its twenty-fifth anniversary. President Roosevelt sent a warm message, and held a reception after the conference ended. The 'Philadelphia Declaration' charted an ambitious course for the ILO in the postwar era. It revised some of the constitutional language, reaffirmed its basic principles, and defined the priorities of social justice and 'a just share of the fruits of economic progress' as central to the avoidance of the return of depression and war. These included full employment, the right of workers to collective bargaining, social security protection, access to medical care, protection of women and children, adequate housing and nutrition, and safe and healthy working conditions. Its human rights emphasis anticipated the language of the UN Declaration of Human Rights in 1948 (ILO 1944). It emphasized, as ILO leaders continue to do, that the ILO is the only international institution that provides a franchise and governance role to workers and employers.

5.1 *Post-War Growth*

Between 1949 and 1968, the number of member nations increased from 55 to 118, and the budget grew fivefold; the ILO moved much closer to universal membership. It developed a relationship with the UN Development Program for cooperative work in developing economies. Its World Employment Program adopted in 1968 focused greater attention on the problems of unemployment and underemployment. Its attack on apartheid led to the withdrawal of South Africa in 1966. Its technical and professional reputation grew; it built a reputation as 'the world's centre of excellence for research and understanding of labour-related issues' (Langille 1999). David Morse, who served as Director General from 1948 to 1970, raised the visibility and influence of the ILO in the USA.

6. *The Cold War and the Crisis of International Labor*

The USA withdrew from the ILO in 1977, but rejoined in 1980. A crisis of confidence had developed around two issues: the increasing bitter US–Soviet Cold War rivalry, and the international effort to isolate and punish Israel; the ILO was weakened seriously by both.

6.1 *AFL and CIO International Competition*

Large-scale organization by Congress of Industrial Organizations (CIO) unions of masses of unskilled and semi-skilled workers posed a major challenge to the AFL's historic dominance in labor matters. CIO officials played major roles in the economic war effort, and built close relationships with the Roosevelt administration. The CIO opposed the AFL's views in international labor affairs and developed its own relationships, building alliances with French and Italian union bodies that were anathema to the AFL's virulently anti-communist positions.

The AFL's views were close to those of the intelligence and foreign policy agencies in the postwar government, and the two forged close financial and working relationships. The CIO played an active role in the formation of the World Federation of Trade Unions (WFTU), which included Soviet unions and unions close to the Soviets, especially in France and Italy. CIO leaders were not friends of communism; their actions were pragmatic efforts to achieve relative equality in international union matters with the AFL.

The 1947 Marshall Plan proposal completed the rift between the Soviet bloc and most unions of the free world. The CIO supported the Marshall Plan and President Truman's 1948 election campaign. It withdrew from the WFTU; both the AFL and the CIO participated in the founding of the International Confederation of Free Trade Unions (ICFTU) in 1949, and were elected to two of the seven vice presidencies (Radosh 1969, pp. 304–47, Reuther 1976, pp. 329–59, 411–27). The AFL–CIO's Cold War obsessions strained relationships with many ICFTU affiliates and weakened its capacity to respond to changing economic and political challenges; this ended only after new AFL–CIO leaders were elected in 1995.

The effort by the WFTU to control the ITSs raised strong resistance. ITS leaders recognized that the achievement in wartime USA of full employment and rising standards of living for workers provided a viable alternative to the Soviet model that had boasted of its progress during the Great Depression. Their lifelong loyalty to social democratic or socialist principles had earned them the hostility of the communist movement, which they reciprocated, in the 1920s and 1930s. Soviet opposition to the Marshall Plan reinforced

their resistance, and their support of a new international body that respected the independence of these long-established institutions. Even in France, where support of the Soviet unions was strong, old divisions reemerged; 'Force Ouvrière,' one observer remarks, 'is a child of France, not of the United States' (MacShane 1992, p. 277). Konrad Ilg, the longtime secretary of the International Metalworkers Federation (IMF), pointed in 1945 to an 'iron curtain … behind which developments are taking place about which we know hardly anything (MacShane 1992, p. 15). (This iron curtain image preceded by several months the more famous words of Winston Churcll.) MacShane describes the opposition of the ITSs to the WFTU as the 'submerged rock that ripped out one of the sides of the WFTU,' while the Marshall Plan was 'the more visible reef' (MacShane 1992, p. 26).

7. *The ILO in the Post-Philadelphia Era and the Cold War*

Early on, the ILO defined two conventions adopted in 1948 and 1949 as basic: No. 87 (freedom of association and the right to organize), and No. 98 (right to collective bargaining). In later years two others were added: No. 29 (elimination of forced or compulsory labor), and No. 111 (elimination of discrimination in employment and choice of occupation). They have acquired a quasi-constitutional standing; even states that have not ratified them are expected as a condition of good standing to honor them, and are subject to scrutiny if they are charged with failure to do so.

Employment issues were highlighted when in 1969—the year the ILO was awarded the Nobel Peace Prize—it launched a multi-year World Employment Program, one of whose products is the annual World Employment Report.

7.1 *US Withdrawal and Reaffiliation, 1977–80*

Cold War tensions reached a peak with the appointment in 1970 of a Soviet official as Assistant Secretary General, drawing strong US objections. US payments were suspended for a year in protest, then resumed. Admission of the Palestine Liberation Organization (PLO) to observer status, over US objections, led to regular attacks on Israel by Arab and other members; the USA argued that these were political in nature, not germane to the ILO's work, but they continued. US employers objected to the admission of Soviet citizens to the employer group, on the grounds that they were no more than agents of the Soviet state. In 1977, the USA endorsed an ILO study critical of forced labor in the Soviet Union, but it failed to pass—'the US had asked for a vote of confidence, and none was forthcoming' (Galenson 1981, p. 65).

The USA filed a letter in 1975 giving 2-year notice of its intention to withdraw. Withdrawal was damaging both financially and politically; the level of interest and awareness of the ILO, even among labor and legal scholars, remains low. The Carter administration concluded that withdrawal had served its purpose, and that US interests would be better served by rejoining, which occurred in 1980. George Meany's retirement from the AFL–CIO presidency helped.

8. *The ILO, the ICFTU, the Trade Secretariats and the Changing Global Economy*

The world's economy and politics were transformed by the end of the Cold War and the large-scale globalization of economic life. Discussion in the ILO resulted in the adoption in 1998 of the 'ILO Declaration on Fundamental Principles and Rights at Work and its Follow-Up.' This followed the 1995 Copenhagen World Summit for Social Development, whose principal organizer, Juan Somavia of Chile, took office in March 1999 as the first ILO Director General coming not from an advanced economy but from 'the South,' symbolic of increasing divisions in levels of economic development and well-being.

Under the terms of the Declaration, the ILO was committed to producing annual reports, beginning in 2000, under the rubric of 'Your Voice At Work,' focusing on each of the basic rights that form the ILO's bedrock principles:

2000—ensuring the right of all workers to form and join unions, with similar rights to employers;
2001—elimination of all forms of forced or compulsory labor;
2002—elimination of child labor; and
2003—elimination of discrimination in employment and choice of occupation.

8.1 *New ILO Leadership*

In his first year in office the new Director General began to address three major challenges that the ILO faced:

(a) Organizational reform and renewal to ensure that the International Labor Office has identified accurately the major objectives to be addressed, and has the staff and structure needed to address them effectively.

(b) Strengthening relations with international and national labor bodies and other institutions to build more effective cooperation in the shared effort to achieving the right balance between growth and equity, market power and social protection, efficiency and justice for working people.

(c) Participation in the processes by which the global economy defines and effectuates the structure of rules and governance for nations and independent

entities, private and public, that wield power and influence, making the ILO, in the words of the Director General, 'a leading organization of the twenty-first century.'

A comprehensive reorganization of the International Labor Office, around a set of specified goals and priorities, was well under way in 2000. The new structure differs significantly from that which preceded it. (An earlier organizational structure is shown in Ghebali 1989, pp. 164–5.)

An ambitious schedule of conferences, speeches and consultations took the Director General to many parts of the world in his first year. Audiences included the ICFTU world congress in Durban, South Africa; the annual convention of the AFL–CIO; the congress of the European Trade Union Congress (ETUC); the TUC annual conference; the May Day workers' jubilee in Rome; the UN General Assembly; the World Trade Organization (WTO) ministerial conference; the Organization of African Unity; and the follow-up conference to the Copenhagen World Summit. The schedule continued at the same pace in 2000 and beyond.

The ILO was able to broker discussions involving the Secretary General of the UN, international labor leaders, and international business organizations on the concept of a 'global compact' which addresses the central issues of equity and representation that the global economy continues to raise as it restructures economic activity and redefines the international division of labor.

Participation in governance is the most difficult of these objectives. The ILO has consultative status with the International Bank for Reconstruction and Development (IBRD) and the International Monetary Fund (IMF) but relations with the WTO remained at the discussion level in 2000.

9. *International Unions and the International Economy*

Many of the difficulties and challenges that face the ICFTU and the ITSs have long histories. Because economic development occurred at different rates in different countries, inevitably unions were engaged in domestic struggles for recognition, power, and influence. Some national union bodies were the offspring of political parties; others, notably in the USA, developed independently of the parties. Some are focused on national political struggles to protect and advance workers' rights and interests, while others see the workplace and the employer as the focus of the struggle, with the state serving primarily as rule-maker, not decision-maker. In some countries, union density has consistently been high, while in others it fluctuates. Some have a single national body and a centralized structure, while others confront multiple claims and competition for workers' support.

In Europe, the ETUC has been successful in developing cross-national forms of cooperative activity and effective collaboration; a shared history, close geographical links, and decades of involvement in the process of economic integration, deregulation of labor markets, and increased cross-national mobility play important enabling roles. Some of the ITSs have developed new leadership and greater ability to organize cooperative activities of mutual support; International Transport Workers was helpful in the US strike by the International Brotherhood of Teamsters against United Parcel Service in 1997, an important milestone in the effort by US unions to restore balance after the erosion in strength that greatly reduced union density and effectiveness after 1980.

Because even the most globally organized multinational corporations operate in countries with governments, unions, political parties, and social movements they are in principle subject to laws that govern labor affairs, social protection, health and safety, environmental integrity, and other subjects of national legislation and attention by the media and the public. Advocates and consumer organizations have been able to expose patterns of exploitation in both underdeveloped and domestic 'sweatshops.'

10. *Conclusions*

The power to affect or control the direction of economic and social policies will remain the central issue, and will be determined, as the past shows, by the relative balance of forces with different goals and priorities, and the degree of unity or division among them. For international labor, the objective remains an economic order that protects and promotes the range of human rights embodied in the ILO basic conventions, and a structure of governance and rule-making that ensures a voice which represents and advocates these rights.

10.1 *The ILO*

The ILO has built over the decades a rich web of international and national legislation, investigations, and interpretations of its conventions and recommendations. Its role in developing social welfare policies, and standards for the regulation of labor conditions in a wide range of occupations, has helped to build credibility in countries in every area and at different levels of economic, social, and political development. It remains the only international institution where the workers and employers have a voice in decision-making and policy determination. It has survived serious crises that threatened its continuity and viability. (For information on the ILO in the year 2000, see Table 1.)

Table 1
Basic information on the in the year 2000

Member nations: 175		
Total budget: US$481.8 million		
Total staff:	Geneva headquarters	Field
Professional:	492	184
General service:	600	438
Number of conventions adopted*: 183		
Number of recommendations adopted*: 191		
Conventions ratified 1995–2000		
Forced labor (No. 29, 1930): 15		
Freedom of association and protection of the right to organize (No. 87, 1948): 14		
Right to organize and collective bargaining (No. 98, 1948): 20		
Equal remuneration (No.100, 1951): 20		
Abolition of forced labor (No. 105, 1957): 29		
Discrimination in employment (No. 111, 1958): 22		
Minimum age (No. 138,1973): 38		
Worst forms of child labor (No. 182, 1999): 8		

* Conventions are debated in two successive years prior to adoption; when ratified they acquire the status of international law. Recommendations carry less legal weight and are not binding

For its first three decades, the ILO was the sole international voice advocating and defining human rights. In the postwar era others have taken up this role; UN human rights covenants set standards for governments. Codes of conduct are negotiated with individual firms that operate in more than one country. The ILO's decision-making structure is based on representation by nations in a period when strong economic and demographic forces challenge the ability of national governments to deal with them. The ILO's efforts to gain a seat at the rule-making table had achieved only limited results at the beginning of the twenty-first century.

10.2 International Trade Union Bodies

The ICFTU and the ITSs were able to move forward after Cold War tensions abated in the last decade of the twentieth century, but they lacked the financial support and organizational linkages needed to engage effectively the corporate and financial interests that came to dominate the international economy in the late twentieth century. International capital deployed a wide range of strategies that continued to build more concentrated corporate power; labor's inventory is more limited. Use of strikes, boycotts, sharing information, building popular support, use of media, and domestic political work all play a role, but unions remained on the defensive in most areas of the world. Union densities declined and labor-linked political parties shifted toward the right or center. The center of gravity of intellectual work in international economics endorsed the values of markets and competition; progressive views about social welfare, labor markets and industrial relations had lost ground and confidence in the closing decades of the twentieth century.

This had begun to change as the costs and consequences of globalization were examined and doubts raised about the validity of these global paradigms. Large-scale and long-lasting unemployment, increased inequality and poverty, illiteracy, and malnourishment (UNDP 1999) all raise the level of skepticism and the degree of openness to new or dissenting views. Popular movements showed signs of new life, and the academic analysis of global issues found more room for critical and dissenting views. In the future, as in the past, the balance of political forces will determine the outcomes of these struggles.

Labor Supply

In economics, the study of 'labor supply' has come to mean the analysis of work behavior where the questions addressed include: How many hours do people work for pay and what factors affect work hours? and What proportion of the population works for pay and what factors affect this proportion? The first question, about the number of hours or weeks that individuals work in the labor market, concerns the intensive margin of work. The second question, whether people work or not, concerns the extensive margin of work. The extensive margin may be measured by the employment–population ratio or by the labor force participation rate. Questions such as: How hard do people work per hour? cannot be examined systematically given the paucity of data on work effort.

The questions above stress work 'for pay.' This excludes voluntary work and unpaid household work. In fact, data are available on both voluntary work (see Freeman 1997) and household work (see Juster and Stafford 1991), and the very same conceptual framework summarized below that is used to study paid work is also employed to understand these other types of work. However, this article concentrates on work for pay and, subsequently, whenever the word 'work' is used, it should be understood that 'work for pay' is meant. Most of the research by economists during recent decades has addressed the supply of labor to the labor market as a whole, not the supply of labor to particular occupations or to particular firms or industries. Research on labor supply to particular occupations or to particular firms uses models similar to the one sketched below to understand the supply of labor to the entire labor market, although there will necessarily be some differences in the analysis. For a review of some research on occupational labor supply, see Freeman (1986). For a study of the labor supply to a single firm, see Nelson (1973). In this article, the research reviewed concerns the supply of labor to the labor market as a whole.

1. *Key Empirical Regularities*

Any satisfactory theory of work behavior should explain the following empirical regularities:

(a) Men work more than women.

(b) In North America and Western Europe, white men work more than black men.

(c) In recent years and in relatively rich economies, those who have been at school longer work more.

(d) Unmarried men work less than married men while, until recently at least, married women work less than unmarried women.

(e) Work hours and employment–population ratios fall in recessions and rise in booms though this procyclical movement is stronger for low-skill than high-skill workers.

(f) Over the past century, in North America and Western Europe, for most types of workers, work hours have fallen and vacations have lengthened. A particularly instructive illustration of this for the USA is provided in Fig. 1, which graphs the usual length of the workday by wage decile. The unbroken line in this graph draws upon information from various surveys in the 1890s while the broken line provides information from a special Current Population Survey in 1991. The length of the workday has fallen for all workers except those at the highest wage decile. Indeed, whereas low-wage workers once worked the longest hours, high-wage workers now tend to do so. Figure 1 describes US women, but the data for US men are similar (see Costa 1999a).

(g) Among men, work rises with age until middle age and then falls.

(h) Although comparisons across countries are frustrated by differences in data collection methods and definitions, it appears that, in the 1990s, average hours worked in the USA exceeded those in Europe.

(i) Average hours worked by self-employed people tend to exceed those by employees (see Aronson 1991). No doubt, instances will be found where these patterns are contradicted, but these empirical findings constitute the norm. A rich literature exists in economics on these issues.

One empirical regularity has received much less attention, the fact that individuals synchronize their work schedules: almost 80 percent of full-time workers in the USA start work between 7 a.m. and 9 a.m. and about the same proportion finish between 3 p.m. and 6 p.m. (Mellor 1986); about 60 percent of all those employed do not work weekends (Smith 1986). Presumably there are strong complementarities in work and leisure activities (i.e. the benefits to one individual from engaging in a given activity are greater if other

Figure 1
Usual length of work day by hourly wage percentile: women aged 18–64, 1890s and 1991

individuals also engage in that activity at the same time) although little research effort has been directed towards identifying the key complementarities. Weiss (1996) has been one of the few to grapple with this issue.

2. *An Informal Statement*

2.1 *Classifying the Variables*

In essence, economists think in terms of an individual's time spent at work as depending upon four classes of variables: (a) pay per unit time at work; (b) other income; (c) certain demographic characteristics that are observed by researchers; and (d) characteristics of the individual that are unobserved by researchers.

Consider these variables in turn. First, the dependent variable: time spent at work. There are many different dimensions of work time, including annual hours of work, annual weeks worked, weekly hours, daily hours, and whether to work or not.

Now the independent variables. 'Pay per unit time at work' is designed to measure the incentive to work or, equivalently, the price of not working. It is usually measured by an individual's average hourly earnings. Economists usually presume that after-tax earnings matter, not pre-tax earnings. Where average hourly earnings do not vary with time at work, then the use of hourly earnings is appropriate to characterize the incentive to work for pay. However, there are a number of instances where the wage per hour is not fixed but varies (often increases) with work hours so average hourly earnings may provide only a local indicator of work incentives. For instance, in many countries, by statute or by union-negotiated collective bargaining agreements, or by the operation of market forces, wage premiums are paid for long hours worked per week. Or job offers come in tied wage-hours packages: one employer may offer a job specifying a wage of US$10 per hour for 40 hours per week while another may specify a wage of US$12 per hour for 42 hours. In these instances, the incentive to work is not provided by a single wage rate that describes all work opportunities.

The variable 'other income' is sometimes represented by the individual's rent, dividends, and interest, so-called nonlabor income. This type of income for an individual is often the consequence of labor income earned at an earlier age and, therefore, will tend to be higher for those who habitually work long hours. In this way, high non-labor income will tend to be a result of, rather than a cause of, long work hours. Hence, some researchers prefer to use some measure of wealth at a young age (if the data are available to measure it). Or 'other income' is sometimes represented by the labor income of other family members.

It is routine to examine the relationship between time at work and wages holding constant certain demographic characteristics, such as gender and race, characteristics that are typically included in surveys and that are available to researchers. Even allowing for differences in wages and other income, work patterns vary by race and gender, suggesting either systematic differences in 'tastes for work' or different work and nonwork opportunities for these groups.

Finally, it is recognized that much of the variation in work behavior across individuals remains unaccounted for after holding constant all the variables that are usually provided in large data sets. Expressed differently, variables unobserved by researchers 'explain' most of the variation in work across individuals. These unobservables are sometimes called 'tastes for work,' but it should, be understood that this is simply giving a name to our ignorance.

2.2 The Nature of the Available Data

It is important in understanding any empirical labor supply research to recognize the essential source of variation in the data that is being exploited to measure the effects of various variables on work. One source of variation is across people: the correlation between work and other variables (especially wages and other income) is computed across people observed at approximately the same time. This correlation is often calculated separately for men and women and for different racial groups. A different source of variation is over time: here, in essence, the average values of each individual's work and other variables are first computed, then variations over time around each individual's average in work and other variables are calculated to form the relevant correlations.

Although it is straightforward to compute these correlations, they are sometimes difficult to interpret. Consider the effect of wages on work behavior, a subject that has been the focus of most of economists' research on labor supply. An ideal experiment from which to infer the effect of wages on work would be to select people in the population at random, assign wages to them prior to their work choices, and then observe whether and how much they work. In this experiment, the parts played by the random selection of the population and the prior assignment of wages to people are very important. Unfortunately, nature does not provide us with these ideal experimental conditions.

First, the wages that people face at any moment are determined in part by individuals' past decisions about how long to stay at school and what skills to acquire. These past schooling and training decisions may have been made with the expectation of capitalizing on them subsequently by working longer hours in the labor market. People who are less averse to market work are more likely to stay at school longer and to acquire the skills that result in relatively high wages later in life. In this event, the correlation between work hours and wage rates incorporates a causation that runs from preferences about work hours to wages rather than the other way around. Wages are not assigned to people in the manner described by our ideal experiment; in part, wage differences across people reflect people's prior decisions and their past and current preferences.

Second, when computing the correlation between work hours and wage rates, the wage rates facing people who choose not to work for pay are usually unobserved. Expressed differently, information on the wage offers that nonworkers are rejecting is not available to researchers. This problem is typically addressed by computing the hours–wage correlation among those working positive hours only. However, this generates the problem that the sample of people who choose to work does not represent a random sample of the population but a highly nonrandom and self-selected sample. The requirement of our ideal experiment that the correlation between work and wages be computed for people who constitute a random sample of the population is not met. This is one manifestation of what has become known as the problem of 'sample selection' and it has been emphasized in Heckman's influential research (e.g. Heckman 1979). The sample selection problem arises whenever factors unobserved by the researcher affect both (a) the selection of the sample over which the hours–wage correlations are to be computed and (b) the hours of work decisions of the individuals. In this case, the ideal experimental condition—the random selection of the sample—is not being satisfied, and the meaning of the hours–wage correlation is subject to more than one interpretation (as shown succinctly by Heckman 1993).

Therefore, the data available to researchers to compute the effect of wages and other variables on work behavior probably do not satisfy certain ideal experimental conditions and this frustrates measuring the behavioral parameters governing the impact of these variables on work choices.

3. Static Models of Labor Supply

3.1 Conceptual Framework

To model an individual's work decision, let his or her preferences for work hours (h) and consumption (c) be embodied in a utility function $U = U(c, h; X, e)$ where X denotes fixed characteristics of the individual such as gender and race that are observed by researchers. Characteristics affecting preferences that are not observed by researchers are given by e. The individual's income–expenditure constraint is expressed as $p \cdot c = w \cdot h + y$, where p is the price of consumer goods, y is nonlabor income, and w is average hourly earnings.

In the simplest and most tractable of cases, p, w, and y are fixed to the individual and independent of choices of c and h. In this instance, provided U has some convenient technical properties, selecting c and h to maximize U subject to the income–expenditure constraint yields an expression that relates hours worked, h, to the budget constraint variables that are given to the individual, namely, p, w, and y, and to the fixed characteristics conditioning his preferences, X and

e: $h = f(p, w, y; X, e)$. This relationship is the labor supply function and it provides a formal justification for the characterization given in Sect. 3, whereby time spent at work is related to four classes of variables: w, y, X, and e. (Because the budget constraint may be written $c = (w/p) \cdot h + (y/p)$, it is evident that there are not three independent price and income variables, namely, p, w, and y, but only two such variables, namely, w/p and y/p.) As usual in economics, for the key empirical propositions, it is not essential that any individual behaves in this easily caricatured, maximizing manner, but that it facilitates the derivation of relationships and provides a convenient benchmark if we assume that the individual behaves as if he were deliberately optimizing. Less terse explanations of this model can be found in many good textbooks such as Ehrenberg and Smith (1997) or Filer et al. (1996).

This framework applies to the individual who chooses to work a positive number of hours ($h > 0$) and to the individual who chooses not to work at all ($h = 0$). In the case of the decision of whether to work, the individual who is currently not working compares the wage per hour he would receive if he worked, the 'offered market wage,' with his reservation wage which is defined as the implicit value of his nonwork time. When his reservation wage exceeds his offered wage, he does not work for pay ($h = 0$); when his reservation wage falls short of his offered wage, he works some positive hours in the market ($h > 0$). Therefore, the higher is the offered wage, the greater the likelihood of an individual working for pay.

The previous statement concerns an individual's work decisions. Many people live in households where joint work decisions have to be made. In these cases, the standard treatment postulates a household utility function that depends upon the household's consumption and the work time of each household member. If incomes and expenditures are pooled, then each household member's work behavior will depend not only on his wage rate but also on the wage rates of other household members.

This household formulation has been the subject of criticism in recent years for failing to specify how the household utility function is derived and for being silent on how resources are allocated within the household (see, for instance, Chiappori 1988). Recent models start with the utility functions of each household member and postulate that the household reaches efficient decisions with respect to its consumption and work behavior. 'Efficiency' here means that, given prices and wages, the work and consumption decisions of the household members have exploited all opportunities to enhance their welfare without cost so that one person's welfare can be improved only by lowering another member's welfare.

One version of these models characterizes household decision making as a bargaining process. Each individual has a level of welfare that can be enjoyed in the absence of cooperation with other members of the household. This is the individual's 'threat point' and is sometimes equated with the welfare the individual would enjoy if he or she left the household. Provided the household remains intact, anything that increases an individual's threat point will increase the individual's share of the benefits from remaining in the household. For instance, if the market wages paid to unmarried women rise, this increases the wife's threat point in bargaining with her husband and, provided the wife remains married, she should enjoy a greater share of resources within the household. This model has been used not only to understand husband–wife decision making and the growing incidence of divorce, but also intergenerational behavior in developing countries when adult children live with their parents. A formal treatment of these issues is found in McElroy (1990) and a more accessible discussion is in Lundberg and Pollak (1996). These models are likely to be a popular topic for future research especially if they are able to add materially to our understanding of household formation and dissolution.

3.2 Empirical Research

A large amount of empirical research has been directed towards the relationship between h and w. This is because changes in income taxes and other sorts of taxes and changes in welfare benefits are tantamount to changes in w (and sometimes in y, too) and the cost and benefits of these tax and welfare policies depend critically on whether and by how much hours worked and employment–population ratios increase or decrease as w is altered.

In labor economics research in the 1970s and 1980s, the most common source of information to examine the relationship between hours worked and average hourly earnings consisted of large cross-sectional data sets, that is, data on individual people observed at approximately the same calendar time. In essence, after controlling for differences among people in many characteristics, the residual correlation was computed between time spent at work and average hourly earnings. In other words, the impact of wages on work was inferred from differences among people in their wages and work after controlling for other variables.

The most common finding in this research was that, among adult men, hours worked and wage rates were mildly negatively correlated while, among adult women, hours worked and wage rates were positively correlated. A summary and evaluation of these studies appear in Killingsworth (1983), Pencavel (1986), and Killingsworth and Heckman (1986). However, the particular results were disturbingly fickle: relatively small changes in the composition of the sample or in estimating methods sometimes had large effects on the magnitude of the work–wage correlations. Mroz (1987) provides an excellent demonstration of this. Recent research has tended to yield somewhat more

consistent and robust results. This is because the more recent research has followed people over time so, in addition to the variation in the data across people, there is also variation in the data for each person over time. When understanding such intertemporal variation, it becomes important to consider life-cycle or dynamic models of labor supply.

4. *Life-cycle Models of Labor Supply*

In life cycle models of the effect of wages on work behavior, it is crucial to ask: What is the source of the variation in observed wages to which individuals are adjusting their labor supply? One source of variation is the life-cycle variation in wages for a given individual, that is, the evolutionary changes in wages as a person ages. Typically, as an individual ages, their wages rise, sometimes at a decreasing rate, until later in life when wages begin to fall. A second source of variation in wages is the difference in wages across people at the same stage in their life cycle. This second source of variation in wages is called the parametric difference in wages across individuals. At any moment, differences in work behavior among people will be a mixture of responses of labor supply to, first, the path of wages as a given individual ages and, second, differences across individuals in wages observed at the same age.

The first of these responses may be observed if the work behavior and wages of a cohort of people born at about the same time are followed as they age. The proportional change in hours worked that follows a proportional change in wages as these individuals age is called the intertemporal substitution elasticity. It is the life-cycle effect of wages on work. Instead of following people born at about the same time, sort these individuals by age group and compute the correlation between work and wages across people within each age group. These people are about the same age, but they are born in different years (as they belong to different cohorts) so that the observations on their work and wages must be drawn from different calendar years. This correlation incorporates the response of labor supply to parametric differences in wages across people.

The first study to lay out these distinctions with clarity and to compute the various labor supply responses was MaCurdy (1981). His estimates of the intertemporal substitution elasticity for adult US men were in the order of 0.23, meaning that a 10 percent growth in wages as an individual ages would induce a 2.3 percent increase in annual hours worked. His estimates were imprecise, but more recent estimates for both men and women derive similar values for the intertemporal substitution elasticity (see Pencavel 1998, 1999).

When individuals are sorted by age and the correlation between work and wages computed across people holding age approximately constant, the subsequent estimate of the impact of wages on work is often (though not invariably) positive: for both US men and women, a representative estimated elasticity of annual hours with respect to wages is of the order of 0.10. (The elasticity of hours with respect to wages is defined as the proportional change in hours induced by a proportional increase in wages.)

Whereas in the research in the 1970s and 1980s it was common to compute negative estimates of labor supply elasticities, in the 1990s the estimates were more frequently positive and appeared less sensitive to modifications in specification and methods. Why should this be? First, there is a better understanding about the need to distinguish conceptually among different possible wage effects on work behavior. In particular, researchers differentiate the incentives for an individual to work at ages when his wages are relatively high (this is the life-cycle effect) from the incentives to work that come from wage differences arising for reasons that are independent of age (this is the effect of parametric differences in wages). Second, the 1990s research had an important time-series dimension, which may be a critical feature given that, over the past 20 years or so, the structure of wages has changed considerably. This generates a variation in wages that was denied to researchers in the 1970s and 1980s who relied exclusively on wage differences among people at a given moment.

Though there remains some disagreement among economists regarding the value of the elasticity of hours worked with respect to wages, it is undeniable that positive estimates of the effect of wages on work would help to explain many features of changes in work behavior over the past 25 years in the USA. Work levels have increased more for women than men, they have increased more for well-educated people than poorly educated people, and they have increased more for married people than for single people. In each of these three comparisons, the wage structure has changed favoring those who work more: the wages of women have risen relative to those of men, the wages of well-educated workers have risen relative to those with less education, and the wages of married people have risen relative to the wages of unmarried people. One simple story compatible with these facts is that changes in technology and other factors have caused changes in the wage structure and—if work–wage relationships are positive—these wage changes have induced relatively more work from those whose wages have risen relative to those whose wages have fallen.

Positive work–wage estimates may also explain some of the empirical regularities listed in Sect. 2. Men work more than women and, other things equal, men are paid more per hour than women. White men work more than black men and, other things equal, white men are paid more than black men. Those with more schooling work more and those with more

schooling have higher average hourly earnings. Unmarried men work less than married men, and unmarried men tend to have lower wages than married men. Unmarried women work more than married women, and unmarried women tend to have higher hourly pay than married women. The work–age patterns for men broadly correspond to their wage–age patterns. No doubt, there are other competing explanations for these regularities, but the naïve positive association between work and wages across these groups is striking.

5. Other Empirical Findings

5.1 Labor Supply and Taxes

One aspect of labor supply research that has occupied a large amount of attention is the impact of income taxation on work behavior. If t is the tax rate, w represents gross (that is, pre-tax) hourly earnings, and y is gross (pre-tax) nonlabor income, then net or post-tax wages are defined as $w^n = (1-t) \cdot w$ and net or post-tax nonlabor income is $y^n = (1-t) \cdot y$. If each individual responds to net wage rates and net nonlabor income, then the relevant budget constraint involves the post-tax variables: $p \cdot c = w^n \cdot h + y^n$.

The problem posed for researchers measuring the effect of income taxes on labor supply is that, in most income tax systems, tax rates change with income (which, in turn, changes with work hours) so that the net wage rate varies as an individual alters his work hours. This means that the incentive to work is not represented by a value for hourly earnings that is fixed to the individual and independent of their work choice. Instead, there is no single value that represents the incentive to work because the net hourly wage at, say, 20 hours of work per week will diverge from the net hourly wage at 40 hours per week. In this instance, the budget constraint, $p \cdot c = w^n \cdot h + y^n$, is no longer linear.

It is not only the explicit income tax system that produces nonlinearities in the budget constraint. Most income-maintenance programs designed to provide support for low-income people also result in nonlinear budget constraints for individuals eligible for such programs. This is because most income-maintenance programs do not transfer a fixed sum that is independent of the recipient's income. On the contrary, most transfer programs are income conditioned: less money is transferred to the recipient as the recipient's income rises, until a point is reached, the so-called break-even point, where transfers are reduced to zero and the individual moves off the welfare program and is faced with just the (positive) income tax system. The rate by which transfer income is reduced as the welfare recipient earns one more dollar is the welfare system's implicit tax rate. Virtually all implicit tax rates are very high, often as high as 100 percent when transfer income is reduced by one dollar for every dollar that the individual earns, so that budget constraints of low-income people are highly nonlinear.

The research on the labor supply effects of income taxes and transfers tries to reproduce the essential features of individuals' after-tax and after-transfer budget constraints. When the tax system can be characterized as generating an after-tax budget constraint for an individual in which after-tax wage rates are continually falling as more hours are worked (that is, a budget constraint that is strictly concave from below as implied by a smoothly progressive tax system), the statistical procedures for estimating the effect of wages and taxes on work behavior are relatively straightforward and tractable. When, however, the after-tax budget constraint has kinks and net wages may rise over some regions as hours increase, the statistical methods become more recondite and the results more sensitive to alternative estimation methods. The variation in the estimates of different studies reported in Blundell and MaCurdy's (1999) survey is striking. The essential source of the difficulty for researchers is that most data sets provide little information about the income tax and transfer programs that households face. Consequently, with the information available on gross wages and income, in effect, researchers try to complete the income tax and transfer algorithms for each individual, but the inaccuracies in this process and the errors introduced must be extensive.

A similar problem exists in trying to determine the impact of welfare or income maintenance programs on labor supply. A popular hypothesis is that some people reduce their work levels and, therefore, their market earnings to become eligible for welfare. This is revealed, it is argued, by the fact that welfare participation (the fraction of households receiving welfare payments) is higher in those states in the USA where the welfare program parameters imply relatively generous benefits. The problem with this argument is that, even in the absence of any work incentive effects of the welfare system, an association between welfare participation and the parameters of the welfare system are to be expected. Where welfare program parameters imply relatively generous welfare benefits, households will accept opportunities to raise their disposable income and participate in the welfare program, even if they do not change their work behavior. The association between welfare participation and welfare program parameters (especially the welfare system's implicit tax rate) has to be specified carefully to identify work incentive effects (see Ashenfelter 1983). Unfortunately, because very few differences across states exist in the statutory implicit tax rate on welfare income, there is little persuasive evidence from welfare programs of work disincentive effects.

Therefore, at present, probably the most reliable estimates of the effect of income taxes and transfers on

Table 1
Joint and unconditional probabilities of employment of white husbands and wives in the USA, 1990

		Probability of wife…		
		…not working	…working	Unconditional probability
Probability of husband…	…not working	0.075	0.059	0.134 (probability of husband not working)
	…working	0.309	0.557	0.866 (probability of husband working)
Unconditional probability		0.384 (probability of wife not working)	0.616 (probability of wife working)	

work behavior are those inferred from studies that compute the impact of changes in gross wages on work. The assumption here is that the effect of a proportional increase in gross wages on work hours equals the negative of the effect of a proportional increase in tax rates on work hours. This implies, given the estimates reported above of the impact of wages on work, that a 10 percent increase in income tax rates will induce individuals belonging to one cohort to work between one and three percent fewer hours at each age than they would otherwise choose to do.

5.2 Family Labor Supply Decisions

The employment probabilities of husbands and wives do not appear to be independent of one another. To show this, consider caucasian households in the USA where both the husband and the wife are aged between 25 and 64 years. (The data are drawn from the 1960 Census of Population.) Table 1 presents the joint and unconditional probabilities of market work of these husbands and wives. Thus, the probability that both the wife and the husband work is 0.557 and the probability that the wife works but the husband does not is 0.059. Hence the sum of these two joint probabilities is the unconditional probability of the wife working which is 0.616 (given in the bottom line of Table 1). Similarly the probability that the wife does not work but the husband does is 0.309 and (as already noted) the probability that both the wife and the husband work is 0.557. Hence, the sum of these two joint probabilities yields the unconditional probability of the husband working which is 0.866 (given in the last column of Table 1).

From these joint and unconditional probabilities can be derived the conditional probabilities and these are listed in Table 2. For instance, the probability that the wife works conditional on the husband working is 0.643, given in the first line of Table 2. Or, the probability that the husband works conditional on the wife also working is 0.904 given in the third line of Table 2. If the husband's and wife's employment probabilities were independent, then the conditional employment probabilities in Table 2 would equal the unconditional probabilities in the final column and the final line of Table 1. In fact, the conditional probabilities of the wife working are 0.643 and 0.441 (given in the first two lines of Table 2) whereas the unconditional probability of the wife working is 0.616 (from Table 1). The conditional probabilities of the husband working are 0.904 and 0.805 (given in the last two lines of Table 2) while the unconditional probability of the husband working is 0.866 (from Table 1). These data suggest that employment independence is closer to being satisfied for husbands than it is for wives. However, for both husbands and wives, the probability that one is employed is greater if his or her spouse is also employed. Consistent with this, working husbands and wives tend to retire at or close to the same time (see Hurd 1990 and Costa 1999b).

There are a number of reasons why employment probabilities of husbands and wives are positively correlated. First, this may reflect something about marital choices: women less averse to market work tend to marry men with similar work preferences. Second, the correlation may be that each party's responses to their shared economic environment. For instance, if both husbands and wives work more in households possessing little nonlabor income, then the positive correlation in work behavior may reflect the common influence of this source of wealth. Third, the correlation may be the outcome of both marriage patterns and economic environments. For example, it has already been reported that those men facing higher wages are more likely to work in the market than lower- wage men and those women facing higher wages are more likely to work in the market than lower-wage women (a). Furthermore, high-wage men tend to marry high-wage women (b). Together, (a) and (b) will generate a positive correlation between the employment probabilities of husbands and wives.

The positive correlation in the market work of husbands and wives may also reflect cross-wage effects. That is, hold the wages of the husband constant: then, do those husbands married to relatively high-wage wives work more than those husbands married to relatively low-wage wives? Conversely, hold the wages

Table 2
Conditional probabilities of employment of white husbands and wives in the USA, 1990

Probability of wife working conditional on husband working	= probability of both husband and wife working divided by the unconditional probability of husband working	= 0.557 ÷ 0.866	= 0.643
Probability of wife working conditional on husband not working	= probability of wife working and husband not working divided by the unconditional probability of husband not working	= 0.059 ÷ 0.134	= 0.441
Probability of husband working conditional on wife working	= probability of husband and wife working conditional on wife working divided by the unconditional probability of wife working	= 0.557 ÷ 0.616	= 0.904
Probability of husband working conditional on wife not working	= probability of husband working and wife not working divided by the unconditional probability of wife working	= 0.309 ÷ 0.384	= 0.805

of the wife constant: do those wives married to relatively high-wage husbands work more than those wives married to relatively low-wage wives? This issue has arisen in the last few decades as a possible reason for the growth in the employment–population ratio of married women. A popular explanation has focused on the slow growth in the wages of married men since the early 1970s: are married women working more because the wages of their husbands have increased so little or, in some instances, have actually decreased? The broad trends in the key variables support such an interpretation because there has been a steady increase in the market work of married women while, for the past 25 years or so, median real wages of married men have increased hardly at all.

Indeed, the work decisions of husbands and wives do seem to be related to the wages of their spouses. In particular, when one spouse's real pay falls, the other spouse tends to work more (see Juhn and Murphy 1997, Pencavel (1998, 1999)). However, these cross-wage effects—the relation between one individual's work behavior and his or her spouse's real earnings–are much less powerful than the own-wage effects (that is, the relation between each individual's work behavior and his or her own real wages). According to these findings, the employment of married women has increased principally because their real offered wages have been increasing and the movements of their husband's earnings have been a factor, but a factor of less importance in accounting for the movements in their work levels.

If women were working more to augment the stagnant pay of their husbands, then the increases in the work of married women should be greatest for those men whose wages have fallen, not for those men whose wages have risen. In fact, the largest increases in work among women have occurred for those women married to high-wage men and the real earnings of high-wage men have tended to increase in real terms since the 1970s. By contrast, the market work of wives of low-wage men has increased much less and yet the real wages of low-wage men have tended to fall. These facts are reported in Juhn and Murphy (1997).

Hence this evidence suggests that husbands and wives tend to substitute their work time for one another: when the wage rate of one party increases (decreases), that person works more (less) and his wife or her husband works less (more). The positive correlation in the employment probabilities of husbands and wives is driven more by marriage patterns and by own-wage effects than by cross-wage effects.

5.3 Work Behavior of Older People

One of the most striking of long-term developments in work behavior is the decline in employment of older men. Of men 65 years and older, 68 percent were in the

labor force in 1890, 42 percent in 1940, 31 percent in 1960, and fewer than 20 percent in the mid-1980s. Interestingly, from the mid-1980s to the mid-1990s, this decline appears to have flattened out. Similar declines in hours of work among those men employed are also observed. By contrast, the labor force participation rate of women aged 65 years and over has changed very little: it was 8 percent in 1890 and a little more than 8 percent 100 years later.

The drop in the amount of work allocated by older men to the market is one definition of retirement. Another definition, often accompanying the first, turns on the receipt of pension or Social Security income. It is tempting to convert this association into a causal relationship: retirement in the sense of the reduction in labor supply among older workers is induced by the opportunity to draw on annuities from accumulated pension funds.

Because the dominant retirement income for the median elderly household is Social Security income, a much researched issue has been the impact of Social Security on retirement. For most of the past 50 years or so, Social Security wealth has been increasing over time while male labor force participation rates have been falling so the aggregate time-series movements in these variables are compatible with a causal role for public pensions. However, monthly income from Social Security was first paid in 1940 to a relatively small fraction of the elderly population at which time labor force participation rates of men 65 years and over had already fallen by more than 20 percent since the beginning of the century. As Costa has noted (1998, pp. 20–21), in the USA and other countries (Britain, Germany, and France), retirement trends do not display a discontinuity around years when, as a consequence of new legislation, public pension benefits start being paid.

However, a role for Social Security affecting retirement behavior is suggested from an examination of the retirement patterns of the members of a given cohort as they age. In particular, since the mid-1960s when early Social Security benefits were first introduced, there has been a spike in male labor force participation rates at age 62 years. It is difficult to understand why there should be such a spike at 62 years other than the discontinuous retirement incentives embodied in the Social Security benefit rules.

In addition, certain private pension programs create incentives to retire before the age of 65 years. Thus, defined-benefit pension plans specify the pension annuity as a fixed proportion of a worker's highest annual earnings and often the actuarial value of such defined-benefit plans is higher for people younger than 65. The fraction of workers covered by defined-benefit pension programs has been falling and that of defined-contribution pension plans increasing. Because pension wealth grows until the funds are withdrawn, defined-contribution plans embody no incentives for early retirement.

The growth in Social Security and in private pensions represent specific manifestations of a more general phenomenon, namely, the increase in wealth that many cohorts have enjoyed this century. This increase in wealth discourages market work at some time during an individual's life and it may be efficient for the typical individual to take this increased leisure not in the form of fewer work hours each year, but in the form of fewer years at work and of earlier retirement.

5.4 *Differences in Work–Wage Elasticities*

In undergraduate textbooks, for many years it has been common to draw graphs of the relationship between hours worked and wages that imply a positive association at relatively low wages and a negative association at relatively high wages. This nonlinear relationship is called a 'backward bending labor supply curve.' Although this curve is a staple of every economics student's education, the empirical support for this relationship is meager. In some instances, researchers have specified the relationships in such a way that a nonlinear and nonmonotonic relationship between wages and work hours was not investigated. In other instances, however, researchers have explored the possibility of this backward-bending curve and found little evidence for it.

With the richer, more recent, data that combine cross-section and time-series variation, the issue has come up for re-examination. It surfaced because the impact of wages on work appeared to be larger for men with relatively low levels of schooling than for well-educated men, and it was a short step to move from this observation to a specification in which the impact of wages on labor supply fell as wages rose. Indeed, according to one set of estimates, the elasticity of annual hours worked with respect to wages is calculated to be of the order of 0.33 at the average wage of men with less than a high school education, and it falls to 0.14 at the average wage of men with more than 16 years of schooling (see Pencavel 1999). Note, however, that although the slope of the hours–wage relationship becomes less positive at higher wages, it never becomes negative, except for a very few people with extremely high wages. A similar result is obtained by Juhn and Murphy (1997).

6. *Conclusion*

Over the past 40 years or so, there has been a very large volume of research on labor supply by economists. This is because the work decisions of individuals represent one of the essential components of labor market analysis (in the classical metaphor, these labor supply decisions represent 'one blade of the scissors,' the other blade being the hiring and employment

decisions of firms) and because questions involving labor supply are closely tied to important issues of the public policy (such as the effect of income taxes on how much individuals work). This research has been increasingly sophisticated in economic and statistical modeling. In addition, much more is known today about work patterns than was known in 1960. Some components of the economist's standard model of labor supply (such as the intertemporal substitution elasticity) have been estimated with confidence. However, there remains some disagreement over the values of other key parameters such as the effect across different individuals of increases in wages on hours worked. Most economists probably believe that, for the typical worker, increases in wages generally induce relatively small increases in work hours although researchers would refrain from confident statements about precise magnitudes.

Labor Unions

Labor unions are interest associations of workers in waged employment. They are formed to improve the market situation and the life chances of their members, by representing them in the labor market, at the workplace, and in the polity, and in particular by collectively regulating their members' terms of employment. Unions emerged in the transition to industrial society in the nineteenth century, together with the de-feudalization of work, the rise of free labor markets, and the commodification of labor. While employing modern means of formal organization, they represent an element of traditional collectivism in a market economy and society. Unions have taken a wide variety of forms and adopted different strategies in different historical periods, countries, and sectors. They are therefore favorite subjects of comparative social science.

1. Unions in the Social Sciences

The literature on unions is vast and extends into several disciplines. In the Marxist and socialist tradition, authors in the late nineteenth and early twentieth centuries debated whether and how unionism might contribute to the overthrow of capitalism or, to the contrary, its stabilization. Democratic reformers like Beatrice and Sidney Webb explored the potential contribution of unionism to the governance of a democratic industrial society. Institutional economists, such as Commons and Perlman in the United States or Brentano in Germany, tried to understand the economic causes and consequences of unionization. Neoclassical economists like Böhm-Bawerk explored the capacity of unions to override market prices and achieve a lasting redistribution of resources, while their successors in the 1960s applied theories of monopolistic competition to analyze the impact of collective bargaining on wages (Chamberlain). Early econometric analyses studied the impact of economic fluctuations on union organization and union activities, including strikes (Ashenfelter). The discipline of industrial relations, which grew after World War II in the US (Dunlop) and Britain (Flanders, Clegg), focused on unions as participants in collective bargaining under the 'New Deal' and in the postwar 'mixed economy.' Sociologists took an early interest in the transformation of unions into centralized and bureaucratic mass organizations with a staff of full-time officials (Cassau). Postwar American research on union democracy was in particular interested in the sources of communist influence in unions, while macro-sociological studies have investigated the origins of unionism in the context of social protest movements and their integration in the modern nation-state (Tilly). Political sociology and political science display a lasting interest in the role of unions in the polities of industrialized democracies. Economists study the economic effects of unions, in particular with respect to relative factor prices, inflation, productivity, and employment (Freeman and Medoff, Calmfors and Drifill, Soskice). Similar concerns figured prominently in historical-institutionalist research and theory on neo-corporatism in the political economy of advanced European welfare states (Schmitter, Crouch). Labor law has long been concerned with the rights of unions *vis-à-vis* employers, and with reconciling collective bargaining and collective industrial agreements with civil law and the freedom of trade and contract. Constitutional lawyers, in particular on the European continent, have tried to clarify the status of unions and collective bargaining in relation to the state and public legislation.

2. The Rise of Unionism in Industrial Countries

Unions emerged in conflict with both economic liberalism and political authoritarianism, striving simultaneously for economic regulation and political freedom. As a result, they were originally treated as conspiracies against free trade, the state, or both. But as unions established themselves as effective labor market cartels, they also became suppliers of labor to those employers willing to deal with them, and in this capacity slowly turned into 'managers of industrial discontent' (Flanders). Similarly, while unions represented the interests of a class opposed to the advance of capitalism, their toleration in the course of democratization contributed to the transformation of liberal into organized capitalism, and was central to the institutionalization of compromise between capital and labor. The integration of unionism and working class collectivism in the institutional framework of modern industrial societies turned unions into legitimate intermediary organizations between their members on the one hand and employers and the state on the other, and transformed class conflict into joint regulation of work and employment. It represents the foremost example of the stabilization of the capitalist economy through democratic politics and institution building.

Early unions saw themselves as democratic organizations of self-help and self-government of workers independent from the feudal or bourgeois pre-democratic state. Often they belonged to broader labor movements that included political parties, consumer cooperatives, mutual assistance funds, educational associations, sports clubs, etc. While unions generally resented interference of the state and the law in their internal organization and activities, they differed widely in structure and ideology. Thus, syndicalist and anarcho-syndicalist unions, which in a number of countries remained significant well into the twentieth century, regarded themselves as constituent units of a direct democracy of producers set to replace both capitalist employers and the bureaucratic apparatus of the modern state. These traditions, which equally opposed capitalism and parliamentary democracy and favored direct action over both collective bargaining and political-electoral lobbying, culminated in the militant council movements of World War I and the revolutions following it, especially in the Soviet Union.

Integration of unions in democratic capitalism, and union recognition by governments and employers, was greatly advanced by the two world wars. Economic mobilization and the governance of the war economy required the collaboration of union leaders, who in many countries came to be co-opted into positions of quasi-public authority. Also, enlisted soldiers had to be promised a better life in a fairer society upon their return from the battlefields, and in defeated countries traditional elites were replaced in the aftermath of war by liberal or socialist governments. Generally, the end of World War I brought political democratization and, precipitated by the threat of socialist revolution, widespread acceptance of collective bargaining. But the first postwar settlement proved fragile in countries

like Germany, Japan, Italy, and Spain, where unionism was soon suppressed by authoritarian regimes and replaced with state-controlled mass organizations of workers that were put in charge of administering state social policy. Similarly, in the Soviet Union workers councils were incorporated in a repressive state machinery and unions turned into 'transmission belts' from the state to the working class. In the United States, by comparison, the New Deal extended union organizing rights while the Swedish Social-Democratic government of the 1930s and the British war cabinet of the 1940s began to develop the contours of the labor-inclusive Keynesian welfare state of the second postwar settlement after 1945.

The 'golden age' of capitalism in the second half of the twentieth century saw the worldwide ascendance of a 'mature' type of unionism, centralized at the level of the national state and pursuing economic and social policy goals through collective bargaining and political-electoral lobbying within the confines of capitalism and parliamentary democracy. This development was part of the consolidation of both democratic capitalism and the nation-state in the countries under American hegemony, where legal recognition of unions and free collective bargaining, extensive social welfare provision, a sizeable public sector, and politically guaranteed full employment made possible the coexistence of liberal democracy and the market economy. The normalization of unionism under postwar 'embedded liberalism' (Ruggie) coincided with national regulation and standardization of the employment relationship and of the status of wage earners as distinguished from employers and the self-employed, which in turn corresponded to the advance of industrial mass production. Far-reaching legal and political regulation of the labor market, introduced to insulate employment and employment conditions as much as possible from economic fluctuations, stabilized union power. The worldwide outburst of labor militancy in the late 1960s, which took national union leaders by surprise, further added to union power, as governments, still feeling politically constrained to provide for full employment, more than ever depended on union cooperation for restoring economic and political stability.

Economic, political, and social change in the 1980s and 1990s caused a roll-back of unionism in most countries. In the 1980s, the British government proved that elections could be won even with high levels of unemployment. Under the leadership of the post-New Deal United States, governments also found less politically and economically costly ways to combat inflation than 'social contracts' with union leaders who had often turned out unable to deliver on their promises of wage moderation. Low inflation and high unemployment coincided with deep industrial restructuring, in response to economic internationalization and a new wave of technological change. Gradually this undermined the Fordist organization of work and the normalized employment relationship unions had helped shape and with which they had learned to live comfortably. Also, the breakdown of Communism in the late 1980s eliminated the systemic opposition to capitalism that had made Western governments willing to make concessions to unions after the two world wars. While private sector unionism has almost disappeared in the world's leading economy, the United States, it is, however, still firmly entrenched in many European countries, due to strong institutional supports left over from the social compact of the postwar era.

3. *Union Organization and Union Growth*

The first unions were local protest movements of the 'working poor.' In the mid-nineteenth century, they were superseded by formally organized craft unions of skilled workers which thrived particularly in the liberal political environment of early industrializing Britain and America. Commanding considerable market power, craft unions represented their members mainly through economic action. In addition to maintaining sizeable mutual assistance funds, many of them were cartels that unilaterally fixed the price of their members' services. From the state craft unions did not expect much apart from freedom of organization. While politically liberal, they were socially exclusive. Not only was membership in them reserved to the skilled. To control the labor supply, draft unions also limited apprenticeship training, prevented employers from hiring non-union members for craft jobs ('pre-entry closed shop' for specific 'job territories'), and defended an organization of work that ensured demand for their members' skills (job control unionism).

Where craft unions became firmly established, they survived beyond the second wave of unionization at the end of the century, when the growing masses of unskilled factory workers began to get organized. Given the weak market position of their members, the 'general' unions that undertook to organize the large factories of the beginning age of mass production had to place their hope on the strength of large numbers. They therefore tried to recruit as many members as possible regardless of skill, although where craft unionism was strong, they mostly remained unions of the unskilled. While craft unions preferred a 'voluntarist' mode of operation keeping the state at arm's length, the new general unions emphasized political action and pressed for social legislation and state intervention in the economy.

In Anglo-America where industrialization and democracy had come early, craft and general unions coexisted well into the twentieth century, with the former deeply influencing the practices and ideologies of the latter. By comparison, in late industrializing countries with authoritarian governments and nar-

rowly limited political and economic opportunities for a market pursuit of collective interests, craft unions were mostly absorbed in inclusive 'industrial unions' organized by economic sectors. As these had originated in often-bitter political struggles especially for universal suffrage, their unionism was embedded in universalistic concepts of social and political reform that differed profoundly from craft particularism or American 'business unionism.' Frequently the new unions were allied to political parties, especially socialist and Catholic, and while craft unions had been fragmented by skill, industrial unionism was often fragmented by political orientation. Indeed as authoritarian governments had initially denied them the opportunity to represent their members economically, some of the new unions remained for long subordinate to political parties.

Craft unions, while narrowly based and normally small, were highly centralized where their members faced national labor markets. With the rise of the nation-state industrial unions, representing their members through political action for organizational rights, favorable labor law, and social welfare legislation, also developed nationally centralized structures. In principle, these were usable for centralized collective bargaining as well, in solidaristic egalitarian pursuit of nationally standardized wages and employment conditions. However, getting members to support common demands in spite of often widely different situations at their workplaces required strong organizations. While political ideology helped, the capacity of national unions to aggregate the interests of a diverse membership depended in large part on whether employers were supportive of negotiation at national level. In countries with an established craft legacy bargaining remained mostly decentralized and fragmented as industrial unions had to allow their members independent pursuit of sectional interests, on the model of and in competition with skilled unions. Sometimes, especially in the United States, unskilled unions managed to establish rights to 'job property' for their members as well and enforced on employers their own version of a closed shop, under which new hires had to join the union within a short period or lose their job (post-entry closed shop).

Union organizational development in the nineteenth and twentieth centuries included the rise of national federations of local and sectoral unions, which occurred in close correspondence with the formation of the modern nation-state and the establishment of liberal democracy. It also involved growing independence of unions, not just from governments but also from friendly political parties, enabling even the industrial unions of the European continent to deal with democratically elected governments of conservative political complexion. Related to this was increasing reliance of unions on collective bargaining with employers as their main mode of operation, with either individual firms or employers associations. This presupposed the elimination of 'yellow' company unions controlled by employers as well as recognition of collective bargaining in labor law, for both of which government support was crucial. Collective bargaining, in turn, required that unions established organizational authority over the strike—the collective withdrawal of the labor power of workers from employers—just as political recognition of unions demanded that strikes were called only for economic purposes, abandoning the syndicalist tradition of the 'general' political strike. Union organizational development further involved integrating the growing number of white-collar workers, either in separate unions or inside encompassing industrial unions, which followed different trajectories in different countries and generally remained much less successful than the organization of blue-collar industrial workforces.

The literature offers a variety of explanations for the growth and decline of union membership over time and the differences in union density rates between sectors and countries. Unions tend to be strong in the core sectors of export-oriented manufacturing, like metal engineering, in large establishments, and in the public sector, while they are weak in private services and in small firms. But cross-country differences are considerable, and indeed on hardly any parameter of social structure do developed industrial societies differ as much. While in some Scandinavian countries around 80 percent of wage earners are union members, in France and the US density had fallen to about 10 percent by the end of the twentieth century. And while union membership relative to the workforce declined during the 1980s in the United Kingdom and the Netherlands, it increased in Belgium and Finland. Fluctuations in membership over time can also be enormous, as they were in Britain where in the three years between 1920 and 1923, union density declined from 45 to 30 percent.

Econometric studies have found that in the United States and Britain in particular, union density tended to increase with nominal wages and inflation, while it was negatively affected by unemployment and an already high level of unionization (Bain and Elsheikh). However, studies of this sort cannot explain the variation in unionization between countries, or ruptures in historical continuity. Institutionalist approaches take into account that union growth includes the acquisition by unions of recognized status, based on agreements with employers or the state helping unions recruit members ('union security'). Often such status is gained in exchange for political and economic moderation. Differences in union density then reflect different opportunities for unions to organize and keep members ('workers don't organize unions; unions organize workers'). In addition to the closed shop in its many official and unofficial versions—which makes membership compulsory by making access to employment dependent on it—employers may assist unions in collecting their membership subscriptions.

Similarly, favorable legislation on union recognition or workplace representation through works councils may improve unions' ability to recruit. In some countries, like Switzerland, non-members are legally obliged to pay union dues, and in Belgium and Denmark unions administer parts of the public social insurance system, enabling them to discriminate against non-members and thereby create additional incentives to join.

More generally, the organizing problems of unions may be described in terms of generic problems of collective action in the rational pursuit of group interests. Union achievements, like higher wages or favorable social policy legislation, are often collective goods in that they cannot be withheld from workers who have not contributed to their production. Apart from sentiments of fraternal solidarity, there is then little incentive for workers to join a union, even if they find the outcomes of union activities desirable. Indeed, given the risk that others will 'free-ride,' members may contribute in vain, as the union may not find enough support to be successful. Like other collective organizations, unions therefore typically offer potential members 'outside inducements' (Olson), i.e., benefits other than the collective goods for which they were originally founded, which unlike these can be limited to members (for example, healthcare benefits). They also strive to make membership less voluntary and obligatory, often with the help of the state or the employers.

4. *Unions as Collective Actors*

As intermediary organizations, modern unions represent their members in the labor market, the workplace, and the polity. Depending on their membership, their organizational structures and traditions, and the constraints and opportunities offered by employers and the state, different unions attach different significance to the three arenas and coordinate their activities in them differently.

4.1 *Unions in the Labor Market*

Unionism, and indeed much of modern labor law, assumes that individual workers are at a disadvantage vis-à-vis employers, and that redress of this imbalance requires that workers combine to face their employer as a collectivity. By regularizing wages and conditions of employment, sometimes also through state legislation, unions try to take wages and conditions out of competition, to make the market more predictable and protect workers' living conditions from its fluctuations. In this sense, Polanyi regards unionism as an element of the social counter-movement against the 'satanic mill' of the 'self-regulating market' of early liberalism.

Economists have long debated whether unions can raise wages above market level. Clearly, they can get nominal wage increases that exceed the increase in productivity, which depending on the government's monetary policy may result in either inflation or unemployment. With respect to the wage structure, in fragmented union systems skilled unions may use their independence to defend wage differentials, causing a wide wage spread between skill groups and industries. Fragmented ('competitive') bargaining may also enable well-organized groups of strategically placed unskilled workers to make high relative wage gains, which in turn may result in a 'leapfrogging' pattern of general, and potentially inflationary, wage increases. Wage differentials are also high in economies in which unions have little or no influence.

By comparison, industrial or general unions typically entertain an egalitarian ideology and strive to compress wage differentials, raising the wages of their less well-paid members more than those of the others. The result tends to be increased capital intensity and unemployment at the lower end of the labor market. Industrial unions therefore favor extensive training and retraining, funded by employers or the state, to increase the productivity of the less skilled to a level where they can earn the high wages negotiated for them. In favorable circumstances, this may lead to a general upgrading of a country or sector's production system, in the direction of more skill intensive and less price competitive production.

Since the 1970s, there has been a debate on the relationship between centralization of collective bargaining and various dimensions of macro-economic performance, such as inflation, growth and employment. In the 1970s centralized bargaining by national or industrial unions was believed by many to be more economically beneficial than fragmented bargaining, as it made it more difficult for bargainers to disregard the costs of redistributive bargaining or productivity-restraining work rules. Later it was suggested that bargaining agents in a decentralized wage setting system were more likely to be disciplined by market pressures, the problem being intermediate levels of centralization and unions both large enough to override the market, and small enough to be able to externalize the costs of their behavior to society. Statistical analyses have remained inconclusive and suggest that the economic effects of bargaining structures are highly conditional on economic and institutional circumstances.

4.2 *Unions in the Workplace*

Comparative research suggests that employers are willing to agree to centralized bargaining if this helps them keep unions out of the workplace. Workplace unionism, especially in a craft tradition, detracts from managerial prerogative and may interfere with management attempts to increase productivity. On the

other hand, even industrial unions need to be present in the workplace, if only to recruit members, monitor the implementation of collective agreements, and generally insert themselves in the governance of the employment relationship and the 'wage-effort bargain' inherent in the labor process. Balancing central and workplace representation, or external and internal union organization, was and is one of the main problems of unionism and industrial relations.

Least of all employers seem to like multi-unionism in the workplace. This has often led to agreement with industrial unions on unified arrangements for plant level workforce representation, like in Italy. In some countries, like the US, single-union representation is established by a legal procedure. In others workplace unionism is merged into institutions of legally based participation, giving works councils elected by the workforce as a whole rights to information, consultation, and co-decision making while ensuring that management has a single counterpart with which to negotiate. While works councils in most countries cannot call strikes, they tend to have close relations with internal and external unions, not least since most of their members are usually also union members.

In a number of Asian countries, unions have evolved into 'enterprise unions' that are only loosely federated above enterprise level. This corresponds to an environment of closed internal labor markets and lifetime employment of core workforces. Enterprise unions tend to be highly cooperative with managerial efforts to increase productivity and competitiveness as they represent the close community of fate between their members and the enterprise that employs them. Often their officials are managers whose career is advanced by serving for a time in a union position. Works councils in European countries also tend to cooperate with management. Unlike enterprise unions, however, they exist next to an external union that can call strikes without regard to the competitive position of individual workplaces.

The economic effects of different forms of workplace unionism are still being debated. For some time, decentralized unionism and workplace bargaining were associated with high strike rates whereas centralized and politically influential unions, like those in Scandinavia, were found to be highly effective without much recourse to strikes. Especially where distributive wage bargaining is moved to the national or industrial level, or where distributive conflict is suspended by jointly faced competitive market pressures, workplace representation was shown to enhance efficiency, among other things by enabling workers to voice complaints as an alternative to quitting. The same effect has been attributed to works councils. By comparison, in countries with adversarial industrial relations traditions, external labor markets, decentralized wage bargaining, freedom of workplace unions to call strikes, and a history of craft unionism and restrictive practices, workplace unionism came to be regarded in the 1960s and 1970s as a source of inefficiency. Here employers began to devise their own structures of workplace cooperation and 'worker involvement,' in the context of the developing practice of 'human resource management,' which often but not necessarily presupposes or aims at a 'union-free environment.'

4.3 Unions in the Polity

In most European countries, the rise of unionism was closely intertwined with nation-building and state formation. T. H. Marshal regards unionism as a step in the evolution from civil, to political, to social rights of citizenship, with unions using political rights to collective organization in the pursuit of social rights, albeit in the civil sphere of the marketplace and through freely negotiated—collective—contracts ('industrial citizenship'). As early repression of unions gave way to inclusion in shared public spaces (Crouch), unions became firmly integrated in the social and political order of the Western European nation-state, especially under the second postwar settlement after 1945.

The high point of union inclusion in advanced industrial countries was the 'neo-corporatist' period of the 1970s and early 1980s. Especially in countries with a tradition of political unionism and centralized collective bargaining, unions were able to get major concessions from governments and employers in 'political exchange' for wage restraint, which in turn was to enable governments to protect full employment with Keynesian means without having to accept excessive rates of inflation ('incomes policies'). Among the concessions gained by unions in this period were legislation on union recognition and access to the workplace; various other forms of 'union security'; legal extension of collective agreements to all firms in an industry; higher social security and public pension benefits; and industrial democracy legislation. Neo-corporatism was more likely to work where governments were of a social democratic complexion; but most conservative governments were also eager not to antagonize the unions. The more politically powerful unions became under corporatist arrangements, the lower as a rule was the strike rate as strong unions were able to get in the political arena what others had to struggle for, with uncertain event, in the industrial arena.

The historically close involvement of union movements with their respective nation-states explains to a large extent why unions and collective bargaining have so far resisted economic pressures for institutional convergence. In fact, the structure of unionism and its status inside its institutional context are an important dimension distinguishing between the different 'models of capitalism' that have attracted attention in the 1990s. The lasting symbiosis between union move-

ments and national states also accounts in large parts for the weakness of international unionism. Such weakness is found even in the European Union, where in spite of deep economic integration national unions have remained highly distinctive in their organizational structures and *modus operandi*, and are jealously guarding their independence.

5. *The Prospects of Unionism Today*

Much of the literature on unions in the early 1960s observed and predicted a decline of unionism in leading industrial societies. In most Western countries, with the notable exception of the United States where union decline continued unabated, this was contradicted by the 'hot autumns' of 1968 and 1969, which were followed by a sharp reversal of membership losses and by unprecedented influence of unions in politics. In the 1990s, however, union membership and power were again declining worldwide. With the American private economy on the way to effective de-unionization, the British government in the 1980s attacked unions' legal and institutional supports, with considerable success. Outside the Anglo-American world, union influence was weakened by the end of politically guaranteed full employment combined with intensified international competition, while the growing importance of the service sector and the 'knowledge economy' and the rise of a more diverse and better educated workforce made it more difficult for unions to recruit new members. Even where institutional conditions remained unchanged, unionism tended to be increasingly confined to the traditional sectors of the economy, which have long been shrinking in size and importance.

In their history unions have become deeply involved in the functional and social integration of the modern nation-state: in the national standardization of employment practices, the organization of redistributive solidarity at national level, and the political governance of the national economy. The decay of the second postwar settlement coincides with strong market pressures for more flexible modes of governance, less political interference, and internationalization of economic transactions. It is not clear whether and how unions, and indeed the nation-state itself, will find a response to the de-nationalization of the global economy. With their membership aging, unions may become defenders of an industrial employment and social security regime that no longer fits the needs of the rising post-industrial sector of the workforce. Being unattractive to the winners of structural change in the highly skilled and female segments of the labor force, unions also seem less than successful in organizing the new underclass of low-paid service workers, many of them immigrants, that has been growing for some time in many industrial societies.

Labor, Division of

Division of labor is a feature of social structuring found in all human societies. Its form varies widely and changes over time. In a narrow sense the concept is used in an economic context to describe the breakdown of a complex task into a number of detailed and specialized tasks. In a social context the meaning is much wider, because labor and hence the consequences of its division impacts decisively societal structures. An example familiar to everyone is the household division of labor. This refers to the differential allocation of tasks to women and men in the family and in childrearing. Following a definition of *labor*, this article will consider the complexity of this concept by focusing on different levels and dimensions of the *division of labor*. Then its role in social development will be dealt with. The division of labor in modern capitalist-industrial societies will be granted the main attention. Finally, the development of social thought on the concept will be briefly examined.

1. *Labor*

Labor or work can be defined as purposeful activity necessary in any human society to secure its existence. Only humans do work in the sense of using creativity, conceptual and analytical thinking together with manual aptitudes to transform nature for their use (see *Work and Labor: History of the Concept*). A distinction between work and labor is often made. The word 'labor' is derived from the Latin *labor* implying toil and distress, and hence labor alludes to arduous work, done under some duress and control by others. But the use of words is in fact not that strict. With regard to the specialization of activities, it is common to speak of 'division of labor' (and not of 'division of work'). Similarly, it is common for example to speak of the 'labor process,' the 'labor market,' the 'labor movement' (including the 'labor unions' in the economic, the 'labor party' in the political sphere), or the 'International Labor Organization' (ILO) and the expression 'work' is not used here.

2. *Divisions of Labor*

2.1 *Concepts: Economic Division of Labor vs. Social Division of Labor*

All empirical evidence shows that labor or work always entails some specialization. *Division of labor* refers to separation of activities and the specialized allocation to different individuals. It is a universal trait of human existence. This does not, however, imply that it is caused by natural differences (biological differences between women and men, for example). Division of labor is always human-made, its forms are socially shaped.

Any definition of division of labor basically must start with the recognition of two different connotations. In its narrow and simple sense, the concept is used in an *economic context*. It describes the splitting up of a complex productive task into a number of specialized, simpler tasks. The most renowned example is that of Adam Smith (1776) for pin needle production. The *increase in productivity* is exactly the ultimate reason for the separation and specialization of tasks in manufacturing.

This form is known as *detailed* or *technical division of labor*. It made its appearance on the stage of human history with all-pervasive force only three hundred years ago in Europe with the establishment of conditions not in use previously: that is manufacturing and the 'invention' of capitalist principles of production.

In a broad sense, division of labor is a precondition for conceptualizing society, as used in a *social* or *sociological context*. Reference to the *social division of labor* implies divisions at different levels of society which comprise its complex structure. Here the attention is on social differentiation such as class, gender, or ethnicity; on the role of power; on forces of social cohesion and disintegration; and on the importance of solidarity and morale. All the major institutions of a modern complex society play a part in the *social division of labor*: in the *economic system* with its elements like the market, competition, capital, contract law, labor market, even differences between (paid) employment and non-paid labor; in the *political system* with its various specialized institutions of the legislative, the executive, and the judiciary; in the *cultural system* with its various socializing institutions for the creation of skills, value orientations, and spiritual meaning.

In a schematic form the *concepts* may be listed this way:

economic division of labor	*social division of labor*
detailed division of labor (e.g., technical division of labor)	*division of labor* (e.g., by gender, occupations)

2.2 *Levels*

It is clear from the above that division of labor is a complex concept and can refer to different levels of human activity. It extends from the household or family on the *micro level*, through work organizations like enterprises on the *meso* (*intermediate*) *level*, divisions in society at large on the *macro level*, to the entire world on the *global level*. Examples of divisions of labor on the various levels are the domestic division of labor, the organizational division of labor, the occupational division of labor, or the international division of labor.

Here is an overview on the levels in schematic form:

Micro-level: e.g., domestic or familial division of labor
Meso- (*intermediate*) *level*: e.g., organizational division of labor
Macro-level: e.g., occupational division of labor
Global level: e.g., international division of labor

2.3 *Dimensions*

It is necessary to trace division of labor in various different dimensions. The most obvious dimension is a broad division of labor between women and men, which all known societies exhibit in some manner or other. This *sexual* (or *gendered*) *division of labor* is obviously important in the area of work, but it also reaches beyond that to social, political, cultural, and religious functions.

Any analysis of the social structure of a society, or a comparative study of different societies, must certainly consider the distinction between these varying dimensions. In addition, some dimensions are relevant at more than one level. The sexual division of labor,

for example, is of tremendous importance at the domestic or family level, but it also plays an important role in the economic realm. It is inseparably connected with opportunities and status in employment on the societal level, and is in evidence even on the international level. (When, for example, the work of British or German male textile workers is nowadays performed by possibly lower paid women in developing countries).

An overview of the more important *dimensions* of the division of labor in schematic form:

division of labor by sex (or *gender*)
division of labor by age
division of labor by occupations
division of labor by skill
division of labor by hierarchy
division of labor by space
division of labor by time.

3. *Division of Labor and Development*

3.1 *The Basis for Complexity*

Taking the broad sweep of human history, the contrast between very simple and vastly extended complex social structures springs to mind. Division of labor and concomitant social differentiation are the processes that underlie shifts towards more complex societies.

Until around ten thousand years ago hunting and gathering bands were small and there was little role specialization beyond a division of labor by sex and age. Only since settling down to agrarian provisioning for survival has human social life slowly developed towards the complexity known from recorded history.

3.2 *Traditional and Modern Societies*

Agrarian (pre-industrial) societies are characterized by the fact that the overwhelming portion of productive tasks are performed in agriculture and self-provisioning of the household. The (extended) *family* is also the productive unit. The social division of labor is low, insofar as only a small proportion of the population is engaged in other occupations, such as specialized crafts, trading, military functions, and religion. *Tradition* is of eminent importance. The distribution of functions in the societal labor process is based on *ascription* (being born into ones role and status), not on *achievement*. The pre-condition for a considerable increase in the division of labor is production of a larger surplus beyond the self-provisioning of the individual families (see *Societies, Types of*).

There was, however, no unilinear progression in history towards ever-greater complexity, no continuous evolution from primitive to modern societies. The development of social forms shows long periods of remission and reversals, as well as change proceeding along more than one line.

Traditional agrarian societies typically are *feudal societies*, and the division of labor is often based on coercion and power. Serfdom (especially among the agrarian population) is widespread, and slavery (for labor that is painful and exacting) is not uncommon.

For thousands of years in human history static forces were dominant in the division of labor. This came to an abrupt end when, in Europe (beginning in England), *capitalism* and *industrialization* began to transform the world. The last two to three hundred years have seen by far more changes in the division of labor than all the previous ages. Compared with development up to then, capitalist transformation marks a quantum leap for the division of labor.

4. *The Division of Labor in Modern Societies*

4.1 *The Institutional Frame*

The capitalist-industrial mode of production was established on the basis of a number of institutions which did not previously exist. There is a very close interconnection between the division of labor and these institutions. The following can be listed as the major specific conditions (e.g., Weber 1922/1968; Marx 1867/1976) (see *Capitalism*).

4.1.1 Separation of household and workplace. With the introduction of manufacturing in special premises, gainful employment and the family become separated. A previously unknown division is introduced between the *public sphere* of work and the *private sphere* of home. The function of the *family* (or the household) changes dramatically as it is no longer a combined unit of production and reproduction. The division implies the separation between *unpaid labor* in the household and *paid labor* in the workplace. This is responsible for a thorough change in the *sexual division of labor*, as it provides a new basis for power relations in the family and for the *gender typing* in employment.

4.1.2 Concentration of labor in the manufacture and the factory. Assembling of workers in great numbers in one place under one direction was the prerequisite to splitting up complex craft work into a multitude of detailed tasks. With this *detailed division of labor*, enormous gains in productivity were possible. This usage of labor carries a number of (economic) advantages: unskilled workers who receive relatively low wages and are easily replaceable can be engaged; and, control over speed and output is easy. Fragmentation into simple repetitive functions is also the basis

for the subsequent mechanization and automation which again pushes productive output. However, the price paid for rising productivity is *alienation* (see *Alienation, Sociology of*).

4.1.3 Private property. In the process of industrialization, property acquires a new social function and is important for the division of labor in two respects. First, it provides for those who plan and control the *legitimacy* to enforce the manufacturing (detailed) division of labor. Second, it provides the basis for the accumulation of wealth. *Profit* becomes the main motive for organizing a labor process. This implies that the social function and the importance of *money* changes completely: from a generalized exchange medium on local markets to a carrier of value and power that makes the world go round.

4.1.4 Free labor. A *labor market*, where labor can be bought and sold as a commodity, was not common in human history. Earlier times depended on domination and power for the use of labor that was often unfree labor (patriarchy, serfdom, slavery). Those were the typical characteristics of a *forced division of labor*. The modern development relies on free contracting, i.e., on *wage labor*. For labor, this implies that social relations of a double character become relevant: on the labor market, the relation is between equals, whereas, inside the workshop, the relation is one of subjugation under domination and power (Rueschemeyer 1986).

4.1.5 Liberalization of markets and competition. The importance of liberalism in greatly increasing the wealth-creating capacity of a nation was strongly emphasized in the classical 'political economy.' Unrestrained by administrative rules of government, a free market encourages producers to specialize in activities where they have a relative or absolute productive advantage. Through specialization, they benefit from greater dexterity, more efficient use of materials, time, expertise, and technology. At the same time, the invisible hand of competition penalizes ineffective producers by removing them from the market and encourages the rational (cost-effective) exchange of goods and services.

4.1.6 Application of science, technological change, mechanization, and automation. In the pursuit of profit and under the constant pressure of competition, science is applied systematically for the creation of ever more sophisticated machines and procedures to render production processes more efficient. Technological change thus becomes a permanent feature of working life. Human labor that remains in the process is forced to fill the gaps left by machinery and to adapt constantly to changing requirements.

4.2 Division of Labor and the Dynamics of Change

4.2.1 Structural change of society. Change has remained a fundamental feature of the division of labor ever since industrialization altered occupational structures in an unprecedented manner. This in turn affects division of labor on all levels, and in all dimensions. In the last decades the highly developed societies have changed to *post-industrial societies*. Leaving industrial production behind as the major field for employment has ushered in the *service society* or *knowledge society*. The occupational division of labor expands into new fields. Provision of knowledge-driven services, evaluations, information, guidance, analysis, etc. outnumbers now by far industrial production work. The huge diversification of the labor structure through industrialism and the rise of service and knowledge work is reflected in the fact that up to 30,000 distinct jobs are listed now in some countries, as compared to no more than 50 crafts and trades in pre-industrial societies.

Knowledge and software have become the main themes in the 'new economy' (Leadbeater 1999). Increases in the professional level of many jobs and the professions as such gain importance as knowledge-occupations (Lane et al. 2000). Production work and hardware decrease, relatively speaking, in importance. This is reflected in the continuous decline in the share of blue-collar work and the growth of white-collar work. Often, manual labor is either relocated in other countries or is eliminated altogether through automation. Together with the often-practised outsourcing of work functions, this brings about considerable shifts for the spatial (or geographical) division of labor. The new information and communication technologies have furthered these trends of global expansion of the division of labor, under which the whole world potentially becomes one workshop.

4.2.2 Changes in work organization. Assembling people in large numbers and assigning them detailed tasks requires coordination and planning to reach the common goal. As a result, organizations have become an indispensable feature of modern life in many areas. At the same time they are of foremost importance for the conditions of work.

Organization theory and management have developed into vast fields of their own. This has developed on three major influences that shaped the division of labor thoroughly.

Emphasis on 'rationality' was the main concern of Max Weber (1922/1968) when he developed the principles of *bureaucracy* as a design for modern administration. For production work, *The Principles of Scientific Management* were developed by Frederick Taylor (1911) which aimed at improved industrial efficiency. Among Taylor's principles, the separation of planning work from execution imposed a division of labor that relied on tight control and hierarchy, destruction of skills and discretion of the workers. Taylor's whole system based the division of labor on a low level of *trust*. The industrialist Henry Ford added the mechanical disciplining power of the assembly line. Furthermore, he combined *mass production* with the cultivation of *mass markets*. Since then, bureaucratic organisation, *Taylorism* and *Fordism*, have been so successful that they shaped the form of the division of labor and working conditions in industry all over the world. This includes the communist or state-socialist countries which thus did not seize their unique opportunity to realize a different form for the division of labor (e.g., Sayer and Walker 1992). Widespread application of Taylorist and Fordist principles of work rationalization led to the 'degradation of work' (Braverman 1974) in mass industry in the twentieth century. The impact on working conditions has been discussed deeply in the ensuing 'labor process debate.'

The grounds for a *New Division of Labour* (Littek and Charles 1995) arose from a number of far reaching changes in the markets, a new quality of competition, and growing pressure for flexibility and customer services which together marked the 'end of mass production.' The abolition of detailed fragmentation of work, tight control, and discretionary power of the hierarchy in order to raise creativity, quality standards, and service orientation were important for the new division of labor. Elements that have gained in importance are decentralization, networking, flexibility, upgraded skills, motivation, self-organization, responsibility, and autonomy. These are conditions which are based on *trust* as a means of coordination, quite the opposite to the systems of Taylor and Ford. The new model is a 'learning organization' with self-regulation of autonomous individuals.

The spread of these new forms was pushed by the technological development which made simple and repetitive tasks redundant though automation. The trend to these new forms, flexible specialization and self-regulated creativity, was further encouraged and enhanced with the development of the 'new economy' (see Sect. 4.2.1).

4.3 Division of Labor, Social Differentiation, and Cohesion

Social differentiation is so closely connected with the division of labor that they could almost be treated as synonymous. The wide development of the division of labor under modern industrialism (mostly in capitalist, but also in socialist or communist form) caused a similarly wide expansion of *differentiation* in society. Along with this expansion, social and economic *interdependence* has increased enormously: each individual in society is dependent on so many others for its existence.

Social differentiation itself has to be examined from various angles, the most important of which are discussed below.

Class and *social stratification* are unthinkable without a connection to the division of labor. They are relevant as a pre-condition, as well as a result of, the division of labor. With regard to *class*, most social scientists would agree that the number of classes needed to describe societal structure in complex societies has to be extended beyond the two basic ones (bourgeoisie and wage-labor) Marx had in mind. Often the concept is replaced altogether by *stratification*. Nevertheless, ownership of productive property is important as a pre-condition for the right to organize labor or otherwise being organized. The gains from economic activity shape wealth distribution. As a result of the differentiated division of labor, the *inequality* of the wealth distribution has grown in most countries over time. At the global level, a similar trend of growing disparity can be observed in the distribution of wealth between rich industrialized countries and poorer developing countries as a result of *international division of labor* in practice.

As a major element in differentiation, *gender* remains a cause for inequality. Even though patriarchy has lost ground and equal opportunity rights are enforced in most modern societies, the effects of a *gendered division of labor* still are to be found in practically all societies. These often include lower income, confinement to lower skilled jobs, reduced access to leading functions, broader employment in precarious jobs and in part time, and so on. This can be explained by the fact that the *household* continues to be the basic social unit around which people conduct their lives (Pahl 1984), and that an unequal distribution of tasks in household work between women and men obviously continues to be practiced more or less throughout the world (e.g., Hakim 1996).

Finally, *social integration and cohesion* become much more important with the growth in inequality that follows the extension of the division of labor. *Cooperation* (as a passive medium) and *coordination* (as an active medium) are necessary to counterbalance the diverging forces and to secure social integration at least at a minimum level. Social integration on the societal level can be based above all on two institutions: trust, motivation, values on the one hand and power on the other (which is based on legitimacy in modern states). The strategy in most highly developed countries is to secure *both* by providing a minimum of social security and administering some

form of social regulation to the market economy. A socially responsible division of labor thus may be seen as the guiding vision for modern countries.

5. *Division of Labor in Social Thought*

Because the division of labor is a fundamental structuring principle of complex societies, it has played an important role in theories about society and social relations. Interest in division of labor was particularly strong in the late eighteenth and the nineteenth century in connection with the unprecedented social changes brought about by capitalist industrialism. This was also the time of the formation of *sociology* and *political economy*. Later, the division of labor as a category in social theory was somewhat neglected (Sayer and Walker 1992), but interest has risen again in the last 25 years. This is mainly due to:

— a broad expansion of studies into the sexual or gendered division of labor and the connections between household work and employment (see *Gender, Economics of*);

— studies on the so-called globalization, which extends the reach of economic activities to a scale of global or international division of labor based on Western business values (see *Globality*);

— studies on the growing pressure for labor flexibility in the new economy, which indicates a loss of dependable employment conditions and of elements that formerly structured work like defined time, space, or occupation (see *Industrial Sociology*).

In the history of theory on the division of labor, a number of key authors should be mentioned *Ancient Greek philosophy*, and particularly Plato and Aristotle, recognized the division of labor or specialization in occupations as a necessity for social well-being. This was linked to exchange which requires a market and a currency (as a medium of exchange). The socializing effect stood in the foreground for Aristotle when he noted that no society made up of two physicians could emerge, but a society containing a physician, a farmer, and other occupations would exist.

At the beginning of modern times, *Adam Smith* (1723–1790) is of the utmost importance for the development of a discipline which became known as political economy. No one has ever placed more emphasis on the division of labor. For Smith, it is practically the only factor driving economic progress. In his book *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776), Smith explored the possibilities for raising productivity along two avenues: the detailed division of labor within the manufacturing process, and the liberalization of markets in the economy as a whole. He recognized the egoistic pursuit of individual interests, but not any feelings of altruism or care for the needs of others, as the driving force of economic activity.

For his contemporary Adam Ferguson (1723–1816), social differentiation through the division of labor stood in the foreground, mainly with regard to occupational differentiation. He considered it as a specific structuring type for human solidarity, as did Durkheim.

Both the economic and the social aspects of the division of labor were analyzed by Karl Marx (1809–83). In a similar way to the classical political economy theorists. Marx elaborated the enormous potential of labor for productivity in manufacturing and big industry. But, drawing on very similar insights, he came to a different conclusion to that of Smith: that there is a *fundamental difference* between division of labor among autonomous parties, 'division of labor in society,' and a division of labor that takes place under the authority and in the interest of one dominant party, 'division of labor in manufacture.' The contrast between 'anarchy' of the market (reflected in the social division of labor) and 'despotism' in the workshop (reflected in the manufacturing division of labor) was highlighted by Marx as mutual conditions and an essential feature of *capitalism* (1867). The separation between owners and non-owners of the means of production found recognition as the basis for class formation in society and for the asymmetry of power in the labor process. He was also strongly concerned with *deskilling* (cf. Braverman 1974) and with *alienation* as a result of the specific capitalist fragmentation of work.

Emile Durkheim (1858–1917), like Ferguson, directed attention mainly to the social division of labor (1893), for which he above all gained reputation. In contrast to more pessimistic views, he recognized that division of labor does not have to create disintegration, but may have a socializing effect. Durkheim thus discerns *mechanic solidarity* in 'primitive' societies from *organic solidarity* in 'complex' societies, while observing the danger of *anomie* and of a 'forced division of labor' in modern development (see *Solidarity: History of the Concept*).

In his analysis of the modern (Western) world Max Weber reached findings very similar to those of Marx. He also held (1922) that capitalist division of labor is something quite specific, based on the role of private property, on profit as the motive for production, and on the application of rational organizing principles. However, he put the weight differently. Weber was interested mainly in fundamental prerequisites of 'modernity,' among which legitimate power and 'rationalization' of all spheres of social life (including dependable rational administration in the form of 'bureaucracy') are of importance.

The *division* of labor by gender or sex received only scant attention from the so-called founding fathers of these theories. Among the few exceptions were Friedrich Engels and Thorstein Veblen. However, attention to this theme has changed considerably over the last decades with the emergence of an

extensive literature of feminist analysis or gender studies (see e.g., Hakim 1996; Pahl 1984).

Laboratory Experiment: Methodology

Experiments are special empirical investigations. They differ from nonexperimental empirical research methods. This article examines this difference (see Sect. 1).

Many researchers feel that only the experimental method offers the advantage of specifying causes and effects. This advantage is based on the unique possibility of controlling extraneous variables that can invalidate the empirical results (see Sect. 2).

By means of this control, an attempt is made to meet the various quality criteria of an experiment. The criteria of internal and external validity were developed within the context of an inductivistic theory, which has been criticized. Sect. 3 presents an alternative deductivistic theory of experiments.

Books dealing with the experimental method refer to the ideal control experiment. Results of empirical studies show the experiment to be a social interaction between the experimenter and the subject and thus to differ greatly from the ideal experiment. Sect. 4 focuses on these differences and their consequences for experimental research in the area of social and behavioral sciences. The experiment has been criticized for various other reasons (see Sect. 5).

1. Experimental vs. Nonexperimental Research

Let us use an example to illustrate the difference between experimental and nonexperimental research. The example concerns whether a specific film documenting the life of Jews in the Warsaw Ghetto affects the attitude of viewers towards Jews. A first study investigates the attitude of subjects who already had seen the film, and compares it to the attitude of subjects who had not. Imagine that this comparison shows that those who had seen the film have a more positive attitude towards Jews. A second study comes to the same conclusion, but in this study the investigator randomly assigns the subjects to viewing the 'film' (experimental condition) or to a 'no film' control condition and then measures their attitudes.

Both studies include two variables. The first variable is dichotomous ('film viewed' vs. 'film not viewed'), whereas the second (social attitude) has more than two values. How can the result of the first study be interpreted? Does the film positively influence attitude, or did those who watched the film have a more positive attitude towards Jews prior to the study? This question cannot be answered. It is therefore impossible to classify the variables as independent and dependent. In the second study, the investigator manipulates the first variable and randomly assigns the subjects to the 'film' and 'no film' conditions using what is in essence, a coin toss. In this way he creates a temporal sequence between the manipulated conditions (independent variable) and the dependent variable 'social attitude.' The subjects are randomly assigned to the conditions in order to prevent pre-experimental attitudes towards Jews differing between the two groups of participants. The result of this study can be interpreted in such a way that the viewing of the film had a positive causal effect on the attitude.

The second study is an example of experimental research. An experiment can be defined by the following criteria. The experimenter creates the con-

ditions, systematically varies them, and applies the principle of randomization. Experiments exhibit at least one independent and at least one dependent variable. The same also applies to quasiexperiments, though here the subjects are by definition, not assigned to conditions according to the principle of randomization (Cook and Campbell 1979). By contrast, the first study is an example of a nonexperimental, correlational study. The variable, film/no film, was not manipulated (varied) but selected by the investigator. The characteristic of 'randomization' is also missing. 'Selected' means that the investigator selected subjects for the study who already had assigned themselves to the conditions.

The terminology just outlined is widely accepted. However, sometimes the term 'experiment' is used with an adjunct. In these cases, the study being referred to is not always an experiment as defined above. This applies, for example, to the term 'ex *post facto* experiment' (Chapin 1947), where the conditions are not manipulated but selected by the investigator. The ex *post facto* experiment differs from a correlational study in that the former includes subsequent controls in order to permit the inference of a cause-and-effect relationship. A criticism of this procedure can be found in Campbell and Stanley (1963). On the other hand, the terms 'laboratory experiment' and 'field experiment' refer to true experiments. The adjuncts refer to different settings in which the experiments take place.

The present article deals with true (randomized) laboratory experiments and excludes other research methods. It describes the principles of experimentation in ways that are independent of any given discipline within the social and behavioral sciences.

2. *Experimental Error and Experimental Validity*

Not all research questions can be experimentally examined. Certain variables such as sex and age cannot be experimentally manipulated. Thus, if the relationship between age and intelligence is of interest, there is no opportunity for experimentation. However, this opportunity did exist for studying whether a specific film influences attitudes towards Jews. In the opinion of many researchers, such an opportunity should be taken because the experiment is superior to other methods for defending causal interpretations (e.g., Carlsmith et al. 1976). Random assignment permits us to conclude that viewing the film is the cause of the more positive attitude (see *Causation (Theories and Models): Conceptions in the Social Sciences*).

Experiments are subject to errors that jeopardize interpreting the relationship between an independent and dependent variable as unequivocally causal. A differentiation must be made between systematic and random errors (Cox 1961). An internal systematic error is present if the subjects who are observed under various experimental conditions also differ with respect to other variables. In this case the independent variable is confounded with extraneous variables. The criterion of internal validity (Campbell and Stanley 1963) has not then been met (see *Internal Validity*).

An external systematic error is present if the conditions of the experiment deviate 'from the conditions under which it is proposed to apply the conclusions from the experiment' (Cox 1961, p. 44). Such an error would exist if the experiment in the example given in Sect. 1 was performed using college students, but the conclusions regarding the effect of the film were not limited to persons with a higher education. In cases of external errors, the criterion of external validity (Campbell and Stanley 1963) has not been met (see *External Validity*).

Although random errors are not correlated with the independent variable, their control is important. Random errors affect the variation of the dependent variable within the experimental and control conditions. The attitude values of the subjects within the experimental condition 'film' deviate more or less from a mean, and the same applies to the attitudes under the control condition 'no film.' These dispersions are the result of so-called random errors. The smaller these dispersions are, the greater the precision of the experiment will be (Bredenkamp 1969). Since the relationship between the independent and dependent variable is statistically analyzed, the reduction of the dispersion resulting from random errors is very important. The concept of a random error differs from that of an error of measurement in classical test theory (see *Classical (Psychometric) Test Theory*). The dispersion of the random errors within the experimental and control conditions includes not merely the variance of the measurement errors, but also that of the true scores as defined in classical test theory.

2.1 *Internal Validity*

Controls to ensure internal validity promote an unequivocal causal interpretation of the relationship between the independent and dependent variables. In order to avoid the confounding of a known extraneous variable with the independent variable, the control techniques of 'elimination' and 'constancy of conditions' are employed. An internal error exists, for example, if a female experimenter measures the attitude of the subjects under the experimental condition, while a male experimenter measures the attitude under the control condition. The sex of the experimenter may have an effect on the dependent variable. To control this error, a single experimenter could collect all the data (constancy of conditions). An extraneous variable is eliminated, for example, if background noise that might reduce the audibility of speech is removed.

Unknown extraneous variables can be controlled by randomization. Randomization ensures that the expected values of the extraneous variables are identical under different conditions. Specific instructions exist concerning the random assignment of the subjects to the experimental conditions (e.gq., Keppel 1973 see *Random Assignment: Implementation in Complex Field Settings*).

Despite these controls, there remains the possibility that a factor is present that jeopardizes the internal validity of the experiment. Thus, for example, simply watching a film—regardless of its content—may have an effect on the social attitude. An experimenter who compares the attitudes under the conditions of film/no film, will overlook this possible error, even if the method of randomization was employed to control internal errors. There should therefore be at least one further condition included under which subjects view a film that is neutral with regard to its attitude toward Jews.

2.2 External Validity

In their highly influential article on the evaluation of experimental and quasi-experimental designs, Campbell and Stanley (1963) also introduced the criterion of external validity. External validity asks the question of generalizability: To what populations, variables, and settings can the experimental effect be generalized? Holding an extraneous variable constant in order to control internal errors always brings along the risk of reducing the external validity of an experiment. If a single experimenter performs the experiment on social attitudes towards Jews, the observed effect might then exist for this experimenter only. In order to examine this question, a second independent variable must be added to the experiment as a control factor so that its effects can be separated from the effects of the experimental independent variable. The control factor is introduced in such a way that it is not confounded with the experimental independent variable (see *Control Variable in Research*).

Of critical importance to external validity is the finding that the more positive attitude resulting from the 'Ghetto film' condition only applies to certain experimenters, not others. This is an example of a so-called 'disordinal interaction' between two independent variables (Bracht and Glass 1968). An interaction is called ordinal if the more positive attitude under the 'Ghetto film' condition occurs with all experimenters, but to varying degrees. In this case, who the experimenter is influences the dependent variable differentially by correlation, but the causal sign of the difference stays the same across all experimenters. The analysis of variance is frequently used for the statistical analysis of multifactorial experiments (e.g., Keppel 1973), and it can determine whether an interaction between the independent variables is present. However, it cannot identify the type of interaction involved.

Only disordinal interactions are problematic for the external validity of an experiment because they identify situations where the causal sign between the conditions of an independent variable varies, being positive with some experimenters in the example chosen but negative with others. Thus, identifying the type of interaction is important, and statistical procedures for doing this are presented in Bredenkamp (1982).

Questions about the population to which an experimental effect can be generalized often concern disordinal interactions (Bracht and Glass 1968). If only persons with college education participate in an experiment, then its external validity is endangered. It would be better to include variation in the level of education in the experiment as a control factor.

The question concerning the variables to which an experimental effect can be generalized presumes that these variables are fallible indicators of a theoretical construct. 'Social attitude' is a construct that can be operationalized in diverse ways. If different dependent variables, all assumed to be indicators of the same construct, are included in the investigation, it is called a multivariate experiment. This type of experiment allows us to examine whether the effects observed for a specific dependent variable also apply to other indicators of the same construct. Indeed, one could also compare several experiments using different indicators of the same construct (Bredenkamp 1980). In order to avoid a mono-operation bias, wherever it is feasible, a given construct should be operationalized in different ways (Cook and Campbell 1979).

Whether an experimental effect can be generalized to experimenters other than those used in a study touches on only one aspect of the setting in which a cause–effect relationship is examined. With regard to generalizability, field experiments are more externally valid than laboratory experiments whose validity for 'the real world' is questionable. Although laboratory experiments offer the advantage of controlling internal errors, they have the disadvantage of limited external validity. However, such considerations presuppose an inductivistic theory of experimental validity, and this has been criticized (see Sect. 3).

2.3 Precision

Increasing the precision of an experiment is important since statistics are used to make the decision about whether there is any relationship between the independent and dependent variable in a given experiment. Two errors can arise in this statistical decision. If there is no relation between the independent and dependent variable (i.e., the statistical null hypothesis is valid), but the statistical analysis

suggests such a relationship, then a type I error has been made whose probability is called α. The second error occurs if a relationship between the independent and dependent variable exists (i.e., the statistical alternative hypothesis is valid), but the statistical test fails to detect this relationship (type II error). The probability of this error is called β. The greater the experimental precision, the lower is the probability β. In other words, the greater the precision, the lower is the risk of retaining a false null hypothesis.

Controls reducing the dispersion of random errors serve to increase the precision of an experiment. One method consists of adding a control factor to the experiment. As mentioned, this measure is also employed in order to check external validity. If, for example, different experimenters collect the experimental data, taking them into account as a control factor can contribute to reducing the variance of random errors (error variance). The effects of the experimenters and their interaction with the treatment (see Sect. 2.2) can then be separated from the effect of the experimental independent variable. The larger the effect of the control factor and the interaction, the higher is the degree to which the error variance is reduced.

In some cases, this statistical procedure is also employeo increase precision when pretests are available. It is conceivable that one's attitude towards Jews could be influenced by a test carried out prior to the application of the treatments. To deal with this, subjects are first ranked according to their pretest values. Subjects with the first k values are then randomly assigned to the k experimental conditions. The same applies to subjects with ranks $k+1$ to $2k$, etc. This method is called matching. The degree to which precision is increased depends on the magnitude of the correlation between pretest and dependent variable (Feldt 1958). Under the aspect of external validity, the performance of a pretest has the disadvantage that the result may be generalizable only to pretested subjects (Campbell and Stanley 1963).

Still other procedures for increasing the precision of an experiment exist. Among these is the possibility of applying all treatments to each subject in a random sequence. In this case, the inter-individual variation of random errors is controlled. The effect of the experimental independent variable is then tested against the intraindividual error variance that is generally smaller than the interindividual error variance. A possible disadvantage of this procedure is the risk of decreasing internal validity due to repeated testing (e.g., carryover effects, fatigue).

3. *A Deductiviristic Theory of the Experiment*

Campbell and Stanley's theory of internal and external validity (1963) is based on inductive inference. This is particularly apparent with regard to external validity. Since no conclusive induction principle exists but statements about internal and external validity presuppose just such a principle, the theory has been criticized by Gadenne (1976).

An alternative, deductiviristic theory of the experiment has been proposed by various authors (Bredenkamp 1980, Gadenne 1984, Hager and Westermann 1983, Erdfelder and Bredenkamp 1994). According to Erdfelder and Bredenkamp (1994) various methodological rules of experimentation can be derived from the general principle of maximizing the fairness and strength of an experiment. Fairness is defined as the probability that a scientific hypothesis will be confirmed in an experiment, if it is actually true. Strength is defined as the probability that a false scientific hypothesis will not be confirmed. If scientific hypotheses are tested statistically, and the acceptance of the statistical null hypothesis is the result that is in accordance with the scientific hypothesis, the following applies (see Erdfelder and Bredenkamp 1994):

$$\text{Fairness} = (1-\alpha)-(1-\alpha-\beta)\,h_0 \qquad (1)$$

$$\text{Strength} = (1-\beta)-(1-\alpha-\beta)\,g_0 \qquad (2)$$

If acceptance of the statistical alternative hypothesis is the result that supports the scientific hypothesis, then Eqns. (3) and (4) hold:

$$\text{Fairness} = (1-\beta)-(1-\alpha-\beta)\,h_1 \qquad (3)$$

$$\text{Strength} = (1-\alpha)-(1-\alpha-\beta)\,g_1 \qquad (4)$$

α and β are the probabilities of type I and type II statistical errors (see Sect. 2.3), g_0 is the probability that the statistical null hypothesis is valid if the scientific hypothesis is not true, and h_0 is the probability that the statistical null hypothesis is not valid if the scientific hypothesis is true. Accordingly, g_1 is the probability that the statistical alternative hypothesis is valid if the scientific hypothesis is not true, and h_1 is the probability of the statistical alternative hypothesis being untrue if the scientific hypothesis holds.

Further discussions will be restricted to Eqns. (3) and (4). They can be similarly applied to Eqns. (1) and (2). If the scientific hypothesis and the statistical alternative hypothesis are logically equivalent, then $g_1 = 0$ and $h_1 = 0$. In this case, fairness and strength correspond to the probabilities of correct statistical decisions, $1-\beta$ and $1-\alpha$. This equivalence seldom applies in psychology. Psychological hypotheses are often related to processes occurring within individuals, while statistical hypotheses refer to populations. Nevertheless, the statistical analysis does make sense provided that the scientific hypothesis (S) implies a statistical hypothesis, for example, the alternative hypothesis (H_1). Randomization is indispensable for establishing such an implication. If the implication $S \rightarrow H_1$ holds, then $h_1 = 0$. In this case, fairness is completely determined by the probability of a correct

decision in favor of the statistical alternative hypothesis. The strength remains unknown because the value for g_1 is not known. However, the falsification theory put forth by Popper (1982) contains methodological rules that can be applied to reduce g_1. The smaller g_1 is, the greater is the strength for a given pair of values of α and β. If $g_1 < 1$ and $S \rightarrow H_1$ holds, then a reduction of the statistical error probability, α, at a fixed value of experimental fairness will increase the strength.

Up to this point, we have ignored the fact that scientific hypotheses usually refer to theoretical constructs that must be operationalized. This operationalization leads to the empirical hypothesis that is actually tested. Obviously, the result of a statistical test cannot be used to assess a scientific hypothesis if its logical relation to the empirical hypothesis is unknown. This problem can be largely solved by stochastic modeling techniques. The stochastic model comprises a structural and a measurement model. The structural model contains the central statements of the scientific hypothesis, while the measurement model formalizes the relationships between the latent constructs and empirical variables (Erdfelder and Bredenkamp 1994).

Within the context of the deductiviristic theory, some of the problems originally formulated by Campbell and Stanley (1963) need to be reformulated (Bredenkamp 1980). In psychology, scientific hypotheses are interpreted as deterministic or statistical universal hypotheses that refer to an unlimited number of individuals. Each subject belonging to the population the hypothesis refers to is fully representative for the purpose of the experiment. If an experiment is performed with more than one subject, this is done merely to control internal errors by randomization and not for generalization since random samples cannot be taken from an unlimited population. In this view, random assignment serves to justify the use of statistical tests and has nothing to do with generalization (Edgington 1995). Indeed, no generalization of the experimental results to extra-experimental settings is attempted. Experiments serve the single purpose of testing scientific hypotheses.

Practical problems are solved by means of technological statements derived from a scientific hypothesis that has been confirmed experimentally. Technological hypotheses refer to treatments that must be applied in order to have specific, desired effects (Gadenne 1976). The technological statement can be the subject of empirical studies in field settings. On the other hand, controlled tests must be performed in order to test scientific hypotheses. The laboratory offers the best conditions for controlling extraneous variables.

Such a deductiviristic theory of the experiment combines aspects of Popper's falsification theory (1982), Lakatos' methodology of scientific research programs (1970), as well as Neyman and Pearson's theory of statistical hypothesis testing (Neyman 1950). The latter theory permits the (compulsory) control of the statistical error probability, β. The book by Cohen (1988) is very useful for social and behavioral scientists in applying this theory.

Recently, Westmeyer (1998) has criticized the deductiviristic theory of experiments. He doubts the compatibility of the theories of Popper, Lakatos, and Neyman and Pearson. In addition, he demands single-subject experiments to test hypotheses that refer to individuals. This latter demand does not contradict principles of the deductiviristic theory. However, for vast areas of experimental psychology, internally valid single-subject experiments (see *Single-subject Designs: Methodology*) that require repeated measurements cannot be carried out (see Sect. 2.3). In these cases, the logical link between scientific and statistical hypotheses and the resolution of the resulting problems are of great significance.

4. *The Ideal and the Real Experiment*

Textbooks contain rules for conducting the ideal experiment. In the end, it is the aim of all rules to make the experiment distinguishable from other procedures by controls that make it possible to trace variation in the dependent variable back to the independent variable while excluding all extraneous factors from the interpretative system.

Empirical studies seem to violate these requirements. According to Friedman (1967) the ideal experiment is a non-social situation. The view that all extraneous variables are controllable assumes that both the experimenter and the subjects are conceived as nonpersons whose behavior towards one another remains constant. The suspicion that this is not the case can be inferred from the fact that textbooks concerning the experimental method set forth no rules for the experimenter regarding his or her behavior during the pre-experimental phase (greeting the participants, questions regarding the individual). An experimenter can induce experimental errors in many different ways. Friedman (1967) discovered variations in behavior during the pre-experimental phase (how often the experimenter smiles at the subject, looks at the subject, etc.) both between and within experimenters. These differing behaviors can be effective extraneous variables (Friedman 1967).

If the experiment is viewed as a social situation in which the experimenter and subject interact, various extraneous factors on the part of the experimenter and the subject could well come into play. Detailed information concerning this can be found in the book by Rosenthal and Rosnow (1969). On the part of the experimenter, it is the expectations that can influence the results if he or she communicates his or her hypothesis to the subjects in a nonverbal manner (experimenter bias). In addition, the experimenter's

personality traits can influence the results (experimenter effect).

On the other side of the dyadic relation stands the participant, who has taken his or her role as subject either voluntarily or involuntarily, who is searching for the hypotheses of the experiment, who aims at producing results that will confirm or disconfirm the hypothesis, and who is more or less apprehensive about evaluation. All these factors can become effective extraneous variables that endanger the clear interpretation of an experimental result. For this reason, various controls have been suggested to minimize these errors (see *Experimenter and Subject Artifacts: Methodology*).

Does the fact that the experiment is actually a social situation affect internal and external validity in the inductive theory or strength and fairness in the deductiviristic approach? It is obvious that not all-potential disruptiviristic factors in an investigation can be controlled. The brightness of the room in which a social psychology experiment is performed usually remains uncontrolled because the experimenter assumes no influence of brightness on the results. However, the stakes are quite different in experiments on visual perception. Potential sources of experimental errors that cannot be controlled by randomization have to be controlled by use of other techniques if there is a well-founded assumption they could produce artificial results. This also applies to the control of possible artifacts produced by the experimenter or subject. Only the confirmation of general artifact hypotheses (e.g., 'in most studies, the results can be traced back to the experimenter's expectations'; 'in many studies, the results can be traced back to the subject's attempts to produce findings that confirm the hypothesis,' etc.) would make general control of the artifacts necessary. To date, general artifact hypotheses have not been confirmed (e.g., Bredenkamp 1980). Of course, this does not preclude the possibility of artificial results in single investigations.

5. *Objections to the Experiment*

Among all empirical research methods, laboratory experiments have most often been criticized. The controls carried out in the experiment serve the single purpose of deciding about a scientific hypothesis with as little bias as possible. The objection to this is that results obtained under conditions of strict control are artificial and cannot be generalized to extra-experimental settings where many factors that were experimentally controlled now come into play. Section 3 has already discussed this problem. It should be reiterated that laboratory experiments test scientific hypotheses, and that they must employ control techniques in order to avoid false conclusions. They serve the scientific goal of explanation (see *Explanation: Conceptions in the Social Sciences*). The solution of practical problems poses other questions that must be answered within the context of technological research.

A second objection refers to the fact that the real experiment is a social situation that differs significantly from the ideal experiment. It has been argued that for this reason all advantages of the experiment refer to a method that does not exist in reality. However, there is no basis for arguing that social processes generally bias experimental results (see Sect. 4).

A final objection posits that experimentation with humans is simply morally unacceptable. It cannot be reconciled with human dignity because, in the interest of reaching scientific goals, the human is reduced to an 'object.' However, a similar objection can also be raised to nonexperimental investigations. If a ban on empirical research using human subjects is derived from this argument, behavioral and social sciences become impossible. Indeed, in many experimental studies, human dignity does not suffer to any greater extent than in everyday situations in which, for example, children are expected to cope with the effects of educational reforms or changes in social relationships resulting from a move to a different place. When carrying out empirical studies, principles No. 9 (research with human participants) and No. 10 (care and use of animals) of the American Psychological Association (1990) must in all cases be observed. Of particular importance is that 'the investigator protects the participant from physical and mental discomfort, harm, and danger that may arise from the research procedures' (American Psychological Association 1990, p. 395).

The problem cannot be resolved by simply relinquishing experimentation. For example, the application of certain therapeutic procedures whose effectiveness has not been demonstrated by controlled experiments or quasi-experiments appears questionable. Thus, while experiments with scientific goals can pose ethical problems, so too can the failure to perform such experiments. Deciding not to experiment may pose ethical problems of equal weight to deciding to do them and must be justified every bit as clearly and cogently.

Laboratory Studies: Historical Perspectives

1. *The Origin and Meaning of 'Laboratory Studies'*

The term 'laboratory studies' dates back to the late 1970s, when it began to be applied to studies of the production of scientific knowledge at its 'natural' site, the scientific laboratory (Latour and Woolgar 1979, Knorr Cetina 1981, Lynch 1985, Traweek 1988). Not all natural scientific knowledge is produced in laboratories, but the laboratory nonetheless epitomizes modern science and knowledge. It is what the factory was to industrialization, the place where particular forces of production are brought together, organized, and unleashed. Laboratories do not produce industrial commodities, but, according to laboratory studies, they do create products, the objects and facts of science. A first characteristic of the original laboratory studies was that they refocused questions of knowledge on the context of knowledge production, moving them away from questions of the validity and representational correctness of scientific findings. Philosophers of science, until then the main authorities on matters of scientific procedure and content, had largely neglected the context of knowledge production, which they called the context of discovery. Historians often defined issues of scientific content as questions pertaining to the history of ideas, detached from local settings. To be sure, both groups also enriched their accounts with studies of crucial experiments, but experiments, as we shall see, are not laboratories. The whole process of knowledge production in the contemporary fact factory of the natural sciences, and the role of the fact factory itself, were, up to the late 1970s, untrodden territory in the social and behavioral sciences. One reason for the interest generated by laboratory studies lies in the fact that they 'conquered' this new territory, that they unlocked a hidden and central chamber in our understanding of knowledge and science. It needs to be recalled that the development of scientific method and the ensuing advances in knowledge are often associated with the transition from traditional to modern societies, carrying much of the burden of explaining the dynamics and the progress of industrialization. Knowledge and

technology also lie at the core of the current trend to global systems and transformation to a 'knowledge society.' Any perspective that contributes to the understanding of these forces will be of interest in the larger context of these developments. A second characteristic of laboratory studies is that they grounded their analyses empirically, using a mix of 'molecular' level methods, most importantly observation and ethnography, ethnomethodological techniques, and discourse analysis. Since much of the knowledge that experts have of their own ways of working is implicit, interview methodologies are not conducive to clarifying these. This empirical approach to knowledge environments and their embedded processes stands in contrast to postmodernist and transformation theory perspectives and their theoretical assessments and critiques of science. It also contrasts with much of the knowledge society literature (Bell 1973), which tends to render knowledge and technology the independent variable—for example, it treats knowledge as the engine of economic change, responsible for such widespread changes as shifts in the division of labor, the development of specialized occupations, the emergence of new enterprises, and sustained growth. In these accounts, 'knowledge' is sometimes conceptualized to fit in with long-standing beliefs about science (an example is Bell's attempt to explicate knowledge in terms of theory, 1973, p. 44), but it is in effect the last thing to be explained and has no reality outside an analyst's models (Stehr 1994).

If the interest in opening the black box of scientific practice is what distinguishes laboratory studies, then the interest in not restricting what is to be looked at inside the black box distinguishes them from previous studies of scientific experiments. The third characteristic of laboratory studies is their inclusiveness with respect to all practices and events implicated in knowledge processes. Experiments have been largely defined methodologically in the history and philosophy of science, where they were investigated; notions like the testing of theories, experimental design, blind and double-blind procedure, control group, factor isolation, and replication are linked to experiments. Students of laboratories focus on a space rather than on particular experiments. This brings to the fore the full spectrum of activities going on in this space and involved in the production of knowledge. Studies of laboratories have shown that scientific objects are not only 'technically' created in laboratories but also symbolically and politically construed. For example, they are construed through the literary techniques of persuasion that one finds embodied in scientific papers, or through the political stratagems of scientists in forming alliances and mobilizing resources. An implication of this has been the awareness that, in reaching its goals, research 'intervenes' not only in the natural world but also—and deeply—in the social world. Another implication is that the products of science have come to be seen as cultural entities rather than as natural givens 'discovered' by science. If the practices observed in laboratories are cultural in the sense that they cannot be reduced to the application of methodological rules, the 'facts' that result from these practices must also be seen as having been shaped by culture.

2. *The Laboratory as a Theoretical Notion*

The significance of the notion of a laboratory lies not only in the fact that it has opened up this field of investigation and offered a cultural framework for 'plowing' this field. It lies also in the fact that the 'laboratory' itself has become a theoretical notion in our understanding of knowledge. Accordingly, the laboratory is not only a 'house' for the conduct of experiments or the physical setting in which knowledge processes take place, but the locus of mechanisms and processes which can be regarded as necessary for the 'success' of science and knowledge.

2.1 *Laboratories as Reconfigured Environments*

Characteristically, these mechanisms and processes are nonmethodological and mundane. One hallmark of the mechanisms and processes with which the notion of a laboratory has been associated is that they imply, to use Merleau-Ponty's terminology, a reconfiguration of the system of 'self-others-things' ('Moi-Autrui-les choses,' 1945, p. 69), and a reconfiguration of the *phenomenal field* in which experience is acquired in science. The system of 'self-others-things' is not the objective world independent of human actors or the inner world of subjective impressions, but the world-experienced-by or the world-related-to agents. Laboratory studies suggest that the laboratory is a means of changing the world-related-to-agents in ways which allow scientists and other knowledge workers to capitalize on human constraints and sociocultural restrictions. The improvement derives from the *malleability* of knowledge objects. For example, there are at least three features of natural objects which a laboratory science does not need to accommodate: first, it does not need to put up with the object *as it is*; it can substitute all of its less literal or partial versions. Second, it does not need to accommodate the natural object *where it is*, anchored in a natural environment; laboratory sciences bring objects '*home*' and manipulate them 'on their own terms,' in the laboratory. Third, a laboratory science does not need to accommodate an event *when it happens*; it does not need to put up with natural cycles of occurrence, but can make them happen frequently enough for continuous study.

Laboratories, then, allow for some 'homing in' on natural processes; the processes are 'brought home' and made subject to the conditions of the local social order. The power of the laboratory (but, of course,

also its restriction) resides precisely in its 'enculturation' of natural objects. The laboratory subjects natural conditions to a 'social overhaul' and derives epistemic effects from the new situation. Social forms, to be sure, are also subject to 'overhauls' in laboratory processes. Questions raised in this context are, who 'is' the epistemic subject, and how is this subject configured in a particular setting? The epistemic subject is the bearer of knowledge, the unit that is productive of scientific findings. This unit cannot be automatically assumed to be the individual scientist, nor even a division of labor among laboratory leader, postdoc, grad student, and technician. In some areas, for example in experimental high-energy physics, this 'unit' now encompasses collectives of considerable size (up to 2,000 physicists), a large and complex machine (a detector), and a level of distributed cognition in which machine analysis and human analysis merge into a single, continuing, circulating discourse. The productive role of the detector in this joint discourse is recognized by participants, who attribute to it the sole epistemic authority to observe and describe the particle processes instigated in its internal environment. But the productive role of discourse as a platform for integrating machine analysis and human analysis and for creating a collective consciousness that is at the same time material and human also needs to be recognized; it is a circulating consciousness that appears to replace the individual as the bearer of knowledge. More generally speaking, purely human orders appear to be transformed in laboratory processes into object-relation regimes in which the objects are machine complexes, organisms, and the like. Laboratory studies have approached these through network notions, where it is assumed that the creation of links between the nodes in a network of human and nonhuman entities is also what stabilizes and universalizes scientific outcomes (e.g., Callon 1986, Latour 1987). They have also looked at these regimes in terms of their contribution to understanding a more general shift toward object relations in contemporary society—a shift fueled and sustained by an enormous expansion of object worlds within the social world and by an erosion and 'emptying out' of primordial social relations. Objects, in this approach, are thought to be the winners of the relationship risks that are manifest in the problems of married and family life and that many analysts find inherent in contemporary human relations (Coleman 1993, Knorr Cetina 2000).

Laboratories can be distinguished from organizations along similar lines. Organizational sociology is relevant to laboratory studies since most laboratories are or are part of complex organizations. But the concept of organization in the social sciences is essentially a concept of the coordination of human groups. Laboratory studies, on the other hand, have tended to see governance structure as inseparable from patterns of coordination that are obtained between persons and objects of investigation. The sociology of organizations pays attention to organizational 'subdivisions,' the sort of formal units and subgroups into which organizations can be decomposed. The subdivisions of interest to the laboratory approach are alternate knowledge environments that are not hierarchically but 'ontologically' related to the larger framework of a lab: the difference between alternate knowledge environments derives from the line of reality developed and 'farmed.' One example of such an alternate reality and of a laboratory within the laboratory is a simulation environment. In experimental high-energy physics, simulation constitutes a parallel world in which nearly all aspects of the physical detector, the particle clashes, and the physics analysis are recreated and worked out. Such 'detour' environments need not be of a different nature, for example, symbolic rather than physical, as in simulation. They may also emerge from particular natural forms that are articulated further in the laboratory. For example, in molecular biology the fruit fly and the slime mold have become worlds of investigation in their own right and have evolved as model realities separated off from the rest of the biological universe. The emergence of alternate realities has brought with it the emergence of special knowledges and new specialists who are the ones dealing with the environment. In the case of the fruit fly, these include a 'Drosophila elite' of several generations bound together by formative psychosocial relationships; they are distinguishable from other scientists who pass through fly rooms during their training through their careers, their gender, and the problems they work on (Kohler 1994, 92ff.).

2.2 *The Constructionism of Laboratory Studies*

A second feature associated with laboratories pertains more to knowledge processes within them, which are seen to be constructive rather than merely descriptive. Constructionism was one of the first and most important results of laboratory studies, and the analytic answer these studies gave to the microprocesses they observed in real-time episodes of scientific work (see *Technology*, *Social Construction of*). Constructionism has been taken as a principle of investigation in laboratory studies: one asks how much of the success of a knowledge claim can be explained in terms of the relevant productive processes before this success is attributed to the representational content of the claim. Given that most knowledge claims that are considered true will eventually become false, it is the representational hypothesis which is thought to be implausible by students of laboratories. The constructionist thesis has also been taken as a substantive assertion about natural reality being humanly constituted in a wider sense. Science, in this view, secretes an unending stream of entities that make up 'the world'—it holds, one might say, a monopoly on specifying and delimiting the material world in which

we live. What exists before scientifically delimited objects are culturally delimited objects, those which humans pick out, shape, and deal with in everyday life. In both cases, the 'material world' flows from human designations. Laboratory constructionists have also granted the existence of an unspecified material world beyond cultural and scientific designation; but this presupposed world has to be distinguished from concrete objects and forces which can be said to exist only after they have somehow been designated and distinguished, built into our accounts, and inserted into daily practice. In that sense constructionists subscribe to an ontology that anchors existence in social and cultural life, not outside it. While the existence of the material world as a physical entity independent of us is granted on principle, the existence of specific objects identified in terms of their character cannot so be granted.

Constructionist thinking in general existed before laboratory studies, but it had not been extended to science. First, as already implied, constructionist metaphors take on a much stronger flavor when they are applied to natural reality, to knowledge and science. To say that kinship systems or gender relations are social conventions and cannot be attributed to 'human nature' is widely accepted—what undergirds this understanding is, among other things, the cultural variation of these systems. But to make the same claim for scientific facts is a different matter, raising the specter of relativism and skepticism. Constructionism, though, should not be assimilated with these doctrines. It is best understood as the attempt to carve out a middle ground between relativism and realism, or as an attempt to point at space beyond the two poles. This space is the one where the complex chains of laboratory transformations of natural and social objects take place, each link involving alternative options, perspectives, interpretations, negotiations, strategies, conflicts, resources, obstacles, and surprises (e.g., Latour and Woolgar 1979, Knorr Cetina 1981, Lynch 1985, Latour 1987)—as well as frequently social, economic, and political groups outside science (e.g., Fujimura 1996, Rabinow 1996). Only if this space remains invisible and the beginning of an experimental series is short-circuited with its end, do realist interpretations become plausible, as do relativist interpretations of knowledge—which interpretation results depends on whether one cuts human work or material recalcitrance and resistance out of the picture. Constructionism, on the other hand, is the view that the space in which a particular intermesh between human work and material recalcitrance is forged holds the key to understanding knowledge.

3. *Knowledge Cultures*

More recent laboratory studies have supplemented the interactional and writing-centered articulation of the constructive character of knowledge processes with a measure of aggregate-level analyses, and they have also unfolded further the material side of laboratories. At the same time, a more narrowly defined interactional model of knowledge production has been expanded in several directions, for example, in the direction of taking into account contextual cultures. The notion of culture had been used in the early laboratory studies to describe the intent of the work; it was also indicative of the methodology used in these studies (ethnography) and of the phenomenon that laboratories appeared to involve whole cultural worlds, that is a large variety of factors not reducible to sociological variables. Nonetheless, there is a sense in which the early laboratory studies lacked a cultural perspective. They limited themselves to one knowledge area and, as a consequence, ignored the cultural diversity of knowledge. They were concerned, one might say, with knowledge rather than with knowledges. With one exception (Traweek 1988), they also investigated laboratories in only one country, the USA; the studies of Latour and Woolgar (1979), Knorr Cetina (1981), and Lynch (1985) were all done in California. Thus these studies also ignored the possible influence of national cultures. Traweek (1988) compared the Stanford Linear Accelerator laboratory with its equivalent in Japan (the KEK near Tokyo), contrasting the two settings with respect to laboratory organization, detector design and building, leadership style, and models for good working conditions in the science she was studying—high-energy physics.

This study also addressed the aspect of the making of a male physics culture, in addition to analyzing specificities having to do with the way institutions are set up in different countries; but it did not extend the analysis to questions of whether and how knowledge cultures differ between sciences. The assumption long made of the unity of science may in fact not be warranted, and may have been sustainable only in the face of a lack of comparative investigations of knowledge. A recent comparative study of high-energy physics and molecular genetics locates differences between these fields in the understanding of measurement and experiment, in the general epistemological approach of a field, in the ontology of objects and machines, and in the conception of epistemic subjects (Knorr Cetina 1999). For example, the study finds a 'liminal' approach in which the regions of positive, phenomenal knowledge are studied and narrowed down through investigating the errors and limits of knowing in place in one science but not in the other. Liminal epistemologies forge a coalition with the evil that bars knowledge by turning these barriers into a principle of knowing. 'Referent' epistemologies, on the other hand, enhance the role of natural objects in selecting experimental results, and are committed to the use of experiential registers as strategies of knowing. Such 'epistemic cultures' may be contextualized by investigations of 'epistementalities' that prevail in

the larger society—beliefs and attitudes about the correct distribution of knowledge, the rights of access to it, the requirement and meaning of transparency, etc. The importance of further research on these topics can be linked back to the idea of a knowledge society as one where expert systems penetrate all areas of contemporary life. In such societies, knowledge cultures may in fact become what territorial cultures had been to industrial society: defining environments which enable and shape social and economic development.

4. Types of Laboratories

A second expansion of laboratory studies beyond the inclusions of knowledge cultures concerns the fact that diverse types of laboratories are now recognized to exist and are included in the analysis. The spaces of knowledge vary historically, ranging from the 'houses of experiment' in seventeenth-century England investigated by historians (Shapin 1988) to the virtual collaboratories stretching across continents in astronomy today. The locally situated benchwork laboratories of molecular biology have to be distinguished from laboratory 'centers' that tie a whole field to a place, and those from interlaboratory fields of interconnected but functionally differentiated stations of work.

4.1 Benchwork Laboratories

Benchwork laboratories correspond to the most common idea of what a laboratory is: a repository of processing materials and instruments in rooms in which research tasks are performed continuously and simultaneously, typically by more than one researcher and by technicians. Such laboratories are specific to particular sciences such as molecular biology (e.g., Lynch 1985, Fujimura 1987, Jordan and Lynch 1992). They can be found at any university but they are also the core units of large research institutions. One characteristic of such laboratories is a two-tier organization differentiating between the laboratory level and the experiment level of activities. On the first level, such laboratories become focused on and identified with their leaders, who spend much time representing and promoting 'their' laboratory, and recruiting resources and personnel for it. On the level of scientists, the laboratory fragments into projects associated with individual researchers around which other components are assembled. Together, these create small lifeworlds comprising— besides a scientist—materials, instruments, bench space, and help from technicians and students. A second characteristic of such laboratories is the embodied character of the work and the intervening technology of experimentation. Intervening in a lab setting can be contrasted with the technology of experimentation in the social sciences, which is based on a theory of nonintervention: in blind and double-blind designs, researchers attempt to eradicate the very possibility that the outcome will be influenced by the scientists involved.

In benchwork laboratories, on the other hand, this tendency is reversed: one of their most notable features is that the objects of experimental work are subject to almost any imaginable procedural intrusion and physical manipulation. A third characteristic of benchwork laboratories is that they encapsulate within themselves a continued traffic of substances, materials, equipment, and observations that spills beyond laboratory boundaries and ties single laboratories into interlaboratory fields.

4.2 Center Laboratories

With the second type of laboratory, such fields may become more strongly structured in terms of centers and peripheries and semiperipheral units. One identifying detail of center laboratories appears to be that resources important to a field become centered in a particular location and space (see also Hilgartner 1995). One reason for this may be the sheer size and expense of the equipment needed. High-energy physics provides an example; in this area, there have long been regional and continental centers explicitly motivated in terms of the resources needed to build the accelerators and detectors that can provide and deal with the energy levels of particular forefront experiments. Given the further rise of energy levels, there is now a global center; perhaps for the first time in the history of science there is one laboratory worldwide (at the turn of the millennium the CERN in Geneva, Switzerland) in which resources and expertise from Europe, the USA, and Asia have been concentrated. This laboratory provides access to groups from all countries and continents equipped to participate in the respective experiments. Such centers are line items in national budgets; they are maintained through regular contributions dedicated to the lab, which is itself the size of a village (for a history of big science, see Galison and Hevly 1992, Galison 1997). Global center laboratories of this sort very nearly absorb within them a whole field, with as yet largely unstudied consequences for epistemic questions such as how consensus is formed about scientific outcomes when fields are interiorized in laboratories.

If their structural position in a field and the interiorization of scientific communities are characteristic features of some center laboratories, the role of experiments in them is another. In the benchwork laboratories considered, experiments have little ontological identity. They simply dissolve into ongoing streams of experimental work that is also continuous with the service work provided for the laboratory. In high-energy physics, on the other hand, experiments are highly visible units which dispose over their own financial resources, which are separate from those of

the larger laboratory. As a consequence, laboratories and experiments are technically, organizationally, and socially divorced from each other. Technically, laboratories build, maintain, and run accelerators and colliders which provide particle clashes that experiments investigate. Experiments, on the other hand, build, maintain, and run the detectors in which the clashes leave their mark. Organizationally, experiments are run by large 'collaborations,' comprising, at the turn of the millennium, up to 2,000 physicists from up to 200 physics departments and laboratories located worldwide, who join up for the purpose of conducting the experiment. Laboratories, on the other hand, dispose over a permanent staff of accelerator physicists, computer specialists, technicians, and others, who conceive of and tend to the scientific and technical infrastructure of the laboratory. Researchers on both sides of the divide depend on one another but often know little of one another. Experiments become relatively closed, total units that may also decide, as independent collaborations and collective actors, to migrate between laboratories (to submit an experimental proposal to another laboratory).

4.3 Network Laboratories and Distributed Laboratories

Though the specific configuration of such center laboratories may be historically distinctive, the idea of a central big science laboratory is not distinctive. An early example is Tycho Brahe's observatory, begun in 1576, where a dozen assistants, along with mechanics and others, collected great quantities of data from which a 'computing division' derived parameters of planetary motion (Heilbron 1992). The Danish king financed this empire, and cheap labor from the surrounding inhabitants took care of its construction, tended Tycho Brahe's garden, and raised his crops. A second example may have been the Society of Jesus, which maintained seminars and collections and which possessed a network of scientific collaborators with whom they conducted extensive correspondence. Perhaps surprisingly, similar 'network' and 'platform' laboratories have reappeared today in a variety of settings. They can be seen as a third type of laboratory, which may be distinguished from bench laboratories and center laboratories by two features: the laboratory is no longer situated in a particular place but extends to and involves a number of parties and locations, and what happens between these locations is central to understanding the outcomes of the lab.

One example of network laboratories is the electronically mediated 'virtual laboratory' exemplified by work in mathematics, theoretical physics, and astrophysics, where scientists use electronic linkages and e-mail communication to join their research efforts on symbolic objects. The notion of a laboratory here captures the phenomenon that the electronic space becomes a *workbench* for participants; a space in which transitory research objects may be stored, particular resources can be found, and dispersed materials can become interactively related and integrated. Center laboratories, when they involve ter-ritorially dispersed collaborating groups, also intermittently expand into such e-mail co-laboratories, but the groups also frequently meet at the center, where they spend prolonged periods of time tending to machines and where a local workforce is maintained. Special cases of such virtual laboratories are beginning to appear in the humanities and social sciences, for example in history, where digitization projects erect interactive platforms for historical research. These platforms make available archival materials that are categorized, cross-linked, and presented with navigation systems for research uses. Such platforms are not simply electronic versions of alphabetically stored books and archival materials. Through carefully thought out and theorized category systems and through the interlinkages they allow for, new questions open up, comparisons become possible, and contextual information can be called forth and integrated with other pieces of information. In addition, the platforms offer possibilities of virtual manipulation, for example, the virtual reconstruction of historical sites or experiments that cannot easily be reconstructed in naturalistic ways. Interestingly, the history of laboratories may be elucidated further through some of these platforms, which assemble information on sites of knowledge production in previous centuries.

5. The Laboratory Perspective

A third extension of laboratory studies takes its lead from family resemblances between laboratories and other physical and virtual spaces. In this case the notion of a laboratory, and the concepts emerging from laboratory studies, are transferred to areas that are not literally laboratories but can be seen as spaces of knowledge. When the above mentioned platforms make available material on historical research sites they include among the sites clinics theaters, lecture rooms, field stations, and even farms—places into which knowledge crossed from laboratories or from whence practices moved into them. Such sites can be studied using a laboratory perspective. This perspective also simply brings into view the phenomenon that matters with which students of laboratories have concerned themselves, for example, the construction of facts, are actually ongoing occurrences in a variety of settings. This is the sense in which the industrial factory itself begins to resemble a laboratory as a site for invention and intervention in which new realities are created (Miller and O'Leary 1994).

We can illustrate this use of the laboratory approach by means of two examples, one from transsexual

research and one pertaining to the factory. In the first case the new sex of a person who desires to have a different sex from the one he or she is born with is seen as a 'fact' that is being constructed in a laboratory made up of the different stations of the treatment program that transsexuals undergo (Hirschauer 1991). The laboratory approach sheds light on the multiplicity of stations that make up the lab, on the constructive and transformative work contributed by the stations, and on the heterogeneity of the frameworks of knowledge involved. In the second case, that of the factory, Japan is brought to Illinois, as it were, in the attempt to reconfigure the American factory in the image of global factory modernization, by redesigning shop floors, recalculating new spatial orderings of production, and molding the worker according to the ideal of a 'new economic citizenship' for plant personnel. Here the factory itself becomes a laboratory for acting upon its own assemblage of locales and internal relations and for refashioning the person who participates in the assemblage (Miller and O'Leary 1994).

The notion that we now live in a knowledge society is relevant here once again. If this view is correct, the range of applications of laboratory studies as a particular perspective along the lines just indicated is large. In a knowledge society, the sites where knowledge is produced and applied multiply, creating an open series. These sites are not limited to science, but rather move outside science. As the above examples also indicate, the laboratory approach is not concerned with knowledge processes as defined in terms of an end result ('correct knowledge') but with what could be called the epistemic attributes embedded in, and, in a knowledge society, conferred upon, many processes—exemplified by institutional reality construction, by object relations, and by the reconfiguration of human subjects. The three extensions of the laboratory approach described here indicate the transformation of what was originally an approach to particular natural sciences into a perspective applicable to such broader questions.

Laicization, History of

During the second half of the twentieth century, sociologists often used the notion of *secularization*. This notion was basically considered as the decrease of religion's influence on modern society. Nowadays, not

only can one notice that the decrease is not complete but one can also criticize that the notion of *secularization* is too broad. For a better understanding, one might want to distinguish a process of secularization from a process of laicization.

When the process of secularization is predominant, the relative decline of religion's influence takes place in parallel to other evolutions, with no major tensions between religious and political or other social forces. Certainly, religious changes, as well as economic, political, etc. changes, may produce internal tensions. But, when all is said and done, the triumphant forces participate in the same social dynamic. Therefore, there is no important clash between the changes within the religious sphere and other social changes. For that matter, Scandinavian countries are a typical example of secularization. The switch to Lutheran Protestantism, particularly linked to the Bible's translation, has favored the development of a national culture. Theological arguments ('theology of the two reigns,' absence of essential differences between clerics and laymen, rejection of the papacy, etc.) have allowed the autonomy of the nation-state towards religion not to provoke important conflicts. Moreover, a joint and progressive democratization of State and Church has taken place. In the end, for example, a national Danish church emerged (*Folkekirken*)—this continues to be the symbol of the identity of nations that have been largely secularized.

The process of laicization differs: the tensions between various social forces take on the aspect of an open conflict where the religious becomes a politico-cultural stake. The symbolization of the national culture, among others, is controversial. Either the State imposes religion to society (*clericalism*) or refuses that religion to continue to be the symbol of national identity (*laicization*). The French case is the main example of such a process.

1. Revolution in France and After: the First Threshold of Laicization

In France, the roots of this conflict are one of the results of the Wars of Religion (sixteenth century) as well as the persecution of Protestants and dissenting Catholics (Jansenists) (end of the seventeenth century and eighteenth century). As a reaction to this, a certain anti-religious dimension appears in the French philosophy of Enlightenment that had permeated a part of the nobility and bourgeoisie. This spirit differed from the English Enlightenment (or the German *Aufklärung*). The latter appeared as a confrontation within a diversified Protestantism, wanting an 'enlightened religion,' the former directly attacked the Roman Catholic Church, '*l'infâme*' as wrote Voltaire, who was a deist.

In 1789, religion pervaded French society. The monolith Roman Catholic faith was made compulsory for the French people. Communion at Easter and confession to a priest were required from everyone. The clergy was the first of the three 'Orders' of the kingdom. The Catholic Church was an inclusive institution exercising power over other institutions, which often only existed in embryonic states. Registration of births, deaths, and marriages, medical and social welfare and education were in the hands of or controlled by the clergy. The monarchy had a religious justification with the theory of the divine right of kings. The king possessed a politico-religious power and the defense of Roman Catholicism was one of the monarchy's basic duties. But gradually the monarchy also established a large autonomous political and administrative structure. A Gallican movement developed the idea of a French Catholic Church, which would be autonomous from the Pope and protected but also partly controlled by the State.

The first collapse came with Article X of the *Declaration of Human Rights*. It proclaimed the principle of religious freedom (August 1789), which was progressively applied to minorities. The Constitution divested the monarchy from its religious character, which was considered as a contract and entered into the nation. The fact that the King did not respect this contract led to the conflicting establishment of the Republic (August–September 1792). The state no longer had religious foundations.

As early as 1789, the Revolution celebrated the new order. First, Roman Catholicism lent a religious foundation to these celebrations. But progressively, a breach between the Catholic Church and the Revolution appeared. There were three reasons for this: the proclamation of religious freedom, the bill of the Civil Constitution of the Clergy (1790)—which accentuated gallicanism and decided that priests and bishops should be elected as political deputies—and the establishment of civil registers for births, marriages, and deaths. The 'religion of the fathers' would not be more capable of celebrating the new society, and the antirevolutionary propaganda became more and more associated with Roman Catholicism. By the year II (autumn of 1793), the institution of revolutionary cults went with a violent struggle (period of the Terror) directed against revealed religions.

Napoleon Bonaparte inherited a chaotic situation. He thought it would be possible to restore a Roman Catholic Church and maintain some of the Revolution's great achievements. After delicate negotiations with the Pope, a Concordat was signed (July 1801). The Roman Catholic Church was proclaimed 'religion of the great majority of the French' but did not have the status of a state religion; the 'organic Articles' recognized two Protestant Churches (Lutheran and Reformed) (1802) and the Jewish religion (1807). In 1804, the Civil Code made no reference to religion.

It is possible to evaluate this situation, using the abstract notion of the first threshold of laicization

(constructed on the basis of Weber's ideal-type), which was the permanent result of revolutionary upsets and is marked by three characteristics.

(a) *Institutional fragmentation*: Roman Catholicism was no longer an inclusive institution. Religious activities were clearly distinguished from 'profane' activities. Educational and health needs assumed gradual autonomy, related to religious needs, and were provided for by specific institutions that were going to develop progressively.

(b) *Recognition of legitimacy*. Revolution did not destroy religious needs that continued to exist objectively. The service provided by religion was a public service and the state paid ministers of recognized religions. Religions were socially recognized as a foundation of social morality.

(c) *Religious pluralism*. The state recognized four religions, it protected and controlled them for they could satisfy the religious needs of their followers and develop moral values. Other religions were more or less tolerated. Relative freedom was even given to those who decided to do without 'the help of religion.'

The French Revolution did not succeed in establishing a durable system of separation of Church and State, whereas the American Revolution did.

In the United States, the Declaration of Independence stipulates that all human beings *are created equal*, *that they are endowed by their Creator with certain unalienable Rights*, which is not the case in the French Declaration of Rights. Why? Because in the United States, religious pluralism allows the dissociation of God from every church.

In France, religious monopoly would let the Roman Catholic Church become the owner of human rights, being the mediator between God and humans. This creates a structural difference in the long run. The American situation may have specific characteristics linked to the master function of religion: social space for cultural pluralism. Stephen Warner (1993) indicates the main differences:

(a) Religion is constitutive for some American subcultures.

(b) Religion in America has historically promoted the formation of associations among mobile people.

(c) Religion in America serves as a refuge of free association and autonomous identity, a 'free social space.'

(d) The second generation of immigrants often transmutes ethnicity into religion because it allows immigrants to assimilate and conserve their identity.

2. *From the First Threshold to the Second Threshold of Laicization*

In France, the compromise of the first threshold of laicization delineates a logic that dominated for almost a century. But the situation that it describes was not static. At first, this was due to the fact that at the beginning of the nineteenth century, a number of aspects of the first threshold were not entirely realized: other institutions were not sufficiently developed to become totally autonomous. Then, especially during the second half of the nineteenth century, there was a growing conflict between the partisans of revolutionary values and those who thought of France mainly as a Roman Catholic nation.

The first conception won. During the 1880s, the Republicans introduced a religiously neutral educational system, which included *a morale laique*. At the end of the century, a new crisis arose from the Dreyfus case. The impression prevailed that the Republic was threatened by the *clerical peril*. The important law of July 1901 on voluntary societies excluded religious congregations from the right to free associations. A new law voted in July 1904 prohibited members of religious orders from teaching. The separation of Church and State appeared to be inevitable and took place in a climate of violent confrontation.

But two models of separation were possible. One model was antireligious and combative. Such was the bill of Emile Combes (Prime Minister). However, it was refused, especially by Jean Jaurès, the socialist leader, who hoped to achieve a law that would bring peace and eventually make it possible to fight social problems. A liberal model prevailed and ensured the freedom of conscience, guaranteed the free exercise of religion, and respected the self-organization of each church (art. 1 and 4) even though it neither 'recognized' nor paid subsidies to any religion (art. 2). This marks the end of the system of 'recognized cults.'

Even in liberal dominance, this model of separation completed a religiously neutral educational system and found a new logic. This can be seen as the second threshold of laicization. As for the first threshold, there are three characteristics:

(a) *Institutional dissociation*: religion was entirely optional because it was no longer considered as the institutional structure of society but rather as a mode of free association.

(b) *Social neutral about religious legitimacy*: religious needs having become a private matter and morality officially *laique*. The question as to the usefulness of religion for society was no longer publicly relevant. (In a logic of the conflict, the opponents to Roman Catholicism asserted that religion and religious morality were dangerous for the Republic and its ideals. This point was a compromise.)

(c) *Freedom of religion*: various religious societies belonged to the sphere of public liberties. The state guaranteed each citizen freedom of conscience and allowed each one to meet with religious societies or associations.

The separation of 1905 was marked by a twofold aspect: the victory of the *laique* camp in the hard and long conflict of the *two Frances* but also the result of a conflict within the Republican party. An implicit

covenant with opponents was searched for in order to reach peace in the long run so that complete victory in the short term would predominate. The conflict did not die immediately: it vanished progressively because religion ceased to be a political problem.

The *Résistance* had united unbelievers and believers in a common struggle. By 1945, the bishops held that there could be a positive meaning to the term *laicity* and, in the next year, *laicity* was officially proclaimed by the Constitution. It was a tripartite government—communist, socialist, and MRP (a political party that is close to Christian Democracy)—that included *laicity* in the Constitution.

3. *Laicization in Various Countries*

Other countries also show cases of the process of laicization which comprise analogies with the French case as well as specificities. Here are three examples. First, Belgium became an independent state in 1831, in a 'unionist' atmosphere, which gathered Catholics and Liberals rather than anticlerics. The outcome was a regime of separation–recognition, accompanied by 'recognized cults' (but no Concordat) which tended to resemble the first threshold of laicization in France—this was possible because the situation was more democratic than that of Napoleon Bonaparte. In 1879, the Liberals attempted to create a Laique school but the Catholic Party, victorious at the 1884 elections, progressively abolished these measures. Therefore, Belgium was never situated in a similar logic to the French second threshold but slowly integrated laicity and *laique* morals in its system of 'recognized cults': 'nonconfessional' morals, school-classes, *laique* advisers in hospitals or prisons, *laique* youth fetes that were similar to the first communion, etc.

For a very long time, Spain lived through a refusal of laicization of any sort. The 1912 Constitution declared that 'the Nation's religion is (…) the apostolic and Roman Catholic religion, the only real one.' But in the 1931 Constitution, the Spanish republic imposed both elements of the first French threshold (abolition of the religious Catholic monopoly, institution of the civil marriage) and the second French threshold (separation, *laique* schools, suppression of religious symbols on public buildings), and even a few measures that go beyond the second threshold in France (for example, chaplaincies were suppressed). During the Civil War, this laicization resembled the situation of the French Revolution rather than that of the Third Republic. The issue lay in Franco's national Catholicism, which re-affirmed Roman Catholicism as 'the only real' religion. Nevertheless, since 1978 there has been no State religion but 'relations based on cooperation with the Catholic Church and other confessions.'

The Italian situation of the mid-twentieth century was more ambivalent than the Spanish one but was not *laique* either. The 1948 national reconciliation respected the agreements of Latran (1929) which was a compromise between the Fascist regime and the Catholic Church. On the other hand, during the same time, it affirmed the mutual independence of the State and Catholicism (State religion). This lasted until 1971, when the constitutional court affirmed the priorities of constitutional norms on the agreements with the Catholic Church. After that, Catholicism ceased to be the State religion, divorce was authorized, and in 1984, the Concordat was re-negotiated and an official pluralism began to exist.

Today's Spanish and Italian systems tend to resemble a laicity that corresponds to the first French threshold of laicization. On the other hand, England possesses an established Church that coexists with a maintained Catholicism as well as nonconformist Churches. This constitutes an original variation of the process of secularization. By the end of the seventeenth century, politico-religious conflicts no longer took place. In Germany, after the Thirty Years' War, the main process was that of secularization but it also integrated elements of laicization (*Kulturkampf*, in particular).

We then could think that the French situation is the most *laique* but this is not the case. The separation between State and Church in Mexico (1917) was very polemical towards religion. The Constitution shows, for example, that State education 'should remain absolutely away from any religious doctrine' and should fight 'fanaticism and prejudices.' It forbids monastic orders, makes sure that religious ceremonies only take place in Churches, which 'will always be under the authority's supervision,' refuses the right to vote to the ministers of cults, etc. Some measures were recently made less strict, but Mexican laicity was historically harsher than French laicity.

The Turkish laicity also stands in a polemical logic when it comes to religion, which explains why it is backed up by the army. Some liberal personalities have tried to render it more liberal and make it come closer to the French laicity but today's situation does not favor such an evolution.

4. *New Problems and European Construction*

Nowadays, whatever the degree of laicization, various societies must face new problems. For example, culturally speaking, the dynamic element in laicity had been the development of a morality independent of any religious authority. But this morality was frequently going to be based on science. Now science and morality tend to be more or less dissociated in many respects. Science was increasingly understood as a *techno-science*, the functional efficiency of which was undeniable but which, far from helping to resolve moral questions, created new ones, more difficult to resolve because of their intrinsic power. The devel-

opment of genetics is significant, and in bio-ethical committees, representatives with a *religious outlook* are often asked to give their point of view. In today's society, there are various debates on morals: questions concerning sexuality, marriage, the representation of violence on television, etc. are brought up. Religious opinions participate in these debates but their solutions are not necessarily imposed on the whole of society.

In several countries, debates concern laicity and Islam directly: for some immigrants' children, this opposes the culture that is taught at school and the culture that is transmitted within the family, which rather finds its roots in tradition. In France the *headscarves affair* is a typical example. But this affair finds significance by showing how difficult it can be for the immigrant populations of Muslim belief or origin—who often settle in the outskirts of a city; areas that are prone to break up and directly subject to increased unemployment and the crisis of the Welfare State—to integrate. On the other hand, Buddhism has integrated without difficulty.

Moreover, the relations between the State and religion in most of the countries of the European Union tend to become a specific case of a larger European model. Italian Professor Silvio Ferrari defines it with the following co-ordinates (Ferrari 1998):

(a) The State is impartial towards the various individual religious subjects.

(b) A religious subsector is singled out within the public sector. This may be understood as a playing or protected area field. (…). (This is the area in which lay most of the differences between France and the other European countries because in France this area is not institutional.)

(c) The State has the right to intervene in this area only to see that the players respect the rules of the game and the boundaries of the playing field.

This model is now deeply rooted in the political and legal culture of contemporary Western Europe. The model is ingrained to such an extent that it has become the basis for the very formulation of the laws in force concerning religious liberties and church–state relationships. This may be seen both in internal conventions and in the constitutional laws of the main European nations. These conventions and laws are formulated to ensure the impartiality of the public powers, which are legally bound to respect the freedom to profess any religious faith (besides art. 9 of the European Convention of Human Rights) and to avoid any discrimination based on religion (art. 14 ECHR). In this entirety, secularization can be put side by side with some elements of laicity by diminishing the differences linked to the existence of an official religion.

To conclude, the ideal type of *laicity* can first be characterized as a twofold refusal: the refusal of an official religion, the standards and prescriptions of which would be imposed on all by means of civil law with the state's affirmation of religious neutrality, and the refusal of an official atheism which would limit religious freedom. More positively, *laicity* can be seen as a close relation between the freedom of conscience and the freedom of thought. The freedom of conscience implies that every individual has the right to believe or not to believe, to retain or to change his beliefs. Therefore, the freedom of conscience leads to the pluralism of beliefs and philosophies within society. The freedom of thought implies that none of these beliefs or philosophies are privileged or imposed by the State to the detriment of other convictions. The State is to respect them all and is to make sure that they can all be expressed freely.

Land Degradation

'Land degradation' is a composite term. It encompasses an array of biophysical processes, each of which may result in a reduction in the quality of the

land. It also includes a range of socioeconomic outcomes, any one of which implies a worsening of the human condition. Specifically, it is now usually defined as the temporary or permanent decline in the productive *capacity* of the land, and the diminution of the productive *potential*, including its major land uses (rainfed arable, irrigated, rangeland, forestry), its farming systems (e.g., smallholder subsistence) and its value as an economic resource. 'Capacity' and 'potential' are, however, elusive to measure: they involve many other issues of identification of environmental change and long-term effects on society (see *Food Security*; *Human–Environment Relationship: Indicators*; *Sustainable Development*). Consequently, land degradation is more usually perceived in terms of its symptoms and biophysical process, from the scenically dramatic (gullies and badlands) to the often invisible (sheet erosion by water, loss in soil physical structure). Other definitions of land degradation abound, and many authors find difficulty distinguishing between it and *desertification*. The confusion accounts for the undermining of the credibility of the debate over the worldwide seriousness of land degradation (Pimentel 1993). Here, land degradation will be viewed in terms of the environmental changes that reduce the productivity and sustainability of landscapes and of the primary renewable natural resource components, especially the soil and vegetation.

1. *Land Degradation: An Old Problem with New Urgency*

Land degradation has been advanced as 'the single most pressing current global problem' (O'Riordan 2000). Yet, it is an old problem (e.g., Jacks and Whyte 1939), that has undergone a series of often-emotive revivals every decade since the Dust Bowl era in the mid-West USA (e.g., Osborn 1948, Carson 1962, Commoner 1972; Blaikie and Brookfield 1986). The historical stereotype of land degradation is that it is a process ruining the planet, and a destruction caused by ignorant peasants, who will in short time reap the folly of their degrading activities. Hailey's (1938) *African Survey* called it the 'scourge of Africa,' providing the reader with images of sediment-choked rivers and barren hillsides. Concern about degradation, particularly the processes of soil erosion, has fuelled many campaigns to combat it, and spawned numerous institutions to address it. In colonial Africa, for example, the Federation of the Rhodesias and Nyasaland funded the largest ever soil conservation research program on the continent between 1953 and 1965 to investigate rates of erosion and runoff, as well as the effectiveness of conservation and types of land use. In Southern Rhodesia, research evidence of the potential seriousness of erosion directly led to the formation of the Department of Conservation and Extension (CONEX), which carried out major conservation planning and design works throughout the country. A somewhat different institutional base was set in Malawi in response to perceived land degradation. The Land Husbandry Branch was formed in 1960 to undertake land use planning. This led to the more holistic concept of 'land husbandry,' including all farm-level production activities, argued as being a more effective tool for delivering conservation than technical, often structural, measures such as earth bunds (contour embankments to intercept runoff and sediment).

In the US, worries about land degradation supported by pictures of (usually) wind erosion engulfing farmhouses and fields, triggered massive expenditure on research and new institutions. The Soil Conservation Service (now the Natural Resources Conservation Service) was the largest single section of the US Department of Agriculture. Farmers were obliged by law to comply with conservation planning regulations and procedures. Compliance involved using research outputs such as the 'Universal Soil Loss Equation' which calculated rates of soil loss for various planned land uses, comparing these with a benchmark known as the 'tolerable soil loss,' a rate at which it was said that future production would not be jeopardized. Some of the science underpinning these procedures is now known to be flawed (Stocking 1996a). Yet, there is no doubt that the sustained research and institutional effort in the US, spurred originally by the Dust Bowl era, has not only raised awareness of land degradation but also done much to conserve that nation's soils today.

At international level, there is now a new urgency in addressing land degradation. While the World Commission on Environment and Development (Brundtland 1987) highlighted sustainable development, land degradation was only then seen as a shadowy adversary in achieving long-term productive agriculture. It was an insidious enemy, often masquerading under other names (see *Desertification*). The series of Sahel droughts in the mid-1980s illustrates the image problem of land degradation. Headlined 'drought,' its main impact came through widespread crop and grazing land failure due to the reduced capability of the degraded soils to support plant growth. The water-holding capacity of a degraded soil is only a fraction of a virgin soil. Land degradation therefore increases the vulnerability of marginal environments and societies.

Nevertheless, in the search for sustainable global futures, land degradation has once again come to the fore. The 1992 United Nations Conference on Environment and Development in Rio de Janeiro revived interest. However, it was not until 1998 that enough signatories drew their pens to ratify the *Convention to Combat Desertification*, the major components of which are national and international proposals to combat land degradation. Today, the fastest-growing

Table 1
Degradation status of global land in crops, permanent pasture, forest, and woodlands

Degradation category	Amount of land affected (million ha)	Lost production (percent)

section of the global funding mechanism (the Global Environment Facility, GEF), which supports the incremental cost of developing countries' efforts to comply with the international environment-development conventions, is for land degradation projects. The driving force for the renewed interest comes from new data from international projects such as the Dutch-based *Global Assessment of Soil Degradation* (see Table 1). The International Food Policy Research Institute uses such data to show that, while food production may largely be maintained by ever-increasing inputs, there are 'hotspots' of serious land degradation in vulnerable places such as north-east Thailand, northern China, and many African drylands (Scherr and Yadav 1996).

2. *Land Degradation: Differing Perspectives and Contexts*

The strident rhetoric of land degradation continues today. Bolstered by the power of numbers, land degradation is pictured today as getting ever worse: 'each year, 75 billion metric tons of soil are removed from the land' (Pimentel, quoted in Reij et al. (1996) who provide a good critique of the selective use of 'scientific' findings). This 'crisis' perspective is, however, becoming tempered with a new realism (Glanz 1999). One recent study questions estimates such as Pimentel's: over 20 years in an intensively cultivated drainage basin in Wisconsin, USA, sediment accretion was only about 6 percent of the rate that occurred in the 1930s, despite large stream and valley changes, while sediment yield was relatively constant (Trimble 1999). If predictions of the past had been true, whole continents would now be laid waste. Manifestly, they are not. So what is happening?

As agriculture intensifies, soils are certainly changing for the worse. Their intrinsic biological functions to support plant growth (e.g., in the natural processes of making nitrogen available to plants) have diminished. Research shows conclusively that land degradation produces poorer soils and reduced crop yields (Tengberg et al. 1998). Mediterranean environments and the tropics in general are especially vulnerable (Conacher and Sala 1998; Eden and Parry 1996). Typically, the first few tonnes of soil loss show the greatest decline in yields. Depending on actual soil type, up to 75 percent of the starting yield can be lost with 1 cm loss of soil (about 130 tonnes per hectare). Production is only maintained by compensating for the diminished state of the soil resources—through providing nutrients artificially, increasing use of irrigation to supply water that would otherwise have been supplied by a rich soil, new crop breeds that can tolerate degradation-induced toxicities, and so on. So successful are the new technologies that for most farmers they work out cheaper to implement than the equivalent conservation measures to maintain the intrinsic soil quality. Perversely, the economics of commercial farming mean that it is more financially viable to increase production while allowing land degradation than to farm conservatively. Nowhere is this better illustrated than in some intensive farming in Europe, where sandy soils have seen a decline in organic matter to as little as a quarter of 1 percent. By standard guidelines from the FAO, these soils are now severely degraded. Yet, never have they produced greater yields (Pretty 1998). With sophisticated rotary boom irrigators, multiple applications of fertilizer, and relatively cheap soil amendments such as lime, 6–10 tonnes of wheat per hectare is typical. The consequences elsewhere in the environment of substituting technology for combating land degradation can be dire (e.g., see *Water Pollution: Terrestrial and Groundwater*). Nevertheless, society appears to prefer to clear up the consequences than tackle the root causes and processes of land degradation.

Land degradation is best perceived today as the net result of a web of causes and consequences, some of which are easily and cheaply manipulated, while others are fixed. With soil productivity providing the core variables of concern that are affected by land degradation, Fig. 1 demonstrates the complex interactions on biophysical, socioeconomic, political, institutional, and cultural factors. Farming systems, the implementation of soil and water conservation practices, and assistance from external agencies (lower two right hand boxes in Fig. 1) could be manipulated relatively easily for the benefit of soil productivity and the reduction in land degradation. Whether it would be economic so to do, or viable with current institutions, is another matter. On the other hand, geology, climate, the international economy and cultural inheritance are all relatively fixed components, providing a backdrop of largely unchangeable influences that may cause degradation when the land is used. Appreciating the scale of the complex influencing factors and their amenability to external intervention is now seen as essential to developing approaches to environmental problems acceptable both to scientists and society (see *Ecology, Political*).

Figure 1
Causes and consequences of land degradation and its impact on soil productivity

3. *Land Degradation: Biophysical Processes*

Land degradation is usually described by the natural resource that is being depleted (e.g., soil/vegetation/environmental degradation) or the biophysical process by which it operates (e.g., soil erosion by wind or water, sodication, salinization, deforestation). In all these processes of environmental change, the soil is normally seen as the focal resource that diminishes in quality with land degradation. As vegetation degrades in quantity and species composition, for example, the soil changes chemically, physically, and biologically. A vicious cycle is evident in most degradation processes: as the soil degrades, so is its ability to support plant growth or other life-support functions. In soil degradation six processes usually are recognized:

(a) *Water erosion*. This includes the splashing of soil particles by raindrop impact; sheet erosion whereby a layer of topsoil is removed by flowing water; and gully erosion where a channel is formed. Gullies are often perceived as the most serious form of water erosion because they are obvious features in the landscape. However, sheet erosion by water removes far greater quantities of soil. Worldwide it is by far the most

common land degradation process in both amount of soil lost and impacts on production.

(b) *Wind erosion*. This is the removal and deposition of soil by wind. It is commonest in, but by no means restricted to, arid and semi-arid areas. A principal cause is the removal of vegetation by, for example, overgrazing or preparation for cultivation.

(c) *Excess of salts*. Salts may accumulate in the water held in the soil (salinization) or sodium cations may increase in proportion to nutrient cations such as calcium attached electrochemically to solid soil particles (sodication or alkalinization). The first is typical of semi-arid areas and of poorly managed irrigation schemes, while the second is largely a natural process accelerated by water runoff and associated concentrations of sodium induced by human land use.

(d) *Chemical degradation*. This includes a variety of processes. Some are related to the loss of plant nutrients by percolating water (e.g., calcium) or by chemical fixing into a form unavailable to plants (e.g., phosphorus); another is the build-up of toxic levels of chemicals. The pH-related change of aluminum into a free form that can be accessed by plants causes the severest impact on production in certain vulnerable tropical soils.

(e) *Physical degradation*. Adverse changes in properties such as porosity, permeability, bulk density and structural stability may arise through farming practices. The commonest physical degradation is the formation of a surface crust by raindrop impact, causing decreased water infiltration and greater runoff.

(f) *Biological degradation*. Organic matter is a transient component of soils. Where it is lost through natural processes such as mineralization at a rate significantly faster than it is resupplied by vegetation, the soil deteriorates in its overall biological functions. This happens on most intensively farmed agricultural soils.

These processes of degradation in soils all threaten the sustainability of agriculture. Usually, several processes occur simultaneously. Water erosion, for example, results in loss of soil structure, surface crusting, waterlogging, reduction in organic matter, and breakdown of stable aggregates. In the face of such an onslaught, soil resources very quickly deteriorate. Farming becomes more difficult and more costly.

4. *Land Degradation: Economic and Social Impact*

Explanations of land degradation have been made at a number of spatial and temporal scales. They express the influence of, and the impact on: (a) the resource endowments of land users; (b) the nature of agrarian society and of the state; and (c) even the imperfections in the international world economy (see Blaikie 1989 for his original presentation of a political economic analysis of land degradation; also O'Riordan 2000 for an updated version). Such an analysis gives a useful entry to socioeconomic understanding of the impacts of land degradation, helping to identify where interventions are possible and by whom. They help to counterbalance the excessively technical and place-based focus of most attempts at combating land degradation. They also explain why many soil and land conservation projects have failed because of inadequate attention to the root social and economic causes of degradation.

A partial listing of social impacts would have to include examples of major disruptions that accompany land degradation. War and conflict, as in the Horn of Africa, and around Liberia and Sierra Leone, have caused massive migrations and concentrations of people in adjacent areas. Pastoralists, in particular, live in sensitive semi-arid environments, where overgrazing of vegetation and trampling by animals is a constant danger. In normal times, society has its local institutions that manage access to the pool of common property resources of rangeland; in times of conflict, these institutions are often first to disappear. Political decisions can also have unintended side effects of promoting land degradation. *Ujamaa* (or villagization), forcibly promoted by Julius Nyerere's Tanzanian Government in 1972–73 on the grounds of better provision of education, health, and communication services, had the effect of concentrating formerly dispersed settlements into villages up to several thousand people. In vulnerable but fertile areas such as Mwanza and Shinyanga, this had disastrous consequences for the soil and land resources close to villages.

The economic impact of land degradation has received attention only recently. Valuation of the quality of land is fraught with uncertainty, and depends upon the perspective of the analyst. There are two principal choices for valuation: the production or the resource value approaches. The first assesses the impact of land degradation in the value of production lost, usually in market prices of the staple crop. This is a useful device for commercial farming situations, where production foregone is a real loss to the land user. The greater cost of farming the land or the increased investments in fertilizers or irrigation to compensate for land degradation have also been added to the value for lost production. The resource value approach, which has been the commonest because the data have been collected from experimental plots in the past, values land degradation in terms of the quantity of nutrients lost in the sediment. The means for placing a monetary value is through fertilizer prices. This second approach tends to give much larger and often unrealistic costs to land degradation than the first. Environmentalists would, however, argue that the resource value approach calculates a cost for society and future generations, and not just the immediate impact on land users.

5. *Combating Land Degradation: Future Directions*

Land degradation is, therefore, a complex biophysical, social, and economic issue, which affects many lands and peoples, particularly in the tropical developing world. The processes involved have immediate on-site impacts, rendering land diminished in quality (see *Human–Environment Relationship: Carrying Capacity*; *Sustainability Transition: Human–Environment Relationship*) and ability to support plant growth (see *Food Security*). Off-site impacts are also significant in, for example, reservoir sedimentation, eutrophication, and other downstream damages. Combating land degradation needs a commensurately broad armory of approaches and techniques, targeted not just at root biophysical causes, but also at social and economic controls, which may persuade farmers that it is in their interests to farm more conservatively.

Seeking the right intervention for the appropriate target is the major challenge for land managers. There are no shortages of techniques to combat land degradation. However, the heterogeneity of local society, the varying wealth status and resource endowments of local people, and property rights that affect security of tenure, all determine whether a technique is rational and viable for any one household. Future research will have to concentrate on matching solutions to specific environmental situations, societies, and economic demands. A better appreciation of indigenous technologies has already led to rehabilitation projects that combine elements of local knowledge with formal science. Low cost technologies which use primarily biological means will be the main focus of interest for the most seriously degraded lands.

The term *land husbandry* has been coined recently to emphasize that control of land degradation must be seen as part of the agricultural production enterprise and environmental management practice. For too long, conservation has been an additional activity. It may have attracted subsidies and incentives, but these in the longer term have simply reinforced the burdensome and uneconomic nature of many of the techniques being promoted. Land husbandry fosters the notion that integrated, grassroots approaches to the land involve the total production cycle, land users' constraints and opportunities, access to land, labor, and capital, and the technical appropriateness of solutions.

M. A. Stocking

Land Reclamation

The term land reclamation can be used in two main ways. On the one hand it can be used to describe actions undertaken by humans to reclaim land from its natural state so that it can be put to some particular use. On the other it is employed to describe ways of restoring ecosystems that have been degraded by human actions.

1. Reclamation From a Natural State

The first of these uses has been employed by historical geographers and others who have sought to investigate the ways in which landscapes have been transformed by human actions. Of particular note here was the work of the American conservationist Marsh (1864). In this magnificent and ground-breaking work he not only described the ways in which humans had modified nature by such actions as deforestation, thereby causing land degradation, but also looked at the ways in which more deliberate actions had been undertaken to transform the face of the Earth. So, for example, in his chapter on '*The Waters*' he described 'works of harbour and coast improvement,' exclusion of the sea by the construction of dikes, as in The Netherlands, the draining of lakes and marshes, the lowering of the levels of lakes, surface and under-draining of soils, irrigation of the world's drylands, and the embanking of rivers to control torrents and inundations. In his chapter on '*The Sands*' he described the ways in which dunes, such as those of the Landes of Gascony in France, could be controlled, stabilized, and made productive by judicious planting.

Since he wrote, there have been many studies that have followed up this theme of the deliberate transformation of landscapes, including notable studies of the draining of the marshes of the Fenland in East Anglia, England, by Darby (1940), or the draining of the Somerset Levels in western England by Williams (1970). Humans have exerted great energy to 'reclaim' certain landscapes, be they the industrious Dutch who have built large tracts of their country by protecting it from the sea, the land-hungry inhabitants of Hong Kong who have built out their high rise urban structures on 'reclaimed land,' the engineers who have lined the Mississippi River with enormous embankments, or the hydraulic engineers who constructed the massive canal systems that irrigate the plains of the Indian subcontinent and elsewhere (Table 1).

A particularly important type of land reclamation is the transformation of landscapes from their forested state into other types of land cover and land use (e.g., agriculture and pastoralism). This is one of the oldest forms of reclamation, which dates back to the Mesolothic and Neolithic. More recent examples include the medieval clearances of forest from central Europe, the removal of native vegetation from extensive tracts of North America since European settlement, and the current spasm of clearance of the rain forest. On a global basis over a third of the earth's land surface has been converted to 'domestic' use.

Table 1
Estimates of the increasing area of irrigated land on a global basis

Year	Irrigated area (10^6 ha)
1900	44–48
1930	80
1950	94
1955	120
1960	168
1980	211
1990 (estimate)	250

2. Reclamation of Degraded Land

The second meaning of the term is one that has come into prominence as it has become apparent that there is an increasing need to restore or reclaim land that has been degraded by human activities. Human actions frequently have rendered land unproductive or have reduced its ecological value. Examples of such actions include the destruction of the land surface by mining activities, the pollution of the ground and of water resources by various types of chemical or biological substances, the salinization of soil and water as a result of irrigation or land clearance, soil erosion resulting from over-cultivation or over-grazing, the loss of woodlands, the spread of desert conditions (desertification), and habitat destruction and associated reduction in biodiversity. The significance and extent of many of these problems is now well known (see, e.g., Turner 1990, Goudie 2000, Thomas 1956, Mannion 1998) and had led to an increasing concern with means of environmental management (Owen and Unwin 1997), of which land reclamation is a part. Connected with land reclamation is the concept of ecological restoration—meaning the desire to return an area to its original state prior to degradation so that it becomes a fully-functioning, self-sustaining ecosystem. Not all land reclamation, however, goes as far a being full ecological restoration. To give an example; an old mining waste tip may be reclaimed for agricultural use rather than being restored as a fully natural and pristine forest. Likewise, a badly salinated and waterlogged tract of irrigated land may be reclaimed for agriculture by the installation of an effective network of drains, but is not restored to its original state as a tract of desert. Concepts and means of land restoration and reclamation have been reviewed by Harris et al. (1996).

3. Examples of Land Reclamation and Restoration

In order to give an indication of the nature and scope of land reclamation and restoration techniques, it is appropriate to provide a small selection of examples. The first of these is to look at means of rehabilitating land that has been damaged by soil erosion. Morgan (1995) provides a review of some of the methods that have been employed, and draws upon the experience

Table 2
Means of reclaiming areas eroded by water action

Revegetation:
(a) deliberate planting;
(b) suppression of fire, grazing, etc., to allow regeneration

Measures to stop stream bank erosion (e.g., stone banks and rip-rap)

Measures to stop gully enlargement:
(a) planting of trailing plants, etc.;
(b) weirs, dams, gabions, etc.

Crop management:
(a) maintaining cover at critical times of year;
(b) rotation of crops;
(c) growing cover crops;
(d) agroforestry

Slope runoff control:
(a) terracing;
(b) deep tillage and application of humus;
(c) digging transverse hillside ditches to interrupt runoff;
(d) contour ploughing;
(e) preservation of vegetation strips (to limit field width)

Prevention of erosion from point sources such as roads and feedlots:
(a) intelligent geomorphic location of roads, feedlots, etc.;
(b) channeling of drainage water to non-susceptible areas;
(c) covering of banks, cuttings, etc., with vegetation

Table 3
Control techniques for reclaiming areas from drifting sand and mobile dunes

Problem	Control methods
Drifting sand	Enhancing of deposition of sand through creating large ditches, vegetation belts and barriers, and fences
	Enhancement of sand transport by aerodynamic streamlining of surface, or changing surface materials
	Reduction of sand supply by surface treatment, improved vegetation cover or erection of fences
	Deflection of moving sand by fences, barriers, or vegetation belts
Moving dunes	Removal by mechanical excavation
	Destruction by reshaping, trenching through dune axis or surface stabilization of barchan arms
	Immobilization by trimming, surface treatment and fences

that was developed not only by pioneers like Bennett (1939), who established and directed the US Soil Conservation Service from the 1930s to deal with some of the problems encountered in the Dust Bowel years, but also upon experience gained in the degraded lands of Africa and Asia. The prime means of controlling erosion (Table 2) is to undertake revegetation, either by deliberate planting or by the suppression of fire and grazing to allow regeneration. Associated with this is the need for crop management, whereby an adequate level of plant cover is maintained at critical times of year, rotation is practised, and intercropping is employed. It is also necessary to prevent erosion from point sources like roads and tracks by the careful use of drains, to protect stream banks with structures like gabions, to stop gully encroachment by means of weirs and dams, and to control slope runoff by terracing, deep tillage, and the application of humus, the digging of transverse ditches to interrupt runoff, contour ploughing, and the preservation of grass strips to limit field width. Wind erosion requires its own techniques (Table 3), including the planting of shelterbelts or windbreaks and the preservation of soil moisture levels (Watson 1990, Middleton 1990). Because of the widespread and detrimental effects of soil erosion, attempts at its control have a very long history, and in Africa, for example, there are many indigenous strategies that have proved remarkably effective (Reij

Table 4
Global estimate of secondary salinization in the world's irrigated lands

Country	Cropped area (Mha)	Irrigated area (Mha)	Share of irrigated to cropped area (percent)	Salt-affected land in irrigated area (percent)	Share of salt-affected to irrigated land (percent)

Table 5
Methods available for reclamation of salinized land

Improvement of sodic soils by the replacement of excessive adsorbed sodium by calcium or magnesium
Provision of adequate drainage to prevent waterlogging
Removal of excess salts by leaching
Water conservation (e.g., use of sprinklers, drip irrigation, cultivation of plants with low water needs, etc.)
Efficient delivery systems that minimise seepage loss from canals and deliver an appropriate amount of water at the night time
Careful leveling of land to enable more uniform application of water and, hence, better salinity control
Use of interception basins to trap saline water

1991) even in the face of quickly rising human population levels (Tiffen et al. 1994). There are also many examples of soil conservation measures that have been successful in reversing degradation, as is made evident, for instance, by the studies of Trimble in the US (Trimble and Lund 1982).

Another example is the reclamation of land that has been afflicted by salinization and waterlogging as a result of the introduction of irrigation. This is a problem that affects large tracts of land in the Indus valley of Pakistan, the Tigris–Euphrates system of Iraq, and many other potentially productive arid areas (Ghassemi et al. 1995) (Tables 4 and 5).

The third example one can give is the reclamation of contaminated ground. The reclamation methods available broadly divide into two types: traditional methods of isolation, covering or removal of contaminated materials; and decontamination techniques. Among the means of achieving isolation are capping the deposits to reduce rainfall infiltration, the installation of vertical barriers to minimize migration of contaminated waters, the digging of diversion trenches to intercept water and/or pollutants from contaminated ground, horizontal barriers beneath the deposits to prevent downward leaching, and break layers of coarse stones to prevent upward movement of contaminants by capillary action. Decontamination techniques can be divided broadly into thermal, separation, solidification/stabilization, chemical, and biological methods. Once the ground material has been treated in these various ways it will be necessary to revegetate the site, though this is not always a simple process, because the materials may be poor or lacking in nutrients, there may be some residual level of toxicity, the materials may have adverse moisture conditions (i.e., too wet or too dry), they may be compacted, or they may be too unstable to permit vegetation to be established. For all these reasons reclamation of contaminated land is often a difficult and lengthy business that may involve the use of fertilisers and essential minerals, the importing of soil, the installation of drains and mulches, stabilisation with geotextiles or by landscaping (e.g., terracing), and an understanding of the best pioneer plants to employ. Leguminous plants, for example, may be especially useful.

4. A Multidisciplinary Endeavor

What these three examples indicate is that land reclamation is a multidisciplinary endeavor that requires the involvement of a wide range of disciplines. Anthropologists may be required to understand and explain social mores, environmental historians may be needed to ascertain what conditions existed before degradation occurred, plant scientists will be required so that appropriate planting strategies are followed, engineers will be required to undertake some of the technical tasks that are necessary, geomorphologists may be useful for providing insights into appropriate terrain shapes, hydrologists will be needed to deal with water flows, and soil scientists will use their expertise to make sure that soils are used in an effective manner. Connected with this is the observation that land reclamation is not merely a technical matter that can be achieved solely by engineering solutions. Much land reclamation involves human decisions (e.g., deciding not to use too much irrigation water, deciding to introduce crop rotations or to plant and maintain shelterbelts, deciding to reduce grazing pressures, deciding to what uses contaminated land should be put, etc.). It is, therefore, an area where social and physical scientists need to come together.

Land Rights and Gender

In largely agrarian economies arable land is the most valued form of property and productive resource. It is a wealth-creating and livelihood-sustaining asset, and for a significant majority of rural households it is the single most important source of security against poverty. Traditionally, it has been the basis of political power and social status. For many, it provides a sense of identity and rootedness within the village, and has a permanence which few other assets possess. In some communities ancestral land also symbolically stands for continuity of kinship and citizenship.

Despite its critical importance, however, the issue of *women's* rights in land (and more generally in property) has until recently largely been neglected in social science scholarship and public policy. In fact, large-scale surveys and agricultural censuses in almost all developing countries collect property-related information by households not disaggregated by gender. At present, we thus have to draw upon small-scale surveys and the numerous village studies: these reveal that typically few women own arable land and even fewer effectively control some. Several reasons (outlined further below) have been put forward on why it is important for women to have effective and independent land rights. But first consider some definitions.

1. Defining Land Rights

Rights (in any form of property) can be defined as claims that are legally and socially recognized and enforceable by an external legitimized authority, be it

a village-level institution or some higher-level body of the State. Land rights can stem from inheritance, transfers from the State, tenancy arrangements, purchase, and so on. They can be in the form of ownership or usufruct (rights of use), and can encompass differing degrees of freedom to lease out, mortgage, bequeath, or sell.

Three additional distinctions are relevant here. First, there is a difference between the legal recognition of a claim and its social recognition, and between recognition and enforcement. A woman may have a legal right to inherit property, but this may remain merely on paper if the law is not enforced, or if the claim is not recognized socially as legitimate. Second, is the distinction between ownership and effective control. It is sometimes assumed incorrectly that legal ownership carries with it the right of control in all its senses. In fact, legal ownership may be accompanied by restrictions on disposal, as among the Jaffna Tamils of Sri Lanka and several communities in Latin America, where a married woman needs her husband's consent to alienate the land she legally owns. Third, we need to distinguish between rights vested in individuals and those vested in groups.

'Effective rights' mean rights not just in law but in practice. Some scholars also stress women's 'independent rights', meaning rights independent of male ownership and control.

2. *Why it is Important for Women to have Effective Land Rights*

Effective and independent land rights for women have been emphasized in recent years on four broad counts: welfare, efficiency, equality, and empowerment (as elaborated in Agarwal 1994).

2.1 *Welfare Implications*

It is well accepted that land access can significantly reduce a household's risk of poverty, but for several reasons land solely in men's hands need not guarantee female welfare.

First, evidence from many countries reveals persistent gender inequalities and a bias favoring males in the distribution of resources within households, including allocations for basic necessities such as healthcare and education and, in some regions, even food. Biases in food and healthcare are revealed especially in anthropometric measures, morbidity rates, and most starkly in female adverse sex ratios (Dreze and Sen 1995).

Second, women without independent resources are highly vulnerable to poverty and destitution in case of desertion, divorce, or widowhood. In parts of South Asia, not uncommonly, even women from rich parental and marital families, deprived of their property shares on widowhood, can be found working as agricultural laborers on the farms of their well-off brothers-in-law. Indeed, widows and the elderly often recognize that entitlement to family care and support can depend critically on whether or not they have property to bequeath (Basu 1999).

In contrast, direct land transfers to women are likely to benefit not just women but also children in greater degree. Evidence from many regions shows that women, especially in poor households, spend most of their earnings on basic household needs, while men spend a significant percentage of theirs on personal goods, such as alcohol, tobacco, etc (Dwyer and Bruce 1988). Studies reviewed by Strauss and Beegle (1996) indicate that in some African countries, in given contexts, the prevalence of child malnutrition is lower among female-headed households compared with male-headed households, even though the latter have higher incomes. In urban Brazil, the effect on child survival probabilities is many times greater from asset income that accrues to the mother than that which accrues to the father (Thomas 1990). Children in rural India are found more likely to attend school and receive medical attention if the mother has more assets (Strauss and Beegle 1996). In other words, women's and children's risk of poverty would be reduced and their welfare enhanced if women had direct access to land, and not just access mediated through male family members.

Land can provide women both direct and indirect benefits. Direct advantages stem from the possibilities of growing not just crops, but trees, a vegetable garden, or grass for cattle. Indirect advantages arise from land serving as collateral for credit or as a mortgagable or saleable asset during a crisis; increasing the probability of women finding wage employment; providing an asset base for rural nonfarm enterprises, and so on. Those with land tend to have substantially greater rural nonfarm earnings from self-employment than the totally landless. In other words, owning even a small plot can be a critical element in a diversified livelihood system, and can improve women's and the family's welfare significantly, even if the plot is not large enough to provide full family subsistence.

These factors are likely to become increasingly important as marital and kin support erodes, and female-headed households multiply.

2.2 *Efficiency Implications*

Secure and more gender-equal land rights would also have implications for productive efficiency. First there is the incentive effect. Although it is widely recognized that security of tenure can be critical for motivating farmers to make productivity enhancing investments in their fields, the need for incentives within the family has received little attention. Some studies suggest that incentives could be as important within families. In

Kenya, for example, the introduction of weeding technology in maize production raised yields on women's plots by 56 percent where women controlled the output, and only by 15 percent on their husbands' plots where too women weeded but men got the proceeds (Elson 1995). Secure land rights for women farmers and their control over the produce could thus prove to be an important element in enhancing production. Second, titles (which serve as collateral in many regions) could help increase output by improving women's access to production credit. This can prove especially critical where women are the principal farmers, as where male outmigration is high, or where widows (or wives) are cultivating separate plots still formally owned by kin. Third, research from Africa suggests that women might use land more efficiently than men in certain contexts. In Burkina Faso, for instance, due to their choice of cropping patterns women achieved much higher values of output per hectare on their own plots than did their husbands on theirs (Udry et al. 1995). Although women's yields for given crops were lower than men's, this was due to their lesser access to inputs such as fertilizers which were concentrated on the men's plots. The study estimated that output could be increased by as much as 10–20 percent if such inputs were reallocated from plots controlled by men to those controlled by women in the same household. In other words, allocative efficiency could improve with more gender equal distribution of inputs. A literature review of the effect of gender on agricultural productivity in several countries of Africa and Asia also concludes that output could be increased notably if women farmers had the same access to inputs and education as male farmers (Quisumbing 1996). Fourth, women are often better informed about traditional seed varieties and the attributes of trees and grasses. This knowledge could be put to better use if they had greater control over farming. Fifth, titles can empower women to assert themselves better with agencies that provide inputs and extension services.

Some oppose women's land claims on the grounds that it will reduce output by reducing farm size or increasing fragmentation. However, there is no consistent evidence of an adverse size effect. In fact, in many regions smaller farms have higher productivity (Lipton and Longhurst 1989, Berry and Cline 1979); and fragmentation can arise equally with male inheritance. Also, where necessary, farmers have dealt with fragmentation in various ways: consolidation through purchase and sale; land leasing arrangements to bring together cultivation units even where ownership units are scattered; joint investment and cultivation by small groups, etc.

While welfare arguments for women's land rights have received some policy attention, there is yet little recognition of the efficiency implications. These are likely to be especially important in regions of high female headedness, or where feminization of agriculture is moving apace as more men than women enter nonfarm occupations. Over time, we can thus expect an increasing proportion of farmers to be female, and women would need special targeting in policies for increasing production and improving food security.

2.3 *Equality and Empowerment Implications*

In the equality argument for land rights, two aspects have been especially emphasized. Gender equality as a measure of a just society, and equality in land rights as a measure of women's economic empowerment. The word 'empowerment' is now used widely in the literature, usually without being defined. One way to define it is would be 'as a process that enhances the ability of disadvantaged ("powerless") individuals or groups to challenge and change (in their favor) existing power relationships that place them in subordinate economic, social and political positions' (Agarwal 1994).

Endowing women with land would empower them economically as well as strengthen their ability to challenge social and political gender inequities. An illustrative example is women's experience in the state of Bihar (eastern India). Here, in the 1970s, after a peasant struggle in which both men and women participated, when women in two villages received land, they said: 'We had tongues but could not speak, we had feet but could not walk. Now that we have the land, we have the strength to speak and walk' (Agarwal 1994). This sense of empowerment accompanying improved land rights also enhances women's ability to assert themselves within the home, in the community, and with the State (the latter for demanding their due in various government schemes, infrastructure, and services). The effect of land access on women's 'bargaining power' within and outside the household has also been theorized (Agarwal 1997).

3. *Sources of Arable Land for Women*

Given its importance, to what extent do women have effective land rights? Consider the three major ways by which women can gain land: inheritance, State transfers, and the market.

3.1 *Land via Inheritance*

In most countries land is largely privatized: in India, for instance, 86 percent is privatized. Inheritance is thus the most important source of land. Typically inheritance is post-mortem, with some rare examples (e.g., from Sri Lanka) of premortem transfers via dowry. Traditionally, three types of inheritance systems prevailed: patrilineal (where ancestral property passed through the male line), matrilineal (where

ancestral property passed through the female line), and bilateral (where ancestral property passed to and through both sons and daughters). Patrilineal inheritance was the most common.

During the twentieth century, in some regions, inheritance laws underwent significant transformation and moved toward gender equality. In other regions age-old and highly gender-unequal inheritance customs continue, or the laws, despite improvement, have yet to provide full gender equality. In sub-Saharan Africa, for instance, most women's land access is mediated by marriage. Women usually receive separate plots for cultivation through their husbands, but tend to lose those usufruct rights on divorce. Only rarely do women have claims through natal kin such as fathers, or through matrilineal inheritance systems (Davidson 1988). In most Latin American countries, by contrast, inheritance laws are relatively gender equal (Deere and Leon 1999). In between come countries such as those of South Asia (where inheritance laws vary by both region and religion): here women can legally inherit from both fathers and husbands, but in most communities their rights are not equal to men's (Agarwal 1994). In addition, there are the transition economies, many of which are still formulating private property laws.

Even where women enjoy legal equality, however, there is a large gap between law and practice. The exact extent of this gap is not known due to the noted dearth of gender-disaggregated data on property, but small-scale surveys and village studies indicate that most women do not inherit what is their legal due. In rural India, for instance, a recent sample study found that only 13 percent of women whose fathers owned land inherited any as daughters, and only 51 percent of those whose husbands owned land inherited as widows (Chen 2000). In Latin America, despite legal equality, daughters are less likely to inherit land, and when they do, they inherit less and poorer quality land (Deere and Leon 1999).

Several social and administrative factors underlie the gap between law and practice. A significant constraint is postmarital residence. Where women are married to strangers in distant villages parents tend to disinherit daughters from fear of losing control over the land. Many women, especially in South Asia, also give up their shares in favor of brothers whom they see as potential sources of economic and social security in case of marital breakup, in the absence of a state social security system. Where women do not voluntarily give up their claims, male relatives may file court cases, forge wills, use threats, and even resort to violence. These constraints are compounded by the approach of many government functionaries who often share the prevalent social biases and obstruct the implementation of laws in women's favor.

The gap between legal rights and actual ownership is often matched by that between ownership and effective control. Marriages in distant villages can make direct cultivation by women difficult. Constraints also stem from illiteracy, high fertility, and social restrictions on women's mobility (as in regions of high female seclusion). These difficulties are compounded by women's limited control over cash and credit for purchasing inputs, and male bias in agricultural extension services.

However, many of the social constraints vary by region. Distant marriages to strangers are more a feature of some groups (e.g., Hindu communities in northern South Asia), than others. Where in-village marriages with close kin are allowed, there is less opposition to women inheriting land. Again female seclusion is not universal and is more a feature of Muslim societies and small pockets of north Indian Hindu communities. More subtle and widespread is the cultural construction of women's behavior and the gendering of social space which restricts women's public participation indirectly.

3.2 Government Land Transfers

A second potential source of land is through State transfers. Typically, however, government land reform and resettlement programs tend to allot land almost exclusively to males. Underlying this is usually the assumption that men are the primary cultivators and breadwinners and women the helpers and dependents. For instance, in the Latin American agrarian reforms carried out between the 1960s and late 1980s, a study of eight countries found that women beneficiaries ranged from negligible in Chile and Peru to 15 percent in Mexico, other countries coming in between (Deere and Leon 1999). Although the allocation criteria appeared gender-neutral, they embodied gendered norms and perceptions that effectively excluded most women. For instance, most schemes required beneficiaries to be household heads (presumed to be male, excepting widows or single mothers); or be permanent wage agricultural workers (who were usually men, women typically being seasonal workers); or to be well educated (where again women were disadvantaged).

In South Asia, similarly, land transfers by governments, whether under land reform or irrigation resettlement schemes, have been almost entirely to men, even in communities that traditionally practiced bilateral or matrilineal inheritance.

Recent policy shifts in most countries have typically taken the form of granting joint titles to both spouses. While this is a step forward in reducing existing gender inequalities, joint titles can also restrict women in gaining control over the produce, or claiming their shares in case of marital conflict or divorce, or exercising freedom in bequeathing the land as they wish.

Gendered assumptions have also guided land transfers following peasant movements. Women have usually been significant participants in such move-

ments but have seldom been recognized as independent claimants. Exceptions are few and far between, such as the earlier-mentioned 1970s Bodhgaya struggle in eastern India, in which women demanded and received independent land shares in two villages (Manimala 1983).

3.3 Lease or Purchase

The third source of land for women is through lease or purchase. This is a limited option, in that individual women usually have much less access than men to monetary resources. Also, rural land markets are often constrained and land is not always available for sale. This option therefore cannot compensate for the gender inequalities in inheritance or government transfers. It can, however, supplement those means, especially if done through collective endeavor. For instance, in parts of South Asia, groups of landless women have been using state-provided subsidized credit for leasing in or purchasing land in groups, and cultivating it jointly. A collective approach to cultivation and management has several advantages over an individual approach. It helps women mobilize funds for capital investment (which they are less able to do individually); provides economies of scale in input use, labor sharing, and marketing; and increases women's self-confidence in demanding technical information and inputs from public agencies (Agarwal 1998).

4. Conclusion

Research on the potential positive impact of effective land rights on rural women and children's well being, women's social and political empowerment, gender equality, and productive efficiency, suggests that concerted efforts by policy makers and grassroots activists are warranted to promote women's land rights. Among the aspects that would need attention are the following: promoting gender-equal inheritance in law and practice; formulating public policies which recognise women as significant farmers, with claims both to land and to infrastructural services such as inputs, credit, and information; initiating gender-disaggregated data collection to monitor shifts in command over landed property; and so on.

Many of these aspects would be relevant for women's property rights in general, even where the importance of arable land as property is declining (or has declined) with industrialization and urbanization.

Equally, efforts will be needed to ensure that existing biases are not replicated in new land reform initiatives and property rights formulations. For instance, agrarian reform is a major policy issue in postapartheid South Africa; and new private property rights in land and other assets are now being constituted in Eastern Europe and the former USSR. Here there are dangers of creating new gender inequalities, as is already happening to some degree (Verdery 1996). But there is also a window of opportunity for turning the tide and taking steps to ensure gender equality in both land and other property.

Land Tenure

1. Introduction

1.1 Scope and Emphasis

Land tenure, connecting to much-debated issues of human territoriality and sovereignty, can be approached at any level of scale, from domestic to cosmic. As presented in this article, land tenure moves beyond the confines of conventional English legal terms like 'rights and duties' and political-economic ones like public or private 'property' or 'ownership.' A wider array of concepts, taking real access, attachment, and mobility into account, is needed. Visas and border blockages matter no less than plot markers or title deeds. Terms and translations—for people, things, and links between—are critical throughout.

Land can refer to space or place, often denoting material substance deemed immovable, and sometimes connoting belonging. In some tongues it takes several distinct words to translate, and corresponding terms may or may not include water, plants, animals, people, and built or dugout structures. 'Tenure' (from L. *tenere*, to hold) or landholding need not refer just to a particular form of legal, political, or economic regime (such as freehold, fiefhold, or collective village ownership) but can indicate human-land attachment in a broader sense, taking account of unofficial, illegal, or occasional use, and of persons living, dead, or unborn.

1.2 Sovereignty and Strife

'Nearly all social struggles in Antiquity,' claimed Max Weber, 'were essentially for the ownership and use of land' (1988, p. 343). He might say the same for recent times. Particular regions have hallmark forms of land tension and strife, simplified and sharpened in mass media if not also in scholarly representation. Such are ethnoreligious struggles over autochthony in the Levant and Northern Ireland; forced transmigration in Indonesia; latifundio, minifundio, squatting, and private militias ('goon' squads) in Hispanic America; small-tribe survival struggles in Amazonia; landlord-tenant exploitation in South Asia; plantation oppression in the Caribbean and island southeast Asia; collectivization and decollectivization in Russia and China and states in their hegemonies; farmer-herder conflicts in the American west or the Sahel; individual titling that threatens women, children, and the rural poor in the African tropics. But none of these regions monopolizes the tenure issue for which it is famed. Tasks for social scientists and humanists include finding particularities and exceptions, bringing to light indigenous practical solutions, and assessing the performance of currently sovereign authorities.

2. Historical Background

Records of land claims and transfers have been dug up among some of the earliest known writings in Mesopotamia from four to five thousand years ago, along with royal edicts canceling subjects' debts and reversing land forfeitures to creditors. Plato's and his student Aristotle's debate about the merits of public versus private landholding in the Aegean *polis* echoes two millennia later in European and American traditions. John Locke, Adam Smith, and Herbert Spencer are still widely cited by private property's upholders, while the young Jean-Jacques Rousseau, Karl Marx, Pierre Proudhon, and (in America) Henry George are champions of its critics.

2.1 Evolutionist Political Philosophy

The spread of European imperial power and the westward expansion of Euro-American settlement in the late nineteenth and early twentieth centuries, accompanied as they were by wholesale expropriation or disenfranchisement of foragers, mobile herders, and swidden (slash-and-burn, long fallow) farmers, led sociologists and anthropologists into the study of land tenure as their disciplines coalesced. Jurist Henry Maine's vision of Roman property law's and human history's evolution from ascribed 'status' to achieved 'contract' was qualified by lawyer-anthropologist Lewis Henry Morgan's conclusion in *Ancient Society* (1877), that individual property was an inadequate basis for civilization's further progress. Societies moved, said Morgan, from (L.) *societas*, i.e. ties based on kinship and other particular ties, to *civitas*, ties based on territorially defined polity, but this did not always mean upward progress either. Karl Marx and Friedrich Engels, inspired by Rousseau and Morgan among others, envisaged history as a one-way flow through stages of prefeudal tribalism, feudalism, capitalism, socialism, and finally a future communism with abolition of private property and state government.

Evolutionist theories based on a largely imaginary prehistory and assumptions of unilinear change continue to resound in legal, political, and economic

circles. But twentieth-century anthropology has made it more apparent how tenure change can zigzag and backtrack, and how many different forms of tenure can be 'modern' at once, sometimes in close co-existence.

2.2 Persons, Things, Systems

Early ethnography in Australia and Native America, and Bronislaw Malinowski's work on Trobriand Island gardening in Melanesia in the 1910s, revealed indigenous concepts in which human groups and spaces (however defined) were deemed aspects of each other, often inextricable from spiritual beings or forces. Research in colonial Africa in the mid-twentieth century depicted how land tenure tied tightly into cognition, language, and translation; kinship and friendship; political control and hegemony; religion and ritual; aesthetics and myth (Biebuyck 1963). Monarchs' and chiefs' control over land (as in Buganda or Ashantiland) appeared to be part and parcel with control over people, but their rights excluded alienation by sale and other rights often identified with ownership. Landholding was justified by clearing, residing, or working on the land, by conquest, by membership in a kin or local group, by chiefly assignment and tribute, or a mix of these. Multiple rights of different groups to use land for different purposes, for example farming, grazing, and thatch, firewood, or clay collection, overlapped in complex ways not captured by terms like 'property' or 'ownership.' In 'acephalous' (politically uncentralized) societies like those of Tiv in Nigeria or Chagga in Tanzania, land territories were often found closely linked to genealogy of clans or lineages, shifting and stretching as these moved, grew, or shrank. Here and elsewhere in Africa, land was spoken of as an active interest not only of the living, but also the dead and unborn. To Audrey Richards, Lucy Mair, and other British-trained social scientists, land tenure appeared as part of complex, functioning cultural systems. Max Gluckman's southern Africa-based work on 'hierarchies of estates' over land, for instance of use, transfer, and administration, influenced a generation of tenure studies. Gluckman (1965) observed that property is not just about rights of people over things, but also about duties between people with respect to things.

2.3 Structure and Process of Inequity: Critical Rethinkings

In the 1960s and early 1970s, Latin American-inspired scholarship on dependency and 'modes of production,' in a Marxist vein, criticized the exploitation of rural and tropical peripheries by metropolitan capitals through agribusiness or plantation owners or the co-optation of comprador (buyer) elites. South America, the continent with the longest history of European colonialism, had, some observed, the most uneven distribution of landholdings. Parisian Marxist structuralists in the late 1970s revised the view that capitalism eroded all other forms of tenure and exchange (quasi-feudalism, family farmholding, etc.), contending instead that it encapsulated and preserved these for its own profit.

In the 1980s and 1990s social scientists with political-economic interest turned their attention to attempts by national regimes to monopolize power over land relations, particularly in Africa. State attempts to nationalize, privatize, or socialize landholding now looked like raw or subtle power grabs (Downs and Reyna 1988, Le Bris et al. 1991). Large-scale resettlement efforts, as in Ethiopia or Indonesia, seemed to some analysts like attempts to remove or disorient potential dissidents. Attempts to 'villagize' scattered farmers or sedentarize mobile herders appeared as attempts more easily to tax, conscript, and regulate them (Scott 1998). Postmodernist and post-structuralist scholars, meanwhile, eschewed the notion of timeless tenure 'systems,' preferring to see complexity, fragmentation, indeterminacy, negotiability, contestability, and historical contingency, in human-land as in human-human interaction. In town and country, they criticized tenure regimes based on race, class, and gender.

Toward the turn of the millennium, a plurality of newly empowered indigenous voices in southern countries helped force scholars and jurists concerned with land tenure everywhere to reassess their most basic terminology and philosophical premises. Assumptions of human dominion over land, of individualistic rights and duties, and of the sanctity of arbitrarily drawn borders and boundaries that blocked human movement, all came under criticism.

3. Metaphor and Rhetoric

Human communication about land draws heavily on metaphoric imagery from the human body (headwaters, heartlands, fertility, etc.), kinship (mother-, fatherland), domicile (gateway to Asia), and other human-centered sources. Such metaphorizing imbues poetry and politics, while imagery of 'grounding' or 'terra firma' imbues legal and scientific discourse. English terms like 'property,' 'rights,' or 'ownership' sometimes carry culture-bound overtones of civilization, justice, or morality. To speak of land as a commodity denies psychological attachments to space and place. To speak of land as a 'resource' implies it exists to serve human use. Between people who assume that humans can own land and master it, and those who assume on the contrary that humans belong to

the land and must respect it and conform to its requirements, communication easily goes awry.

People who derive their livelihood from land in different ways perceive and communicate about it in different geometric and geological idioms. Whether in the Andes, the Sahel, or Lapland, transhumant herders who must focus on linear access routes tend to clash with farmers who focus on fields along the way, when animals eat or trample crops. Seasonal and tidal wetlands and mudflats (as in the Niger delta, in the Sudanese Sudd, or along the Senegal River) are frequently contested by farmer-fishers, ecologists, and developers using different terminology.

4. *Land and Tenure Reform*

While land reform, in English, conventionally refers to redistribution of holdings, land *tenure* reform refers to changes in the more basic rules and understandings by which land is occupied, used, or transferred. Among many kinds of tenure reform are proclamation of sovereignty or eminent domain, implementation of titling (i.e. registration), and change in rules about transfer (loan, rental, sale, inheritance, etc.). Dozens of twentieth-century national tenure reforms sought to individualize or collectivize landholding.

Their histories are full of ironies and surprises. Frequently, reforms aimed at improving distribution of holdings have ended up worsening it, whether because of unequal information, implementer bias, deceit, or reneged deals. Moreover, reforms aimed at boosting production have often reduced it instead, for instance because new owners or occupants lacked farming experience or acquired the land only for speculation. Land tenure is so tightly bound up with kinship, religion, and other aspects of culture that a newly imposed tenure regime seldom expunges what was there before. More often, it just crowds new procedures together with old, allowing the wealthy, powerful, astute, or well connected to gain at others' expense by manipulating confused or conflicting principles.

There are exceptional cases of successful land and tenure reform. One celebrated example is Taiwan's land redistribution in 1953, swiftly and efficiently implemented after a period of Japanese occupation had weakened local resistance. Attempts to emulate it elsewhere have seldom succeeded.

4.1 *Bureaucratic Simplification*

Bureaucratic administration, tending to push toward abstraction and universalism in its publicly professed goals, simplifies complex realities of human culture and ecology, sometimes beyond recognition, to make people or spaces manipulable for taxation, military conscription, etc. Empty spaces on maps, or designations like 'vacant' or 'underproductive,' help justify land grabs, disfavoring swidden farmers, transhumant herders, foragers, and other occasional users. Titles issued to individuals ignore claims of dependents. But subjected people may thwart imposed tenure regimes, for instance by continuing to transfer fields without informing state authorities, as happened in Kenyan and other African cases of titling reforms over the second half of the twentieth century. Real and paper tenure diverge further.

Nowhere do real people live their lives consistently by capitalist or socialist principles, whatever they may think they do. In agropastoral Africa, for instance, land farmed by families or individuals may be expected to be opened for grazing by the animals of some broader public after harvest. Property shifts between public and private, or remains subject to multiple tenure 'systems' simultaneously.

4.2 *Collectivization and Villagization*

Collective ownership and production have been part of utopian visions since Plato's *Republic* or before, and many different attempts have been made to bring these into reality in monasteries or other single- or mixed-sex religious or secular communes, sometimes modeled upon families. Mexico's *ejidos* after the 1910 revolution, and Israel's kibbutzim more recently, have been closely watched by admirers and critics alike. Marxist-inspired attempts to collectivize landholding under state aegis in the Soviet Union between 1917 and 1931, and in China after 1949, have been emulated in various parts of the world, notably eastern Europe, Vietnam and Cambodia (Kampuchea), Cuba, Tanzania, Ethiopia, and Lusophone African countries including Angola and Mozambique.

While late twentieth-century Chinese history has shown that some forms of state-organized collective farming can raise productivity, improve distribution of food and other vital resources, or both, if starting from a feudal or quasi-feudal baseline, people in few parts of the world have been able to emulate socialist tenure reforms with lasting success. Commonly, work-incentive problems get in the way, and local populations chafe under centralized bureaucratic control of their lives.

Notable failures have been attempts to concentrate rural people into villages where the land could not sustain them, as in Tanzania's compulsory villagization from 1973 to 1976 (an experiment duplicated in Ethiopia a few years later). Similarly, savannah borehole well projects, for instance in Botswana or across the Sahel, have led to overconcentration of animals and overgrazing. Two policy conclusions on herders and farmers are clear enough: (a) people who live spread out, or mobile, usually have good reasons

for wanting to stay that way; (b) good intentions, in land tenure reforms, are about as likely to produce harmful as helpful results.

4.3 Titling and Individuation

Another kind of tenure reform is the titling or registration of individual claims for the first time. 'Private' property is often used to mean individual property, but the two need not be the same. State and local governments and landholding companies have several ways of registering land titles and transactions. Among the most commonly applied in former British colonies is the Torrens system, devised in Australia and New Zealand in the 1860s, where it allowed grid allotments for new settlers.

Where people already live, titling land in the names of individuals, under state guarantee, does not necessarily increase security of tenure as often assumed. It may decrease it. Instructive was the General Allotment Act (or Dawes Act) of 1887, by which the US government allowed for the awarding of individual land titles to Native Americans (or First Peoples). Between 1887 and 1932, about two-thirds of Native American lands were lost to immigrant settlers and speculators, who were not slow to exclude its former inhabitants and users.

British, French, and Belgian colonial administrations appear to have paid this story little heed in launching land titling programs in their colonies. Early twentieth-century titling initiatives were expanded to nationwide scale in the Kenyan model established under the Swynnerton Plan in 1954 and passed into law in 1957. That model, which still continues, was being emulated elsewhere in Africa at the turn of the millennium.

At least as often as not, land titling in new states and perhaps old seems to speed the concentration of holdings into fewer hands. Individuals newly freed of social constraints on selling, mortgaging, or pledging erstwhile family or clan land do not always make wise decisions. Speculators and accumulators use urban capital and rural off-farm incomes to buy out disadvantaged rural people in periods of drought, plague, or unfavorable prices.

The mortgage, a deadlined pledge linking land or other property to credit, plays a key part in this process. Borrowers who fail to repay by a specified date forfeit their land to the lender or lender's agent. The mortgage appears regularly in histories of rural dispossession, not least in England, where law about it has changed many times, and in North America. While seemingly vital to urban and industrial economic life, in rural areas mortgage loans are more treacherous to farming people, particularly where rainfall, infrastructure, and crop markets are unreliable. Although rich like poor may lose lands, mortgage foreclosure contributes heavily to class stratification. Inland tropical settings often lack sufficient industrial or commercial opportunity to absorb newly landless or land-poor people. Even where land titling is accepted, mortgaging is morally debated in many cultural and legal traditions. *Shari'a*, the sacred law of Islam, forbids mortgaging as sin.

When, and whom, is titling likely to help? Threatened indigenous minorities frequently seek titles to defend their home territories—and by extension, their livelihood and way of life—from more numerous and powerful outsiders who threaten to dispossess or displace them. These may include fortune seekers like ranchers and rubber tappers, as in Amazonia or Malaysia; homesteaders and land speculators, as in the American west; planters, as in the Caribbean; or politicians and their favorites, as in equatorial Africa.

Land titling is never a politically neutral process of recording information. Usually someone gains and someone loses. Gainers are often richer, better-connected, and better-schooled people; erstwhile land borrowers or land clients, who may become owners; and people who emigrate or seek to speculate in land without having to occupy or farm it. Losers include ancillary rightholders and dependents, and members of fast-reproducing families. Just as rural people have circumvented or resisted state directives to villagize or collectivize their landholding under socialist policies, as in Tanzania or Ethiopia, they have reasserted the rights of collectivities—clans, lineages, age sets, or voluntary associations—under individualistic capitalist ones, as in late twentieth-century Kenya or Côte d'Ivoire.

4.4 Fragmentation and Consolidation

While economists and agronomists have often favored large consolidated blocks of land for mechanization and economies of scale, anthropologists and ecologists, observing their subjects' resistance, have found that fragmented holdings may make sound ecological and economic sense in some settings. Unreliable rainfall, acute pest problems, and dicey markets encourage a cultivator to keep a hand in diverse cultivars and microclimates to avoid a total loss. Maintaining multiple holdings also helps conceal wealth from neighbors or tax collectors.

4.5 Irrigated Lands

Nowhere is control over land more hotly political than in irrigated areas, where central authorities may seek to dictate settlement, land and water allocation, inheritance, etc. The centripetal draw of high farm yields in irrigation schemes is sometimes counteracted by the centrifugal push of struggles over control over community and family life, as in the Jahally Pachar

rice scheme in the Gambia. Where flood control is a main concern, as in much of irrigated China (or Bangladesh), bureaucratic polities tend to be highly centralized and authoritarian. Where it is not, as in much of Africa, regimes attempting to emulate such models have enjoyed little popular support, often proving fragile and short-lived—particularly where ethnic mixture compounds the adjustment problems of living in close, compulsory synchrony.

All irrigation but the smallest scaled involves inequalities in access to water. The privilege of upstream location in the trench network, implying superior control, often coincides, as cause or effect, with personal or familial wealth or power.

4.6 *Displacement and Resettlement*

Development programs like irrigation schemes and hydroelectric dams; military travel and war; and environmental hardships like droughts and floods all entail resettlement of large numbers of people. If the land of destination is unoccupied, usually there is something undesirable about it. If it is occupied, then someone has to move over and friction is likely. Late twentieth-century anthropological studies of resettlement, notably by Elizabeth Colson, Thayer Scudder, and collaborators among Gwembe Tonga in Zambia (formerly Northern Rhodesia), showed how resettled people adjust to extreme stress and trauma in patterned and predictable phases. Among their problems are the shaken confidence in whatever leaders are seen to have allowed the misfortune to happen. Helping or allowing communities or neighborhoods to move intact, in so far as their members wish, seems to mitigate the ill effects by keeping at least their social 'landscape' familiar. But no kind of human 'development' intervention is harder to orchestrate, or more prone to produce catastrophe, than forcing resettlement.

4.7 *Agrarian Encroachments*

Many contemporary 'foraging' peoples reside in difficult environments not of their choosing, for instance in southern and central Africa and northern Canada, where 'race' discrimination has been a factor. Attempts to use these peoples as windows into human prehistory—to see how hard people worked, how peacefully they lived, or how well they cooperated—have often led to spurious conclusions.

Foraging, swidden farming, and mobile herding peoples worldwide suffered a varyingly steady diminution of their lands, and sometimes severe dislocation, from before the eighteenth until the late twentieth centuries, often in episodes where racism played a part. The history of Native American foraging and farming peoples after Columbus—a story of military conquest, deceit, misrepresentation of consent, and treaty reneging by Euro-Americans—hit one of its low points in President Andrew Jackson's Indian Removal Act of 1830, which forced Cherokee, Seminole, and other settled agricultural Native Americans from their southeastern homes to Oklahoma, at the loss of thousands of lives. In another kind of extreme case, Australian law did not recognize the rights of indigenous (or Aboriginal) peoples to land until 1976. In the twentieth century, swidden farmers in tropical and subtropical zones worldwide faced serious threats to their livelihoods under encroachment from sedentary farmers, agribusinesses and other concerns, and under their own population growth. Loss of land for these peoples, as for foragers and pastoralists, has often meant disruption of culture and society in myriad, sometimes indirect ways. The new century and millennium present the challenge, if not of reversing this history, of allowing dignified livelihood to persons constricted or displaced.

4.8 *Reserves and Exclusion*

Official attempts to fence off wilderness reserves have achieved checkered results, particularly in poorer regions and countries in Africa south of the Sahara and in mainland Southeast Asia. One clear lesson from these attempts is that foragers, herders, or swidden farmers excluded from accustomed lands will tend to subvert the new classification unless somehow included in rewards accruing from tourism, mining, or other commercial exploitation of new parks or reserves.

5. *Advocacy and Practice*

The activist international defense of land rights of threatened indigenous minorities, particularly in sparsely settled regions pressed for new resource exploitation by outsiders (Amazonia, Alaska, central Africa, northern Australia, Irian Jaya, and elsewhere), crystallized in the Copenhagen-based International Work Group for Indigenous Affairs in 1968, London-based Survival International, in 1969, and Cambridge, Massachusetts-based Cultural Survival, Inc., in 1972, as well as other human rights defense groups. A worldwide movement of indigenous human rights groups, mutually emboldening, has raised public consciousness and achieved changes in national legislation like the Alaska Native Claims Settlement Act in 1971, Australia's Aboriginal Land Rights (Northern Territories) Act in 1976, and from Canada, the demarcation of Nunavut at the end of the century as a largely autonomous territory for First Peoples. Still, the International Labor Office's Convention 107,

claiming that 'the right of ownership, collective or individual, of the members of the populations concerned over the lands which these populations traditionally occupy shall be recognized,' and the World Bank's tribal peoples policy issued in 1982, have mainly been honored in the breach (Bodley 1999). Participating in the active design of constructive tenure processes along lines more faithful to indigenous systems and aspirations, and showing respect to indigenous terminology, remains a challenge.

6. *New Frontiers*

As social scientists and humanists look beyond simplistic dichotomies like 'public vs. private' (or collective vs. individual), or 'rights and duties,' they perceive many yet unstudied forms of tenure. These may offer important solutions to work-incentive problems typical of socialism, on the one hand, and maldistribution problems typical of capitalism on the other. Other terms, concepts, and policy frameworks are needed that respect access, stewardship, and sentiments of attachment, and that allow for human population flows between territories.

Shifting attention between micro and macro scale, geographers, archaeologists, and others have sought to connect their work on the ground with findings newly accessible from 'remote sensing,' of landforms and land occupation and use, from air and space. Rural land tenure remains better studied than urban and peri-urban, and ground tenure better than water tenure. Border and boundary issues are land tenure issues on a large scale. Problems of land quality and distribution can be addressed not only by altering tenure regimes within nations, but also in allowing people to move between nations or continents more freely. Land tenure is not just about getting in, but also about getting out.

A challenge for social and biological scientists alike is to connect the understandings about territoriality observable from human action on the land, with understandings becoming obtainable through ethology and the electrochemical study of the human brain. Human biology has yet produced few if any conclusive findings about territorial instincts in humans, but enough species exhibit recognizable social and cultural patterning in their territorial relations to make it seem unlikely that human spatial perceptions and attachments result from uniquely human social or cultural processes alone.

Meanwhile, as more languages have become involved in the academic study of land and tenure, the reexamination of the most familiar, but deeply cultural and potentially exotic, concepts and categories—like 'land,' 'property,' and 'rights'—has continued.

Land Use and Cover Change

The rather ungainly term 'land use/cover change' is fitting, for it conveys the conjoint nature of this branch of human–environment research. This article considers the merging of scientific perspectives that has been necessary to understand the dynamics of human land-use practices and the social and natural environments that shape, and are shaped by, those practices. This endeavor is aimed at estimating past human impacts on the earth, with a view to projecting possible future impacts.

1. *Land Use and Land Cover*

While closely related, the terms land use and land cover refer to quite different dimensions of the earth's surface that have largely been investigated in distinct scientific traditions. Land cover refers to the biophysical attributes of the earth's surface and immediate subsurface. This includes vegetative layers (both natural and artificial), exposed soil or rock, and ice, as well as human constructions such as buildings and pavement. While some land covers are considered pristine or at least minimally touched by the human hand (e.g., remote tropical rain forests), others are recognized as transformed or radically altered (e.g., urban areas).

Land use, meanwhile, refers to the human intent to which the land surface is put. While use registers as an imprint on a given location in terms of the change in land cover that would otherwise exist, it also includes the motivations, constraints, and enabling conditions that give rise to the use. Land cover and land use each imply both state and process variables, and have multiple and overlapping properties whose appearance depends to a great degree on the particular ways in which they are observed.

Because of the compound nature of the questions relating human land use practices to land cover states and changes, addressing them involves an amalgam of analytical perspectives spanning, for example, the social and physical sciences, quantitative and qualitative approaches, and academic and policy concerns. Each of the research traditions involved brings its own theoretical perspective and modes of inquiry, and their coupling is not always easy. In particular, the need to merge locally specific explanations of how and why people use land in particular ways, with broader patterns observed at regional or global scales brings into sharp relief a long-standing conundrum of scientific inquiry—scale dependence: the dynamics of land use/cover changes vary depending on the spatial and temporal scale at which they are observed (see *Local–Global Linkages: Environmental Aspects*). Nevertheless, the enterprise is bound together by the desire to understand how biophysical conditions, particularly 'initial' land cover, shapes human activities (opportunities and constraints), and how these activities, or land uses, alter these pre-existing conditions, thereby shaping future livelihood options.

2. *Human–Environment Relations in Land Use/Cover Change*

The relationship between humans and the natural world appears to be a universal concern of Western thought, occupying a central place in Greco-Roman, Arab, and European mythology and philosophy (see *Human–Environment Relationships*). Modern attempts to characterize the impact of human activities on the earth include George Perkins Marsh's seminal work *Man and Nature* (1864), which has been updated by major multidisciplinary efforts, including *Man's Role in Changing the Face of the Earth* (Thomas 1955) and *The Earth as Transformed by Human Action* (Turner et al. 1990). During the 1990s, the public discussion over the threat of human-induced alterations to the earth's bio-geochemical cycles (e.g., 'global warming') has shifted from speculation to skepticism and finally to widespread acceptance and debate over the details of where, when, and with what consequences such changes may occur.

The bulk of global change science remains dedicated to improving our understanding of the functioning of the earth's climate system, for example through the modeling of carbon dynamics (see *Climate Impacts*). However, as the biophysical systems are better understood, greater attention has been focused on the human dimensions, including the major anthropogenic sources of global change, the consequences of that change in terms of the sustainability of livelihood systems, of the vulnerability of particular groups of people and places, and of the societal perceptions of and responses to change (Kasperson et al. 1995; see *Human Dimensions of Global Change*). These concerns require understanding the human systems—economic, political, cultural, and sociotechnical—associated with human activities at particular places and times (Moran 2000).

Many human activities are known to cause significant disruption of global bio-geochemical cycles, particularly the combustion of fossil fuels. The modification of land cover is also a significant anthropogenic source of bio-geochemical disruption, especially the replacement of forest with grasslands and croplands, and the application of chemical fertilizers and pesticides to croplands. Other important questions driving global change research concern the reduction of biological diversity, both directly through species extinction resulting from human activities, and indirectly through the destruction of habitat (see *Mass Killings and Genocide, Psychology of*). Here again a solid understanding of land use/cover dynamics is required.

These concerns are of more than academic interest; policy is actively being crafted to limit human impacts on the environment at both regional and global scales. The effectiveness of environmental laws and agreements depends on sound scientific understanding of the impact of land use practices, in order to target critical areas and to monitor compliance. Accordingly, research programs have been developed at national and international levels, including the Land Use Cover Change (LUCC) Project, under the aegis of the International Geosphere-biosphere Programme and the International Human Dimensions Programme (Lambin et al. 1999). Land use and cover change research constitutes a bridge between the understanding of the biophysical aspects of global change and the human dimensions of sustainability (see *Sustainability Transition: Human–Environment Relationship*).

Two fundamental, linked, sets of questions underlie land use/cover change research: the first concerns the nature, location, and rates of anthropogenic modification of land cover; while the second seeks to understand the reasons behind land-use practices leading to such modifications. The first set of questions is generally examined at relatively broad scales, often using satellite imagery to determine spatial and temporal patterns of change, while the explanation of land use practices requires local-scale research, and often involves interviews with land managers and direct observation of land management practices. As answers to these two sets of questions take shape, it becomes possible to model the trajectories of change that have been observed, and to project future land-cover outcomes.

3. *Land Cover Change*

Despite having been studied for more than a century, land cover change is still poorly understood, but recent technological and methodological advances show great promise. Two advances in particular bear noting: the ability to observe the current state of the earth's surface from space, and the ability to reconstruct past land-cover patterns through the techniques of the paleo- and historical sciences.

Remote sensing of the earth refers to the use of instruments carried on aircraft and earth-orbiting satellites that detect energy reflected or emitted from the earth's surface in different portions of the electromagnetic spectrum. The land cover of most inhabited portions of the earth has been periodically recorded through aerial photography since the 1950s, facilitating the production of land-cover maps. Since the 1970s, satellite remote sensing data have provided more frequent views of large areas (see *Remote Sensing and Geographic Information Systems Analysis*).

Land-cover research has utilized two sets of satellite imagery, though the distinction between them is disappearing. One set of satellites (e.g., the Landsat, SPOT, and ERS platforms) provides relatively high spatial resolution, sampling the earth's surface on the order of tens of meters, along swathes of 100–200 km. While such imagery is capable of distinguishing several types of land cover, the satellites take weeks to observe the entire surface of the earth, and views of land cover are often inhibited by cloud cover or other atmospheric conditions, especially in the tropics.

Nevertheless, several efforts have achieved reliable views of land cover from high-resolution imagery at continental, or subcontinental, extents by creating mosaics of images (e.g., North America, Europe, Amazonia, and East Africa). Most of the focus to date has been on those areas where transformation of the earth's surface has been most dramatic in recent times—the tropics. The clearance of forestlands has garnered special attention, both because of the potential impact on climate change and biodiversity, and because of the relative ease with which this particular form of land-cover conversion can be detected through remote sensing. Estimates of rates of deforestation are becoming more reliable, and researchers have identified so-called hotspots, where habitat destruction—usually deforestation—is most rapid and biodiversity therefore threatened (see *Deforestation–Forestation*).

Another set of remote sensing systems, primarily intended for the observation of weather, has been acquiring daily views of the earth for over a decade. These images can be compiled to create cloud-free images for ten-day or monthly intervals. These data sources typically suffer from poor spectral and spatial resolution, however advances in processing this rich time series are yielding unique information on seasonal and longer-term climatic patterns, such as El Niño. Separating these natural cycles and rhythms is crucial to the reliable detection of anthropogenic land-cover change. Over the last few years of the twentieth century, significant achievements have been made in the development of global land-cover databases. Global land-cover maps have recently improved in spatial resolution by about an order of magnitude, with reliable databases now produced from data from a single year of observation at a spatial resolution of about 1 km. New satellite systems promise to improve this spatial resolution by a factor of four in the near future, with spectral definition better tuned to land cover change detection. These land-cover data are complemented by similar, related global databases at similar spatial resolutions concerning, for example, human population density and the incidence of fire. (Reviews can be found in special issues of the *International Journal of Remote Sensing* **21** (2000, no. 6/7) and *Photogrammetic Engineering and Remote Sensing* **65** (1999, no. 9).)

The detail and reliability of the information provided by both sets of sensors are constantly being enhanced through improvements both in the instruments themselves and in the technology and skill with which the data are processed. As the data from the

various satellite systems are better integrated, the gap will close between the global coverage and local case studies using aerial photography and high-resolution imagery. Attempts at such integration have highlighted the disparities between analytical schemes for characterizing land cover, as well as the difficulties of merging information about biophysical and social dimensions of land-use/cover dynamics (National Research Council, NRC 1998).

In addition to the very detailed record of land use and related land-cover impacts provided by remote sensing over the second half of the twentieth century, our knowledge of prior land-use impacts is also growing through the analysis of pollen in sediment cores and other paleo-ecological and archaeological techniques. Such techniques have enabled the estimation of the earth's land cover 6000 years ago (GAIM 2000), and detailed reconstructions are being made for the past three centuries by projecting current land cover back in time using historical agricultural and demographic information. The convergence of remotely-sensed and other historical sources with prehistoric reconstructions will provide a much fuller picture of the earth's land cover throughout the time of significant human impact, yielding valuable insights on long-term trajectories of change, and of possible path-dependency in the evolution of regional land-cover patterns.

4. *Land Use Change*

Elements of land-use practices have been a staple topic of investigation for numerous disciplines in the social sciences, including anthropology, archaeology, demography, economics, geography, history, political science, and sociology. Through different lenses, scholars in these fields have sought to explain how and why people in different parts of the world have developed technology and social systems in response to local environmental conditions, how these human actions have in turn shaped the local environment, and how people then respond to these changing conditions (Redman 1999). Thousands of case studies have been undertaken, usually concerning communities or small regions, and some efforts have been made to synthesize these cases in order to extract general principles and to develop a unified theory. While the history of land use in Europe is well documented (e.g., Darby 1956), land-cover transformation has been perceived to be most dramatic in the tropics in recent years, and a great deal of attention has been accorded these regions, with particular attention to agricultural land-use practices (e.g., Ruthenberg 1976).

A broad range of factors has been proffered to explain local land-use practices, with perhaps the greatest effort spent examining agricultural change and the role of population growth (see *Agricultural Change Theory*). The now-famous work of British economist Thomas Malthus, who predicted famine as an inevitable result of population growth in Europe, has fostered huge debate within the social sciences. Another major landmark was the work of Ester Boserup (1965), who turned the Malthusian thesis on its head, attributing agricultural development in Asia to land pressure driven by population growth. Subsequent refinements have described a range of land use change trajectories that may emerge from land pressure and suggested how the driving forces of change are mediated by social and environmental factors at many levels (Turner and Ali 1996).

In addressing the relationship between population growth and land degradation, political-economic analyses hold external forces responsible when land managers engage in environmentally destructive land use practices (see *Land Degradation*). Likewise, cases have been articulated of population growth leading to the rehabilitation of natural resources, including afforestation (see *Land Reclamation*). A great deal of work has been done to examine the role of demographic factors in land use change, with particular emphasis on government-subsidized settlement programs in Latin America, and rural–urban migration in Africa and Asia. Results suggest complex relationships between land-cover dynamics and the provision of infrastructure (especially roads), family development cycles, urban wage employment, and other factors that vary strongly by region (e.g., Lambin et al. in press; see *Property Rights*).

In the case of forest cover, global-scale empirical evidence reveals a complex relationship between forest cover and population density, suggesting that as population density rises in newly settled regions, forest cover has often been removed for the purposes of agricultural expansion. Another period ensues during which wood fuel is replaced by other sources (e.g., fossil fuels) and agricultural intensification allows for the production of sufficient food on less land. Eventually affluence rises to the point where attention to environmental rehabilitation becomes feasible and afforestation becomes the dominant trend.

5. *Land-use/Cover Dynamics*

Perhaps the main challenge of land use/cover change science is to forge robust linkages between the broad views of land cover change provided by remote sensing and other techniques, and the fine-grained understandings of land-use dynamics. In weaving together these diverse strands of inquiry, land use/cover change research examines the observed paths, or trajectories, and projects them into the future. While this may not lead to prediction, it will suggest what might happen should present trends continue and, perhaps more importantly, suggest other possible futures. There are significant obstacles to achieving this integration of land-use and land-cover perspectives, but advances in geographic information technologies and new analytical techniques show great promise.

Most early models of land cover change were either empirical (mimicking the observed relationships between variables, such as forest cover and population density), or mechanistic (describing a limited range of landscape processes according to simple equations) (Kaimowitz and Angelsen 1998). While such models have the advantage of requiring minimal, empirical evidence (e.g., maps of forest cover and population density), their utility is limited by the assumption that such relationships will persist and are the main determinants of landscape change (Lambin 1994). In order to incorporate the information gleaned through research on land-use dynamics more realistically, a new generation of dynamic simulation models are being developed that model the behavior and even the learning processes of individual actors in the landscape. Other developments include the generation of land use/cover change scenarios and the analysis of syndromes of vulnerability to environmental change.

Landsat Imagery in Geography

The Landsat series of satellites have produced one of the most valuable remote sensing records of change in the earth's land surface. The particular value of their data lies in the length of their record, which goes back almost continuously to 1972. Their value also arises from their relatively detailed scale or resolution compared with many space-borne sensors, since this means that the impacts of human activities such as deforestation or urbanization can be readily detected and monitored. Much useful information can be obtained from Landsat images through visual inspection of photographic hard copy. But the derivation of reliable quantitative information usually relies on careful processing of digital data from the satellites' sensors. Landsat data have been used for numerous different applications, many relating to land cover. This term refers to the biophysical state of the earth's surface cover and provides a valuable input for the mapping and monitoring of land use. Other uses of the data include water and air pollution monitoring, and mineral discovery (Jensen 2000, Lillesand and

Kiefer 1999). Landsat data and the products derived from them are often best used when placed within the framework of a Geographic Information System (GIS).

1. The Landsat Series

The first Landsat satellite was placed in orbit on September 23, 1972 (Table 1). Several subsequent satellites have been launched successfully, with the exception of Landsat 6, which failed to reach orbit. All the other satellites have exceeded their nominal lifetimes. The first three Landsat satellites (given the original name of ERTS or Earth Technology Resources Satellite) had a Multispectral Scanner System (MSS) as the prime sensor, yielding data with spatial resolution of 79 m. Subsequently Landsats 4 and 5 not only had the MSS sensor but also included the sensor called the Thematic Mapper (TM), which has a resolution of 30 m. On Landsat 7 the Enhanced Thematic Mapper (ETM) was the sole sensor on board; its properties are similar to those of the TM, but it has some capability for providing more detailed images (see Table 1). All instruments collect data by focusing radiation from the earth on detectors; the resultant recorded signals represent the amount of incoming radiation in digital form. Radiation from several different wavebands is measured simultaneously. These signals can then be used to create hard-copy pictures such as those illustrated here, or can be made available as digital files that can be subsequently processed by the user. The spatial resolution of the sensors indicates the smallest size of object detectable, but the latter is also dependent on the contrast between the object and its surroundings. Also, digital processing of the data can generate products with different pixel sizes. Hence, although the basic resolution of the MSS is 79 m and the TM is 30 m, many of the standard products purchased by users will have pixel sizes of 57 m and 28.5 m respectively. The frequency of images acquired from Landsat varies considerably. Landsats pass over every part of the earth's surface approximately once every 16–18 days but in practice images are collected far less frequently, due to factors such as cloud cover and lack of recording capacity of satellites. In the early 1970s a systematic attempt was made to acquire global coverage. In contrast, during much of the 1980s and 1990s, when the system was operated by commercial entities, data were often only acquired when a firm customer had been identified for a particular scene. Only with the launch of Landsat 7 was an acquisition strategy implemented to ensure total global acquisition of cloud-free images on a seasonal basis.

All Landsats have a sun-synchronous orbit, which means they can take images of every location at the same time each day. This greatly assists in change detection. One of the important progressive improvements in the Landsat sensors during their history has been their better calibration, resulting in an increasingly accurate record of the earth's surface.

2. Distinctive Role of Landsat Data

The high resolution and long record of Landsat data make them especially useful for the detection and monitoring of human impacts on the earth's surface. There are other satellite systems with similar sensing capabilities to those of Landsat. These include the French SPOT (Satellite Probatoire pour l'Observation de la Terre) series of satellites with a spatial resolution of 20 m (and 10 m for a panchromatic band) and the IRS (Indian Remote Sensing Satellite) series launched by the Indian Space Agency. Images from these are capable of being used in the same way as data from Landsat. However, neither has the longevity or comprehensiveness of the spatial coverage provided by Landsat's sensors.

Table 1
Landsat satellites, their sensors and characteristics

Landsat Satellite Number	Launch date	Finish of data collection	Sensors on board satellite (see below for properties)
1	September 23, 1972	January 6, 1978	MSS
2	January 22, 1975	February 5, 1982	MSS
3	March 5, 1978	March 31, 1983	MSS
4	July 16, 1982	July 1987	MSS and TM
5	March 1, 1984	Operational	MSS and TM
7[a]	April 15, 1999	Operational	ETM

a Landsat 6 never achieved orbit.
Characteristics of sensors
MSS bands: visible (0.4–0.5 μm, 0.6–0.7 μm); visible/near-IR boundary (0.7–0.8 μm); near IR (0.8–1.1 μm) and thermal infrared (10.41–12.6 μm)
Spatial resolution: 79 m, except 237 m for thermal band
TM bands: visible (0.45–0.53 μm, 0.52–0.60 μm, 0.63–0.69 μm); near-IR (0.76–0.9 μm); mid-IR (1.55–1.75 μm, 2.08-2.35 μm); thermal (10.40–12.5 μm)
Spatial resolution: 30 m, except 120 m for thermal band
ETM bands: visible (0.45–0.515 μm, 0.525–0.605 μm, 0.63–0.69); near IR (0.75–0.90 μm), mid IR (1.55–1.75 μm, 2.09–2.35 μm); thermal IR (10.4–12.5 μm); panchromatic (0.52–0.9 μm). Spatial resolution: 30 m, except 60 m for thermal band and 15 m for panchromatic band

Figure 1
Comparison of images from the Landsat Enhanced Thematic Mapper and high-resolution data from IKONOS of Los Alamos, New Mexico, shortly after the Cerro Grande fire, May 2000 (includes material © Space Imaging L.P.). (A) A Landsat ETM scene. The dark areas show areas burnt during the fires of 2000. The area is approximately 15 km across. (B) An image of a small part of the Thematic Mapper image (see small box in Fig. 1a). This image was taken by the IKONOS satellite and is shown here with a resolution of 1 m

Complementing Landsat data are those at coarser resolutions, notably from the NOAA series of satellites. Advanced Very High Resolution Radiometer is of particular value in monitoring seasonal variations in crops and other types of vegetation (D'Souza et al. 1996), but only at the coarse resolution of around 1 km. Much finer resolution data from commercially launched satellites (or from intelligence data released to the general public) provide much more detailed images than Landsat in which human activities can more readily be interpreted (Fig. 1); their availability is much more restricted than Landsat data.

3. *What do Images from Landsat Show?*

Successful use of Landsat data requires an understanding of the basics of how radiation interacts with the earth's surface and its atmosphere (Lillesand and Kiefer 1999). The higher the amount of incoming radiation in a given waveband (Table 1) the higher the digital number recorded by the sensor. All the bands of the sensors except for the thermal infrared band sense the amount of reflected radiation, including the near and mid infrared. TM bands 1 through 3 sense radiation in the part of the spectrum sensed by the human eye, TM band 4 senses the near infrared which is sensitive to the reflectance by the physical structure of healthy vegetation, and TM bands 5 and 7 are sensitive to the amount of water in leaves as well as the physical and chemical composition of soil materials. For the thermal infrared bands, higher recorded values relate to the temperature of the surface.

Pictures derived from Landsat images are usually false-color images in that they represent the sensed radiation by use of colors readily recognizable by the human eye, but do not show the actual appearance of the surface to the unaided human eye (Parkinson 1997). Figure 2 shows TM data. The atmosphere can substantially distort the signal received by the Landsat sensors.

4. *Extracting Information from Landsat Imagery*

Extracting information from Landsat data basically involves finding out what amount of recorded radiation corresponds to samples of known ground conditions radiation and using these relationships to extrapolate throughout the whole image. In practice, if reliable results are to be obtained a quite complex set of technical procedures have to be performed (Lillesand and Kiefer 1999). First, even obtaining images of the right place and date may require interrogation of several different archives, because as yet there is no single comprehensive archive; the

Figure 2
Examples of deforestation depicted on Landsat images. (A) Deforestation in Cochabamba State Bolivia, image was obtained by the Thematic Mapper on October 4, 1986; the impact of the road pattern on deforestation patterns can be clearly seen. Similar patterns of land use change are found in many other tropical areas. The area is approximately 40 km across. (B) The same area as for Fig. 2B, obtained on July 12, 1999. (C) Deforestation near Santa Cruz in central Bolivia, resulting from government resettlement of people from the highlands in settlements known as the San Julian colonies. The image was obtained on July 2, 1986 and is approximately 53 by 42 km in extent. (D) The same area as for Fig. 2C on March 26, 2000, showing the agricultural expansion between the two dates. (E) Classification of the two Landsat images depicted in Figs. 2C and 2D.

United States Geological Survey has the most comprehensive set of images. Ground reference data will often have to be collected, though higher resolution remotely sensed data can sometimes act as a useful surrogate for ground data (Fig. 1). Pre-processing of the Landsat data is commonly required. Correction of

Figure 3
Urban growth from Landsat imagery for Washington, DC and the surrounding areas of Maryland and Virginia. (See Masek et al. 2000 for further details)

the data may be required to avoid problems such as variability in sensor performance over time and reduction of atmospheric distortions, when change detection is being carried out. Reprojection of the data will often be necessary to ensure the data are co-registered with conventional map bases and are co-registered with each other if more than one set of Landsat images are used. Because of the importance of a common spatial framework for Landsat data, and other spatial data sources as well as field data, GIS is commonly used.

A choice will need to be made between different information extraction procedures. Reliance solely on traditional photo-interpretation methods is relatively uncommon nowadays. Even where photo-interpretation methods are adopted, users will employ digital enhancement methods to aid the interpretation. Computer-based methods, normally using some type of statistical decision rule, are most commonly applied, since they allow the most internally consistent and detailed results. Once the information has been extracted using such methods, editing by skilled interpreters can enhance the quality of the result. Finally an assessment of the accuracy of the result should be carried out using field or other reference data not used in earlier stages, so that the reliability of the end products is understood.

5. *Applications of Landsat Imagery*

Landsat images have been used for a wide range of applications, including many concerned with the transformation of the biophysical environment by humans and the impact of the physical environment on human society. One of the more important applications has been in the monitoring of forests, especially in tropical regions. Deforestation in the tropics and sub-tropics is a longstanding phenomenon, but one which has accelerated greatly in recent years. Its significance in the impact on the global carbon cycle and hence on global warming, on massive reductions of biodiversity (because of the species richness of these areas), and on its impact on the sustainability of these regions.

Until relatively recently there was considerable controversy about the actual rates of tropical deforestation. The analysis of Landsat data has done much to reduce uncertainties over both the rate and location of deforestation. Some of the higher estimates of deforestation for the Brazilian Amazon were shown to be incorrect (Skole and Tucker 1993). The need for spatially comprehensive Landsat (or similar resolution) data to obtain accurate estimates has been confirmed (Tucker and Townshend 2000). Different types of land management can be readily discerned from the resultant spatial patterns depicted on Landsat data (Fig. 2). The overall pattern of deforestation is clearly linked to the location of transportation corridors and settlement. Deforestation within countries is often a direct result of government-sponsored resettlement, as in Brazil and Indonesia, as well as international investment in agriculture, as in southern Bolivia, where World Bank loans have encouraged extensive industrial soybean production (Steininger et al. 2000).

Urbanization is another process of land transformation that can be monitored using Landsat data (Masek et al. 2000). Figure 3 shows the expansion of built-up areas near Washington DC between the 1980s and 1990s. Although reliable aggregated data are available in many developing countries, the benefit of products derived from Landsat lie in the flexibility of aggregation and disaggregation of spatial units. In developing countries, in particular, products derived from Landsat data will often be much more up to date than locally derived official data.

The use of Landsat and other forms of remote sensing in the social sciences can be found in the collection of papers edited by Liverman (1998).

6. *Conclusions*

Data from the Landsat series of satellites provide an invaluable source of information on the earth's environment, especially properties of the land surface, and how it has been affected by human activities. Not only do the resultant images provide timely information on current conditions, but as time passes they provide an increasingly useful historical record.

Landscape Architecture

A landscape is the synthesis of all the natural and cultural features—fields, buildings, hills, forests, farms, deserts, and water—that distinguish one part of the surface of the earth from another part. Landscape architecture is the art and science of arranging land so as to adapt it most conveniently, economically, functionally, and aesthetically to any of the varied wants of people.

Frederick Law Olmsted, Sr (1822–1903) was largely responsible for creating the discipline. He adapted European landscape gardening ideas to American places. The driving force for Olmsted was how to make increasingly industrial and crowded cities more livable. Olmsted's work as well as his goals for the discipline defined the field. Beginning in the mid-nineteenth century, he and his colleagues designed urban parks; new suburban communities; parkways; campuses; state, national, and international parks; city and regional plans; cemeteries; and estates. In the process, a truly American art form was born, which has had international influence.

Landscape architecture was developed in four periods. First, varied European styles emerged in landscape gardening, including the Moorish in Spain, the Italian Renaissance, the French Baroque, and the highly original English picturesque, as well as distinct, yet synthetic, styles in the Netherlands, Germany, and Poland. Second, the contributions of Olmsted and his collaborators established a broader social agenda. Third, a modern movement emerged just before the World War II, which reached fruition in the decades that followed the war. Finally, landscape architecture has played an influential role in the environmental movement from the 1960s to the present. In each of these four periods an Asian influence has been present.

For example, especially the English landscape style exhibited an awareness of Chinese and Japanese gardens.

1. European Precedents

In Islam, the Mediterranean city, building, and garden design tradition of the Greeks and Romans was maintained as the Dark Ages descended on Europe. The Islamic tradition emphasized the organization of space based on an application of principles from geometry and other branches of mathematics. Interior courtyards were favored for housing, with the judicious use of water. Water played an important role, not only for drinking and irrigation, but also for cooling. The arrangement of space, the manipulation of water flows, and the careful application of building materials, such as masonry and ceramic tiles, contribute to a pleasant living environment.

The Islamic garden is the 'Paradise Garden' of the *Koran*. These places were to be a manifestation on earth of a heavenly condition. Its rigorous ordering according to geometrical principles is a logical corollary and makes it equivalent to a mandala. The Islamic approach had a significant impact in the Iberian peninsula. As Spain was conquered by the Christians, Islamic ideas about design and planning filtered into European thinking. Among the structures built by the Moors in Spain, their dramatic, fortress palace at Granada, called the Alhambra and built between the thirteenth and fourteenth centuries, would make an especially important impression. In particular, its inner courtyards (the Court of Myrles and the Court of the Lions) provide models for how water and shade can be manipulated for human comfort and delight.

The Islamic world was one of the influences on the Italian renaissance. The early phase of this learning revival was especially strong in Tuscany, where the influence of Moorish design on the hillside villas around Florence is evident. For example, the powerful Medici family built hillside gardens at Fiesole (1458) overlooking Florence. They were also responsible for the extensive Boboli gardens behind the Pitti Palace in Florence. The outdoor spaces of these villas were remarkable both in Tuscany and later around Rome as the Medici introduced the style there and eventually elsewhere in Italy. While there were adaptations of Islamic ideas and uses of materials, the Italian designers also drew on ideas from ancient Rome, especially those of Marcus Vitruvius Pollio, and forged a new style. In works such as the gardens of Villa Lante (1518) and Villa D'Este (begun c. 1550), architects such as Donato Bramante (1444–1514), Pirro Ligorio (1491–1580), and Jacopo Barozzi da Vignola (1507–73), sculpted earth, water, and plants in new ways. Geometric patterns were carved into hillsides, with water flows directed to erupt strategically at dramatic fountains, framed by rows of trees and shrubs that guided the eye to various focal points. Water is an essential feature of Italian gardens, of almost all designed landscapes really, just as are hard stone and living plants, because the polarities of the senses can be exposed.

The great French garden designer André Le Nôtre (1613–1700) took these Italian forms and enlarged them with Baroque proportions. The natural expanses of the French countryside were not as constrained as the hillsides of Italy and the power of the Sun King eclipsed that of even the Medici. Begun in 1661, Louis XIV's palace at Versailles recreated a vast, five-square-mile portion of the French countryside into an elaborate system of grand vistas. A main east–west axis and several crossing axes of various sizes divide the space into a series of parterres with connecting *allées* bordered with massive, carefully manicured trees. As with the Italian gardens, Le Nôtre created fountains and other focal points at strategic points along the sight lines, but whereas trickles of waters collect into gushing fountains in Italy, a grand canal an elaborate, mechanical pumping system was created at Versailles. From the apex at the château, the landscape underscored who controlled and ruled this place.

A contrasting landscape style emerged in England, as it became a sea power connected to the Americas and the Orient and influenced by growing ideas about democracy. While John Locke (1632–1704) wrote about the inalienable rights of people to pursue life, liberties, and property, poets like Alexander Pope (1688–1744) waxed on about learning from the genius of the place. As the Englishman Horace Walpole (1717–97) observed of William Kent (c. 1685–1748), one of the innovators of his nation's landscape design tradition, 'He leaped the Fence and saw that all Nature was a garden.'

Kent, Lancelot 'Capability' Brown (1716–83), and Humphrey Repton (1752–1818) sought to improve the English landscape. They arranged estates with asymmetrically placed clumps of trees, broad undulating greenswards, serpentine lakes, and surrounding belts of woodlands in the grounds of Stowe (1736), Rousham (1738–41), Kensington Gardens (c. 1744), Bowood (1763–71), Blenheim Palace (c. 1765), and Ashburnham Palace (1767). Their romantic designs used small classical and Asian influenced structures as focal points. The English landscape garden became known as an imitation of nature. Where straight lines dominated the Moorish, Italian, and French designs, curves preponderated in the British Isles from the eighteenth century on.

Watkin (1982) argues persuasively that the English landscape tradition drew its inspiration for its non-geometric 'picturesque' qualities from the Chinese garden. The English and other Europeans were exposed to the Chinese approach especially by returning French Jesuit priests. The Chinese garden contains complex symbolic meanings for its cultural and phys-

ical context. These gardens, as well as subsequent adaptations and transformations in Korea and Japan, are richly symbolic as microcosms.

Ancient Roman gardens, as well as rising English nationalism, also influenced the picturesque approach. Watkin notes that the third Earl of Shaftesbury, 'called for the creation of a national style and a national taste based on the spirit of national freedom, which he believed was enshrined in the Whig oligarchy …' and to achieve this style the model was 'the free commonwealth of republican Rome as well as the culture of China' (1982, p. 2).

This growing philosophy, affected largely by the teachings of Locke, coincided with the English colonization of the New World and would have a lasting imprint in North America. Meanwhile, the English landscape style and the contrasting geometric forms from the continent impacted approaches in other European nations, which also developed their own styles, notably in the Netherlands, Germany, and Poland. In the Netherlands especially, the term landscape (*landschap*, in Dutch) has deep cultural significance, because much of the land in the nation has literally been made. The Germans borrowed from the English approach, but contributed a more scientific understanding of nature, laying the groundwork for contemporary concepts of ecology and sustainability. The Poles combined formal and informal spaces in conscious melding of nature and culture, at places such as the grounds at Wilanów Palace and Lazienki Park.

2. *Olmsted and his Collaborators*

American landscape architecture came into being after several decades of marination in the English style. Andrew Jackson Downing (1815–52) was certainly an adherent to the English school of landscape gardening. Frederick Law Olmsted, Sr. had been influenced profoundly by the English style, especially Birkenhead Park, which he visited during an 1850 trip to the British Isles. Birkenhead is a suburb of Liverpool. Its park was designed specifically for the public by Joseph Paxton (1803–65) in 1844. Previous parks in England and elsewhere in Europe were the estate gardens of the aristocracy donated to a city or loaned to the public.

A second direct impression from the British Isles on Olmsted's work was his partnership with the English architect, Calvert Vaux (1824–95). In spite of the strong English influences, Olmsted was an original. He altered the name of the field from 'landscape gardening' to 'landscape architecture' and established a new discipline that transcended making gardens for the very rich and powerful.

Olmsted's incredible start in landscape architecture was the design and construction supervision of Central Park in New York City with Vaux beginning in 1857. Through Central Park, Olmsted sought to bring the benefits of open space to the urban masses. The urban park would provide a healthy antidote to the crowding and pollution brought on by the Industrial Revolution. Central Park was an immediate success. This led to Olmsted to establish a landscape architecture practice, initially with Vaux and later with his sons. The practice was responsible for urban parks in Brooklyn, Boston, Chicago, Montreal, and, eventually throughout North America.

The discipline that Olmsted founded was defined by the scope of his own work as well as that of his son (Frederick Law, Jr., 1870–1957) and nephew–adopted son (John C. Law, 1852–1920). In addition to urban parks, Olmsted designed Riverside, Illinois—a prototype suburban new community; contributed to the preservation of Yosemite and Niagara Falls—setting the state for national and international parks; and participated in the planning of the World's Columbian Exposition of 1893 which created the inspiration for the 'City Beautiful Movement.' Toward the end of his prolific life, Olmsted, Sr. also designed an estate for the very wealthy George W. Vanderbilt, but Biltmore was also an experimental forest and farm. At Vanderbilt's Biltmore, the French-trained American forester and conservationist Gifford Pinchot (1865–1946) first applied his 'multiple use, sustained yield' concept, a precursor to contemporary sustainability.

While the Olmsteds broadened the scope of landscape architecture, the style they employed was strongly English-influenced. The 'pastoral aesthetic,' as well as the associated Whig political philosophy, resonated with Americans. The aesthetic was appropriate for large portions (but not all) of the North American continent. When Olmsted worked in California on the design of the Stanford University campus plan, the style, more Spanish than English, was more suitable for the climate and history of the state.

Stanford was but one of the campuses that Olmsted, his sons, and their collaborators designed. In addition to designing campuses, Olmsted was involved in other aspects of higher education. He was a strong supporter of the land-grant colleges, established by Justin Morrill (1810–98) in 1862, to offer education in the agricultural and mechanical arts and sciences. Morrill, Olmsted, and others believed that the interests of agriculture and industry had been ignored by the established universities in the United States which followed more elitist goals. Many of these land-grant schools began requiring landscape gardening courses in the late nineteenth century and one (Iowa State) offered Olmsted its presidency.

Landscape architecture impacted the elite schools too. Perhaps, Olmsted's brightest young collaborator was Charles Eliot, son of the president of Harvard. The younger Eliot organized probably the first comprehensive, multidisciplinary ecological inventories of Mount Desert Island in Maine during the 1880s. With the Olmsted firm, Eliot developed a plan for the Boston metropolitan region in 1893. He proposed an 'emerald necklace' for the region that linked park and

open space systems while making environmental improvements for flood control and water quality. Eliot died of spinal meningitis prematurely at age 38 in 1897. In his memory, his father established the landscape architecture program at Harvard that would lead the discipline through much of the twentieth century.

3. *The Modern Movement in Landscape Architecture*

In the early twentieth century, landscape architecture established itself as a profession in North America and northern Europe and Japan. Professional associations were founded, including the American Society of Landscape Architects (1899), and leading universities, such as Harvard and the growing land-grant schools, initiated departments or programs. However, much of the idealism of the Olmsteds dwindled, as the progressive branch of the field embraced the new profession of city planning. The leading landscape architecture historian Norman Newton noted that 'single-track eclecticism' took over especially in the Harvard department as practitioners flocked to build estates and exclusive neighborhoods for the wealthy.

However, it was at Harvard where a counter movement against this eclectic garden-design dominance began. In the late-1930s, students Garrett Eckbo (1910–2000), Dan Kiley (b. 1912), and James Rose (1910–91) rebelled against the Harvard curriculum. Their quest for a more modern, a more creative, approach to landscape design coincided with the arrival of Walter Gropius (1883–1969) at Harvard in 1937. Gropius helped institutionalize the Bauhaus philosophy of design within this leading American academic institution.

Meanwhile, in California, Thomas Church (1902–1978) had developed a practice revolving around gardens for the middle and upper-middle class. Celebrated in *Sunset* magazine, the Church garden provided an ideal for the new American outdoor, suburban lifestyle. Between the rebellious Harvard trio and Church, a modern movement in landscape architecture developed. This modernism is characterized by both its democratic spirit, that is, making the benefits of landscape design available to a wide spectrum of people, as well as by its spare cubist- and surrealist-inspired forms. For example, Eckbo designed Depression-era multifamily housing in California for the Farm Security Administration. These schemes are functional, spatial arrangements, designed to provide shelter and a delightful environment for working people in challenging economic situations. Eckbo was one of many landscape architects who contributed to the economic and social recovery of the nation through various public works projects from the greenbelt new towns to the national parks and forests.

American modernists found inspiration in the works of the Brazilian Roberto Burle Marx (1909–94) and the Mexican Luis Barragán (1902–88). However, arguably modernism in landscape architecture coalesced through the work of Hideo Sasaki (1919–2000) and Lawrence Halpern (b. 1916). As both student and teacher gravitating between the University of Illinois and Harvard, Sasaki defined landscape architecture during the 1950s. In his San Francisco home, Halpern's work reflected a free spirit, in harmony with the 1960s. Their work returned in scope and scale to that established in the previous century by the Olmsteds—urban parks, new communities, campuses, and, increasingly, corporate headquarters.

4. *The Ecological Era*

During the 1960s, the way people viewed their relationship to the Earth changed fundamentally. Since the World War II, the specter of nuclear destruction clouded the future. In the quest to prevail in the arms race, the Soviet Union and the United States raced to the moon. Something unexpected happened. Images of the Earth from space were transmitted into living room televisions and breakfast newspapers. On July 20, 1969, Neil Armstrong stepped on the moon and altered our view of Earth. From that barren orb, it became clear that the Earth is alive. Boundaries are human impositions. The world we inhabit is both fragile and beautiful.

Even before the *Apollo* images were broadcast, voices for protecting the Earth had been raised. Aldo Leopold (1886–1948) urged people to view land as community, and Rachel Carson (1907–1964) demonstrated the dangers of poisoning our nest. To this chorus, Ian McHarg (1920–2001) urged that we 'design with nature.' His book by the same name provided a new theory for landscape architecture, and altered other fields as well, notably planning, architecture, and the environmental sciences.

From his University of Pennsylvania (Penn) base, McHarg married a traditional landscape architecture technique with contemporary concepts from ecology for his new theory. Map overlays had been used by landscape architects since the Olmsteds and Eliot. McHarg suggested that information be collected in a systematic, chronological order to reveal interactions, relationships, and patterns. Natural phenomena, such as climate and geology, influence processes like water flow and soil development, which in turn affect the location of plants and animals. McHarg suggested that by conducting such an ecological inventory of a place opportunities and constraints for various possible land uses can be identified. The values of people living in the place can then be used to determine how these opportunities and constraints indicate a range of suitabilities for potential land use.

This approach influenced how environmental impact assessments are undertaken and provides the

underlying theory for geographic information systems (GISs). GISs are used for displaying, analyzing, and storing spatially-related data in computers. The initial technological and theoretical advancement of GISs largely came from landscape architecture (and, sometimes, planning faculty) such as Carl Steinitz (Harvard), Bruce MacDougall (Penn then the University of Massachusetts), Julius Fabos (University of Massachusetts), Lewis Hopkins (University of Illinois), and Thomas Dickert (University of California–Berkeley).

McHarg recognized that in order for human communities to take full advantage of ecological knowledge, a fundamental value shift was necessary especially in western nations. He argued that the Judaic–Christian philosophy of 'multiplying and subduing the earth' has deleterious consequences for the environment. McHarg found hope in Native American and Asian religious beliefs, worldviews that stressed harmony with nature, rather than dominance.

5. *Prospects: Following Nature's Lead*

The ecological revolution promulgated by McHarg at Penn went beyond influencing techniques and technology. The ecological prospective advocated a fundamental shift in the way we design and plan. Ecology is the study of how all living creatures, including people, interact with each other as well as with their physical and biological environments. Such understanding is essential for sustainable development and regenerative design. Ecological design involves understanding the regional context in which humans live, a recognition of natural limits and capacities, and an ability to build at an appropriate scale.

Landscape architecture practices, such as Andropogon in Philadelphia, Jones and Jones in Seattle, and Design Workshop in Colorado have continued to refine and advance McHarg's concepts about ecological design and planning. Iconoclastic practitioners such as Rich Haag in Seattle, A. E. Bye in Connecticut, and Laurie Olin in Philadelphia have adopted a less empirical, more intuitive, yet still ecological, approach to their work. Other practices, such as Hargreaves Associates in San Francisco and Civitas in Denver, initially rejected an ecological based approach in favor of a more fine arts orientation, but eventually gravitated toward addressing ecology, because of the complexity of the urban and suburban sites where they work demanded it.

Meanwhile, theorists such as Anne Whiston Spirn, Elizabeth Meyer, and James Corner suggest new insights into how to read landscapes, with ecology providing the vocabulary for such readings. Landscape architects are unique among artists and architects in that their mediums for creation are mostly living entities. They work with natural processes and materials, which is a complex undertaking. As the Roman architect Vitruvius observed in his second book on architecture '… all things are generated as the Nature of Things has determined, not for the pleasure of man, but disparate as though by chance.'

The necessity to understand the nature of places is basic to the art of landscape architecture. Ecology provides the language for reading landscapes. Such understanding leads to an appreciation of critical regionalism. Understanding and acknowledging the diverse cultures of places is fundamental to such regionalism. American landscape architecture appears to be adaptable to many places internationally. Such internationalism is neither an international 'style' nor a form of cultural imperialism, rather it is a flexible approach, sensitive to cultural pluralism.

Landscape design as a distinct art can first be recognized in the Moorish gardens of Spain and in the hillside Renaissance villas of Italy as well as the contemplative places of China, Korea, and Japan. All the early examples represent cultural adaptations to climate and topography. The Italian style was expanded to grotesque proportions in the French Baroque, and was then muted to the practical scale of the Dutch polders. The English landscape school leaped the garden wall, and the Americans introduced landscape aesthetics to the city, the suburb, and the wilderness. Landscape architecture is now crossing continental divides and finding Nature in the whole world.

Language Acquisition

The ability to learn language is present in almost every human child (Lenneberg 1967). Children who are born blind have few problems learning to speak, although they may occasionally be confused about words for colors or geographic locations. Children who are born deaf readily acquire a rich system of signs, as long as they are exposed to native sign language speakers. Even a child like Helen Keller, who has lost both hearing and sight, can still acquire language through symbols expressed in touch and motion. Children with neurological disorders, such as brain lesions or hydrocephalus, often acquire complete control over spoken language, despite a few months of early delay. Children with the most extreme forms of mental retardation are still able to acquire the basic units of human communication. Given the pervasiveness and inevitability of first language acquisition, we often tend to take the process of language learning for granted. But language is the most complex skill that a human being can master. The fact that nearly all of us succeed in this task indicates how remarkably well the structure of language adapts to our underlying abilities. Language is immensely complex, but its complexity is accessible to all of us.

Linguists tend to think of language as having a universal core from which individual languages select out a particular configuration of features, parameters, and settings (Chomsky 1982). From this perspective, child language is an interesting slice of the universal pie. The shape of this slice is presumably limited both by formal universal constraints and by the child's mental abilities or developmental status.

Psychologists (Fletcher and MacWhinney 1995) view language learning from a very different perspective. To the psychologist, language acquisition is a window on the operation of the human mind. This window allows us to view the structure and functioning of neural circuits in the brain. It also allows us to understand how these circuits support processes such as reinforcement, generalization, imagination, and thinking. To understand these processes better, psychologists conduct controlled experiments in which children learn new words, sounds, and rules. They may measure these processes using neural imaging techniques, or they may simply study the changes in the language of the child across time.

Important and engaging though these scholarly perspectives may be, the best way to appreciate the dynamics of language development is to assume the perspective of the child. By taking this perspective, we can understand the challenges the child faces and the ways in which each are overcome.

1. *Early Audition*

William James (1890) described the world of the newborn as a 'blooming, buzzing confusion.' However, on the auditory level, the newborn's world is remarkably well structured. The cochlea and auditory nerve provide extensive preprocessing of signals for pitch and intensity. In the 1970s, researchers discovered that human infants were specifically adapted at birth to perceive contrasts such as that between /p/ and /b/, as in *pit* and *bit*. However, subsequent research showed that even chinchillas are capable of making this distinction (Werker 1995). Thus, it appears that much of the basic structure of the auditory world can be attributed to fundamental processes in the mammalian ear.

Beyond this basic level of auditory processing, it appears that infants have a remarkable capacity to record and store sequences of auditory events. For example, if the six-month-old hears a sound such as /badigudibagadigudigagidu/ repeated many times, the parts that are repeated will stand out and affect later listening. In this example, the repeated string is /digudi/. If infants are trained on such strings, they will grow tired of this sound and will come to prefer to listen to new sound strings rather than those that have the boring old /digudi/ string (Saffran et al. 1996). These habituation effects are strongest for stressed syllables and syllables immediately following stressed syllables. Recent studies of these effects in auditory memory suggest that we are born with an ability to store and recall the sounds of human language. It is as if the infant has a tape recorder in the auditory cortex that records input sounds, replays them, and accustoms the ear to their patterns.

Babies also demonstrate preferences for the language that resembles the speech of their mothers. Thus, a French infant will prefer to listen to French, whereas a Polish infant will prefer to listen to Polish (Jusczyk 1997). In addition, babies demonstrate a preference for their own mother's voice, as opposed to that of other women. Together, these abilities and preferences suggest that, during the first eight months, the child is remarkably attentive to language. Although children are not yet learning words, they are acquiring the basic auditory and intonational patterns of their native language. As they sharpen their ability to hear the contrasts of their native language, they begin to lose the ability to hear contrasts not represented in the native language. If the child is growing

up in a bilingual world, full perceptual flexibility is maintained. However, if the child is growing up monolingual, flexibility in processing is gradually traded off for quickness and automaticity.

2. Early Articulation

During the first three months, a baby's vocalizations are nothing more than cries and vegetative adaptations. However, around three months, at the time of the first social smile, babies begin to make the delightful little sounds that we call 'cooing.' These sounds have no particular linguistic structure, but their well-integrated intonation makes them sure parent pleasers. By six months, the baby is producing structured vocalizations, including a larger diversity of nasals, vowel types, and syllables with the canonical consonant–vowel (CV) structure. The basic framework of early babbling seems to be constructed on top of patterns of noisy lip-smacking that are present in many primates (MacNeilage 1998). These vocal gestures include some form of vocal closure followed by a release with vocalic resonance. Essentially, this is the CV syllable in which a consonant is followed by a vowel.

Until the sixth month, deaf infants continue to babble normally. However, by the age of nine months, deaf infants lose their interest in babbling. This suggests that earlier babbling is sustained largely through proprioceptive and somaesthetic feedback, as babies explore the various ways in which they can play with their mouth. After six months, babbling relies increasingly on auditory feedback. During this period, the infant tries to produce specific sounds to match up with specific auditory impressions. It is at this point that deaf children no longer find babbling entertaining, since they cannot obtain auditory feedback. These facts suggest that, from the infant's point of view, babbling is essentially a process of self-entertainment.

In the heyday of behaviorism, researchers viewed the development of babbling in terms of reinforcement theory. They thought that the reinforcing qualities of language would lead a Chinese baby to babble the sounds of Chinese, whereas a Quechua baby would babble the sounds of Quechua. This was the theory of 'babbling drift.' However, closer observation of the babbling of eight-month-olds indicates that virtually no such drift occurs. By 12 months, there is some slight drift in the direction of the native language, as the infant begins to acquire the first words. Proponents of universal phonology have sometimes suggested that all children engage in babbling all the sounds of all the world's language. Here, again, the claim seems to be overstated. Although it is certainly true that some English-learning infants will produce Bantu clicks and Quechua implosives, not all children produce all of these sounds.

3. The First Words

The child's ability to produce the first word is based on three earlier developments. The first is the infant's growing ability to record the sounds of words. The second is the development of an ability to control vocal productions that occurs in the late stages of babbling. The third is the general growth of the symbolic function, as represented in play, imitation, and object manipulation. Piaget (1954) characterized the infant's cognitive development in terms of the growth of representation or the 'object concept.' In the first six months of life, the child is unable to think about objects that are not physically present. However, as infants learn more about objects, they become able to associate their properties with their own actions and other features of the context. In this way, subtle cues can be used to dredge up fuller representations from memory. For example, a child may see a dog's tail sticking out from behind a chair and realize that the rest of the dog is hiding behind the chair. This understanding of how parts relate to wholes supports the child's first major use of the symbolic function. When playing with toys, the 12-month-old will begin to produce sounds such as *vroom* or *bam-bam* that represent properties of these toys and actions. Often these phonologically consistent forms (Peters 1983) appear before the first real words. Because they have no clear conventional status, parents may tend to ignore these first symbolic attempts as nothing more than spurious productions or babbling.

Even before children have produced their first conventional word, they have already acquired an ability to comprehend as many as 10 conventional forms. They learn these forms through frequent associations between actions, objects, and words. Parents often realize that the prelinguistic infant is beginning to understand what they say. However, they are hard-pressed to demonstrate this ability convincingly. Researchers deal with this problem by bringing infants into the laboratory, placing them in comfortable highchairs, and asking them to look at pictures, using the technique of visually reinforced preferential looking (Woodward et al. 1994). A name such as *dog* is produced across loudspeakers. Pictures of two objects are then displayed. In this case, a dog may be on the screen to the right of the baby and a car may be on the screen to the left. If the child looks at the picture that matches the word, a toy bunny pops up and does an amusing drum roll. This convinces babies that they have chosen correctly and they then do the best they can to look at the correct picture on each trial. Some children get fussy after only a few trials, but others last for 10 trials or more at one sitting and provide reliable evidence that they have begun to understand a few basic words. Many children show this level of understanding by the tenth month—often 2–3 months before the child has produced a recognizable 'first word.'

Producing the first word is a bit like stepping out on stage. When babbling for their own entertainment, the only constraints infants faced were ones arising from their own playfulness and interest. If they wanted to allow a sound to vary within certain limits, that was fine. Now, when faced with the task of producing word forms, the articulation has to be extremely accurate and within conventional limits. The forms of early words often deviate radically from the adult standard. The many simplifications that the one-year-old introduces to adult phonology are well known to students of phonological development (Menn and Stoel-Gammon 1995). Children tend to drop unstressed syllables, producing *hippopotamus* as *poma*. They repeat consonants, producing *water* as *wawa*. And they simplify and reduce consonant clusters, producing *tree* as *pee*. These phonological processes echo similar processes found in the historical development and dialectal variation of adult language. What is different in child language is the fact that so many simplifications occur at once, making so many words difficult to recognize.

4. Early Semantics

As the child's stock of words grows, it becomes harder to keep words apart from each other. To solve this problem, children have to choose between two opposing strategies. On the one hand, children may try to be conservative in their first uses of words. For example, a child may use the word *dog* to refer only to the family dog and not to any other dog. Or a child may use the word *car* to refer only to cars parked outside a certain balcony in the house and not cars in any other context. This tendency toward undergeneralization can only be detected if one takes careful note of the contexts in which a child avoids using a word. The flip side of this coin is the strategy of overgeneralization. It is extremely easy to detect overgeneralizations. If the child calls a tiger a *kitty*, this is clear evidence for overgeneralization. Of course, it is always possible that the children really meant to say something like, 'That animal over there reminds me a lot of my kitty.' However, if the child intended this, they would be operating with a rather strange set of ideas about how words are used.

At first, both undergeneralization and overgeneralization are applied in a relatively uncontrolled fashion. Children's first applications of undergeneralization are unreasonably rigid and they soon learn that words are meant to be generalized. At the same time, the child's first attempts at generalization are also often wildly overproductive. For example, a child may use the word 'duck' first to refer to the duck, then to the picture of an eagle on the back of a coin, then to a lake where there were ducks, and finally to other bodies of water. These 'pleonastic' extensions of forms across situations are fairly rare, but they provide interesting commentary regarding the thinking of the toddler when they do occur.

Scholars from Plato to Quine have considered the task of figuring out word meaning to be a core intellectual challenge. Quine (1960) illustrated the problem by imagining a scenario in which a hunter is out on safari with a native guide. Suddenly, the guide shouts 'Gavagai!' and the hunter, who does not know the native language, has to quickly infer the meaning of the word. Does it mean 'Shoot now' or 'There's a rhino' or perhaps even 'It got away'? Without some additional cues regarding the likely meaning of the word, how can the hunter figure this out?

The problem facing the toddler is similar to that facing the hunter. Fortunately, the toddler has some good cues to rely on. Foremost among these cues is the parent's use of joint attention and shared eye gaze to establish common reference for objects and actions. If the father says *hippo* while holding a hippopotamus in his hand, the child can use the manual, visual, verbal, and proxemic cues to infer that the word *hippo* refers to the hippopotamus. A similar strategy works for the learning of the names of easily produced actions such as falling, running, or eating. It also works for social activities such as *bath* or *bye-bye*. The normal child probably understands the role of shared eye gaze even before learning the first words. At three months, children maintain constant shared eye gaze with their parents. In normal children, this conta maintains and deepens over time. For autistic children, contact is less stable and automatic. As a result, autistic children may be delayed in word learning and the general growth of communication.

Shared reference is not the only cue toddlers use to delineate pick out the reference of words. They also uses the form of utterances to derive the meanings of new words. For example, if toddlers hear 'Here is a zav', they know that *zav* is a common noun. However, if they hear 'Here is Zav', then they know that *Zav* is either a proper noun or perhaps the name of a quantity. If they hear 'I want some zav', they know that *zav* is a quantity and not a proper or common noun. Cues of this type can give a child a rough idea of the meaning of a new word (Smith 1999). Other sentential frames can give an even more precise meaning. If the child hears, 'This is not green, it is chartreuse', then it is clear that *chartreuse* is a color. If children hear, 'Please don't cover it, just sprinkle it lightly', then they know that *sprinkle* is a verb of the same general class of *cover*. The use of cues of this type leads to a fast, but shallow, mapping of new words to new meanings.

5. Word Combinations

Throughout the second year, the child struggles with perfecting the sounds and meanings of the first words. For several months, children produces isolated single words. However, eventually they need to go beyond

this one-word level. They need to associate predicates such as *want*, *more*, or *go* with arguments such as *cookie* or *Mommy*. The association of predicates to arguments is the first step in syntactic development. As in the other areas of language development, these first steps are taken in a very gradual fashion. Before producing a smooth combination of two words such as 'my horsie', children will often string together a series of single-word utterances that appear to be searching out some syntactic form. For example, a child might say 'my, that, that, horsie' with pauses between each word. Later, the pauses will be gone and the child will say 'that horsie, my horsie.' This tentative combination of words involves groping on both intonational and semantic levels. On the one hand, children must figure out how to join words together smoothly in production. On the other hand, they also must figure out which words can meaningfully be combined with which others.

As was the case in the learning of single words, this learning is guided by earlier developments in comprehension. We have to assess children's early syntactic comprehension by controlled experiments in the laboratory. Here, again, researchers have used the preferential looking paradigm (Golinkoff et al. 1999). To the right of the child, there is a TV monitor with a movie of Big Bird tickling Cookie Monster. To the child's left, there is a TV monitor with a movie of Cookie Monster tickling Big Bird. The experimenter produces the sentence 'Big Bird is tickling Cookie Monster.' If children look at the matching TV monitor, they are reinforced and a correct look is scored. Using this technique, researchers have found that 17-month-olds already have a good idea about the correct word order for English sentences. This is about 5–6 months before they begin to use word order systematically in production.

The grammar of the first word combinations is extremely basic. The child learns that each predicate should appear in a constant position vis-à-vis the arguments it requires. For example, in English, the word *more* appears before the noun it modifies and the verb *run* appears after the subject with which it combines. Slot-filler relations can control this basic type of grammatical combination. Each predicate specifies a slot for the argument. For example, *more* has a slot for a following noun. When a noun, such as *milk*, is selected to appear with *more*, that noun becomes a filler for the slot opened up by the word *more*. The result is the combination 'more milk.' Later, the child can treat this whole unit as an argument to the verb *want* and the result is 'want more milk.' Finally, the child can express the second argument of the verb *want* and the result is 'I want more milk.' Thus, bit by bit, children build up longer sentences and a more complex grammar. This level of simple combinatorial grammar is based on individual words as the controlling structures. This type of word-based learning is present even in adults. In languages with strong morphological marking systems, word-based patterns specify the attachment of affixes, rather than just the linear position of words. In fact, most languages of the world make far more use of morphological marking than does English (Slobin 1985). In this regard, English is a rather exotic language.

5.1 Missing Glue

The child's first sentences are almost all incomplete and ungrammatical. Instead of saying, 'This is Mommy's chair', the child produces only 'Mommy chair' with the possessive suffix, the demonstrative, and the copula verb all deleted. Just as the first words are full of phonological deletions and simplifications, the first sentences include only the most important words, without any of the glue. In some cases, children simply have not yet learned the missing words and devices. In other cases, they may know the 'glue words' but find it difficult to coordinate the production of so many words in the correct order.

These early omissions provide evidence for two major processes in language development. First, children try to make sure that the most important and substantive parts of the communication are not omitted. Unfortunately, children make this evaluation from their own, egocentric perspective. In an utterance like 'Mommy chair' it is not clear whether the child means 'This is Mommy's chair' or 'Mommy is sitting in the chair', although the choice between these interpretations may be clear in context (Bloom 1973). The second factor that shapes early omissions is phrasal frequency. Children tend to preserve frequent word combinations, such as 'like it' or 'want some.' These combinations are often treated as units, producing errors such as 'I like it the ball' or 'I want some a banana.'

5.2 Productivity

Productivity can be demonstrated in the laboratory by teaching children names for new objects. For example, we can show a child a picture of a funny-looking creature and call it a *wug*. As we noted before, the positioning of the word *wug* after the article *a* induces the child to treat the word as a common noun. Children can then move from this fact to infer that the noun *wug* can pluralize as *wugs*, even if they have never heard the word *wugs* (MacWhinney 1978).

Three-year-olds also demonstrate some limited productive use of syntactic patterns for new verbs. However, children tend to be conservative and unsure about how to use verbs productively until about age five years. From the child's perspective, these laboratory experiments with strange new toys and new words tend to encourage a conservative approach. As they get older and braver, children start to show productive use of constructions such as the double object, the passive, or the causative (Brooks et al.

1999). For example, an experimenter can introduce a new verb like *griff* in the frame 'Tim griffed the ball to Frank' and the five-year-old will productively generalize to 'Tim griffed Frank the ball.'

The control of productivity is based on two complementary sets of cues: semantics and co-occurrence. When children hear *a wug*, they correctly infer that *wug* is a count noun. In fact, because they also see a picture of a cute little animal, they infer that *wug* is a common, count, name for an animate creature. These semantic features allow them to generalize their knowledge by producing the form *wugs*. However, we could also view this extension as based on co-occurrence learning. The child learns that words that take the indefinite article also form plurals. On the other hand, words that take the quantifier *some* do not form plurals. In this way, the child can use both semantic and co-occurrence information to build up knowledge about the parts of speech. This knowledge can then be fed into existing syntactic generalizations to produce new combinations and new forms of newly learned words. The bulk of grammatical acquisition relies on this process.

5.3 The Logical Problem of Language Acquisition

The problem with productivity is that it produces overgeneralization. For example, an English-speaking child will soon learn to form the past tense of a new verb by adding one of the variant forms of *-ed*. This knowledge helps the child produce forms such as *jumped* or *wanted*. Unfortunately, it may also lead the child to produce an error such as *goed*. When this occurs, we can say that the child has formulated an overly general grammar. One way of convincing the child to reject the overly general grammar in which *goed* occurs is to provide the child with negative feedback. This requires the parent to tell the child, 'No, you can't say *goed*.' The problem here is that children seem to ignore parental feedback regarding the form of language. If the child calls a hamburger a *hot dog*, the parent can say, 'No, it is a hamburger.' The child will accept this type of semantic correction. But children are notoriously resistant to being corrected for formal grammatical features.

The fact that children tend to ignore formal correction has important consequences for language acquisition theory. In the 1960s, work in formal analysis convinced some linguists that the task of learning the grammar of a language was impossible unless negative feedback was provided. Since negative feedback appeared to be unavailable or unused, this meant that language could not be learned without some additional innate constraints. This argument has led to many hundreds of research articles exploring the ways in which children's learning places constraints on the form of grammar. Referring back to Plato's *Republic* and the Allegory of the Cave, Chomsky and others have characterized the task of language learning as a logical problem.

In fact, children have more resources available to them than Chomsky seems to suggest. Using these resources, the child can recover from overgeneralization without negative feedback. In the case of *goed*, everyone agrees that recovery is easy. All the child has to do is to realize that there is only one way of producing the past tense of *go* and that is *went*. In other words, the irregular form *went* comes to block production of the overregularized form *goed*. Here, recovery from overgeneralization is based on the competition between the regular pattern and the irregular form.

Consider another example. Suppose that a child decides that the verb *recommend* patterns like the verb *give*. After all, both verbs involve a beneficiary and an object being transferred. However, only *give* allows a double object construction, as in 'John gave the library the book.' Most people find 'John recommended the library the book' ungrammatical. One solution to this error is to avoid making it in the first place. However, a more general solution is to record the strength of the competing syntactic patterns. The correct way of saying 'John recommended the library the book' is to say 'John recommended the book to the library.' This correct formulation should be strengthened whenever it is heard. As the strength of the frame for the verb *recommend* grows in comparison to the ungrammatical frame, the use of the competing frame is blocked. This solution assumes that the child realizes that the two frames are in competition. It may be that reaching this realization requires some attention to syntactic form. However, this solution does not require children to pay attention to corrective feedback. Instead, they only need to attend to correct sentences and to make sure that they understand that these are competing ways of saying roughly the same thing.

6. Emergentist Accounts

In the 1980s, a sharp division existed between accounts of language acquisition that emphasize learning and those that emphasize innate knowledge of universal grammar. At the start of the twenty-first century, there is no longer a clear separation between alternative approaches. Instead, the challenge facing researchers is to formulate a sets of mechanisms that are rich enough to account for the details of these emergent processes and which are grounded on the facts of human neurophysiology. To achieve this, many psychologists rely on the formalisms of neural network theory, which is also known as connectionism (McClelland and Rumelhart 1986). This framework uses large numbers of units and the connections between these units to capture the patterns of language. This web-like architecture of nodes and con-

nections is intended explicitly to resemble the structure of the human brain with neurons, synapses, and weights on synaptic connections. Neural network models have provided good accounts for the acquisition of morphology (MacWhinney et al. 1989), phonology (Plaut and Kello 1999), and syntax (Allen and Seidenberg 1999).

A major limitation of many current models is their failure to pay sufficient attention to the child's perspective on learning. In the late 1990s, researchers began to correct this problem. Models that rely on concepts derived from dynamic systems theory (Smith 1999) and the theory of attention (Merriman 1999) have proven useful in accounting for word learning by focusing on the ways in which concrete situations provide learners with cues. Newer formal models also relate word learning to children's physical control of their own body (Bailey et al. 1997) and their own perspective as a causal agent (MacWhinney 1999). These new developments may also allow us to understand how language works to embed children into the fabric of social life (Vygotsky 1962).

7. Conclusion

Language is a unique marker of humanity. It distinguishes the human species from the rest of the creation, and it allows us to share our thoughts and feelings. Language is the most complex skill that any of us will ever master. Despite this complexity, nearly every human child succeeds in learning language. This suggests that language is optimally shaped to mesh with the abilities of the human mind and body. On the one hand, the universals of human language match up with our neurological, cognitive, and physical abilities. At the same time, parents provide rich contextual and emotional support to guide children through the process of language discovery. By studying language learning, we learn more about universals of human language, the shape of social interaction, and the structure of the human mind.

Language and Animal Competencies

If language were only a unitary dimension, we might, indeed, insist that it is language that sets humans apart from animals—immutably and forever. But language is not a digital phenomenon. Just as 'Love is a many splendored thing…,' as a song proclaims, so is *language*! It is a highly complex system that seemingly culminates with the eloquent use of voice in oration, poetry, and song as well as in debate, lectures, argument, and conversation. As a consequence, language has frequently been equated with speech and studied accordingly. We are convinced, however, that speech is only one of a set of media that allows for the expression of language, hence not a requisite to language. If the highly effective and coordinated mechanisms of speech and hearing had not evolved, our species would likely have refined other basic media for language—graphics, whistling, signing, drumming, and so on. Thus, we hold that although learning to talk/speak is a developmental imperative unique to humans, the basic requisites of language are not. Indeed, research documents that several animal species have the potential to acquire processes and skills that are essential to language as we know it in our own species.

At least one notable scholar of human language has asserted, in a recent lecture, that the question, 'Do animals have language?' is not scientific (Pinker 1999). Why? Because language cannot be defined to everyone's satisfaction. By that token, of course, then no one (and certainly not the scholar of reference) should assert that animals do *not* have language. The fact is that definitions of constructs (e.g., personality, learning, thinking, intelligence, language, etc.) can never be honed to everyone's satisfaction. Notwithstanding, definitions of terms are necessary to science.

Here, our working definition is that

> language is a biobehavioral system that provides for the learning of meanings of symbols and for their use to exchange information within a social context. Symbols may be based in any modality—sound (e.g. speech, hearing, drumming, whistling, etc.), vision (e.g. writing, geometric figures, movements with hands and body, etc.), touch (e.g. Braille), and so on.

It is meaningfulness that differentiates symbols/words from other stimuli. The meanings of words (e.g., semantics) are the result of social usage, hence the meanings of words are subject to radical change across time. The language system is open in that new words may be added and old words deleted. The language system also provides for the generation of novel messages through the interactive use of words (e.g., rules of grammar and syntax provide for 'I'm buying a house dog' to differ radically in meaning from 'I'm buying a dog house,' though the words used remain constant). The ability to comprehend language is an absolute requisite to competence in productive use/expressions of language. Hence, the first essential process of language acquisition by the human child is comprehension, that is, understanding language used by others. Later, the child typically begins to use/produce that language through speech and gesture.

The following review of animal language research, conducted over the course of the past half-century, documents that language is a continuum, a highly complex biobehavioral system that is clearly traceable to animals, and notably to the great apes (Gardner et al. 1989, Premack 1970, Rumbaugh 1977, Fouts and Fouts 1989, Miles 1990, Savage-Rumbaugh and Lewin 1994), pinnipeds (Herman 1987, Schusterman et al. 1993), and parrots (Pepperberg 1990), all having demonstrated the ability to learn and use symbols with semantic competence (e.g., for symbols to acquire meaning and to represent things/events not necessarily present). The primary foundation of language is in the comprehension of speech or of the units of any other language system, and not in the production of speech. Because of its openness and generativity (e.g., to the addition of new word-symbols and to the modulation of their meanings through social commerce), language should not be viewed as or called an instinct (e.g., unlearned, highly predictable expression of genetically defined behaviors, synchronized and expressed through the course of biological development and maturation). The acquisition of language, whether by the human child or ape, is highly contingent on specific aspects of early rearing; and apes, if reared from birth in a language-structured environment (e.g., one in which language is used throughout all dimensions of their rearing experiences to the end of encouraging their comprehension and anticipation of all events), can understand hundreds of novel sentences of request that they hear even for the first occasion in tightly controlled research procedures. Formal training procedures, based on stimulus–response–reinforcement, used to cultivate language competence in animals are less effective than appropriate social/language rearing to the cultivation of language and notably to the ability to comprehend human speech. Apes can use their language skills to coordinate problem solving, either between themselves or with caregivers, that otherwise would be impossible (Menzel 1999). Apes' brains are lateralized both in structure and function, though the circuits/systems used for language might not, in detail, be identical to ours in language acquisition and use (Rilling et al. 1999).

1. *Language Acquisition in Animals*

Research by Keith and Cathy Hayes (Hayes and Nissen 1971) clearly demonstrated that chimpanzees could not speak with any significant facility and that if they had any potential for language, another medium of expression would have to be developed in order to study it. Allen and Beatrix Gardner (1969) used a modification of the American Sign Language for the Deaf, a manual and gestural language system of a kind

that Yerkes and Learned (1925) suggested might be fruitful for the study of apes' language potential. Manual signing systems were also used by Miles (1990) and Terrace (1979). Premack (1971) used a set of plastic tokens as units of a vocabulary and made significant contributions to defining the essence of words.

Rumbaugh's (1977) group succeeded in developing a computer-monitored keyboard and system with which the chimpanzee, Lana, became very proficient in learning 'stock sentences of request' that were effective in obtaining food (i.e., Please machine give piece of banana), viewings of movies, slides, and the outdoors (i.e., Please machine make window open), and special human companionship and other privileges (i.e., Please Tim tickle Lana). All keys of her keyboard were embossed with distinctive lexigrams that functioned as words—hence they are termed 'word-lexigrams.' Lana's many accomplishments included the learning of names of six colors and six objects (with each object being painted each of the six colors, for a total of 36 items), with which she could give, upon request, either the color or the name of a designated object from a set of several objects. For instance, with a random array of the objects displayed to her, she could accurately answer questions, such as 'What name of this that's (red, green, etc.)?' vs. 'What color of this shoe?'

Somewhat later, chimpanzees Sherman and Austin (Savage-Rumbaugh 1986) learned functionally how to use lexigrams in order to make requests for specific items. Eventually it was clear that for them their lexigrams actually represented the items that they had earlier simply requested. This conclusion was based on their near errorless ability to classify via two lexigrams, one standing for 'food' and the other for 'tool,' each of 17 lexigrams on a trial-1 basis in a controlled test. With these basic skills of using lexigrams to request items or to name them, they then were able to move on to a number of remarkable interactions that entailed their coordinated communications and behaviors to solve problems that netted prized incentives for them and, also, to announce what it was that they were about to do—to announce which item it would be that they would retrieve from a random set of foods and drinks (Savage-Rumbaugh 1986).

An even more significant finding was obtained in work with bonobos, a rare form of chimpanzee (*Pan paniscus*). Sue Savage-Rumbaugh and her colleagues (Savage-Rumbaugh et al. 1993, Savage-Rumbaugh and Lewin 1994) worked with Matata, a bonobo, with training methods that had worked so well with Sherman and Austin (common chimpanzees, *P. troglodytes*). With Matata, however, they had almost no success. Serendipitously, however, it was discovered that Matata's adopted son, Kanzi, who as an infant only observed Matata's training situation, had spontaneously learned (e.g., without formal training) it all! It was only when Matata was separated from him, when he was $2\frac{1}{2}$ years old, that his learning became manifest. Then, at his own initiative, he formulated novel requests, announced intended actions, and proposed games that were not even part of Matata's sessions. By age four years, he understood several dozen spoken words. His learning as an infant was noted for its 'silence' in that his behaviors had given no indication to the researchers that he was mastering such complex relationships and language skills. By age four years, Kanzi was competently understanding and using lexigrams with his caregivers and, quite unexpectedly, gave evidence of understanding much of his caregivers' spoken English. Formal tests revealed that he knew the referents/meanings of at least 150 spoken words.

Kanzi's accomplishments go well beyond the highly significant fact that by observation alone he learned his initial lexicon (Savage-Rumbaugh and Lewin 1994, Savage-Rumbaugh et al. 1998) and also eventually came to understand spoken English words. Although there have been long-standing assertions that an ape, here and there, 'understands' a few English words, none began to equal Kanzi's understanding of hundreds of words—not just individual words, but novel sentences of request as well. Kanzi, age seven years, was tested with Alia, a $2\frac{1}{2}$-year-old child, with 660 novel sentences (e.g., neither familiar, trained, or modeled by others). Some requested that they act in reference to places, persons, and materials, while others called for them to act with reference to objects and locations (Savage-Rumbaugh et al. 1993)—'Take the gorilla (doll) to the bedroom'; 'Give Karen a carrot,' 'Take the vacuum cleaner outdoors,' 'Hammer the snake,' or 'Get the lettuce that's in the microwave oven,' and so on.

In addition, there were a variety of requests that entailed reversals such as 'Make the doggie bite the snake,' vs. 'Make the snake bite the doggie.' Alia and Kanzi promptly fulfilled about 70 percent of the novel requests upon their first presentation. On reversal requests, Kanzi was 81 percent correct, whereas Alia was 64 percent correct.

Kanzi's remarkable achievements, traceable to his early rearing, are in sharp contrast to the devastating effect that impoverished rearing during early infancy has upon the cognitive and social competence of common chimpanzees. If their rearing environments (e.g., the first two years or so) are sorely limited and socially impoverished, they never fully recover. They remain both cognitively and socially compromised (e.g., poor at breeding, parenting, and social communication commerce), even when tested at age 14 years as young adults (Davenport et al. 1973). Primates' general social and cognitive competence are very dependent on their early environment. The same is true for the human child.

Significant research has also been reported with a parrot. Pepperberg (1990) trained Alex, an African gray parrot, using what she called the 'model-rival'

method. Here, Alex observed linguistic interactions between two people who served as 'models' and 'rivals.' The model/rivals talked about and exchanged objects of interest to Alex. Alex entered the conversation at will and eventually was highly skilled in asking for, choosing, or describing the color, shape, and materials of the objects with which he was familiar. For both Kanzi and Alex, the language acquisition contexts were designed to encourage spontaneous responding and designed such that uses of words were efficacious. Typical classical or operant conditioning experiments have emphasized the mastery of a single response in a specific context. By contrast, the training contexts for Kanzi and for Alex drew upon a great variety of different lexical responses.

The data of these projects and successful replications thereof (Brakke and Savage-Rumbaugh 1995, 1996, Savage-Rumbaugh et al. 1998, Pepperberg 1999) have had major affects upon how we now should view animals' abilities.

2. *Tool Making by Observational Learning*

Kanzi also learned by observation how to make and use stone tools to gain access to baited food sites. Kanzi was never trained to create the flakes in any specific manner. His model was an anthropologist, Nick Toth, who created stone flakes through striking two rocks together (Savage-Rumbaugh and Lewin 1994, Toth et al. 1993). Over time, Kanzi acquired skill both in creating stone flakes and evaluating their probable effectiveness for cutting ropes of varying thickness. As a tool lost its cutting edge, Kanzi would make a new, more effective one. Kanzi's causal understanding of tool fabrication and use was demonstrated in three very impressive ways. Early in his efforts, he innovatively started to throw one rock on to a hard surface or on to another rock on the ground. Thus, Kanzi first appeared to understand that it was the fundamental force of one rock striking another that created the flakes. Second, he rapidly learned how to assess whether a given flake would be sufficient to the task at hand—be it to cut a rope or a piece of leather. Inadequate chips were discarded and replaced with new ones as needed. Third, eventually Kanzi came to hold the cobble so as to hit it on an edge of less than 90 degrees, thereby producing large and very sharp chips of flint.

3. *Language and Inferences of Causality*

There is evidence that language serves to make animals more competent in general—as though they understand more readily cause–effect relationships and how things work (Michotte 1963, Piaget 1930, 1974). For instance, Kanzi quickly learned, by brief observation, how to use a joystick to control the movement of a cursor-icon on a monitor and to play video games, including PacMan. Earlier, both Sherman and Austin had quickly learned the use of a joystick, again as a result of a brief demonstration (< 15 min) (Savage-Rumbaugh 1986, Savage-Rumbaugh and Lewin 1994). We had anticipated that they would have great trouble in learning to use the joystick (Rumbaugh et al. 1989) and were surprised that they learned so quickly and by observation alone. They seemingly saw/understood 'how it worked' very readily and what was to be gained by using it with precision. By striking contrast, apes with little or no language skills from our laboratory have generally required either protracted operant training or months of observing a competent cohort.

4. *Cooperation Enabled by Symbolic Communication*

Savage-Rumbaugh's (1986) project with Sherman and Austin was designed to cultivate symbolic communication so as to coordinate problem-solving efforts. After considerable training on a variety of tasks, the apes became quite accomplished in their cooperative efforts. For example, one of the chimpanzees could observe food being placed in a container that required a specific tool for opening it—a requisite to getting the prized incentive within. The other chimpanzee was not allowed to watch the placement of the food into a secured container, and, thus, did not know what tool was needed. Tools needed varied with containers and included a lever, key, a sponge, a cord, and so on. The chimpanzee who saw the food secured thus could infer what tool would be needed. A request by that chimpanzee was then made of the other one to supply it with a tool, specified by selection of the appropriate word-lexigrams at the keyboard that contained more than 100 symbols. If the symbol-encoded request was fulfilled, then the chimpanzee receiving it used the tool to open the secured container. The incentive, thus obtained, was then shared with the chimpanzee who complied with the tool-users' request. Both chimpanzees were competent in both tasks—asking for and vending the tool as specified across trials. The knowledge base with which they coordinated their efforts was documented on the several occasions on which Austin by mistake gave Sherman an incorrect tool (e.g., not the one requested). On those occasions, Sherman would throw the tool down (e.g., reject it) and then bring Austin's attention once again, via the lexigrams keyboard, to the name of the tool that had been requested and needed for the incentive to be obtained.

Clearly, this task could be solved only by social communication through the use of learned symbols. Savage-Rumbaugh (1986; also Savage-Rumbaugh et al. 1998) reports many other strong instances of goal-

directed communication. For instance, when Sherman and Austin spontaneously used labels from food cans and boxes to communicate when their keyboard was denied to them (e.g., turned off) and also when Kanzi and others helped novice research assistants find word-lexigrams that they were having difficulty finding for their own use on the keyboard.

For these and other reasons, we believe it constructive to add the category of emergents to the traditional dichotomy of learning embraced by the traditional dichotomy of respondent and operant conditioning. Emergents are exemplified in the appearance of highly complex and even unanticipated competencies on the basis of protracted generalized, rather than specific, experiences and through observation (Rumbaugh et al. 1996).

5. *Summary and Conclusions*

At the dawn of a new millennium and consonant with Darwin's postulate of psychological as well as biological continuity between humans and other animals, there is strong evidence that language should be viewed as a continuum (Deacon 1998), with its fundamental roots being firmly planted most clearly in apes—our nearest living relatives (Andrews and Martin 1987). This evidence, rooted in 50 years of dedicated effort measured in decades and careers of scientists and staff, is solid. It has survived countless peer reviews for funding and publication. Apes, pinnipeds, and parrots have potentials for language skills that can be cultivated through early rearing and social exchanges. Yet there are a few influential scholars of note who, quite matter of factly, reveal at best only a limited understanding of the research or even total disinterest. They fail to recognize the evolutionary and neurobiological significance of the animal research and seemingly are satisfied to accept rhetoric in lieu of data and scientific reason. Yet, time surely will vindicate those who argue, from scientific data, that the evidence of animal species' potential for language is of inestimable significance from the perspectives of science, philosophy, language, and public policy. For science, the data vindicates the Darwinian perspective of psychological continuity from animal to human, a continuity afforded by biological continuity (Andrews and Martin 1987). For philosophy, the data declare that human quality of life, thought, and culture need to be understood from a comparative perspective. For students of language, the data declare that the roots, primitive though they might be, for language and cognition are traceable to nonhuman genes (e.g., to animals). For public policy, the data declare that animals are not the mindless, senseless beast machines that Descartes declared them to be. Unique we humans are, to be certain; but then, so are all other species of life. More powerful than they we are, though whether we are more worthy merits reconsideration. At least some animals, notably the great apes, are not properly viewed as chattel, for they are sentient thoughtful beings, in measure. Their behaviors tell us of the evolutionary history of eons past of animals' ground that they share in common with us.

Language and Ethnicity

As 'language' is defined elsewhere in this volume, only 'ethnicity' needs to be defined here before the relationship between the two is discussed.

Ethnicity is a form of collective identity, and thus belongs to the same class of phenomena as religious affiliation, lineage, clan, or class membership. It is the awareness of belonging to an ethnic group, and the belief that others belong to other groups of this kind. Ethnic groups differ from other groups, like voluntary associations or age-sets, by the following criteria: they comprise people of both genders and all ages, or, as Elwert (1989) puts it, entire families. Even where exogamy extends far beyond the nuclear family, ethnic groups comprise enough such exogamous units to guarantee self-sufficiency in biological reproduction: marriage partners can be provided within the ethnic unit. This means that ethnic groups have the potential to recruit members by birth, and, indeed, that is how they recruit most of their members. It does not mean that this is the only form of recruitment and that there is no ethnic conversion.

The criterion of self-sufficiency in biological reproduction sets the lower limit of the size of an ethnic group. The upper limit is set by the criterion of alterity. As ethnic groups define themselves and are defined in contradistinction to other such groups, an ethnic group can never comprise all of humankind. Ethnic groups tend to be medium-to large-scale human aggregates, typically ranging from thousands to millions. Many ethnic groups, including those which do not have a 'nation-state' to their name, exceed many independent states in the size of their populations. 'ethnic group' and 'nation' form a pair of concepts, the first stressing cultural aspect, the second political ones. 'nation' includes the additional element of statehood in one or the other form. One can say that an ethnic group plus a state in which it predominates or a claim to such separate statehood is a nation. The fact that political rights like self-determination are attributed to nations in the political and juridicial discourse does not help to define which ethnic group qualifies as a nation and which one does not. Any ethnic group can claim to be a nation and become one through such a claim. The only difference between a mere ethnic group and a nation without state is that the latter claims political sovereignty and the former does not necessarily do so. This distinction may not be very helpful in solving practical political issues, but social science does not provide a more helpful one.

Ethnicity is a cultural construct and its construction materials are cultural as well. There are other cultural constructs which are partly based on biological givens, like gender on biological sex, but in all cases in which ethnicity claims to be based on biological facts like discontinuities in the distributions of genes (race), such claims can be shown to be without a biological basis. Genes may cluster in different ways, but they never mark ethnic boundaries. Ethnic groups are never based on race, but very frequently on beliefs about race. Another element ethnic groups tend to attribute to themselves, often counterfactually, is a venerable age, and therefore ethnicity can in some ways be said to be a pseudobiological category: ethnic groups view themselves as natural and stable in time like biological

species. Other parts of culture, in addition to beliefs about race, which play a part in the construction of ethnic groups, include the reference to real or imagined historical events, peculiarities of customs, and the like. No two ethnic groups have a set of criteria which is alike, but typically ethnic discourses make reference to a plurality of such criteria. If only one such criterion is stressed, like religious affiliation, one would not speak of an ethnic group, but, rather, of a religious one.

For our present topic it is of special importance that language tends to be (but by no means always is) high up in the catalog of cultural criteria used to mark the boundaries between ethnic groups. This makes the question of the relationship between language and ethnicity appear tautological in some cases. Where language is used as the primary marker of an ethnic boundary (Barth 1969), ethnic and linguistic units tend to be congruent. In post World War I Europe, the language census has in numerous cases simply replaced the declaration of political will of local communities in effecting boundary corrections between nation-states (Dench 1986). On the other hand, through the school system and the exclusive use of the majority language for administration, national languages or languages which enjoy a special status in certain areas, have been imposed on linguistic minorities (Gellner 1981). Congruence between linguistic communities and ethnic units/nations has thus been promoted on the interstate level by adjusting political boundaries to language distribution areas and on the intrastate level by extending a language policy to the boundaries. In spite of the fact that these processes have been at work for some time, still only a small fraction of the world's nations are linguistically homogeneous (Ra'anan 1989).

While in some cases ethnic and linguistic units are coterminous, at the other extreme we find ethnic units, well defined by other criteria, which have nothing to do with language. The Garre of north eastern Africa conceive of themselves as one ethnic group because of their common genealogy and clan organization, their shared pastoral nomadic culture, and their desire, not always fulfilled, to keep peace with each other. The Garre are divided in four linguistic clusters which cross-cut other criteria of differentiation like clanship. Some of them speak an Oromo dialect close to the one of the Boran, while some speak Af Rahanweyn, yet others Af Garreh Kofar. The latter two are closely related Somali-like languages but are kept clearly apart by their speakers. There are also Garre who speak Somali proper. Oromo is a different language well beyond comprehension. It belongs to the same lowland branch of the east Cushitic languages as the Somali-type languages, but internal differentiation within this branch is high. The fact that the Garre are also divided between three nation-states (Kenya, Ethiopia, and Somalia) has nothing to do with this linguistic differentiation, since speakers of all four languages are found among the Garre of all three states. The only language which is spoken exclusively by Garre appears to be Af Garreh Kofar, but to the outside observer it is difficult to distinguish that language from Af Rahanweyn which is spoken by hundreds of thousands of non-Garre, namely Somali of the Rahanweyn clan-cluster. It does happen that Garre who do not share one of these Cushitic languages are obliged to converse with each other in languages from totally different language families, like Swahili (Bantu) or English (Germanic) which they have acquired at school, an institution frequented by only a minority of them for mostly short periods.

If there are enough other elements (political, economic, cultural) on which a feeling of ethnic belonging and commonality is based, such an ethnic unit can tolerate a high degree of linguistic diversity. If these other foundations are absent, no amount of linguistic homogeneity can prevent disruption. Even within a language formerly perceived as one, now three different languages can be distinguished if the political will so dictates. This is exemplified by the split of the Serbo-Croatian language into Serbian, Croatian, and Bosnian.

The close association between a nation and its national language is a fairly recent development of political ideology even in Europe, and more so in other parts of the world to which this idea has been exported. Originally the term mother tongue (*Muttersprache*) referred to the language learned from the mother or wet nurse as distinct from the language of the male sphere, of officialdom and scholarship, i.e., Latin (Ahlzweig 1994). Through romanticism and the evolving linguistic nationalism this term later acquired political overtones. The modern national states of Europe have, in their formative period, taken little account of the map of language distribution. Personalities claimed in retrospect as forerunners of German, Russian, or other nationalisms, in their real lives often preferred to speak French. The ethnicization of the state, its culturalization and its evolving association with a particular language was a gradual process in the development of modern Europe. Linguistic obstacles were sometimes artificially raised between nations. As their national standard the Norwegians have chosen from among their many dialects the one most different from Danish.

Not only languages but also language families have been politicized by identifying them with groups of people who were often ascribed racial characteristics, as a result of which they were either accorded privileges, or denied such privileges and even such basic rights as freedom and the right to live. Nowadays nobody outside the lunatic fringes would use the term Semite, to the extent that it is still used at all, in any other sense than speaker of a Semitic language. But there are other such terms of Biblical derivation like Cushites and Hamites which still continue in political careers which were unforeseen by the late eighteenth-, nineteenth-, and twentieth-century European his-

torical linguists who applied them to clusters of languages they found to derive from shared ancestral forms. One can hear Oromo nationalists in Ethiopia arguing for the inclusion of minority groups and their territories into Oromia on the grounds that, although they are not Oromo, they are also Cushites. Ideologies about the repulsion of Hamitic intruders are at the root of the genocide against the Tutsi in Rwanda, although the Tutsi, in fact, speak the same Bantu language as their Hutu murderers, and historical theories that they ever spoke a different language are questionable to say the least. Ironically, too, the term Hamitic is no longer used by linguists. This may serve as a recent example that linguistic classifications, once they cross the boundaries of the academic sphere, can develop a dynamic of their own and that such a dynamic can be quite a murderous one.

Linguistic nationalism often appeals to romantic notions about the relationship between a particular language and other aspects of the culture of its speakers. The language we speak is believed to influence our thinking in a subtle way, giving language a much deeper cultural implication than that of a mere boundary marker between different cultural/ethnic units. Such ideas, which go back to Johann Gottfried Herder (1744–1803), cannot be explained away by pointing to the ways in which they are instrumentalized by nationalists. In Herder's view, a language is the 'collective treasure' of a nation and, since each language shapes the perspective on the world in a different way, the intellectual wealth of mankind consists in the diversity of its languages, i.e., in the number of such treasures (Schlesinger 1991, p. 12f). Or, in the words of a modern Herderian: 'It is ethnic and linguistic diversity that makes life worth living. It is creativity and beauty based upon ethnic and linguistic diversity which makes man human' (Fishman 1989, p. 15). Very differentiated assumptions about the interrelationship between language and thought have also been put forward by Humboldt (1988), while a more simplistic view, basically a linguistic determinism, was proposed much later by Whorf (1962). Whorfians have also claimed the earlier Sapir as one of their persuasion and speak of a Sapir–Whorf hypothesis. A fuller analysis of the interrelationship of language and thought or language and cognition would go beyond the scope of an article on language and ethnicity (for a summary see Schlesinger 1991).

The above-mentioned possibilities, that an ethnic group is completely coterminous and identified with the community of speakers of a certain language, and the opposite case, of a total lack of such a congruence and the absence of any association between an ethic group and the language(s) spoken by it, are two extremes of a range of variation. Between these extremes we find language and ethnicity interacting in a great number of ways. To examine how language relates to ethnicity, and which languages/ethnic identifications persist in which functions in a plurilingual and culturally heterogeneous setting, i.e., to study the ecology of languages, the following variables need to be taken into account: demographic variables, like the sizes of language communities and their growth rates, and their compact or dispersed form of settlement including the forms of mixture with speakers of other languages; political and juridical variables, like the status of a language and the institutions in which it is used, and the presence or absence of ethnic stratification of the labor market with which language status often correlates; ethno-cultural variables, like the association of a language with a group's history or religion, and the potential of a language in terms of range of vocabulary and tradition of writing; interactional variables like communicational mobility and degree of multilingualism of speakers, specialization of the functions of speech varieties in diglossic and polyglossic settings, and routines of interactions between ethnic groups/speech communities; variations on topic, to explore the influence of different topics on the choice of a language; predominant/exclusive use of a language in the public/private sphere, and the linguistic distance between the languages in contact (Haarmann 1986, pp. 11ff). This list is not meant to be exhaustive.

Some of these variables are illustrated. In contact situations, languages may undergo functional differentiation. The original language in bilingual communities may become restricted to sacral functions. Ethnicity and language choice should not be studied in isolation from other dimensions of social identity like gender and age. Minority people may revert in their old age to the language of their childhood, while their professional lives have been dominated by languages of wider currency (Dow 1991). The past interaction between languages, their differences in potential and prestige in different semantic domains, and the relationships between the speakers of those languages and the cultural values attached to their ethnic identities, are reflected by loanwords. Contrary to the widespread assumption that loanwords are typical for specialized concepts, these often extend far into the basic vocabulary and may designate parts of the body or kinship terms (Haarmann 1986, pp. 186ff, Schlee 1994). In intensive language contact situations, borrowing is not restricted to the lexicon and there may be light or heavy structural borrowing (Thomason and Kaufman 1988, pp. 74f).

Written language and writing systems show a stronger tendency to be maintained as sacred, and/or symbols of ethnic identity, than does spoken language. Aramaic-speaking Christians became speakers of Arabic, which they also used for writing and in which they produced a considerable literature, but for a long time they continued to use their earlier Syriac alphabet because they identified the Arabic alphabet with the Qur'aan and Islam. The mirror case is provided by Muslims in the post-*reconquista* Spain who wrote

Spanish in Arabic characters. Jews throughout Europe for centuries wrote the respective majority languages of the countries in which they lived, with a sprinkling of Hebrew words, in Hebrew characters. Where the new alphabet, like the Arabic alphabet in non-Arabic countries converted to Islam, is associated with holy texts, the opposite may occur. Many different languages have been written in the Arabic script, and other writing systems, some of them ancient, have fallen into disuse (Lewis 1998).

Also linguistic variation within the performance of one speaker in the same speech act can highlight aspects of language and ethnicity. A narrator may switch in a story back and forth between languages and/or more or less standardized/creolized varieties of these languages to depict characters to whom different ethnic and other social identities are attributed. Also, in presenting themselves, polyglot people, or people who master more than one register of a language, can play with options of identification rather than being tied to one form of speech and the ethnicity, or more generally the identity, it connotes (LePage and Tabouret-Keller 1985).

Language and Gender

In all known societies, gender is a key construct, involving binary distinctions such as man–woman, male–female, masculine–feminine, and in all known societies language plays a crucial role in constructing and maintaining these distinctions. This is achieved in part through the language system itself (note, for example, the inherent bias of the so-called English generics *man* and *he*), but this article will focus on the ways in which language is used by speakers to construct gender and to maintain gender differences.

1. Gender-exclusive vs. Gender-preferential Differences

As long ago as the seventeenth century, differences in the language used by women and men were remarked upon in anthropological writings. Missionaries and explorers came across societies in which they claimed to find distinct languages for male and female speakers. In fact, their accounts exaggerated the reality; what can be found in some languages are phonological, morphological, syntactic, or lexical contrasts where the speaker's gender determines which form is chosen. An example of this is Yanyuwa, an Australian aboriginal language; in this language, the choice of particular case-marking suffixes depends on the gender of the speaker.

Gender-exclusive differences of this kind mean that speakers who use a form inappropriate to their gender will be strongly reprimanded. Bradley (1998) quotes a

Yanyuwa male who reminisces 'I spoke like a woman and [my mother] yelled at me, "Hey! you are a man, you have no foreskin, why do you talk like a woman?" I was shamed.' Such linguistic differences clearly function to keep gender roles distinct. However, most of the linguistic variation associated with gender found today involves gender-preferential rather than gender-exclusive differences. This means that, rather than there being linguistic forms associated exclusively with one gender, there is instead a tendency for women or for men to use a certain form more frequently. The difference between gender-exclusive and gender-preferential usage seems to correlate with differences between nonindustrialized societies, such as the Yanyuwa, and industrialized societies, such as Britain and the USA. Nonindustrialized societies tend to have clearly demarcated gender roles, whereas in modern industrialized societies, gender roles are much less rigidly structured.

2. *Quantitative Sociolinguistic Research*

Researchers investigating gender-preferential differences in grammar and pronunciation use a quantitative approach; results showing phonological or grammatical differences are presented in terms of either raw numbers or percentages, and statistical tests are used to demonstrate the significance of these findings. This approach is common throughout the sciences and social sciences, and it has proved a valuable tool for sociolinguists exploring gender-preferential differences (as it can demonstrate gender difference despite the fact that women and men are using the same linguistic forms). This approach was developed by Labov in his pioneering book, *Sociolinguistic Patterns* (1972), and it has provided sociolinguists with a model for work on linguistic variation; the model is often referred to as the Variationist Paradigm.

In terms of gender, the most robust finding to emerge from research in a wide range of speech communities is that female speakers tend to use linguistic forms closer to the prestige norm more frequently than male speakers of a similar social background (see, for example, Trudgill 1998, Eisikovits 1998, Milroy 1980). It has even been claimed that this should be viewed as a sociolinguistic universal (Holmes 1998). Many explanations have been put forward for this finding, none of them wholly satisfactory; four of these will be examined briefly here.

2.1 *Explanations for Gender-differentiated Language Use*

First, the notion of covert prestige was developed to describe the positive value assigned to vernacular (nonstandard) forms by working class and male speakers. It is argued that male speakers tend to orient to the covert prestige of vernacular forms while female speakers tend to orient to the overt prestige of standard forms.

A second explanation derives from social network theory which demonstrates how individual speakers are members of social networks which have the power to enforce group norms (Milroy 1980). In the case of language, social network theory predicts that group pressures will enforce linguistic norms. Since women and men tend to belong to different (gender-based) social networks, then different norms are maintained.

A third explanation emphasizes the role of economic factors, that is, the pressures exerted by the job market which bring some speakers, but not others, into contact with more standard speech forms (see, for example, Nichols 1998).

Finally, a more recent explanatory framework is proposed by Eckert (1998, 1999) in her research into the speech of adolescent speakers in Detroit, USA. Eckert found that girls' linguistic usage was more extreme than that of boys: girls with more middle-class values used forms closest to the prestige standard, while girls with more working-class values used the most advanced vernacular forms. Drawing on Bourdieu's notion of a symbolic market, Eckert argues that female speakers have to use more standard (or more vernacular) speech because they are marginalized in the linguistic marketplace. (For further discussion of language variation and change, see *Sociolinguistics*.)

3. *Gendered Communicative Competence*

Early research on language and gender concentrated on what were seen as core features of language: phonetics, phonology, syntax, and morphology. Later, researchers began to turn their attention to broader aspects of talk, the conversational strategies characteristic of male and female speakers which constitute their communicative competence (see *Communicative Competence: Linguistic Aspects*). Communicative competence is a phrase coined by Dell Hymes. He argued that it was essential to incorporate social and cultural factors into linguistic description, since when children learn to talk they learn not just grammar but also a sense of appropriateness. It is not sufficient for a child to be linguistically competent; he/she must also known when to speak, when to remain silent, how to tell a joke, how to be polite, etc.

As children become more competent as speakers, so they learn to talk in ways appropriate to their gender. Becoming a girl or a boy means talking like a girl or a boy. Women and men characteristically draw on different strategies in conversational interaction, strategies such as paying compliments, hedging, apologizing, swearing. Women's and men's behavior in conversation suggests that they have a different understanding of how a compliment or an apology is done. (Examples of such differences can be found in

Holmes' paper on compliments in New Zealand English, Brown's paper on politeness in a Mayan community in Mexico, and Goodwin's paper on directives in Black peer groups in Philadelphia, USA, all in Sect. 2 of Coates 1998.) Such differences have led some researchers to talk of different female and male 'styles' in conversation (see Maltz and Borker 1998).

At a broader level, it even seems that male and female speakers prefer different modes of conversational organization (see Coates 1996, 1997a). Male speakers tend to choose a one-at-a-time model of turn-taking, where speaker turns are carefully demarcated, and where speakers occupy the conversational floor one at a time, often for long solo turns. By contrast, female speakers in relaxed informal conversation with friends characteristically opt for a more collaborative model of turn-taking, which allows speakers to share the conversational floor and construct talk jointly. This latter mode of conversational interaction can be called the 'jam session' model.

3.1 Conversational Dominance

One cluster of conversational strategies has been observed to function in conversation as a way of enabling certain speakers to dominate their partners in talk. Asymmetrical patterns of talk are always a sign of power imbalance, and asymmetry has been found in research which focuses on mixed talk in a variety of social contexts, with men's greater usage of certain strategies being associated with male dominance in conversation (see the papers in Coates 1998, Sect. 3).

The following linguistic strategies can be involved in conversational dominance: interrupting another speaker; failing to respond to another speaker's utterance, or delaying a response; talking too much (that is, occupying the conversational floor for long stretches of time and thus preventing other speakers from participating); or talking too little (silence can be a very effective device to control the direction in which conversation goes, or whether conversation can take place at all).

The research evidence is that male speakers regularly use these strategies to dominate talk. Research on language in the classroom reveals that boys get to talk on average twice as much as girls, and this pattern persists in public arenas with adult speakers. In the private sphere, male speakers in a range of studies have been found to dominate their female friends or partners through using these strategies.

4. Difference or Dominance?

Two approaches to gender variation in language have dominated sociolinguistic research in the area of language and gender until very recently; these are the difference approach and the dominance approach. To put it very simply, research which takes a dominance perspective interprets the differences between women's and men's linguistic usage as reflexes of the dominant–subordinate relationship holding between men and women. Research which takes a difference perspective, by contrast, sees the differences between women's linguistic usage and men's linguistic usage as arising from the different subcultures in which women and men are socialized (this approach is sometimes called the subcultural or two-cultures approach).

Early work on language and gender took a dominance approach. The reaction against this, and the subsequent flourishing of the difference approach, arose not because researchers denied the existence of dominance and oppression in male–female relationships, but because researchers, particularly feminist researchers, became unhappy at the negative portrayal of women in work using the dominance approach. Women's language was described as weak, unassertive, tentative, and women were presented as losers, as victims.

Researchers who began using the difference model in the 1980s argued that the dominance model had become a deficit model, that is, a way of interpreting the linguistic facts which represented men's language as the norm and women's language as deviant. The advantage of the difference model is that it allows researchers to show the strengths of linguistic strategies characteristic of women and to celebrate women's ways of talking. For those carrying out research involving mixed talk, the dominance approach provides a useful explanatory framework, but for researchers investigating same-sex talk it seems less appropriate, since dominance and oppression are not obviously helpful categories for the description of all-female talk (or of all-male talk, for that matter, but it is only very recently that sociolinguists have turned their attention to the informal talk of men—see Johnson and Meinhof 1997).

Probably the main problem with the difference approach is its assumption that all interactional difficulties between women and men can be called 'miscommunication.' However, the idea that miscommunication is at the heart of male–female problems has immense popular appeal, and has become widely known throughout the English-speaking world since publication of the book *You Just Don't Understand* (Tannen 1990) and other similar works.

The popularization of the discussion about male–female differences and miscommunication means that the difference approach is now seen as problematic, because it is associated with a political stance which ignores male dominance. However, interesting work on same-sex talk continues to be carried out which implicitly draws on a difference or subcultural approach. But in many areas researchers have moved on, assimilating ideas from European social theory. In particular, current research into linguistic variation takes the view that gender is not a given but is

accomplished through talk, and that speakers have available to them a whole range of (often conflicting) discourses (see Coates 1997b, Fairclough 1992, Weedon 1987).

5. *Language and Gender Research: New Directions*

In the early years (the 1960s and 1970s), research into the interaction of language and gender relied on a predominantly essentialist paradigm which categorized speakers primarily according to biological sex, and used mainly quantitative methods. Next, in the 1970s and 1980s, came a period which recognized the cultural construction of categories such as gender. During this period, more qualitative, ethnographic approaches predominated. In recent research, a more dynamic social constructionist approach has emerged which makes possible the combination of quantitative and qualitative research.

Researchers are now urged to 'think practically and look locally' (Eckert and McConnell-Ginet 1998). In particular, researchers are urged to work in terms of communities of practice, a concept which they adopt to assert the dynamism of living communities, and to underscore the fact that personal identity is not constructed in a vacuum, but in the many communities of practice individuals belong to. Gender, one aspect of personal identity, is not a given, but is constantly created and recreated in social interaction with others in these communities of practice.

Moreover, gender is complex: the binary distinctions men–women, male–female, masculine–feminine tend to distort—and oversimplify—our thinking. It is unhelpful to think of men and women as being totally different: male and female speakers differ in many ways, but there are also many areas of overlap. It is also important to realize that using the terms 'masculinity' and 'femininity' in the singular is a stylistic convenience: there is no singular masculinity or femininity. Gender is fluid and variable and at any point in time there will be a range of masculinities and femininities extant in a culture, and these will vary in terms of class, sexual orientation, ethnicity, age, etc., as well as intersecting in complex ways. Finally, masculinity and femininity cannot be understood on their own: the concepts are essentially relational. In other words, femininity (for example) is only meaningful when it is understood in relation to masculinity and to the totality of gender relations (see Connell 1995).

At the end of the twentieth century, sociolinguistic research has moved on from the simple correlation of linguistic form with social category. Researchers now analyze spoken and written data with the aim of understanding how gender is constructed in everyday life and of assessing the role of language in the creation and maintenance of contemporary masculinity and femininity. There is increasing emphasis on the need to be aware of similarities as well as differences between male and female speakers, as well as to assert the plurality of masculinities and femininities. Finally, the spread of language and gender research to non-English speaking communities is widening understanding of the key issues, since it seems that whatever the language of a community, gender politics manifest themselves in similar ways all over the world.

Language and Literature

Literary linguistics is a type of linguistics which studies language in literature, and asks whether the form and use of language in literature are different from the form and use of language in general. This can lead to a further question about function: whether special kinds of form and use of language serve the particular functions of literary texts—to be culturally valued artefacts, to stimulate emotion, and to communicate important meanings. Alongside these questions there is another question about literary form (such as the division of a poem into lines), and its relation to linguistic form (such as the division of a text into sentences): whether these kinds of division into constituent parts are fundamentally similar or different in kind.

1. *Literary Linguistics*

Linguistics looks for generalizations and so treats any text, any instance of language, just as an example of general processes at work and hence of interest only to the extent that it demonstrates those general processes. In contrast, literary criticism, at least traditionally, is interested in the text in itself, its characteristics considered unique and special, carrying traces of the historical moment of the text's production and of the individual genius of the author who produced it. This is a fundamental distinction between linguistics and literary studies, abstraction as opposed to concreteness, generalization as opposed to specificity, and means that any combination of linguistics and literary studies must compromise in one direction or the other.

Linguistics might put itself at the service of literary studies by offering to analyze the underlying linguistic system which is instantiated in a specific text; this is an approach often associated with more functionalist orientations in linguistics. Functionalist literary linguistics characteristically uses linguistics to illuminate the workings of language in a particular text, and in particular to establish an interpretation of the text. This 'critical linguistics' spreads beyond literary studies, into the analysis of media texts (in 'critical discourse analysis'). It has also been influential in language teaching, with linguist-educationalists arguing that the student better understands a language by analyzing its use in literature (see Widdowson 1975).

Alternatively, literature might serve linguistics by offering the literary text as evidence for generalizations about a particular kind of language: the language of literature. This is particularly associated with formalist literary linguistics, such as Generative Metrics, closely allied to Generative Phonology. Formalist literary linguistics looks for generalizations specific to language in literature, and ways in which literary practice develops from the abstract principles underlying all language. Formalist literary linguistics has its roots in Russian Formalism and related movements, and in its early stages was particularly associated with the work of Jakobson (1960). Through Jakobson, it influenced the structuralist anthropology of Claude Lévi-Strauss, and then the structuralist literary analysis of Roland Barthes, in which literary studies briefly adopted the generalizing and universalizing tendencies of linguistics. The history of formalist literary linguistics can be traced in a series of anthologies and conference proceedings: Sebeok (1960), Freeman (1970, 1981), Fabb et al. (1987), Kiparsky and Youmans (1989); see also Fabb (1997).

2. *What Makes 'Literature' Different?*

The language of literary texts may sometimes differ from the language of nonliterary texts, but this is not a defining characteristic of literature. What makes a text literary is not form, but function. Jakobson (1960) proposed that verbal behavior might perform any (and any combination) of six distinct functions, one of which was the poetic function. In literature, the poetic function dominates. For Jakobson, a text functions poetically when it draws attention to its own form—when our attention is drawn to the text itself and not just to what it means. Bauman (1975) suggests that the poetic function itself has a further purpose, which is to enable a literary text to be performed; for Bauman it is performance, understood as a type of social behavior requiring evaluation by an audience, which defines a text as literary. The poetic function draws attention to the form of the text in order to permit evaluation by the audience according to the text's adherence to rules of form. For both Jakobson and Bauman a literary text can differ from a nonliterary text only in terms of function; in principle the same text could be made

literary or nonliterary depending on the extent to which it is made to draw attention to its own form, by being presented or performed in different ways.

Though it is function rather than form which makes a text literary, the poetic function can nevertheless give rise to distinctive kinds of literary form. A literary text tends to differ from a nonliterary text in two fundamental ways relating to form: in having specialized kinds of *constituent structure*, and in having 'difficult form,' form which is not straightforward to ascertain. Specialized kinds of constituent structure include lines of verse, metrical constituents such as the foot, and narrative constituents such as 'orientation,' 'coda,' or narrative episodes. These specialized kinds of form are regulated by rules which the text can overtly adhere to, thus drawing attention to form. Difficulties for interpretation arise from formal ambiguities, as well as from exploitations of the ways in which verbal communication works to produce effects such as metaphor and irony. By making the text difficult, attention is drawn to the workings of the text and thus again the poetic function is performed. These formal complexities and difficulties may also be responsible for some of the aesthetic effects of literary texts, if the experience of complexity constitutes one of the kinds of aesthetic experience.

'Literature' can exist either in the medium of writing or speech. (Because the term implies writing, 'literature' is sometimes substituted in literary linguistics by the medium-neutral term 'verbal art.') Language in written literature and language in oral literature differ, just as writing and speech differ. Any medium both constrains and enables certain kinds of aesthetic possibility in its own medium-specific way. Thus we might ask whether spoken literature makes special use of the characteristics of speech in order to carry out literature-specific functions; the same question arises for written literature. Some kinds of literary–linguistic form are restricted to speech. Metrical verse is the most obvious example, because it organizes the components of sound: loudness, pitch, and duration. There have been proposals that certain kinds of linguistic form are restricted to writing; thus Banfield (1982) proposes that certain kinds of sentence, expressing a character's inner experience but at the same time describing that experience from another's point of view and so paradoxically combining two centers of perspective, are 'unspeakable,' found only in writing (Fludernik 1993 and other authors have suggested that complexities of this kind can also be understood as exploitation of the 'looseness' of communication, see Sect. 7).

3. *Metrical and Parametrical Form*

Verse is a kind of text defined by its having a particular constituent structure: it is divided into lines. The line is marked out as a constituent by different means in different types of verse: in free verse it is marked out as a constituent by sentence structure, layout on the page, and performance; in canonically parallelistic verse the line is characterised by parallelism with other lines (see Sect. 4); in metrical verse the line is regulated by metrical rules which fix the length of the line, measured in phonological units such as the syllable or the mora (a 'weight unit' contained with the syllable). The metrical rules can also determine a rhythm within the line, in terms of the sequencing of relatively stressed and unstressed syllables, or relatively heavy and light syllables.

One of the key questions about language in literature is whether literary language ever has its own distinctive kind of linguistic form, not just a way of using general linguistic form, but a separate rule-system which governs literary language. Metrical verse perhaps offers the best opportunity of finding specifically literary-linguistic form of this kind, because in metrical verse the rules which govern the meter appear to be similar to linguistic rules, while also differing from linguistic rules. The similarities involve phonological rules, the rules which govern how sounds are combined into words. First, metrical rules build 'tree structures' (hierarchical constituent structures) which resemble the tree structures of phonology. Second, the metrical rules form a set of interacting rules so that apparent exceptions can be understood in terms of rule interaction and even appear to operate on abstract structures, like phonological rules. Third, the metrical rules differentiate strong and weak phonological constituents, just like the phonological rules which organize the rhythmic structure of speech in general. Formalist literary linguistics has always seen metrical verse as the most important kind of text for understanding the relation between linguistic rules in general and specifically literary linguistic rules, and there has often been a close relation between work in phonology (the sound-structure of the language) and metrics; as new theories of phonology have emerged, so new insights become available into metrical structure. (Representative samples of linguistic work on meter include Halle and Keyser 1971, Attridge 1982, Hayes 1989, Hanson and Kiparsky 1996. See *Language and Poetic Structure*.)

Metrical rules control small phonological units. These include the morae which are counted in Japanese verse; the syllables counted in Welsh verse, organized into stress patterns in English verse, and weight patterns in Latin verse; and the phonological feet (combinations of syllables grouped around a strong syllable) counted in older Germanic verse like *Beowulf*. But it is also fairly common to find another kind of rule operating simultaneously with the metrical rules, and governing larger phonological units such as the word. These word-boundary rules—caesura and bridge rules—govern where words can begin or end within the line, and may contradict the constituent structures built by the meter. Thus Homer's line is

divided into six constituents ('feet'), and thus can be divided into two halves with three feet in each half. But word-boundary rules operate to ensure that the middle of the line does not coincide with the end of a word; instead a word must end just before or just after the middle boundary as defined by the foot constituent structure. The fact that word-boundary rules sometimes contradict the metrical rules with which they co-occur suggests that contradiction and complexity are design features of literary linguistic rules, perhaps because contradiction and complexity are a source of aesthetic experience. Poetic word-boundary rules are of interest to linguists partly because of their interaction with metrical rules, but also because they are sensitive to different levels of linguistic structure; Devine and Stephens (1984) have shown for Greek that in tragedies, word-boundary rules govern the lexical word, while in comedies the rules govern the 'phonological word' (which contains a lexical word plus neighboring grammatical words). This shows that literature-specific rules are able to differentiate abstract linguistic structure.

4. *Parallelism*

Most verse traditions are governed by one of two basic organizatory systems: meter or canonic parallelism (free verse, a third organizatory system, has become increasingly common in the twentieth century). *Canonic parallelism* (the term is Jakobson's) is parallelism as a structuring principle in verse holding throughout a text. Parallelism draws on the linguistic structure of the text: parallel pieces of text (usually lines, or half-lines) differ in certain respects but have some fairly salient linguistic component in common. In phonological parallelism, a sequence of sounds is repeated: the Welsh system of *cynghanedd* (harmony) requires the consonant sequence in the first half of a line to be repeated in the second half of the line; in some Gaelic songs the sequence of stressed vowels is the same in every line; and in Efik tonal riddles the sequence of tone changes is the same in both halves of the riddle. In syntactic parallelism, phrase structure is repeated; the words are different but they belong to the same parts of speech organized in the same manner. Syntactic parallelism is often tied to the third type of parallelism: lexical parallelism, in which words with related meanings are paired in adjacent sections of the text (see Fox 1988).

Parallelism is another instance of a literary practice where linguistic form is controlled in a literary text. Canonic parallelism has some similarities to meter, and functions in a similar way; both, for example, draw attention to form (hence define the text as verbal art) through ostensive repetition of form. However, parallelism and meter clearly operate by different principles; in parallelism the only general rule is 'imitate the preceding line/half-line,' while in meter the line has its structure because it is governed by a complex set of metrical rules. Thus, parallelism does not appear to involve a distinctive kind of linguistic form, but instead is a way of using linguistic form to build literary form. It is worth noting that parallelism has emerged apparently independently in widely dispersed literatures, for example, Mayan, Russian, Tswana, Egyptian, and the isolated cultures of New Guinea. In contrast, almost all known metrical traditions can be historically connected, and traced back to Indo-European or Arabic origins (and these may themselves be connected). It is relatively uncommon for metrical traditions to emerge apparently spontaneously elsewhere (rare exceptions include Somali and the East Australian Dyirbal). This correlates with a hypothesized difference between parallelism as a development of possibilities inherent in language, and meter as a rule system separate from language in general and not implied by language in general.

5. *Narrative Structure*

Narrative is a type of discourse, including as a subtype 'literary narrative.' Questions about language in literary narratives are thus to some extent the same as questions about language in narrative as a general discourse genre. One of the most influential linguistic works on narrative told to interviewers, Labov and Waletzky (1967), describes true stories in which the narrator was in danger. Though these are not literary narratives, they nevertheless have characteristics which literary narratives share. Labov and Waletzky drew particular attention to three characteristics. First, sentences in the narrative can be separated into ('storyline') sentences whose sequence mimics the sequence of events and ('non-storyline') sentences whose role is to provide contextual information. Subsequent research has shown that storyline and nonstoryline sentences typically differ in their linguistic form (storyline clauses tend to be higher in transitivity; may have the verb in a more prominent position, etc.). Second, the narrative as a discourse has a clearly structured trajectory; it often begins with an 'orientation' constituent, and ends with a 'coda' constituent, and there is a movement from a complication to a resolution. Third, the point at which the complication is resolved is often made salient by particular linguistic devices; this practice is called the 'evaluation' by Labov and Waletzky, and may involve an explicit judgment on the narrative by the narrator; more generally it draws the hearer's attention to the point of the narrative. This strand of work on narrative offers a way of thinking about literary narratives as developments of narrative as a general discourse genre, but does not involve a specifically literary kind of form. Nevertheless, it is possible to see how literary narratives exploit these basic possibilities to generate

effects such as suspense, to create complex and ambiguous structures, and to draw attention to narrative form (thus performing the poetic function).

Focus on the language of specifically literary narrative comes from another tradition, particularly associated with Dell Hymes's work on American Indian narratives (Hymes 1981). In this tradition, the narrative is seen to have a constituent structure analogous to verse constituent structure (typically nonmetrical, but sometimes with canonic parallelism), in which the text's constituent structure is signaled by the salient use of grammatical material—connective words ('and,' 'so,' 'then'), hearsay elements ('it is said'), shifts in tense, and so on. As Tedlock (1983) argues, components of speech, such as intonational contours or the placement of pauses, can also have an important role in marking out constituency. This research tradition also looks at the organization of content into episodes within the narrative, and ways in which episode boundaries are signalled by grammatical means. This research, sometimes involving the reanalysis and reconstruction of texts gathered in the early twentieth century from now lost languages, has as one of its goals to assert the literariness of the texts, by revealing their complexity. This clarifies one of the ideological goals which is characteristic of literary linguistics in its more ethnographic and anthropological modes: to promote the artistry of traditional verbal arts, demonstrating that traditional literatures from marginalized cultures can be as complex as the canonical literatures of the 'first world.'

6. *Access to Abstract Linguistic Form*

With Transformational Generative Grammar, Noam Chomsky invented a way of thinking about a sentence or a word as the 'surface' manifestation of a set of interconnected representations (see *Generative Grammar*). Each instance of spoken or written language is in this sense like the tip of an iceberg, with multiple representations underlying each sentence and each word. Users of the language have no direct access to those underlying representations, in which a sentence might have its phrases ordered differently from its surface representation, or a word might have sounds which are different from those which appear on the surface; this is an 'encapsulated' type of knowledge which is hidden away from introspection.

In this tradition, one of the things which has interested linguists about literary texts is the possibility that underlying sentence or word structures might be manipulated directly in the construction of some literary texts. This would be an extraordinary access to linguistic material which is normally hidden. Along these lines, Austin (1984) argues that instances of distorted phrasing in poetry by Shelley might involve the violation of specific constraints on transformational rules. Thus the line 'And the swift boat the little waves which bore' sounds odd because there is leftward movement of 'the swift boat' which is the object of the verb 'bore,' out of a relative clause in a noun phrase; this is a violation of the 'complex noun phrase constraint,' which was proposed in 1960s transformational grammar to regulate abstract syntactic structure. Austin shows that Shelley violates constraints as though he has access to the underlying workings of the language, which ought to be hidden to introspection or intervention. Similar kinds of argument have been made about sound structure. Thus Malone (1988) argues that rhymes in Turkish poetry seem to be somewhat dissonant on the surface but can be seen to be underlying perfect rhymes, if the linguistic process of 'vowel harmony' is factored out. Vowel harmony alters the abstract vowels which make up a word to ensure that surface vowels in the same word 'harmonize' to have similar features. Thus in these poems the rhyme shows more regularity at an abstract level than on the surface of the text.

The possibility that abstract and supposedly 'inaccessible' form is manipulated in literary texts might interestingly suggest that authors (and audiences) can have privileged though presumably unconscious access to kinds of linguistic form which are normally not available to introspection. This suggestion that literature is special in its relation to language would find favor with some traditional (specifically Romantic) views of literature. But in some cases, it might also be suggested that authors use a slightly different 'language' from the ordinary language, which operates according to slightly different rules. In some cases, these different literary languages might correspond to archaic versions of the contemporary language.

7. *The Communication of Literary Meaning*

The communication of meaning is a primary function of most ways of using language. Communication has two components. The encoding of meaning into form (performed by the vocabulary and syntax of the language, such that a sentence encodes a proposition) is one component which provides evidence for the informative intention of the communicator. But other kinds of evidence can be added, and may override the evidence offered by the encoded meaning; these kinds of evidence can come from the way in which the form is used, and rely on the context in which the communicative act occurs (including the cognitive context of the interlocutors—what they know). This second component involves inferencing, and falls under the scope of pragmatics. It is here that most of the interesting questions about literary meaning have been asked.

Metaphor is a characteristic 'meaning effect' in literary texts. In a metaphor, the encoded meaning (what is actually said) is not the communicated meaning (what is intended and can be inferred). Two lines of enquiry into metaphor have proved particularly fruitful for linguistics; both take the position

that metaphor is not specific to literature but is characteristic of the way language works in general. In the approach particularly associated with the work of George Lakoff and co-workers (Lakoff and Johnson 1980), the vocabulary of a language is claimed to be structured by metaphor, collected into sets of relations between words and meanings which develop basic metaphors, the 'metaphors we live by.' Thus, for example, the use of the term 'journey' to stand for 'life' is a metaphorical substitution which underpins many other substitution (we get a start in life, reach the end of our life, choose a path, etc). Metaphors in literature draw upon the 'metaphorical' structure of the vocabulary in general, using this as raw material and potentially innovating on it, as when Robert Frost writes a poem on *The Road Not Taken*; thus language in literature makes special use of the potential of language in general. A second approach is taken by Sperber and Wilson (1995), who see the possibility of metaphor as a development of the way in which communication works. In verbal communication, a literal meaning is encoded into the linguistic form of a sentence, but that literal meaning need not itself be the intended meaning; instead the literal meaning can constitute indirect evidence for an intended meaning which is not actually stated. This is true of all verbal communication; it is also the basis of metaphor, where the literal meaning is not the intended meaning, but instead offers evidence by which the intended meaning can be inferred.

A second characteristic 'meaning effect' in literary texts involves the attribution of a source for any thought which is communicated, and the attribution of an attitude or a set of attitudes towards that thought. Again Sperber and Wilson (1995) have proposed an influential way of seeing the literary uses of attribution and attitude—in effects such as 'free indirect speech' or irony—as developments of the possibilities of communication in general. The simplest case in verbal communication is for the thoughts expressed by the communicative act to be attributed to the communicator, along with the assumption that the communicator believes those thoughts. These attributions are part of the communicative process; they are worked out by the hearer or reader alongside the working out of the referential content of the communicative act. The attribution of source and attitude is affected by the same 'looseness' which gives rise to metaphor. In literature, the possibility of looseness in the attribution of speaker is exploited in techniques such as the use of hearsay particles (which displace the source of a thought onto persons unknown, with various literary consequences), or free indirect speech (which blur the source of a thought between narrator and character). Literature also exploits the possibility of 'looseness of attitude' in modes such as irony; in irony, the communicator does not have the 'unmarked' attitude of belief towards the thoughts which she expresses. Instead, she typically communicates her own disbelief and at the same time re-assigns the source of the thoughts to another person or set of persons who are assumed to believe those thoughts.

8. *The Communication of Literary Form*

A fundamental element of linguistic form is linguistic constituent structure (see *Constituent Structure: Syntactic*; *Phonology*). The interpretation of speech involves the assignment of a phonological constituent structure to the sequence of sounds, and the interpretation of a sentence involves the assignment of a syntactic constituent structure to the sequence of words. Literary texts have their own distinctive kinds of constituent structure, examples of literary form (rather than linguistic form). Examples include lines and stanzas in verse, or the orientation and coda and division into episodes in narrative. Each of these kinds of constituent structure is specific to literary texts, each adding noticeably to the formal complexity of the text and thus drawing attention to form and performing the poetic function. An interesting question about these kinds of constituent is whether they are similar in kind to types of syntactic or phonological constituent.

As a way of thinking about this question, it is helpful to consider two distinct ways in which a text can have a specific constituent structure. A text has phonological and syntactic constituent structure because it is processed by phonological and syntactic rules; these structures enable words to exist, to be spoken and to relate to one another in an interpretable manner. These kinds of constituent structure are in principle determinate; they can be discovered by linguistic investigation though they may not be obvious on the surface. In contrast, constituent structure might also exist as a description of the text only to the extent that it is interpreted as being present in the text, by analogy with the interpretation of implied meanings. The constituent structure in this sense is a self-description which is evidenced by the text, basically a kind of meaning, rather than being like linguistic form. Evidenced constituent structure of this kind might sometimes be vague or indeterminate, ambiguous or contradictory, and there is some reason to think that many kinds of literary constituent structure are evidenced in this manner. This includes the division of verse into lines, or the division of a narrative into functional constituents like 'evaluation' or structural constituents like 'episode.' In all cases, the text contains evidence that these constituents exist—usually some element at the beginning or end of the constituent (such as a connective like 'so' at the beginning of a narrative, or a rhyme at the end of the line). Of the various kinds of literature-specific constituent structure, only metrical constituent structure seems to be 'inherent' and determinately present in the manner of phonological structure. If these speculations are right, then most kinds of literary constituent are best

understood under a theory of pragmatics, which looks at interpretation—in this case, the interpretation of form.

Sperber and Wilson (1995) suggest that the experience of weak implicature—a large number of weakly evidenced interpretations stimulated by a text—is a 'poetic effect'; perhaps this is the cognitive component of a certain kind of aesthetic experience. This might be linked with a position held by some within literary studies and particularly postmodern literary studies. This is that textual complexity is a source of aesthetic experience, with complexity manifested in ambiguity, uncertainty, and vagueness, contradictoriness, looseness, and so on. 'Difficulties' in meaning and in form, both of which are literary exploitations of the pragmatic aspects of language, might thus be seen as ways of generating aesthetic experience. When we consider also that even the most regulated kind of literary linguistic form—metrical form—seems to be designed to give rise to complexity and contradiction, we might conclude that whereas linguistics seeks the underlying order in language, a literary linguistics might look at how the ordering principles of language give rise to the kinds of productive disorder which we experience as aesthetic.

Language and Philosophy

Linguistics arose partly from the need to teach Greek to Egyptian children during the Hellenistic period in Alexandria, and partly from the philosophical analysis of the notion of truth by, mainly, Plato and Aristotle. The philosophical origin has been with the study of language ever since. In the twenty-first century, philosophy has renewed its interest in language in various ways (the 'linguistic turn'). Language has been seen as providing a way to break through the Kantian dilemma of the unknowability of bare reality, and as an instrument for the perceptible expression of thoughts, and thus as a key to the inner workings of the mind and the position of humans in the world. The philosophical concern with language is not always distinguishable from the study of meaning: semantics (with its logical leanings) and philosophy are still intimately connected.

1. The Paradox of Knowledge

The fact that whatever there is supposed to be 'out there' in the 'real' world cannot be known directly, without the intervention of human cognitive processing, and indeed that it cannot be proven that there is a world 'out there,' has been a main concern in philosophy since Descartes. Kant gave what seems to

be the final formulation: the thing in itself (*das Ding an sich*) cannot be proven to exist and cannot be known. Yet humans generally assume that there is a world 'out there,' and that they have reliable knowledge of it. Many philosophers have since tried to find a way out of this paradox.

Following Leibniz, Bertrand Russell developed the program of *logical atomism*, meant to reduce all thoughts and all sentences to logically atomic propositions and their truth-functional compositions—in fact, to expressions in his language of Predicate Calculus now used universally in mathematics and the sciences. By hypothesis, this systematic logical analysis would then be the closest humans can get to bare reality (the 'furniture of the world'). By 1930 Russell had given up this idea, considering it unrealistic. His student Wittgenstein pursued the same idea in his *Tractatus Logico-philosophicus* (1922), though in a somewhat different and not altogether coherent fashion, and also concluded around 1930 that it was unfounded. Even so, this program has been very influential in subsequent philosophy. For example, Russell's Theory of Descriptions (1905), which was part of his logical atomism, dominated the theory of reference throughout the twentieth century.

After 1930, Wittgenstein attempted a different approach to the paradox of knowledge. He took to reflecting about language in a nonformalist way, against the background of questions of knowledge and being. He taught that language had no rules, that linguistic interaction was a 'game,' and that word meanings were based on 'family resemblance.' These views (Wittgenstein 1953) have since been rejected as false or imprecise. Yet his influence has been considerable, especially among students of literature and art, and also in the Oxford-based Ordinary Language Philosophy (OLP).

OLP was another influential confrontation with the paradox of knowledge, dominating much of Anglo-Saxon philosophy between 1945 and 1970. Its program, partly inspired by Wittgenstein's teachings about language after 1930, consisted in exploring to what extent a meticulous analysis of the ways words are used in ordinary discourse will reveal the reality of things, and also whether philosophical questions about them are or are not vacuous. Both aims remained unfulfilled. The age-old philosophical questions proved resistant to this kind of linguistic analysis, and the reality of things did not come much closer.

By 1970 there was a consensus among Oxford philosophers that they should reorient themselves and widen their scope. The reasons for the failure were mainly the exclusive focus on English, neglecting the other thousands of languages in the world, the lack of formal theory, and the refractory character of the questions dealt with. Even so, OLP led to two developments that have proven to be of great importance.

The first was *presupposition theory*, initiated by Strawson (1950). For the first time in the history of philosophy, presuppositions were recognized as a special kind of entailment of sentences. Since 1950 presupposition theory has been an important part of either semantic or pragmatic theory (the matter is controversial; see, for example, Carston 1998, Seuren 2000).

The second was *speech act theory*, initiated by Austin (1962). Austin raised the question of the truth value of 'performative' sentences such as 'I hereby promise to marry you.' If they are true, they are so because they have been pronounced seriously: they make themselves true by being pronounced. It appears that they cannot be false. This led to many studies, mainly in pragmatics, of the socially committing character of seriously uttered sentences. An integration with semantics, however, has not so far taken place.

A specific and much publicized angle on the paradox of knowledge was taken by Quine in Chap. 2 of *Word and Object* (1960). Here he discussed the difficulty of explaining how a language learner can learn the precise meaning of a new word, for example *gavagai* said by an exotic native on the passing of a rabbit. No amount of repetition in different circumstances will ensure that the learner gets exactly the meaning intended by the speaker. Yet the precise meaning will be learnt after a while. Quine called this the problem of the 'indeterminacy of radical translation.' It appears that the *gavagai* problem is but an instance of the general and yet unsolved problem of the acquisition of adequate knowledge of what is in 'other minds,' and indeed of adequate knowledge of anything.

2. *Intensional Contexts*

For Aristotle, truth consists in a correspondence of what is said (or thought) and what is the case. This implies that the choice of a word makes no difference for the truth value of a sentence, as long as it refers to the entity intended. This is the principle of Substitution Salva Veritate (SSV), formulated by Leibniz as (roughly) 'Things referred to by words that can stand in for each other without change in truth value are identical.'

Frege (1892) found that SSV does not work for referring expressions in *intensional contexts*, i.e., in clauses embedded under a verb reporting a third party's thoughts, such as 'John believes that the Morning Star is inhabited.' Since the Morning Star is identical with the Evening Star, both being the planet Venus, if the sentence given is true, the sentence 'John believes that the Evening Star is inhabited' should automatically also be true. This, however, is not so, since John may think that the two are not identical, and he may think that the one is inhabited but the other is not.

Frege solved this by positing that clauses embedded under verbs of thought refer not to their truth or falsity in the real world but to the thought expressed, and by observing that 'the Morning Star is inhabited' is a different thought from 'the Evening Star is inhabited,' which blocks SSV. Subsequent philosophers of language, being more of a positivist mind, rejected Frege's appeal to thoughts and sought alternative ways of solving the problem of intensional contexts, which thus became the starting point for the development of formal semantics in the twentieth century.

3. *Formal Semantics*

Since Aristotle, philosophers and linguists have striven to define the logical structure of sentences, i.e., the translation of sentences into some logically analytical language. In modern times this has been the Language of Predicate Calculus (LPC) devised by Russell, with its quantifiers and variables. These efforts are motivated by the wish to specify as exactly as possible under which conditions the propositions expressed by sentences are true or false. Logic is taken to provide such a specification; language is not; hence the desire to relate the latter to the former by translation.

The most explicit way of achieving this is formal or model-theoretic semantics, which defines how linguistic elements are to be translated into LPC, and how, for any given 'world,' LPC expressions are to be valued true or false. By generalizing over all possible 'worlds,' the truth conditions of sentences should, in principle, be statable, including those that involve intensional contexts. Clauses under verbs of thought are now taken to refer not to thoughts but to the sets of those possible worlds in which they are true. Sophisticated formal machineries should then account for the phenomena.

This program was initiated by Montague (1973). Although it seemed very promising during its first years, it has met with serious difficulties. It seems in principle unable to grasp certain cognitively determined aspects of lexical meaning (e.g., why can a speed bump be called *Schwelle* in German, but not 'threshold' in English?). More seriously, it fails to solve the problem of intensional contexts. Since a clause *C* containing a contradiction is false in all possible worlds, it should be synonymous with any other contradictory clause *D*. Yet 'John believes that not all circles are round' is not synonymous with 'John believes that not all bachelors are unmarried,' even though both embedded clauses are necessarily false and hence refer to the empty set of possible worlds; likewise for necessarily true clauses, which refer to the set of all possible worlds. This problem has so far proved unsolvable in the context of model-theoretic semantics (Dowty et al. 1981, pp. 170–5), for which reason many semanticists are now looking for a more cognitively oriented semantic theory.

4. *Thoughts and Propositions*

Talk about 'thoughts' is hazardous. There is not only the difficulty of grasping deep cognitive processes but also the fact that what we call thoughts occur at different levels of explicitness and consciousness. Here, a thought is taken to be (the result of) a mental process whereby the subject assigns a property to one or more entities, creating a representation of a possible situation. A thought that is ready for conversion into a sentence is a *proposition*. The property is expressed by the *predicate* of the proposition, the entities by *terms*. Propositions are always in the scope of a speech act operator SAO defining the speaker's social commitment with regard to it. [SAO + proposition] is converted into a sentence by the lexicon and grammar of the language in question.

5. *The Semantics of Predicates*

Predicates signify a property of one or more elements belonging to a certain class. For each predicate *P* there is a set of conditions to be fulfilled by any entity *e* for it to deserve *P*. These are the *satisfaction conditions* of *P*. In forming a proposition, the speaker considers one or more entities *e* as having the property signified by the predicate, thus forming a mental representation of a possible situation. Propositions are normally written as 'P(a),' where *P* stands for (refers to) the property and *a* refers to the element(s) *e*. If *e* actually has the property signified by *P*, the proposition is true; if not, it is false.

Some predicates are applicable only to sets of individuals. Predicates such as 'congregate,' 'disperse,' 'be numerous,' etc. require subject terms referring to groups, not individuals. Likewise, a predicate such as 'collect' requires an object term referring to a group, as one cannot collect an individual stamp, but one can collect stamps. Such predicates are higher-order predicates with regard to one or more of their terms.

It is the lexicographer's daily business to define satisfaction conditions of predicates, and the lexicographer's daily experience to find that this is extremely difficult. Often an appeal is required to what is *prototypical* in a community. Thus, the predicate 'bald' requires the (relative) absence of hair in prototypical places of the body (the top of the head for humans). Often conditions are approximative, as for the predicate 'flat,' which expresses an approximation to two-dimensionality. More often, conditions are vague, as with predicates such as 'good,' 'bad,' 'please,' 'love.' Subjective evaluations often play a central role, as with 'pleasant' or 'beautiful.' Whether this is also the case with predicates such as 'good' or 'true,' or whether these predicates are satisfied exclusively by the ontological properties of the subject term's referent is a much debated philosophical issue.

It seems useful to divide satisfaction conditions into two classes: first, the preconditions, which define the

right category of entities; then the update conditions, which define the entities that fall under the predicate. Thus, the predicate 'married' requires preconditionally that *e* be a person of marriageable age; then requires as an update condition that *e* be bound by legal marriage to another person, with all that this entails. 'Divorced' requires preconditionally that *e* has been married before and states that this is no longer so.

When *e* is semantically not of the right kind, as in 'The river Thames is divorced,' we speak of a *category mistake*. Lexical opposites, such as 'polite' and 'impolite,' generally stay within the same category ('rational being').

The preconditions play an important role in the *interpretability* of the resulting proposition. Whether the preconditions are actually satisfied in the world is irrelevant for mere interpretation: actual truth values are immaterial for comprehension. What counts is that the preconditions are fulfilled in the cognitive context preceding the utterance in question. The conditions to be fulfilled by (preceding) discourse for an uttered sentence *S* to be interpretable are the presuppositions of *S* (Seuren 1994). Presuppositions result from the preconditions of predicates.

Some predicates, in particular those of the possessive complex, such as 'have,' 'with,' or 'of,' need an appeal to common knowledge for their satisfaction. Compare the following sentences with the predicate 'have':

(1a) Each room in our hotel has a shower.
(1b) Each student in our faculty has a supervisor.

(1a) requires a one-to-one correspondence of rooms and showers for truth, whereas for (1b), a one-to many relation between students and supervisors suffices. It does not seem feasible to record such differences in the lexicon, since the decisive criterion is found not in the linguistic description of 'have,' but in general world knowledge: one has to know how things work in hotels and faculties to decide on the truth or falsity of sentences such as (1a,b).

Lexical meanings are, moreover, inherently dynamic: they are naturally extended, restricted, shifted, and even misapplied in ways that are nevertheless perfectly understood and often even become conventionalized to the point of becoming part of the lexicon. 'Sad,' for example, can be used intransitively, as in 'a sad mood,' but also causatively, as in 'a sad story.' Yet this process is not freely productive: 'nervous' can only be used intransitively, as in 'a nervous person,' but not causatively, as in 'a nervous story.'

Other forms of dynamic use are known as figures of speech or 'tropes,' mainly metonymy and metaphor. Metonymy is the use of a noun for something which is closely related to that for which the noun is normally used: 'crown' for 'monarch,' or 'grave' for 'death.' Metaphor is a much more complex trope, perhaps best defined as an implicit comparison. Deliberate category mistakes often lead to metaphor, as in 'The train was waltzing at sunset round the walls of Verona' (E. M. Forster 1975). Although 'waltz' requires a subject referent that is capable of dancing, a condition not fulfilled by trains, the choice of this predicate forces the reader momentarily to consider the train referred to as such a being, which provokes the artistic effect intended. Other metaphors arise as a result of applying an incorrect predicate to an entity referred to, as when someone asks you where you left your 'horse,' meaning your car. Tropes often become conventionalized ('dead metaphors'), and may enter the lexicon of the language. Conventionalization of tropes is a principal source of lexical enrichment.

The most important philosophical point about lexical meaning is the necessity to appeal to cognition. Satisfaction conditions cannot be defined purely in terms of 'objective' properties of the entities concerned. The cognitive aspect is particularly important with regard to the discourse dependency of lexical meanings, a lexical reflex of the general fact that thoughts do not occur in isolation but always in a wider context. This is bad news for model-theoretic formal semantics, which assumes that meanings are fully determined by conditions of truth and satisfaction in models containing no minds, but only a language, worlds, and an interpretation function from elements in the language to elements in the world(s).

6. *Reference*

Reference is the relation between definite argument terms of a predicate and things in the world. The reference relation is *intended* by the speaker and *comprehended* by the listener. Reference is a necessary condition for the proposition to have a truth value. A host of problems has arisen in connection with the reference relation. We shall make global mention of the main problem areas. Detailed analyses are to be found in the specialized literature.

6.1 *The Identification Problem*

The first problem is how speakers and listeners fix upon the intended entities by the use of definite terms. A term such as 'the dog' is naturally rendered as 'the *x* such that *x* is a dog' (Bach 1968). The problem is how the determiner 'the *x*' can pick out, from the set of dogs, the one particular dog intended by the speaker. The answer is trivial when the set contains just one element, but human speakers refer successfully even when the sets in question contain many elements.

This problem has occupied countless philosophers, most of whom recognized that contextual and cognitive factors must play a role. Russell (1905) proposed to eliminate definite terms by refinterpreting them as instances of existential quantification. This Theory of Descriptions should not only solve the identification

problem, but also the problems of reference to nonexisting entities and of reification (see below). Russell's famous example is (2a), rendered by him in logico-semantic terms as (2b):

(2a) The present king of France is bald.

(2b) $\exists x\ [\mathrm{Now}[\mathrm{KoF}(x)] \wedge \mathrm{Bald}(x) \wedge \forall y[\mathrm{KoF}(y)\ x = y]]$

(there is an x such that x is now king of France and x is bald and such that for all y, if y is king of France, x is identical with y)

The definite term 'the present king of France' has been replaced by an analysis in terms of the existential quantifier and a 'uniqueness clause' saying that for all y, if y is king of France, x is identical with y, which means that there is exactly one king of France.

Russell's analysis, though widely accepted for a long time, is inadequate for semantic analysis. This appears from embedding in emotive-intensional contexts. A sentence such as (3a) does not mean what (3b) means:

(3a) Nora was disappointed to find that the king was bald.

(3b) Nora was disappointed to find that there was a person who was both king and bald and that there was no other king.

The recognition that the Russellian reduction program does not work for language, and that definite terms must be reinstated is gaining ground. The identification problem has thereby returned in full force.

Further problems to do with the identification of reference objects are Quine's distinction between opaque and transparent reference, and Donnellan's between referential and attributive use of a definite term. The former, first presented in Quine (1953, pp. 139–59), has to do with the choice of the predicate P in a definite description. When P is selected by the speaker, so as to facilitate identification by the listener, there is *transparent reference*. It is, however, also possible for P to be selected by a person whose thoughts are spoken about, in which case the reference is *opaque*. For example,

(4) Sarah is convinced that the stupidest boy will get the scholarship

is ambiguous. On the transparent reading, the boy referred to is considered stupid by the speaker, but not by Sarah, while on the opaque reading Sarah takes a dim view of the award committee.

In line with Russell's Theory of Descriptions the difference has been analyzed as one of scope. The two readings of (4) would thus be (leaving out the uniqueness clause; 'SB': 'stupidest boy'):

(5a) $\exists x\ [\mathrm{SB}(x) \wedge \mathrm{Convinced}(\mathrm{Sarah}, [\mathrm{Get}(x, \text{the scholarship})])]$

(5b) $\mathrm{Convinced}(\mathrm{Sarah}, [\exists x\ [\mathrm{SB}(x) \wedge \mathrm{Get}(x, \text{the scholarship})]])$

The problem with this solution, however, is that the negation of (4):

(6) Sarah is not convinced that the stupidest boy will get the scholarship

still has the transparent-opaque ambiguity, whereas the negations of (5a,b), respectively, lead to a different result: (7a) means that there is no stupidest boy of whom Sarah is convinced that he will win the scholarship, which is not what (6) means; only the presumed opaque (7b) seems viable:

(7a) $\neg\exists x\ [\mathrm{SB}(x) \wedge \mathrm{Convinced}(\mathrm{Sarah}, [\mathrm{Get}(x, \text{the scholarship})])]$

(7b) $\neg\mathrm{Convinced}(\mathrm{Sarah}, [\exists x\ [\mathrm{SB}(x) \wedge \mathrm{Get}(x, \text{the scholarship})]])$

Be that as it may, after the 1970s the issue more or less disappeared from the literature.

The second distinction (Donnellan 1966) is that between attributive and referential uses of definite terms. In what Donnellan calls *referential use*, the predicate P of the definite term merely serves to identify a given entity. When, at a party, one uses the expression 'the man holding a martini' and there is only one person who can possibly be intended, the reference is successful, even if it turns out that what the man was holding was in fact a glass of water. In *attributive use*, on the other hand, P is used to refer to whatever unknown entity will satisfy P, as when I say 'Smith's murderer is unknown.' 'Smith's murderer' is used here as a parameter expression (like 'temperature,' 'name,' 'phone number'), whose value is still to be identified. Now P cannot turn out to be false or mistaken while the reference is still successful.

Donnellan recognized that Russell's analysis of definite terms does not account for attributive uses, but he failed to provide an alternative analysis that does. The subsequent philosophical literature, where Donnellan's distinction is often mentioned but never accounted for, likewise fails to provide a solution.

6.2 Reference and Ontology

A second cluster of reference problems is to do with the ontological status of the entities referred to, in particular reifications and nonexisting reference objects.

There is reification when speakers know that a definite description does not refer to an actually existing entity but to whatever is captured by a mental construction, as in 'the average London cabdriver,' 'the military-industrial complex,' or 'the difference between A and B.' In such cases, the (usually complex) predicate P of the definite description does not denote a set of entities considered to be ontologically real, but requires a (vague or precise) formula of interpretation that will reduce the satisfaction conditions of P to what may be considered ontologically bare entities in certain relations to each other.

Russell (1905) presents his Theory of Descriptions as a solution to the reifications problem as well, but he fails to show how it works. The subsequent literature has, accordingly, neglected this aspect of Russell, as it has neglected reifications in general.

Quine (1960) speaks of 'ontological commitment' to the entities referred to in the use of a natural or formal language. However, whatever 'ontological commitment' speakers of natural languages have with regard to the things they talk about is entirely a matter of language-independent belief. Speakers using reifications know that the world contains no 'entities' of the kind suggested by the reifying terms. Yet they use them as if they really were referring terms.

Reification resembles what in computer science is called 'object-oriented' programming, i.e., a method whereby complex descriptions are bundled together under a formal definition and treated as if they were terms referring to objects in the model, whereas their definition says that they are not. Object-oriented programming has turned out very efficient, because it enables the user to handle complex relations as if they were single objects. It looks as if Nature made the same discovery when it was working at the development of human language. Exactly *how* Nature implemented its version of object-orientedness is a matter for future research.

A second central problem is that of nonexisting reference objects, Russell's main concern in his Theory of Descriptions. In (2a), the definite description 'the present king of France' does not refer to an existing entity susceptible to baldness. Does it, then, refer to a nonexisting entity? Russell, like Quine, rejected the notion of nonexisting entities on the grounds that they might be said to both have and not have any given property, which would make them unfit for rational analysis. In Russell's view, which is considered standard, the being asserted by the existential quantifier is actual, real existence, and not some form of virtual being.

While Russell's analysis might seem to solve the problem of nonexisting entities for extensional sentences such as (2a), it fails for cases such as:

(8) Jones always talks about the present king of France

which may well be true even if there does not now exist a king of France. Formal semantics stipulates that a predicate such as 'talk about' may take an 'intensional' object term referring to possible entities in possible worlds, but here the problem of intensional contexts repeats itself: talk about a square circle is not the same as talk about a living corpse, yet they are both uninstantiated in any possible world. The problem of nonexisting reference objects has not so far been solved.

6.3 Donkey Sentences

Since Geach (1962) the problem of so-called *donkey* sentences, such as (9a,b), has dogged the theory of reference:

(9a) Every farmer who owns a donkey feeds *it*.
(9b) If a farmer owns a donkey *he* feeds *it*.

The name 'donkey sentences' derives from the relevant examples in Geach (1962, p. 116ff.), their modern source, which all involve donkeys. Geach, however, copied Walter Burleigh (1988, p. 92), who introduced donkey sentences around 1328 in the context of his theory of reference (*suppositio*): *Omnis homo habens asinum videt illum* (every man who has a donkey sees it).

The problem is that donkey sentences cannot be translated into standard LPC, which has only two kinds of terms: constants (definite referring terms) and variables. 'It' in (9a,b) and 'he' in (9b) cannot be constants, since they need not refer for the sentences to be true. So they must be variables. But variables must be bound by quantifiers, and this is impossible, due to scope problems. The LPC translations of (9a,b) should be (10a,b), respectively:

(10a) $\forall x[\text{Farmer}(x) \wedge \exists y[\text{Donkey}(y) \wedge \text{Own}(x,y)] \text{Feed}(x,\mathbf{y})]$
(10b) $\exists x[\text{Farmer}(x) \wedge \exists y[\text{Donkey}(y) \wedge \text{Own}(x,y)]] \text{Feed}(\mathbf{x},\mathbf{y})$

The bold-faced variables are unbound, which makes (10a,b) uninterpretable. Attempts at binding the variables under wide-scope universal quantification ('for all farmers *x* and for all donkeys *y*, if *x* owns *y*, then *x* feeds *y*' for (9a,b) alike) founder not only because they violate the principle of 'parity of form' (Russell 1905: 483), but also because they fail to work when intensional operators are inserted, as in:

(11a) Every farmer who is glad he owns a donkey is sad he has to feed *it*.
(11b) If a farmer is glad he owns a donkey, *he* is sad he has to feed *it*.

Due to scope problems, there is no way in which (11a,b) can be adequately analyzed, either analogously to (10a,b) or under wide-scope universal quantification.

Any solution will require an extension of standard LPC with referring pronouns that are not bound variables. In fact, a simple test shows that the problematic pronouns in (9a,b) are not bound variables at all, but referring terms. In general, referring pronouns can be replaced with an *epithet*, i.e., an unaccented descriptive noun phrase expressing some evaluative judgment. Bound variable pronouns or reflexive (logophoric) pronouns do not allow for such a replacement: in (12) the epithet cannot function as a bound variable:

(12) No man expects his friend to betray *him* (!*the poor devil*).

Yet epithet replacement functions perfectly well for (9a,b):

(13a) Every farmer who owns a donkey feeds *the wretched animal*.
(13b) If a farmer owns a donkey, *the man* feeds *the wretched animal*.

The problem for LPC and standard semantics is, however, that if the pronouns in question are referring terms, interpretation of (9a,b) is blocked when there

are no farmers or no donkeys. Yet these sentences are considered true in such cases. This constitutes a serious dilemma.

6.4 The Cognitive Turn

The main affliction of twentieth-century philosophy of language and semantics is the inability to come to terms with the cognitive factor in language and language use. Sentences and terms do not physically sit on situations and reference objects, respectively. The relation between the former and the latter is mediated by cognizing humans. Yet philosophers and semanticists have pretended that the mind was not there. We are faced today with the effects of this aberration. Now that the view of the mind-brain as a massive computation plant has opened new perspectives, solutions come in sight for many of the problems enumerated above. It would be premature, however, to try and specify in what ways a cognitive account of meaning and language use can be of help in solving the extant problems.

Language and Poetic Structure

Language is the material out of which poetry is made. Language itself is, of course, a complex phenomenon, involving both a characteristic structure, consisting of a grammar and a lexicon, and characteristic uses, such as communication and expression. All of these elements play a role in poetic structure. This entry, however, will focus mainly on grammar, and its relationship to such characteristic aspects of poetic structure as meter, rhyme and alliteration, and syntactic parallelism. These define the core forms of versification found across the world's languages, and create poetic effects even when they are not used regularly enough to constitute versification. In recent decades, they have been the subject of striking new directions of research, as a result of new directions of research in grammar.

1. Grammar and Verse

Versification by definition imposes formal constraints on language beyond those to which it conforms intrinsically. To describe those constraints for any given verse form is a surprisingly challenging intellectual problem, because individual lines within a form are all different from one another, often artfully so for expressive purposes. It is thus a problem, as Jakobson (1981a) influentially put it, of abstracting the invariant 'verse design' away from the variation

embodied in all the 'verse instances.' Even for those verse forms, especially in written traditions, for which some constraints have been articulated, the problem remains a challenging one, in that poets' actual practice may not necessarily match the articulated constraints: some lines which appear to violate them may nonetheless be included in compositions in the form, at the same time that some which appear to conform to them may nonetheless never be used. Such mismatches suggest that the articulated constraints may not constitute a complete and true description of what a poet instinctively knows about a form.

Construing the problem of describing a verse form as making explicit the unconscious as well as conscious knowledge a poet has of what defines the form makes it, as Halle and Keyser (1972) point out, analogous to the problem of describing grammar itself. In Chomsky's (1965) influential formulation, grammar is the knowledge a fluent speaker of a language has, partly consciously and partly unconsciously, of what would or would not be well-formed instances of the language. In phonology, for example, the subsystem of grammar dealing with sound structure (see *Phonology*), an English speaker knows not only that the combination of sounds in 'brick' is an actual word and that in 'blick' is not, but also that 'blick' is a possible word, whereas '*bnick' is not only not an actual word but also not a possible word; the '*' indicates its ill-formedness. Similarly in syntax (see *Syntax*), an English speaker knows that a sentence like 'The cat stretched sleepily' is a possible sentence of English while '*Sleepily cat stretched the' is not. To describe the grammar of a language is to make the constraints which constitute such knowledge fully explicit. The research program within linguistics which adopts that goal is 'generative linguistics' (see *Generative Grammar*), and its analog for verse is sometimes termed 'generative poetics.'

Describing a verse form involves grammar in substantive aspects as well. Although meter, rhyme and alliteration, and syntactic parallelism are often described metaphorically as contributing music to poetry, the entities which define them—particular configurations of syllables and stress, vowels and consonants, noun phrases and verb phrases—are, of course, quite specific to grammar. This means that as research into grammar has sought to discover the fundamental entities and organizational principles of grammars, new formal structures have become available to serve in descriptions of verse forms, sometimes leading to striking new insights into familiar forms. By the same token, research into verse forms has sometimes suggested or supported hypothesized entities or principles of grammar.

In this regard, two ideas which have shaped grammatical research have been particularly significant for research into versification. One is the assumption, going back to de Saussure (1983) and carried on in generative grammar, that grammar is at some level purely formal: phonology is not reducible to sound, and syntax is not reducible to meaning. The entities of grammar defining verse forms may thus sometimes prove to be surprisingly abstract.

The other is the conceptualization of the grammar of any particular language as one instance of a common phenomenon of human language. Although this idea also has a long history, including notably for poetics the interest in it taken by Jakobson and his circle, it was given a particularly galvanizing formulation in Chomsky's (1965) suggestion that the most basic formal properties of grammars might be essentially similar across all languages because they are innately determined. This hypothesis of 'universal grammar' motivates the relevance of wide-ranging cross-linguistic phenomena to the formalization of any single language's grammar. For versification, this means that evidence for particular ways of analyzing the structures figuring in a verse form may come from languages unrelated to that of the verse in question.

The observation that the goals and vocabulary of the description of verse are similar to those of the description of grammar invites the deeper question of whether there can be a theory of versification, as there are theories of grammar, and, if so, what specific relationship of versification to grammar such a theory might posit. After all, there are differences as well as similarities: we can usually tell in an instant whether language is verse or not. Again it was Jakobson (1962–81a) who influentially suggested that it is specifically the sequencing of entities which are in some way equivalent in the language which constitutes poetic effects. Interpreting this in light of the formal and universalist understanding of grammar characteristic of generative theories, Kiparsky (1981b, 1987) ventured one of the first testable theories of versification, hypothesizing that verse forms might be constituted by repetition of exactly those phonological and syntactic structures to which the constraints which constitute grammars universally make reference.

One of the simplest observations in support of this idea is that each of the major forms of versification corresponds to a major subsystem of grammar. Let us turn then to some specific recent examples of descriptive and theoretical claims following this line of inquiry, and then consider some of its consequences and limitations.

2. *Meter*

The phonology of every language involves two distinct though interrelated subsystems, one dealing with rhythm, such as the quantitative grouping of sounds into stressed and unstressed syllables, and the other dealing with what is technically termed 'melody,' referring not only to tones, but also to the qualitative characteristics of segments, such as what makes a 'p' different from a 'b.' Verse forms which impose

constraints on rhythmic structure beyond those given by the phonology are meters.

The dominant meter of the modern English poetic tradition, the iambic pentameter, affords a well-developed example of how changes in the goals and substance of grammatical description have wrought changes in the conceptualization of a familiar verse form. Traditionally, the iambic pentameter has been described as having a basic form of five feet, each consisting of an unstressed syllable (^{x}) followed by a stressed one ($^{/}$):

(a) $^{x/|x/|x/|x/|x/}$

While many lines, such as (bi), have exactly that rhythmic structure, many others, such as (b) (ii)–(iii), do not:

(b) (i) So long as men can breathe and eyes can see (Shakespeare, *Sonnets* 18, 13)

(ii) Pluck the keen teeth from the fierce tiger's jaws, (19, 3)

(iii) For how do I hold thee but by thy granting, (87, 5)

Such variations have traditionally been attributed to the possibility of substituting different kinds of feet with different patterns of syllables and stress, such as trochees ($^{/x}$), spondees ($^{//}$), phyrrics (^{xx}), or anapests ($^{xx/}$), so long as any sense of the basic form doesn't get lost. But as Halle and Keyser (1972), building on Jespersen (1933), point out, unless it makes explicit under what conditions the basic form would indeed get lost, such a description fails to capture what the poet knows that leads to acceptance of some variations as metrical, but avoidance of other imaginable ones as unmetrical. The construct in (c), for example, sounds like prose, not verse, and in fact has a rhythmic structure not found in any lines in Shakespeare's sonnets:

(c) *Imaginable lines are avoided.

Yet it can be analyzed into basic and substituted feet just as the lines in (b) (ii)–(iii) can; nothing in that description of the iambic pentameter captures its fundamental difference of unmetricality.

Much research has gone into the question of how the iambic pentameter can be modeled so as to in fact represent this knowledge. Most fundamentally, Halle and Keyser (1972) suggest that the meter needs to be distinguished from the actual rhythmic structure of the line, and formalized in two components: an abstract rhythmic template, composed of weak (W) and strong (S) metrical positions, and simple constraints on how certain aspects of the rhythmic structure of the line can be mapped into the template. Observing that lines such as those in (d), which are rhythmically similar to those of (b) (ii)–(iii) but have polysyllabic words where (b) (ii)–(iii) have monosyllables, do not appear in Shakespeare's sonnets, Kiparsky (1977) proposes specifically the template and constraints in (e), informally restated:

(d) (i) *Pluck immense teeth from enraged tigers' jaws

(ii) *For how do I prosper but by the granting

(e) (i) ws ws ws wsws

(ii) Each metrical position corresponds to a syllable.

No weak metrical position corresponds to a syllable which is strong relative to another syllable in the same word.

This proposal is shaped in substantive ways by a model of linguistic rhythm itself as essentially relative, with elements at successive levels grouped into constituents in which one element is strong and any others weak (Liberman and Prince 1977), such that a polysyllabic word involves a relationship of relative strength between syllables that a monosyllabic word does not. Thus, lines like (b) (ii) can be mapped into the template in (e) (i) in accordance with the constraints in (e) (ii), while (d) (i), let alone (c), cannot:

s w

(f) (i) Pluck the keen teeth from the fierce tiger's jaws,

(ii) *Pluck immense teeth from enraged tiger's jaws

The cross-linguistic study of rhythmic systems within Liberman and Prince's model has led to the discovery of a rich range of abstract structures, with surprising consequences for the description of many other aspects of metrical structure as well. For example, the familiar possibility of 'feminine endings,' the inclusion of an extra unstressed syllable at the end of a line as in (b) (iii), proves to have an analog in the grammar of rhythm, in that in many languages final syllables are regularly 'extrametrical,' or outside the basic groupings which define stress patterns (Hayes 1995). And the possibility in some iambic meter of 'trisyllabic substitution,' or inclusion of extra unstressed syllables within a line as in (g), has been attributed to the role of a particular linguistic grouping of syllables called a 'phonological foot,' which in many languages takes the form of either a single stressed syllable, like 'sea' or '-ract,' or two syllables of which the first is stressed and light, like 'cata-' (Hayes 1995, Hanson and Kiparsky 1996).

(g) In cataract after cataract to the sea (Tennyson, 'OEnone,' 9)

This possibility has in turn illuminated the structure of other English meters which were previously ob-

scure, such as Hopkins' 'Sprung Rhythm' (Kiparsky 1989), as well as meters of entirely unrelated traditions, such as Finnish. In fact, the universal theory of grammatical rhythm is so well-developed at this point that it has been possible to propose a universal theory of meter based on it (Hanson and Kiparsky 1996), though its cross-linguistic explanatory value remains largely still to be explored.

A template and constraints as in (e) are, of course, only the most basic elements of a metrical description. Even for English iambic pentameter, there are systematic exceptions to the constraints of (eii), as well as additional strictures that they do not capture, and the details are different for every poet and genre; as Kiparsky (1977) observes, describing an individual poet's practice within a metrical tradition is analogous to describing dialects within a language. While formalizing these complexities has likewise made progress by drawing on insights into grammatical structure, many open questions remain. For example, knowledge of a meter clearly includes recognition not only of the limits of well-formedness, but also of specific effects of metrical complexity and simplicity that can be created within those limits. How is that knowledge expressed in models like that in (e)? Is even knowledge of well-formedness best modeled through identification of a limit, or of gradient distance from a prototype (Youmans 1989)? Interestingly, while such questions pose challenges for metrical description, they do not necessarily challenge the theoretical assumption of the close relationship of meter to grammatical rhythm; rather, parallel questions have been posed about modelling grammar itself.

3. *Alliteration and rhyme*

The family of poetic effects which includes alliteration and rhyme is often referred to as 'sound patterning.' The term is somewhat unsatisfactory, however, since it is not clear why these forms have any better claim to be described as 'sound' than meter does, at the same time that sound is not really what any such forms involve, so much as phonological structure. Since the structure they involve is specifically melodic, a more appropriate collective term for them might be 'poetic melody,' parallel to 'poetic meter.'

Again it was Jakobson (1963) who, in an influential analysis of Germanic alliteration, showed how explicit characterization of such forms as repetitions can lead to discoveries about their relationships to grammar. In Old English verse, for example, syllables in certain positions must alliterate, meaning they begin either with the same consonants, as in (h)|(i); or with any vowels, as in (h)|(ii):

(h) i. Da <u>m</u>iddangeard <u>m</u>oncynnes Weard
'then middle earth mankind's Guardian'
ii. <u>e</u>ce Drihten <u>æ</u>fter teode
'eternal Lord afterwards made'

Jakobson observes that no characterization of alliteration in terms of identities of sounds can generalize across this differential treatment of consonants and vowels, and instead relates it to syllable structure. Segments which precede the most sonorous element in each syllable, typically though not always the vowel, constitute an 'onset': in 'rate,' for example, it would be the [r], or in 'trait' the [tr]. Modifying Jakobson's own analysis somewhat, Kiparsky (1970, 1981) points out that if , in 'ate' there is simply no onset, or an empty one, then alliteration can be characterized simply as requiring structural identity of corresponding syllables up through the first segment in the onset. Moreover, onset structure explains another peculiarity of Germanic alliteration, in that exceptionally for the clusters [sp, st, sk], the second segments must also be the same. As Jakobson noted, there is evidence that the [s] in these configurations is outside the core onset structure, or 'extrasyllabic' (compare the fact that in modern English, onsets normally contain no more than two segments, but initial [s] in an onset like that of 'straight' is excepted); thus, the second segment in the cluster really is the first in the onset, and its required identity follows. This explicit account of the locus of Germanic alliteration stands as a model for the analysis of other melodic forms: while rhyme, for example, in all its various forms like full rhyme, slant rhyme or assonance are all assumed to be formalizable, and in ways that similarily draw on grammatical structure, the details of poets' actual practice have seldom been fully worked out in conjunction with explict theories of syllable structure.

Another way in which poetic melody draws on grammatical structure involves the explicit characterization of ways in which sounds can be similar.

In language, segments are often pronounced systematically differently depending on their phonological context. Modelling such knowledge has typically relied on two key assumptions. First, segments are not monolithic, but composed of distinctive features (see *Phonology*). Second, individual lexical items have an 'underlying structure' which may be distinct from their 'surface structure' which determines pronounciation, because phonological processes may alter some features in some contexts (Chomsky and Halle 1968). Poetic melody exploits this kind of knowledge in a variety of ways. First, as Zwicky (1976) suggests for the rhymes of English rock lyrics, a form may simply require corresponding sounds to differ by no more than one feature: in *made* and *babe*, for example, [d] and [b] differ only in their place of articulation feature, and in *made* and *late*, [d] and [t] differ only in their feature of voicing, or vibration of the vocal cords. Second, Kiparsky (1970) suggests that poets' practice is sometimes based on underlying rather than surface forms. For example, Malone (1987) notes that Irish has a grammatical process which nasalizes voiced stops ([b, d, g]) in certain contexts, which explains why

poets allow a word like *bo* 'cow' to alliterate with *mban* 'white (gen.pl.)': the initial sound of the latter is underlyingly [b], though the nasalization process makes it different on the surface Third, poetic forms sometimes require identity of some features but not others, a phenomenon also found in Irish. Irish rhymes require that segments in corresponding positions belong to the same class of consonants; for example, one such class is the voiced stops [b,d,g], such that *éc* 'death' (in which the 'c' spells [g]) can rhyme with *bét* 'misdeed' (in which the 't' spells [d]). That this class is targeted by the nasalization process which gives *mban* makes it a particularly clear instance of what Kiparsky hypothesized to be the general case in verse forms, of the equivalences that define them being the same equivalences which figure in grammar.

Collectively, the foregoing ideas and the cross-linguistic studies which support them suggest that melodic forms support a good deal of variety across verse instances in the same way that metrical forms do, but formalizing their verse designs has generally received less attention. In English, for example, Zwicky's (1976) study has inspired many interesting observations of variation in the high art rhyme tradition as well, but few studies have worked out explicit models of the possible complexities and their limits in the practice of individual poets, let alone characterized them as variations on an overall tradition. A particularly interesting theoretical impetus to such studies has recently come, however, from cross-linguistic studies of reduplication, systematic processes in which all or part of the beginnings or ends of words are copied to derive new words or forms of words, as illustrated in (i):

(i) i. Gothic past tense: haitan 'call' hai-hait 'called'
slepan 'sleep' sai-slep 'slept'
ii. Chamorro intensives: dankolo 'big' dankolo-lo 'really big'
bunita 'pretty' bunita-ta 'very pretty'

As Kiparsky (1973) points out, melodic verse forms often involve the same kinds of grammatical analyses that reduplication does; thus, as the intricate variety of reduplication systems has begun to be studied, universal theories of poetic melody analogous to those advanced for meter have begun to be possible for the first time (Holtman 1994, Yip 1999).

4. *Syntactic Parallelism*

Finally, in many languages it is not phonology, or at least not phonology alone, which defines verse forms, but morphology and syntax, through requirements of parallel structures from line to line. One of the most influential traditions of this kind is that of ancient Hebrew poetry, exemplified by the passage in (j), together with a translation of it by Jakobson (1981b):

(j) ʔittī milləbānōn kallāh
with me from Lebanon bride
ʔittī milləbānōn tābōʔī
with me from Lebanon come!
tāšūrī mērōʔš ʔămānāh
depart from the peak of Amanah,
mērōʔš śənīr wəḥermōn
from the peak of Senir and Hermon,
mimmə ōnōt ʔărāyōt
from the lairs of lions
mēharərēy nəmērīm
from the mountains of leopards!
('Song of Solomon' 4:8)

Here again, making explicit what the evident repetition consists of raises interesting grammatical questions. The fifth and sixth lines transparently have a common morphological and syntactic structure: the individual words differ, but the grammatical classes of their component parts and resulting wholes are identical: prepositions, plural nouns, etc. But the structures of the third and fourth lines appear to differ in that there is a verb, tāŝūrī 'depart' in the third which is absent from the fourth, and a conjoined noun in the fourth, *w′hermon* 'and Hermon,' which is absent from the third. From the point of view of syntax, however, a noun phrase consisting of a single noun can be identical to one consisting of conjoined nouns: in English, for example, a preposition which requires a noun phrase object will be indifferent to the internal structure of the noun phrase, so that [[from]$_P$ [Mary]$_{NP}$]] and [[from]$_P$ [[Mary]$_{NP}$ and [John]$_{NP}$]$_{NP}$] are structurally identical at the level of their [P NP] structure. Similarly, in certain constructions involving parallelism in language itself, a verb which is absent in the surface structure may be understood to be present underlyingly, under identity with a verb in a conjoined clause: in [[Mary [ate]$_V$ fish]$_S$ and [John [ ]$_V$ meat]$_S$], the syntactic well-formedness of the second clause requires the assumption that the unpronounced verb is present at some level of analysis. Even in the first two lines, as Jakobson (1966) points out, the vocative *kallah* 'bride' and the imperative *tabo/i* 'come' share a function of direct address, which may entail further syntactic similarities. Thus, even parallelism which appears to be principally semantic may involve identical syntax at an abstract level. The forms of syntactic parallelism across languages—Finnish, Chinese, Galician, for example—are as diverse as the languages themselves, but all merit further study from a syntactic point of view.

5. *Conclusion*

Versification represents, of course, only one of many ways in which language contributes to poetic structure. For every subsystem of grammar of which some elements define a verse form, other elements remain free to create poetic effects of other kinds: phrasal

rhythms (Cureton 1992); syntactic suspensions (Austin 1984). And even the most traditional elements of verse are not necessarily used pervasively as verse forms, but sometimes only fragmentarily, or in traditional terminology 'ornamentally' rather than 'structurally.' In Shakespeare's sonnets, for example, alliteration and syntactic parallelism come and go within a form versified by meter and rhyme, in a manner which is not fundamentally different from the way meter and rhyme come and go in poems of Eliot which are not versified at all. And not just the grammar but also the lexicon can be the source of significant patterns of repetition. But even as only a limiting case, discoveries of the nature of the relationship of versification to grammar provide remarkable evidence of how forms which seem the height of artifice may in fact be rooted in ways of perceiving which, if the hypothesis of universal grammar is correct, operate as naturally as vision or hearing (Fodor 1983). Such discoveries have consequences for poetic effects of all kinds, whether traditional or innovative, pervasive or fragmentary, natural or genuinely artificial.

Perhaps more strikingly, the focus on versification here has not touched on such fundamental functions of language as communication or expression, which are particularly complex and interesting in the case of poetry. To some extent, this reflects the observation that communication is not unique to language: it has been argued by Sperber and Wilson (1986), for example, that in ordinary language, the phonological and syntactic parsing of a sentence makes only a minimal contribution to what it actually communicates, which in fact depends on an open-ended, context-dependent process of general reasoning which unlike the structural analysis of grammar is common to how information of all kinds is interpreted. At the same time, however there is at least one way in which versification invites its own kind of reasoning: as Wimsatt (1954) notes, the repetitions which consititute versification consistently invite the question of how whatever is designated by similar forms might themselves be alike. In this way, as Jakobson (1956) suggests, there is a metaphorical way of thinking inherent in poetic structure, which is not only a matter of its meaning, but also of its form.

Language and Social Class

Linguists have known for some time that differences in language are tied to social class. Ross (1954) suggested that certain lexical and phonological differences in

English could be classified as U (upper class) or non-U (lower class), e.g., *serviette* (non-U) vs. *table-napkin* (U), one of the best known of all linguistic class-indicators of England at the time.

Similarly, in the United States, some surveys of regional dialect recognized the importance of social status in geographical variation, and distinguished three categories of subjects based on the fieldworker's classification: Type I—little formal education, little reading and restricted social contacts; Type II—better formal education (usually high school) and/or wider reading and social contacts; and Type III—superior education (usually college), cultured background, wide reading and/or extensive social contacts. These types correspond roughly to social status.

Until the 1960s, however, most studies of variability were concerned primarily with regional variation or dialectology, following a tradition established in the nineteenth century. These studies concentrated their efforts on documenting the rural dialects which it was believed would soon disappear. Only during the latter half of the twentieth century would the concern for status-based differences in language become a primary rather than a secondary focus, when sociolinguists turned their attention to the language of cities, where an increasing proportion of the world's population lives in modern times. The rise of urbanization is connected with an increase in social stratification reflected in linguistic variation.

1. *Beginnings of Sociolinguistics*

Research focusing on social dialects is sometimes referred to as social dialectology, and occupies a central place in quantitative sociolinguistic research on urban speech varieties, beginning with William Labov's (1966) work in New York City. He was the first to introduce a systematic methodology for investigating social dialects and the first large-scale sociolinguistic survey of an urban community. Unlike previous dialectological studies, which generally chose one person (usually an older male) as representative of a particular area, this survey was based on tape-recorded interviews with 103 people who had been chosen by random sample as being representative of the various social classes, ages, ethnic groups, etc., to be found in New York City. This approach solved the problem of how any one person's speech could be thought of as representing a large urban area.

Previous investigations had concluded that the speech of New Yorkers appeared to vary in a random and unpredictable manner. Sometimes they pronounced the names *Ian* and *Ann* alike and sometimes they pronounced post-vocalic /r/ (i.e., *r* following a vowel) in words such as *car*, while at other times they did not. This fluctuation was termed 'free variation' because there did not seem to be any explanation for it. Labov's study and subsequent ones modeled after it, however, showed that when such free variation in the speech of and between individuals was viewed against the background of the community as a whole, it was not free, but rather conditioned by social factors such as social class, age, sex, and style in predictable ways. Thus, while idiolects (or the speech of individuals) considered in isolation might seem random, the speech community as a whole behaved regularly. Using these methods, one could predict that a person of a particular social class, age, sex, etc., would pronounce post-vocalic /r/ a certain percent of the time in certain situations.

Through the introduction of these new methods for investigating social dialects by correlating sociolinguistic variables with social factors, sociolinguists have been able to build up a comprehensive picture of social dialect differentiation in the United States and Britain in particular, and other places, where these studies have since been replicated.

2. *Methods*

In order to demonstrate a regular relationship between social and linguistic factors, we have to be able to measure them in a reliable way. Of the principal social dimensions sociolinguists have been concerned with (e.g., social class, age, sex, style, and network), social class has probably been the most researched. Patterns of social class differentiation are often assumed to be fundamental and other so-called sociolinguistic patterns of variation, e.g., stylistic and gender variation, are regarded as derivative of them (Labov 1972).

Many sociolinguistic studies have followed the generally accepted sociological practice of relying on indicators of social status, such as education, occupation, income, etc., grouped individuals into social classes on the basis of these factors, and then looked to see how certain linguistic features were used by each group. The method used in New York City to study the linguistic features was to select items which could be easily quantified; in particular, phonological variables such as post-vocalic /r/, which was either present or absent. This was one of the first features to be studied in detail by sociolinguists.

3. *Results*

Varieties of English can be divided into two groups with respect to their treatment of this variable: those that are *r*-pronouncing (rhotic) and those that are not *r*-pronouncing (non-rhotic). Today in Britain, accents that have lost postvocalic /r/ as a result of linguistic change generally have more prestige than those, like Scottish English, that preserve it. In many parts of the United States the reverse is true, although this has not always been the case. Table 1 compares the pro-

Table 1
Percent of postvocalic /r/s pronounced

New York City	Reading	Social class
32	0	Upper-middle class
20	28	Lower-middle class
12	44	Upper-working class
0	49	Lower-working class

Table 2
Percent of nonstandard forms in Norwich

Social-class	(ing)	(t)	(h)
Middle-middle class	31	41	6
Lower-middle class	42	62	14
Upper-working class	87	89	40
Middle-working class	95	92	59
Lower-working class	100	94	61

Table 3
Incidence of glottal stops in all environments compared to medial position

Class	I	IIa	IIb	III	Total
All environments	48.4	72.9	84.3	91.7	74.3
Medial position	0	7.2	42.5	68.8	29.6

Table 4
Verbs without -s in Detroit and Norwich

Class	Detroit	Norwich
Upper-middle class	1	0
Lower-middle class	10	2
Upper-working class	57	70
Middle-working class	–	87
Lower-working class	71	97

nounciation of postvocalic /r/ in New York City with that of Reading, England. The results show that in New York City the lower one's social status, as measured in terms of factors such as occupation, education, and income, the fewer postvocalic /r/s one uses, while in Reading the reverse is true. Like many features investigated by sociolinguists, the pronounciation of postvocalic /r/ shows a geographically as well as socially significant distribution.

Just as the diffusion of linguistic features may be halted by natural geographical barriers, it may also be impeded by social class stratification. Similarly, the boundaries between social dialects tend for the most part not to be absolute. The pattern of variation for postvocalic /r/ shows 'fine stratification' or continuous variation along a linguistic dimension (in this case a phonetic one) as well as an extralinguistic one (in this case social class). The indices go up or down in relation to social class, and there are no sharp breaks between groups. A major finding of urban sociolinguistic work is that differences among social dialects are quantitative and not qualitative.

There are many other variables in English which show similar sociolinguistically significant distributions, such as those studied by Trudgill (1974) in Norwich in an urban dialect study modeled after the New York research. Table 2 shows the results for (ing), (t) and (h). The numbers show the percentage of nonstandard forms used by different class groups. The variable (ing) refers to alternation between alveolar /n/ and a velar nasal /ɔ/ in words with *-ing* endings such as *reading, singing*, etc. The lower a person's social status, the more likely he/she is to use a higher percentage of alveolar rather than velar nasal endings. This is often referred to popularly as 'dropping one's g's,' and is a well-known marker of social status over most of the English-speaking world.

The variable (h) refers to alternation between /h/ and lack of /h/ in words beginning with /h/ such as *heart, hand*, etc. Unlike received pronunciation (RP), most urban accents in England do not have initial /h/ or are variable in their usage of it. For these speakers who 'drop their h's,' *art* and *heart* are pronounced the same. Again, the lower a person's social status, the more likely he/she is to drop h's. Speakers in the north of England, Scotland and Ireland retain /h/, as do speakers of American English. The variable (t) refers to the use of glottal stops instead of /t/, as in words such as *bottle*, which are sometimes stereotypically spelled as *bot'le* to represent the glottalized pronounciation of the medial /t/. Most speakers of English glottalize final /t/ in words such as *pat*, and no social significance is attached to it. In many urban dialects of British English, however, glottal stops are more widely used, particularly by younger working class speakers in London, Glasgow, etc.

By comparing the results for the use of glottal stops in Norwich with those for (ing) and (h), some interesting conclusions can be drawn about the way language and social class are related in this English city. Looking first at frequency, even the middle class in Norwich uses glottal stops very frequently, i.e., almost 50 percent of the time, but this isn't true of (h). There is of course no reason to assume that every instance of variation in language will correlate with social structure in the same way or to the same extent. Most sociolinguistic variables have a complicated history. Some variables will serve to stratify the population more finely than others; and some cases of variation do not seem to correlate with any external variables, e.g. the variation between /i/ and /ε/ in the first vowel of *economic* is probably one such instance. Phonological variables tend to show fine stratification and there is more socially significant variation in the pronunciation of English vowels than in consonants.

Table 5
Social class, style and sex differentiation in (ing) in Norwich

		Style			
Class	Sex	Word list	Reading	Formal speech	Casual speech
Middle-middle	m	0	0	4	31
	f	0	0	0	0
Lower-middle	m	0	20	27	17
	f	0	0	3	67
Upper-working	m	0	18	81	95
	f	11	13	68	77
Middle-working	m	24	43	91	97
	f	20	46	81	88
Lower-working	m	66	100	100	100
	f	17	54	97	100

In the case of glottal stop usage, what is socially significant is how frequently a person uses glottal stops in particular linguistic and social contexts. The use of glottal stops is particularly socially stigmatized in medial position, e.g., *bottle, butter*. A hierarchy of linguistic environments can be set up which seems to apply to all speakers. Glottal stops are more likely to occur in the following environments.

Most frequent
- Word final + consonant — e.g., *that cat*
- Before syllabic nasal — e.g., *button*
- Word final + vowel — e.g., *that apple*
- Before syllabic /l/ — e.g., *bottle*

Least frequent
- Word medially — e.g., *butter*

Although all speakers are affected by the same internal constraints in the same way, they apply at different frequency levels, depending on social class membership and other external factors. Table 3 shows the incidence of glottal stops in relation to social class in Glasgow for all environments compared with that occurring only in medial position (Macaulay 1977). Class I is the highest and contains professional people, while Class III is the lowest and contains unskilled workers. The results show that glottal stops are the norm for this community (74.3 percent), if we look at all the environments. Even the highest social class uses glottal stops nearly half the time, and the lowest class, almost all the time. However, if we look at medial position, the highest social class uses no glottal stops in this environment, while the lowest class uses 68.8 percent.

Although grammatical variables have been less frequently studied than phonological ones, they have tended to show sharp stratification; that is, they display a large social barrier between the middle class and the working class. Table 4 shows the results of a study of a grammatical variable in Detroit (Wolfram 1974) and Norwich (Trudgill 1974). The variable concerns the use of nonstandard third person singular present tense verb forms without *-s*, e.g., *he go*. Only working class speakers use these forms with any great frequency and this is more so in Norwich than in Detroit. The gap between the middle and working class norms is also greater in Norwich than in Detroit, reflecting the greater social mobility of the American social system. There are also other varieties of British English, e.g., in parts of the north, south-west and south Wales, where the present tense paradigm is regularized in the opposite direction and all persons of the verb takes *-s*, i.e., *I goes, you goes, he goes*, etc.

4. *Social Class Differentiation in Relation to Other Sociolinguistic Patterns*

The intersection of social and stylistic continua is one of the most important findings of quantitative sociolinguistics: namely, if a feature occurs more frequently in working class speech, then it will occur more frequently in the informal speech of all speakers. There are also strong correlations between patterns of social stratification and gender, with a number of now classic findings emerging repeatedly. One of these sociolinguistic patterns is that women, regardless of other social characteristics such as class, age, etc., tend to use more standard forms than men.

Table 5 shows the results of Trudgill's (1974) study in Norwich of the variable (ing), i.e., alternation between alveolar /n/ and a velar nasal /ɔ/ in words with *-ing* endings such as *reading, singing*, etc. in relation to the variables of social class, style, and sex. The scores represent the percent of nonstandard forms used by men and women in each social group in four contextual styles, i.e., when reading a word list, reading a short text, formal speech, and casual speech.

Generally speaking, the use of nonstandard forms increases the less formal the style and the lower one's social status, with men's scores higher than women's. Although each class has different average scores in each style, all groups style-shift in the same direction

in their formal speech style; that is, in the direction of the standard language. This similar behavior can be taken as an indication of membership in a speech community sharing norms for social evaluation of the relative prestige of variables. All groups recognize the overt greater prestige of standard speech and shift towards it in more formal styles.

Summing up these sociolinguistic patterns involving social class, gender, and style, sociolinguists would reply to the question of who is likely to speak most nonstandardly in a community: working-class men speaking in casual conversation. Conversely, middle-class women speaking in more formal conversation are closest to the standard. In Table 5, for instance, we can see that middle-middle-class women in word-list style never use the nonstandard form, while lower working-class men use it all of the time. Note, however, that the differences between men and women are not equal throughout the social hierarchy. For this variable they are greatest in the lower middle and upper working class. Such patterns reveal basic linguistic fault lines in a community, and are indicative of the uneven spread of the standard and its associated prescriptive ideology in a speech community. Similar results have been found in other places, such as Sweden and the Netherlands.

5. *Social Class Differentiation and Language Change*

Because variability is a prerequisite for change, synchronic variation may represent a stage in long-term change. By examining the way in which variation is embedded into the social structure of a community, we can chart the spread of innovations just as dialect geographers mapped variation and change through geographical space.

Sociolinguists have distinguished between 'change from above' and 'change from below' to refer to the differing points of departure for the diffusion of linguistic innovations through the social hierarchy. Change from above is conscious change originating in more formal styles and in the upper end of the social hierarchy, and change from below is below the level of conscious awareness originating in the lower end of the social hierarchy. Gender is critical here too. Women, particularly in the lower middle class, lead in the introduction of new standard forms of many of the phonological variables studied in the United States, the UK and other industrialized societies such as Sweden, while men tend to lead in instances of change from below.

Where hypercorrection occurs, as with post-vocalic /r/ in New York City, the lower middle class shows the most radical style shifting, exceeding even the highest group in their use of the standard forms in the most formal style. The behavior of the lower middle class is governed by their recognition of an exterior standard of correctness and their insecurity about their own speech. They see the use of postvocalic /r/ as a prestige marker of the highest social group. In their attempt to adopt the norm of this group, they manifest their aspirations of upward social mobility, but they overshoot the mark. The clearest cases of hypercorrection occur when a feature is undergoing change in response to social pressure from above, i.e., a prestige norm used by the upper class. In New York City the new /r/ pronouncing norm is being imported into previously non-rhotic areas of the eastern United States. Hypercorrection by the lower middle class accelerates the introduction of this new norm. The variable (ing), on the other hand, has been a stable marker of social and stylistic variation for a very long time, and does not appear to be involved in change and hence does not display hypercorrection.

Language and Social Inferences

A social event can be represented linguistically in a great variety of different ways. For instance, we can talk about a specific act of economic transaction by using one of a number of interpersonal verbs (to buy, to sell, to pay, to purchase, etc.). The very same act can

be represented in terms of the motives that gave rise to the act (e.g., to like, to want, to desire). Referring to the qualities of the actors (untrustworthy, keen, greedy, stingy, generous, etc.) is yet another set of available linguistic options to represent the transaction. The choice of verbs and/or adjectives that is made about how a social event is represented influences the types of thematic features of the situation that are attended to.

Thematic features of an event refer to a variety of social inferences that are tacitly indicated to a reader or listener of such a communication. The choice of interpersonal terms (verbs and adjectives) in representing an event has been shown to lead to a variety of inferences about a social event. These are about who the implied causal agent for the event is, how long the event is implied to have lasted, inductive and deductive inferences about the qualities of the persons in the event, *inter alia*.

Interest in this field emerged in the 1960s and 1970s when social psychologists (e.g., Abelson and Kanouse 1966) and linguists (e.g., Garvey and Caramazza 1974) discovered that interpersonal verbs influence the inferences people make in an orderly fashion. It was in the 1980s that this field was more systematically charted. This started with the discovery that interpersonal verbs referring to visible actions—and consequently classified as verbs of action (e.g., to help, to buy, to cheat)—systematically imply that the subject in a sentence is the agent of the event or the person who caused the event (as in 'John cheats Edward'). In contrast, verbs of state (e.g., to love, to respect, to abhor)—which refer to unobservable interpersonal states—systematically convey the impression that the causal origin for the event is to be found in the sentence subject (e.g., 'John respects Edward'). Thus, the verb used in such sentence constructions can systematically direct the thematic focus of an event to either the sentence subject or object as the causal origin of the event (e.g., Brown and Fish 1983). Another illustration of this can be seen in the use of action and state verbs in question formulation. These verb types tacitly issue instructions to a respondent by conveying information about how the thematic agency of an answer should be structured. Thus given the very same event, an interviewer's choice of 'Why did John *trust Edward?*' (state verb) instead of 'Why did *John confide in* Edward?' (action verb) imposes a specific focus on the theme of the interviewee's answer. The question requests an answer that is primarily about the qualities that make Edward trustworthy, rather than John's motives and reasons for confiding in Edward (Semin 2000).

Implied causation and thematic focus are not the only systematic inferences that are mediated by interpersonal language. We communicate about a social event in order to pass on what we saw, heard, or believed. In talking about an event we make implicit choices about how to represent it in our communication. By means of these choices a communicator structures the linguistic representation of an event implicitly, albeit strategically, in order to convey a diversity of inferences to the recipient of the message. Generally, we do not consciously reflect upon our particular choice of verbs and adjectives when we talk about a particular event. Thus, we might refer to the same event by saying 'John pushed David,' 'John challenged David,' 'John hates David,' or 'John is aggressive,' to name just a few options. These choices vary from a term that is very concrete, and refers to a directly perceivable and contextually specific act (pushing), to a term that is most abstract, that maintains no references to any specific context, relationship, or situation and expresses a nonvisible quality in the form of an adjective (aggressive). 'Challenge' and 'hate' occupy intermediate positions. The former verb still refers to a concrete act without preserving the direct reference to the act. The latter refers to an unobservable psychological state that characterizes a specific relationship between two people. The concrete–abstract dimension on which interpersonal language can be systematically classified has been shown to carry a number of tacit, systematic, and general inferences (Semin and Fiedler 2001). It is important to note that while any of the four speech acts about the 'hostile' nature of an event is intended to impart information about what has occurred, the particular choices of interpersonal terms in formulating the speech act conveys additional tacit information that is not consciously accessed. This information can be about who caused an event, who was responsible for the event, whether or not the behavior was under the voluntary control of the agent, whether it was determined by the personality make-up of the person, or situationally caused, and so on. Thus, different properties of interpersonal language such as verb type or abstraction–concreteness lead to a variety of tacit social inferences. So far we have discussed the types of social inferences mediated by interpersonal language. Two issues arise. The first is about the context within which language and social inferences are relevant. The second issue concerns the psychological processes that lead to specific patterns of language use in a message and those processes that are induced by the tacit properties of a message.

The context issue becomes a comprehensible one when one inserts 'language and social inferences' into a communication framework. The simplest exemplification of a communication framework requires (a) *a transmitter* who produces a message about an event (e.g., a hostile act), (b) a medium upon which the *message* is mapped—language, and (c) *a recipient*. The transmitter of a message has plans about an intended action in the form of cognitions that are mapped upon language. The behavioral execution of cognition as intended action constitutes a speech act. The particular message that is structured by an intended action can thematically focus an event in such a way that A (A hit

B—action verb) rather than B (A hates B—state verb) is the causal locus for the event. Such a message is designed to structure the representation of the event such that the recipient of the message makes the appropriate social inferences (e.g., A engaged in behavior under voluntary control, A intended the act, A caused B to be harmed, etc.) Let us consider another example, to illustrate the point in a different context. A police investigator interviews a rape victim who is expected to be trustworthy or untrustworthy. In the former case, the interviewer is likely to pose questions that imply the agency of the perpetrator to the events that led to the incident (e.g., 'Did he dance with you?—implying 'Did he initiate the dancing?'). In the latter case, where the investigator expects the victim to be untrustworthy, the question may actually be like 'Did you dance with him,' implying that the victim was the initiator for the ensuing event.

Thus, one function of language is to give overt expression to cognitions as intended actions, by providing the *transmitter* with the means to formulate a verbal act. The second related function is to structure the specific way in which the *recipient* of the message represents the event. This representation involves also the social inferences that the transmitter intended when structuring the message. Thus, a communication framework helps locate the functions that interpersonal language and associated social inferences have in a transmitter and recipient context.

So far we have covered the following:

(a) the inferential properties of language and

(b) a communication framework that specifies

(i) how a transmitter uses language to give public shape to intended actions, and

(ii) how language in the form of a message shapes the representation (and inferences) of a recipient.

The second issue involves the nature of the psychological processes. This issue has two facets. First, what are the psychological processes by means of which the transmitter produces messages with a specific set of inference inducing patterns rather than others? Second, what types of psychological processes are induced in the recipient by the specific linguistic properties of a message?

We begin by illustrating the types of psychological processes involved in message production and how a closer examination of the linguistic properties of a message facilitate highlighting cognitive and motivational processes underlying message production. One specific example is to be found in the research on the transmission and maintenance of stereotypes. This is best represented by the research on the 'linguistic intergroup bias' (Maass 1999). This bias refers to the tendency to describe positive behaviors by members of the ingroup and negative outgroup behaviors by the use of abstract language. In contrast, negative ingroup behaviors and positive outgroup behaviors are communicated by the use of concrete language. By describing positive ingroup and negative outgroup behaviors in abstract terms (e.g., adjectives/traits such as 'friendly,' 'hostile'), the communicator implies that the behaviors in question stem from enduring qualities that are unlikely to change and are likely to be repeated in the future. In contrast, using concrete language (e.g., verbs of action such as 'to help,' 'to hinder') suggests situationally specific behaviors that are not likely to recur at a future point in time. The bias has been shown to be driven by motivational and cognitive factors. Thus, the differential abstract versus concrete language use is motivated in order to preserve a positive ingroup image and derogate the outgroup and has been shown to be much stronger when the ingroup identity is threatened. Moreover, it has also been shown that stereotype consistent behaviors are communicated at a more abstract level than stereotype inconsistent behaviors. This expectancy driven bias constitutes the more general case in that it suggests that all other things being equal (i.e., motivational factors) the abstractness–concreteness of a message is driven by expectancies. Basically, the 'linguistic intergroup bias' is responsible for the transmission and maintenance of stereotypes and prejudice (Maass 1999). The 'linguistic intergroup bias' is one illustration of how transmitter-specific cognitive and motivational processes shape the linguistic properties of a message. Of course, by the reverse logic it is also possible to infer what specific psychological transmitter processes are at hand by analyzing the linguistic properties of a message.

We now turn to recipient-specific processes. Here the focus is on controlling the linguistic properties of a message and examining its psychological implications. First, messages controlling for verb type or abstractness concreteness have systematically been shown to induce the social inferences described earlier. Thus, recipients of messages that arise through the linguistic intergroup bias do interpret the message as intended—confirming that the linguistic properties of the message are responsible for the transmission of stereotypes. Further research suggests that if an event is represented by the use of concrete language (e.g., verbs of action) rather than abstract terms (e.g., verbs of state or adjectives), then it is more vividly represented, processed more systematically, and recalled better and with fewer intrusions. In contrast, representing an event abstractly leads to more heuristic processing, poorer recall, and more intrusions in memory. Moreover, if people are asked to recall an event by using a concrete term ('When was the last occasion that you *helped* somebody?') as a retrieval cue, then they recall events that are significantly more recent than when they are asked to recall an event with an abstract retrieval cue ('When was the last occasion when you were *helpful?*'). Thus, properties of interpersonal language also have recipient-specific cognitive processing implications in terms of recall, or representation, aside from the specific social inferences that they mediate.

Language and Society: Cultural Concerns

1. Introduction

Every language provides its speakers with a unique, intricate and constantly changing medium of expression. The structure of any language embodies a myriad of prepackaged meanings, a large proportion of which are language-and-culture specific, in two respects: first, in not having exact counterparts in other languages of the world, and second, in reflecting, embodying and helping to perpetuate a particular social, cultural, and historical experience. The purpose of this article is to demonstrate this in relation to three linguistic domains—words and phraseology, grammar, and language in use—and to delineate some of the conceptual and methodological issues involved. A somewhat similar theme is pursued under the aegis of the Sapir–Whorf hypothesis (see *Sapir–Whorf Hypothesis*), which concerns the influence of language on world-view. This article, however, is concerned with more subtle and fine-grained effects.

These issues have been of pressing concern to language study from at least the time of Johann Herder and Wilhelm von Humboldt. They were carried into American linguistics and anthropology in the early twentieth century by Franz Boas and then Edward Sapir. Similar concerns continued to occupy anthropology, especially cognitive and symbolic anthropology, in the second half of the twentieth century, but in linguistics these concerns became marginalized with the ascendency of Chomskyan generative grammar; though to some extent the flame was kept alight by the ethnographic wing of sociolinguistics in the work of Dell Hymes and associates (cf. Bauman and Sherzer 1974; Gumperz and Hymes 1986). In the 1980s and 1990s, however, the dominance of generative grammar began to wane, leading to what one commentator dubbed 'the greening of linguistics,' with renewed interest in pragmatics, functionalism, anthropological linguistics, and cross-cultural semantics (cf. Foley 1997; Goddard 1998). In a parallel development, mainstream psychology became more interested in ethnopsychology and in the new field of cultural psychology (Shweder 1990, Schweder and Sullivan 1993). These developments set the stage for a revitalization of studies into the interconnections between language, culture, and society.

A complex of methodological problems connected with cross-cultural semantic analysis confronts this emergent interdisciplinary field. How can one ensure that any set of semantic descriptors is not biased by the language from which it is drawn? How to achieve the maximum resolution of complex meanings? How can the process of semantic analysis be freed from subjectivity and vagueness? According to the most well-developed model of cross-cultural semantic analysis, the 'natural semantic metalanguage' (NSM) approach, the most promising solution to these problems depends on identifying a viable set of universal semantic primes (or primitives), i.e., simple concepts which have linguistic exponents (as words or word-like elements) in all languages (cf. Wierzbicka 1996; Goddard and Wierzbicka 1994, in press). Cross-linguistic research indicates the existence of at least 60 semantic primes, including (using English exponents): I, YOU, SOMEONE, SOMETHING, PEOPLE, DO, HAPPEN, SAY, THINK, KNOW, WANT, GOOD, BAD, BIG, SMALL, THIS, ONE, TWO, OTHER, THE SAME, WHEN/TIME, WHERE/PLACE, BECAUSE, IF, CAN, NOT, LIKE. This restricted and universal vocabulary of simple meanings can be used as a kind of 'semantic bridge' in terms of which to articulate complex language-specific and culture-specific meanings in maximum detail. Because it is grounded in simple words of ordinary language, this approach makes hypotheses about subtleties of meaning accessible to the intuitions and judgments of native speakers, thus improving the verifiability of the analyses. The NSM approach is not universally accepted, however, and much valuable work in cross-cultural semantics is still conducted in essentially informal terms.

2. Words and Phraseology

Even between genetically related languages spoken by people of relatively similar cultures (such as the languages of Europe), there are sizable semantic differences in all aspects of the lexicon. Sapir (1949) was thus right when he said that 'vocabulary is a very

sensitive index of the culture of a people.' Most people have no difficulty in accepting the culture-specific nature of words for items of material culture and for social institutions, but many find it hard to accept the extent of cross-linguistic differences in terms for value concepts, emotions, speech acts, and social categories, to mention only a few examples.

Often it is possible to nominate certain highly salient and deeply culture-laden words in a language as 'key words' of that culture, i.e., words whose meanings can provide a key to understanding whole domains of cultural attitudes, values, and behaviors (Williams 1976; Wierzbicka 1997). For example, it can be argued that among terms for value concepts, English *freedom*, Japanese *wa* 'harmony,' and Malay *kesetiaan* 'loyalty,' 'faithfulness' have key word status. Among ethnopsychological concepts the same can be argued for English *mind*, Malay *hati* 'heart,' and Russian *duša* 'soul.' Single-word glosses are never adequate, however, and a reasonable understanding of the key words of any culture requires dedicated and disciplined semantic investigation. Cultures vary across time, as well as across space, so a close analysis of meaning shifts can be revealing of sociohistorical change. For example, it can be shown that the English word *friend* has weakened considerably in meaning since Shakespeare's time, when it designated an exceptional, intimate, and life-long bond of trust, affection, and mutual assistance. This shift can be seen as linked with a shift towards more flexible and broadly-based (if 'shallower') mode of social relationships.

Languages differ not only in their inventories of culture-specific words, but also in the number of words they have for speaking about a particular domain of meaning. A relatively high number of words in a single domain (lexical elaboration) is often reflective of sociocultural facts. For example, compared with most indigenous cultures, European languages have a very large stock of expressions to do with measuring and reckoning time (words such as *clock*, *calendar*, *date*, *second*, *minute*, *hour*, *week*, *Monday*, *Tuesday*, etc. *January*, *February*, etc.). At the same time, there are linguistic universals of time, such as WHEN, AFTER, and BEFORE (cf. Keesing 1994).

Two further ways in which vocabulary and phraseology can reflect sociocultural facts concern the innovation of new words and the borrowing of words from other languages. In general, new words and phrases are indexes of social change, for example, the expressions *housemate* and *online* reflect social and technological developments of mainstream English-speaking culture of the late-twentieth century. Linguistic borrowings index the extent and mode of cultural influence, as witness, for example, the massive borrowing of Chinese words into Japanese, of Latin and Greek words into English, or Sanskrit and Arabic loans into Malay. Some scholars argue that permeability to loans is itself an index of the social openness of a community.

3. *Grammar*

Proponents of linguistic relativity argue that inasmuch as speaking a language obliges individuals to continually attend to particular semantic and conceptual distinctions, this must to some extent 'shape' the habitual thinking of its speakers. Approaching the issue this way means focusing on obligatory grammatical rules and processes. On the other hand, it can be argued that optional choices in grammar, i.e., aspects over which speakers may exercise some choice and control, are more likely to reflect subtle sociocultural meanings. A familiar example is the contrast between so-called 'intimate' and 'formal' second-person pronouns in European languages, such as French *tu* vs. *vous*. Much more extensive is the honorific system of Japanese, whereby verbs carry suffixes which indicate degrees of respect felt by the speaker in relation to the individuals being spoken about. In Slavic languages, systems of expressive derivation reflect the central place of warmth and affection in Slavic cultures; in Polish, for example, a personal name like *Maria* can have as many as 10 different derivatives (*Marysia*, *Marysieńka*, *Maryśka*, *Marysiuchna*, and so on), each reflecting a slightly different emotional attitude and mood. It will be useful to look in some detail at two more examples, from Russian and from English.

3.1 '*Fatalism*' *in Russian grammar*

The Russian language has a large family of impersonal dative-infinitive constructions which refer to inexplicable things that happen to people against their will or irrespective of their will (Wierzbicka 1992). For example, the sentence *Ne budet tebe pasporta* 'There'll be no passport for you' involves a dative pronoun, a negated existential verb, and a noun in the genitive case. The sentence conveys a subtle message, not fully evident in the English translation. Essentially, a construction of this kind rules out the possibility of someone being able to obtain something beneficial and desired, implying at the same time that this is due to the fact that someone in a superior position does not want it to happen.

Another construction combines negation, an infinitive verb, and a human noun in the dative case, for example, *Ne vidat' tebe ėtix podarkov* 'You'll never see those presents.' This construction is not so common in everyday speech, but is highly characteristic of Russian folk literature and folk speech: *byliny* (folk epic), *plač* (lamentation), in folksong, in proverbs and sayings. It conveys the impression that a desired outcome can never eventuate due to some elusive and mysterious force or power that is, so to speak, 'above' humanity.

A third construction combines a human noun in dative case with a mental verb in the 3sg reflexive form, for example, *Segodnja mne vspomnilas' Praga-sady* 'Today I was reminded of Prague, of its gardens.' This

depicts a mental event simply happening inside a person inexplicably, and, in a sense, irresistibly. The most important Russian expression of this sort is the ubiquitous *xočetsja* lit. 'it wants itself to me,' which suggests a spontaneous and involuntary desire. In some ways this parallels English constructions like *It occurred to me* … or *It seemed to me* …, but whereas the pattern has a limited scope in English, in Russian it is both fully productive and extremely common.

In these and other constructions, Russian furnishes an excellent example of the grammatical realisation of a semantic theme; in this case, the theme of *sud'ba* 'fate,' of not being in control, of living in a world which is unknowable and which cannot be rationally controlled.

3.2 Personal Autonomy and the English wh-imperative

Compared with many languages and cultures, English makes only scant use of its imperative construction, e.g., a simple *Do this*!, whose core meaning is 'I want you to do this.' Much more frequent is the use of one of a brace of more elaborate locutions (so-called wh-imperatives), such as *Will you do this? Would you do this? Could you do this? Would you mind doing this?* and so on. These constructions can be seen as hybrids: in form they are questions, but since they convey the speaker's wish that the addressee do something, they have a similar function to imperatives.

It can be argued that the English wh-imperatives represent a linguistic reflection of the importance, in Anglo culture, of a cultural principle that can be labeled 'personal autonomy.' Roughly speaking, this calls upon people to respect the right of other people to make their own decisions about what they will and will not do. To use a bare on-the-record imperative could be seen to infringe this principle, hence the potentially confronting message that 'I want you to do something' is embedded into a more complex configuration which acknowledges the addressee's autonomy by inviting them to say whether or not they will comply. In form at least the addressee is presented with the option of refusing.

Similar examples of grammatical elaboration being driven or motivated by culture-specific pragmatics or cultural values could be given from many languages and cultures (cf. Enfield in press). Often such phenomena arise from the routinization of particular culture-specific patterns of usage.

4. Language in Use

4.1 Discourse Particles and Interjections

These elements exist in the border zone between grammar and discourse. While they are usually not obligatory from a strictly grammatical point of view, they are often an essential part of native-like fluency. Interjections stand as independent utterances, whereas discourse particles are integrated into the syntax of a larger utterance; but both express a speaker's here-and-now feelings, thoughts, wants, and reactions to what is happening or to what is being said. When their semantics are examined in close detail, both types of element tend to be highly indicative of sociocultural priorities, values, and attitudes.

The very common Japanese particle *-ne*, for example, conveys the message 'I think you would say the same,' consistent with the Japanese cultural value placed on harmony and consensus-seeking. English interjections and interjectional phrases such as *Well* and *on the other hand* reflect the Anglo emphasis on balance and tolerance of opposing views. A multiplicity of Polish discourse particles (such as *ależ*, *skądże* and *przecież*) and related interjectional phrases express disagreement, exasperation, and impatience, consistent with the Polish preference for spontaneous expression of emotion and lack of any inhibition on expressions of conflict or disagreement.

4.2 Linguistic Routines

These are fixed, formulaic utterances or sequences of utterances used in standardized communicative situations, for example, greetings, partings, thanks, excuses, condolences, compliments, jokes, curses, small-talk, and so on. They can range in size from a single word to lengthy interchanges, and usually occur very frequently. The overall meaning of a routine cannot be 'read off' from the literal meaning of the individual words involved, e.g., *How do you do?* is not a question about health.

In general, routines are highly culture-specific both in form and in the way they relate to the sociocultural context. To illustrate, one can compare some fixed expressions in English and Ewe (Ghana and Togo, West Africa). In many societies, when one realises that something good has happened to another person, it is usual to say something expressing one's own good feelings at the news. For example, in English one might say *Congratulations!* or *Well done!*; both expressions imply that the addressee is responsible to some extent for the happy event. In Ewe, on the other hand, appropriate things to say refer to *Máwú* 'God,' *tɔ́gbéwó* 'ancestors,' or *ŋú-wò núwó* 'beings,' expressing messages such as 'God is strong,' 'Ancestors are strong,' or 'Beings around you have worked.' Although one function is to register and display one's happiness at the good event, the Ewe formulae are not focused on the individuals concerned. This reflects the religious belief system which holds that everything that happens is ultimately the work of *Máwú* who may work in diverse ways through the ancestors or other spirits and divinities.

4.3 Speech Genres

Bakhtin (1986) defined speech genres as 'relatively stable and normative forms of the utterance' into which we 'pour' our everyday speech. The concept is a very broad one, subsuming examples which differ in size and complexity as widely as (to illustrate from English) *joke*, *toast*, *speech*, *letter*, *eulogy*, *submission*, and *lecture*. Bakhtin stressed that the repertoire of genres available to a speech community changes according to historical and sociocultural conditions.

This conveniently can be illustrated with the (now passé) Polish 'micro genre' of the *kawał* (plural *kawały*) which, roughly speaking, was a kind of conspiratorial joke. Most *kawały* were political, expressing national solidarity vis-à-vis foreign powers which have been so much a part of the Polish historical experience: the foreign partitioning powers in the nineteenth century, the Nazi occupation during World War II, the Soviet-imposed communist regime in postwar Poland. *Kawały* circulated widely, the anonymous creations of an oral culture. Like English *jokes*, they were intended to promote pleasant togetherness, i.e., to make the speaker and the addressee feel good together, but one did not value a *kawał* for its ingenuity, novelty, or sophistication (as one did, and does, *dowcipy* 'witty jokes'). More important was the feeling it gave of belonging to an in-group, the implication being 'I can say this you, but there are some people I couldn't say this to.' For example, in 1981 after martial law had been imposed in an effort to suppress the Solidarity movement, every new demonstration, strike, or protest was ascribed to 'Solidarity extremists.' A *kawał* from that time gave examples from a 'TV Dictionary' as follows: 'two Poles—an illegal gathering; three Poles—an illegal demonstration: 10 million Poles—a handful of extremists.' Clearly, though the Polish genre *kawał* may overlap in some respects with the English genre of a *joke*, it is not identical with its nearest English counterpart. Equally clearly, the precise nature of the Polish genre was a response to (and an index of) social conditions of Poland.

4.4 Speech Styles

Speech styles represent specialized 'ways of speaking,' that are recognized (and, usually, named) by the speech community as appropriate for use with certain categories of interlocutors or in certain situations. When examined in detail, both the stylistic conventions and social parameters of the speech styles can show much about sociocultural conditions. One common pattern can be illustrated from Yankunytjatjara (Central Australia), which has a special indirect speech style *tjalpawangkanyi* (*wangkanyi* 'talk') for use with people whose kin relationships call for constrained behavior, and a boisterous joking or teasing style (*inkatjingani*) for use with people whose kin relationships imply mutual acceptance and a lack of any power relationships (Goddard and Wierzbicka 1997). *Tjalpawangkanyi* has a distinctive vocal delivery (softer, slower, higher pitch) and an exaggerated rising intonation, as if to give the impression that the speaker is merely musing aloud. Direct references to the addressee, including imperatives and vocatives, are carefully avoided. Overt expressions of denial, refusal, or disagreement are also scrupulously avoided. There is liberal use of discourse particles and interjections that express uncertainty, hesitation, and minimization. Another striking feature, reported also of respectful speech styles in many other places, is generality of reference. Speakers avoid using any expression which unambiguously indicates a person, place, or thing, preferring vague locutions like 'that one (person)' and 'around here.'

The social meaning of *tjalpawangkanyi* refers to the Yankunytjatjara social emotion *kunta*. Usually glossed as 'shame,' 'embarrassment,' or 'respect,' this involves a sense of social difference and discomfort in the other person's presence, and the desire to avoid doing anything which might cause the other person to think anything bad about one. The strongest *kunta* is evoked by the respectful *umari* ('avoidance') relationship between a man and his parents-in-law, which absolutely prohibits personal contact of any kind. Less severe *kunta* is felt in the presence of the siblings or cousins of *umari*, and in other relationships where propriety is important, the very relationships for which *tjalpawangkanyi* is appropriate. In this culture, then, the indirect speech style can be seen both as a kind of partial avoidance and a way of giving voice to *kunta*. In other societies, indirect speech styles can serve quite different purposes.

Yankunytjatjara joking styles are at the other end of the spectrum to *tjalpawangkanyi*. They bend, flaunt, or even parody the normal conventions of interaction. All the linguistic forms excluded from *tjalpawangkanyi*, including imperatives, vocatives, contradiction, exclamations, and sensitive vocabulary items, flourish in this style. Participants delight in banter, mock insult, and make the most of any chance to defy, challenge, or demean each other. Sometimes there will be sexual innuendo and risqué comments that consciously play on kin-role expectations. In extreme versions such banter becomes blatantly obscene. Joking, uninhibited speech styles are reported from many societies around the world. Although at a general level one can say that they express 'solidarity,' 'intimacy,' or the like, the rich social meanings involved cannot really be summed up in a few words, and detailed study reveals subtle but important differences.

4.5 Discourse Styles

At an even broader level, entire speech communities can be characterized as having certain tacitly-shared

understandings about how it is appropriate to speak in particular, culturally-construed situations. In some societies it is normal for conversations to be loud, animated, and bristling with disagreement, while in others people prefer to avoid contention, to speak in well-considered phrases, and guard against exposure of their inner selves. In some societies, silence is felt to be awkward, while in others it is welcomed. In some societies it is considered very bad to speak when another person is talking, while in others this is an expected part of a co-conversationalist's work (Tannen 1981). Researchers in the ethnography of communication and in cross-cultural pragmatics are concerned to spell out the differing norms, values and attitudes (sometimes called cultural scripts) which underlie and explain these behavioral differences (Saville-Troike 1989).

Cultural norms about expressing emotions (what one feels) vary widely. For example, in mainstream Anglo societies the expression of negative feelings is relatively constrained (cf. 'cheerful' English routines such as *How are you? I am fine*). In Russian and Polish societies, by contrast, a greater value is placed on the immediate and spontaneous expression of emotions, 'bad feelings' as well as good ones. In yet other societies (for example, in Malay society and in Japanese society) the cultural ideal is to maintain a calm equanimity of expression, moderating the expression of good feelings as well as bad ones. These differences are reflected also in facial expressions and other aspects of nonverbal communication. Needless to say, these characterisations are only approximate. Many modulations and variations are found across cultures.

Even within a single language group there can be significant differences. For example, it can be argued that contemporary Anglo–American culture has developed some distinctive routines and expressions for expressing enthusiasm, optimism, and a 'positive attitude': *Wow! Great! How nice! That's fantastic! I had a terrific time! It was wonderful! Have a nice day!* Sociological studies of cultural attitudes toward emotions have also shown that Americans place an exceptional emphasis on enthusiasm.

Along with differences in emotional expression, other broad parameters of social variation in discourse style concern the expression of conflict or opposition between interlocutors' views (what one thinks) or wishes (what one wants). Japanese society, for example, is a society in which overt expression of differences and disagreements is discouraged, on account of the prevailing cultural value of *wa* (roughly, 'harmony'). For example, a well-known article by a Japanese author (Ueda 1974) is titled *Sixteen Ways to Avoid Saying 'No' in Japanese*. In Jewish culture (Schiffrin 1984, Blum-Kulka 1982), on the other hand, an overt and intense clash of views and evaluations is not only considered nonthreatening but is often actively welcomed.

Differences like these not only contribute powerfully to the texture of everyday social interaction and to the character of interpersonal relationships, but, arguably, exert an influence, through socialization, on the formation of personality types.

Language and Thought: The Modern Whorfian Hypothesis

Let us begin with something that means nothing. The opening lines of Lewis Carroll's nonsense poem *Jabberwocky*, are, in the original English:

'Twas brillig, and the slithy toves
Did gyre and gimble in the wabe.
All mimsy were the borogoves,
And the mome raths outgrabe.

And in French:

Il brilgue: les tôves lubricilleux
Se gyrent en vrilland dans le guave.
Enmîmes sont les gougesbosqueux
Et le mômerade horsgrave.

Finally in German:

Es brillig war. Die schlichten Toven
Wirrten und wimmelten in Waben.
Und aller-mümsige Burggoven
Die mohmen Räth' ausgraben.

The poem means nothing, other than the images it evokes. In a Pulitzer Prize winning series of essays on thought, Douglas Hofstader (1979, p. 372) maintained that each translation will evoke different thoughts in the user, because terms like the (according to Hofstader) earthy 'slithy' (slime, slither, etc.) evoke different associates than the associates evoked by the intellectual-sounding French *lubricilleux*. To the English ear, *Die schlichten Toven* sounds ominous. Is language controlling our thought? More particularly, do the forms of the approximately one thousand natural languages spoken today exert any influence upon the thoughts of their speakers?

Leonard Bloomfield (1933), a prominent linguist during the 1920s and 1930s, said that thinking was 'talking to oneself.' One way to interpret this statement is to say that thinking is an internal communication that takes place in the same language that external communication does. If so, the denotative properties of external language should influence internal thought: if you can't say it, you can't think about it. The anthropologist Edward Sapir (1921) took a stronger position. He maintained that people could only perceive those categories of the external world that are coded in their language, i.e., that if you cannot say it you cannot see it! Sapir's student, Benjamin Lee Whorf, adopted a rather more flexible view. For brevity, I shall refer to the position that language exerts a controlling influence on thought as the Whorfian hypothesis. (Some authors maintain that the term Sapir–Whorf hypothesis would be more accurate, but I believe that Whorf's amplification was great enough to justify the single reference.)

The Whorfian hypothesis is closely related to Bloomfield's notion of thinking as an internal conversation, so it is appropriate that we first look at this idea. Bloomfield's picture of the relation between language and thought was consistent with behaviorist theories that dominated psychology in the 1920–50 period. When the behaviorists spoke about thinking at all they spoke about the manipulation of response-produced internal stimuli, i.e., subvocal words. The strong position that all thought is internal language cannot be maintained, for there is ample evidence that people can think by manipulating internal visual images, and perhaps other sensory images as well. It has also been denied that the forms of the external language have any pervasive influence on thought at all.

One of the major theses of the 'cognitive revolution' that swept over psychology and linguistics in the 1950s was the contention that language and thought are independent. This argument derives from the seminal work of Noam Chomsky (1957, 1963) on the role of generative grammar in language. The clearest exposition of the language–thought distinction may be in the writings of Jerry Fodor (1975). Following Chomsky, Fodor argued that internal thought takes place in a special language, 'mentalese,' that is roughly equivalent to the predicate calculus. Expressions in mentalese are then translated into expressions in external languages according to the rules of the particular external language involved. An important assumption of the Fodor–Chomsky approach is that any expression in mentalese can be expressed by at least one (and usually many) expressions in any natural language. Therefore, any expression in language is translatable into an expression in any other language. Because the thoughts behind these translations occur in mentalese, the form of the external expression plays little role in thinking. This will be called the intertranslatability hypothesis. It will play a crucial role in the argument to be presented here.

The intertranslatability hypothesis is a statement about the competence of two languages to express each other's ideas. It says nothing about the difficulty of language-specific information-processing actions

required to go from the mentalese expression to the external statement in the two languages. The distinction is important.

To begin the current discussion, let us consider how language is used. One way is as a communicative act: a speaker (or writer) tries to create a thought in another person. Many studies have shown that it is possible to overwhelm the information-processing capacities of a receiver by presenting linguistic messages that are too complex to understand. Therefore, language contains devices to call attention to different aspects of the message to be communicated. For instance, attention can be focused on a topic by the device of first mention. The sentences

(a) John loved Mary.

(b) Mary was loved by John.

say the same thing, in one sense, but in (a) John is the focus of attention, while (b) is about Mary. Similarly, the provision of undisputed facts can shape meaning in subtle ways. Consider:

(c) President Eisenhower, the former five-star general, spoke to his cabinet.

This suggests that President Eisenhower did not conduct cabinet meetings in the folksy way that Abraham Lincoln is said to have done.

Whorf himself cited examples like (c) to show that the categories available in a language influence thoughts about the world. For instance, early in his professional life, Whorf worked as a safety engineer. He observed people smoking around gasoline drums that were labeled empty, disregarding the fact that a drum that has been emptied of liquid gasoline may contain highly volatile fumes. Whorf argued that the semantic association of the English term 'empty' led workers to the incorrect interpretation that the drums were inert. This is very close to Hofstader's observation that the meaningless terms 'slithy' and 'lubricilleux' will evoke different associates, and thus a different interpretation of Lewis Carroll's nonsense poem.

All languages use devices like this, and there is no doubt that thinking can be framed by subtleties of language. What is more questionable, and to the psychologist more interesting, is how the language available to a perceiver can be used to influence the way that perceivers can describe a situation to themselves.

At this time we return to Sapir's extreme position that a person literally cannot perceive a physical difference unless the person has a word category that depends on it. This proposition was tested, and apparently falsified by Eleanor Heider (Rosch) (Heider and Oliver 1972). Rosch studied color perception in the Dani, an aboriginal people on the island of New Guinea, in what is now the Indonesian province West Irian. The Dani language has only two terms that are roughly equivalent to 'dark' and 'light.' However, Rosch found that color discrimination in the Dani was the same as the color discrimination of English speakers. Rosch's work was widely cited in textbooks as conclusive evidence against Sapir's position that language can influence perception. Then, almost 30 years later, Roberson et al. (2000) conducted a follow-up study that raises questions about the earlier work. Roberson et al. used somewhat improved experimental techniques in a study of color perception in the Berinmo, a Papua New Guinea group whose language contains only five basic color terms. The Berinmo were most sensitive to color changes at the borders of the color categories in their language, whereas English speakers showed maximal color discrimination at the borders in their language. For instance, English speakers were maximally sensitive to colors that did or did not cross the blue–green boundary line, while Berinmo speakers were maximally sensitive to crossing the *nol–wor* boundary, which lies within the range of the English term green.

Another aspect of color naming has often been overlooked. Naming can affect memory even though it does not affect perception. Suppose that an English speaker is induced to call a particular object whose color is in the blue–green range either 'blue' or 'green.' Subsequently, the speaker's memory for the object's color will be distorted toward the prototypical hue of the name used to describe the object. This phenomenon can be thought of as a specific case of a much more general phenomenon. Examples of a category are remembered as more prototypical in appearance than they actually are. The general phenomenon has been demonstrated for categories as disparate as the position of a point in a clearly marked region of a page and the personality characteristics of people assigned to social roles, such as 'professor' or 'neo-Nazi.' Because our thought is heavily dependent on memory, the categories that language provides are important.

The decisions required to construct a linguistic statement can focus attention on selective aspects of a situation. This argument has been developed by Daniel Slobin (1996), who has coined the term 'thinking in speaking.' In order to describe a situation to ourselves or to another we have to decide what linguistic constructions (morphemes, syntactical forms, etc.) to use. The decisions required to choose between linguistic constructions focus attention on certain aspects of a situation. If it can be shown that different natural languages force a person's attention toward different aspects of a situation then we would have evidence for a Whorfian effect.

Whorf himself thought that he had observed such an effect in his studies of the way that the Hopi, a Native American people (and one of the larger tribal groups still extant) thought about time. According to Whorf, Hopi verbs stress cyclic stages (e.g., growth, decay). This sort of linguistic frame is used to discuss time. By contrast, English verb forms specify discrete states; the past, present, and future. Whorf believed that as a result, the Hopi had a different view of time than did speakers of 'standard European languages.'

Whorf's fieldwork with the Hopi has been criticized on the grounds that he did not 'really' understand Hopi. This claim is almost impossible to evaluate. Whorf did his fieldwork in the 1920s. The modern Hopi are much more integrated into the standard US culture than they were in 1920, and few speak the language as a first language. Therefore, we cannot interview the current Hopi and, with confidence, either object to or confirm Whorf's fieldwork. However, a similar claim has been made for the contrast between two of the most widely spoken languages in the modern world; Spanish and English. In fact, because of a unique feature, the claim is *for* Spanish speakers against at least all romance and Germanic languages.

Spanish has two forms of the verb 'to be,' *ser* and *estar*. The *ser* form is generally used to indicate permanent states and properties, while *estar* is used for continuing actions or temporary states. Two examples are:

(d) *Soy un hombre* = I am a man.

(e) *Estoy en mi oficina* = I am in my office.

Sera and her colleagues (Sera et al. 1997) have found that the use of *ser* or *estar* assists Spanish-speaking children in distinguishing between permanent and temporary properties of objects, in a manner that is unavailable to English-speaking children.

The use of classifier systems provides a second example of how 'thinking in speaking' can produce a Whorfian effect. Some of the languages distributed around the Pacific Rim require the use of classifiers before certain types of nouns. For example, Japanese requires the use of the term *bo* before things that are long and narrow, as in:

(f) I have three bo pencils.

In this example, shape classification, the property upon which classification is based, is perceivable. This is not always the case. Chinese uses a classifier for 'things that can be grasped by the hand' (Zhang and Schmitt 1998). Dyribll, an Australian aboriginal language, has a classifier for things derived from certain myths. It is applied, among other things, to 'women, fire, and dangerous things' (Lakoff 1987).

Languages that use classifier systems force the speaker to attend to certain features of objects. As a result, speakers of languages that use classifiers give higher similarity ratings to pairs of objects that share a classifier than do people whose language does not require classifiers. For example, Chinese speakers in Hong Kong, whose language classifies door keys, rulers, and pliers as 'things that can be grasped by the hand,' rate these objects as being more similar to each other than do English speakers, who do not use classifiers (Zhang and Schmitt 1998).

'Thinking in speaking' can provide effects if the development of appropriate linguistic forms calls attention to a nonlinguistic relation that is important in the world. Miller and his colleagues (Miller et al. 1995) report a more subtle effect involving number names. In every language, digit names up to the base term are arbitrary. That is, there is no reason other than history that 1 = one, 2 = two and so on up until 10. By contrast, the formation of English number names from twenty (2×10) onwards incorporate a mathematical relation; twenty-one = $20 + 1$, and even three hundred and forty-five = $300 + 40 + 5$. The number names for 11–19 are irregular in two ways. 'Eleven' and 'twelve' are arbitrary names, and a special regularity, thirteen = $3 + 10$, etc. is used instead of stating the most significant digits first, as is done for integers greater than twenty. Spanish is irregular also, although in a slightly different way. The integers from 11 to 15 have special names (*once*, *doce*, *trece*, *catorce*, *quince*), followed by the regular form with the most significant digits first (*dieciséis*, *diecisiete* = $10 + 6$, $10 + 7$). By contrast, in Mandarin Chinese, the spoken number names for all digits follow a regular convention. The Chinese equivalents of the digits eleven and twelve are $10 + 1$, $10 + 2$, as if English speakers said 'teenone, teentwo' or Spaniards said 'dieciuno, deicidos.'

Miller et al. observed that when children in English- and Spanish-speaking countries learn elementary arithmetic they have an unusual amount of trouble with operations involving numbers whose names have special terms, 11–12 in English and 11–15 in Spanish. Chinese-speaking first and second graders have no such trouble. Miller attributed this to the fact that irregular number names failed to reinforce numerical relations in the way that regular number names do.

Miller's research can be looked upon as a case in which different languages vary in the facility with which they express facts about the external world, but the facts can still be expressed. Research on terms for spatial relations provides an example of a situation in which a language may not be able to express certain facts. Most languages have words for expressing relationships in both an egocentric frame of references (right, left in English) or in an abstract geographic frame of reference (north, south, etc.). However, there are some languages that only have terms for one of these frames. Speakers of languages that are restricted to geographic frames interpret 'looks the same' to mean that two views of objects maintain their geographic orientation, while speakers of languages that have egocentric terms interpret 'looks the same' to mean that egocentric orientations are retained in two views (Levinson 1996). On the other hand, if a language only has terms for egocentrically defined relations it can be difficult to describe spatial layouts to people who have not observed them (Hunt and Agnoli 1991).

Hunt and Agnoli (1991) offered another argument for the Whorfian hypothesis. They pointed out that working (short-term) memory capacity is a major bottleneck in speech comprehension. Furthermore, the bottleneck seems to depend on the number of word forms that are to be held in short-term memory rather than the complexity of the concepts to which the

words refer. Therefore, specialized vocabularies evolve to provide a convenient way to let people talk about concepts of interest. Borrowing an argument form Whorf, Hunt and Agnoli suggested that having such specialized vocabularies facilitates thinking about theme. To a computer specialist the statement:

(g) The hacker put a cookie on the client's machine.

is certainly more compact than the equivalent in more standard English:

(h) The person attempting to break the security of a computer system for nefarious purposes put a program that surreptitiously records and reports the activity of a computing machine on the machine of a person who is using a desktop computer to gain entry to the Internet via another machine, called a server.

There has been a running argument between supporters and opponents of the Whorfian hypothesis over whether or not the existence of specialized vocabularies such as these constitutes a facilitation of thought by language. Whorf himself believed it did, arguing that Eskimos (Inuit) were better able to think about snow than English speakers. (Whorf overestimated the richness of the Inuit vocabulary for snow, but they do make distinctions that English does not, so his point is still valid.) Hunt and Agnoli do the same, arguing that words are used to package ideas, as illustrated by examples (g) and (h). As these examples show, it is possible to translate computer jargon into normal English, but the result is a pragmatically incomprehensible sentence.

Granted that examples like this can be made up, do they occur? The answer is that they can, and in situations in which the topic may be quite serious. In the late 1999–early 2000 period, a serious political dispute broke out between the government of Taiwan, which calls itself the Republic of China (ROC) and the mainland government, which refers to itself as the People's Republic of China (PRC). The two had been separate and hostile for over 50 years, but in the 1990s fairly extensive commercial relations developed between Taiwan and the mainland. Taiwanese (ROC) politicians said that, therefore, it was time to begin formal relations on a state-to-state basis. PRC officials reacted in fury, and literally threatened war if Taiwan attempted to establish two Chinese nations.

According to *New York Times* reports of the incident, part of the problem was that the Mandarin Chinese language uses the same word for 'state = formal machinery of government' and 'nation = unitary cultural and social entity.' On a de facto basis, PRC officials had been dealing with the ROC as a separate state for years. Unacknowledged contacts already existed between the formal machineries of the two governments. On the other hand, PRC leaders have an official and deeply held claim to be the only legitimate Chinese nation. To them the ROC is the government of a temporarily renegade province. Therefore, any claim to separate nationhood was, in the PRC ideology, a cause for war. ROC officials then claimed that they had only proposed government-to-government, rather than nation-to-nation, discussions. In order to expand on this claim, some officials resorted to English, even when speaking to other Chinese speakers.

The anti-Whorfian psychologist has two rejoinders to examples like these. One is to claim that these examples refer to the communication of ideas rather than the formation of them. This is consistent with the notion that 'basic thinking' takes place in an alinguistic, unobservable mentalese. Bouchard (1997) has remarked, in quite another context, that you can always explain an observation by appealing to unmeasured variables. The remark applies here. The notion of mentalese has a great deal of appeal because it fits with certain notions about generative models of language. However, it is not clear whether or not mentalese could be replaced with a reduced form of natural language terms, permitting thought directly in a speaker's language. And it is even less clear how this question could be investigated objectively.

The other anti-Whorfian rejoinder is that all these examples show is that language adjusts to cultural demands. Words and their related concepts are easily added to the lexicon. Modern English defines 'hacker' in a different way than it was originally used in computer science. More dramatically, a gay bachelor of the 1920s would not be gay in the sense the word is used in 2000. The anti-Whorfian argument is that cultural demands force language to adjust to cultures, rather than letting language restrict cultural change. Therefore, any restriction imposed on thought by lack of lexical entries for concepts like hacker or state versus nation is only temporary and probably not very important (Pinker 1994).

This objection is a value judgment rather than a hypothesis about facts, so it cannot be supported or refuted by scientific argument. It also brings us to another important point. We have been discussing specific points at which the form of a natural language may influence the thinking of its speakers. There is a 'romantic' version of the Whorfian hypothesis that claims that language may reinforce and/or restrict certain very broad cultural ways of thinking. This assertion is based on the assumption that there are definable cross-cultural ways of thinking, itself an assumption that requires analysis.

No one doubts that different cultures vary in their beliefs and value systems. This is part of the definition of culture. At the same time, modern psychologists and neuroscientists are confident that the content-free aspects of information processing, such as the distinction between short-term and long-term memory, work in the same manner for all normal human beings. If the differences between languages are regarded as a matter of setting parameters to govern the operation of a species-general universal grammar, then it is unlikely that the parameter setting would determine behavior outside of language. This is the approach

taken by linguists and psycholinguists working in the generative grammar tradition. On the other hand, if both linguistic abilities and cultural knowledge are due to general learning experiences, mutual interactions are more likely.

Some popular beliefs appear to acknowledge a belief in the romantic Whorfian hypothesis. French is said to be the language of lovers, and German the language of soldiers and engineers. In the extreme, this is silly, for differences between natural languages certainly do not preclude broad categories of activity or belief. Frenchmen built the Suez Canal, and the German romantic song 'Lili Marlene' was hummed by homesick soldiers on two sides in two wars.

What we need is more precise evidence of a linguistic effect. Let us take a fairly frequent accusation against US society. European commentators have remarked that contemporary US society mixes superficial personal familiarity with an almost cold treatment of close acquaintances. It is also true that English, unlike many other languages, uses the same form of address, 'you,' for formal meetings and for conversations between close friends. We have no objective measure showing that French people or Spaniards, whose language does include different forms of personal address, are in fact more formal in business and more intimate with their friends than are English speakers.

The closest that we can get to scientific evaluation of romantic Whorfianism is to look at correlations between definable properties of a language and global impressions of a culture. For instance, A. Wierzbicka, a Polish expatriate to Australia, has written extensively on the contrast between the Polish and English languages and what she sees as the relative emphasis on group solidarity and intimacy in Polish society and the personal speaking autonomy in the English-speaking societies. One of her favorite examples is the English convention of using indirect requests, as in

(i) Could you close the window?

This would normally be taken as a request for action rather than a request for information. Wierzbicka (1991) claims that Polish speakers prefer the more direct

(j) Close the window.

The problem is that we do not have any objective definition of 'emphasis on personal autonomy.' The problem is compounded by the fact that different subgroups in a large society may use their language in different ways. They may also vary in general cultural attitudes. Several of my Polish-speaking acquaintances dispute Wierzbicka's assertion about Polish, saying they would normally use a form like (i) rather than (j). Similarly, I, an English speaker, regard both (i) and (j) as appropriate uses of English, depending on the circumstances. I also suspect that the relative frequencies of direct and indirect requests vary a great deal across social groups and situations within English-speaking cultures. Besides, even if you could establish a correlation between language uses and situations, the causal relations would remain unknown. Does the culture adjust to the language or the language to the culture?

My point is not to dispute Wierzbicka's particular assertion. I am more concerned with the general point. Scientific hypotheses about the relationship between language and thought have to point to specific features of both language and cognition. Without adequate operational definitions we cannot investigate general assertions about relationships between language and thought.

Where, then, are we with respect to the Whorfian hypotheses? Linguistic effects on thought have been shown in specific domains, such as spatial reasoning, color perception, and memory, and the control of attention. The latter effect is particularly important, because the deployment of attention determines what goes into memory, and what goes into memory very largely determines how we think about things. The effects are generally rather small, but they occur every day a speaker uses language. Whether or not language exerts an important control on thought depends upon how one defines 'important.'

Grand romantic statements about language controlling, or at least heavily influencing, thought are harder to prove or disprove. This is at least as much because of vagueness in specifying what objective acts of thought are to be controlled as it is because of vagueness in specifying what aspects of language do the controlling.

I do not think that this state of affairs would have surprised Whorf. In his own work he was very much a student of the particular. The broader notions of what I have called romantic Whorfism come largely from his interpreters. The Whorfian hypothesis is not a proposition to be verified or disproven. It is a scorecard, telling us the extent to which language and thought are entwined.

Language Contact

Language contact is any situation in which speakers of two or more languages communicate with each other—usually in person, but sometimes in writing (including email). This article gives a brief overview of the general topic in both its social (Sect. 1) and its linguistic aspects (Sect. 2).

1. *Language Contacts in Time and Space*

Languages have been in contact ever since human populations began spreading out into new territories and splitting into independent subgroups. No community in today's world is so isolated that its language remains untouched by outside influence over a long period of time; probably no language has been so isolated at any time in the last several thousand years. Every so often news reports trumpet the discovery of a 'stone-age tribe' that has been isolated from all other communities (and their languages) for thousands of years. A prominent late-twentieth-century case is that of the Tasadays, a small group that was discovered in the rainforest of the island of Mindanao in the Philippines. But the Tasadays, although they are not a hoax (as has been claimed), are certainly not a stone-age tribe (as was originally claimed for them): they are estimated to have been isolated from their nearest neighbors only for five to ten generations (Reid 1997; see also Headland 1991).

Most of the world's people are bilingual or multilingual. Attitudes toward the use of two or more languages within a community vary widely, however. Sometimes the highly visible symbolic status of language makes it a convenient pretext for interethnic hostilities: conflicts over language policies have erupted over the past few decades in many countries, among them the former Yugoslavia, where Croatian nationalists demanded linguistic autonomy years before the country's break-up; South Africa, where lethal riots broke out in the 1970s over the apartheid regime's insistence that the use of Afrikaans be increased in the townships' school systems; and Sri Lanka, where violent Tamil separatist activities were triggered by the 'Sinhalese-only' policy that the government established in the mid-1950s.

But a great many language contacts all over the world display no tendency toward conflict. Long-term bilingualism and multilingualism often flourish as a result of such social institutions as exogamy and regular trading relations with neighbors. Nor is cooperative multilingualism confined to small hunter–gatherer cultures. In some modern nation-states, for instance Switzerland, languages coexist peacefully, even productively.

For the vast majority of contact situations around the world we have no specific information about their onsets. Nevertheless, we can identify a variety of ways in which languages come into contact. At an earlier time in human history, some language contacts must have been established when groups met after moving into previously unoccupied territory; now that the world has no unoccupied habitable territory, this mode of contact onset is no longer available.

In more recent human history, probably the most common way in which languages come into contact is the movement of groups or individuals into other people's territory. Such movements can be peaceful immigrations, by people who wish to become integrated with the host population and people who want to work in agriculture or other industries. They can also be forced immigrations, as in the notorious Atlantic slave trade and in smaller-scale cases of slavery and indentured servitude. Or the movements can be more or less hostile encroachments by invading armies. The USA, Australia, and northern Europe, for

instance, have all been prime immigration destinations over the past century, and the resulting linguistic contacts have been the subject of a rich scholarly literature (to mention just three of innumerable examples, see Haugen 1953, Clyne 1997, and Backus 1996). Language contacts resulting from forced immigration have also received a great deal of scholarly attention, especially in the study of pidgin and creole languages (see e.g., Arends et al. 1994). Not surprisingly, given the long history of European and other colonial expansions, the literature on contacts initiated by invasions is the largest of all—covering contacts ranging from ancient Egyptian expansions to the European Age of Exploration, to Arab conquerors and indigenes in the Maghreb, to Russians and the peoples of the Russian Far East, and many others.

Some language contacts are ephemeral, others are extremely stable, and still others are in between. The stability of a language contact situation depends on many different social factors, among them the relative status and size of immigrant and host groups or of invaders and invaded; the degree to which one or more of the groups in contact desire complete amalgamation with the other group(s); the balance between 'other-directed' and 'self-directed' world views, and attitudes toward multilingualism itself, among multilingual groups in contact (Foley 1986, p. 27ff); and, when there is a dominant group, the amount of pressure it exerts on subordinate groups to shift to its own language.

2. *Linguistic Results of Language Contact*

The major linguistic aspects of language contact can be divided into several categories, including at least contact-induced language change, mechanisms of interference, the emergence of contact languages, and language death. But a preliminary comment is in order: one possible linguistic result of language contact, even under the most intense contact conditions, is no change at all. It is true that the great majority of long-term intense contacts all over the world involve significant contact-induced changes; but there are cases where lexical and even structural borrowing are rigorously avoided, so it is not safe to predict that contact-induced change is inevitable.

2.1 *Contact-induced Language Changes*

We can point to a number of linguistic and especially social predictors in trying to understand when and why contact-induced change occurs. Only the most trivial predictor is absolute: there can be no contact-induced change without contact. But other predictors also permit generalizations that are robustly supported by the linguistic evidence. One of the most important social predictors is the presence vs. the absence of imperfect learning of a target language by a group of people (Thomason and Kaufman 1988, Thomason 2001); another is the admittedly vague concept of intensity of contact. Strictly linguistic predictors, such as universal markedness and typological distance between source and receiving languages, are also important, but they are easily overridden by social factors.

If there is imperfect group learning—typically but not always in a case of group language shift—and a sufficiently intense contact situation, the first interference features to appear in the receiving language are phonological and syntactic features; morphology lags behind, and so, though for other reasons, does lexicon (except, sometimes, in the case of a shift by a superstrate group to a substrate group's language). So, for example, Latvian, a member of the Baltic subgroup of the Balto-Slavic branch of Indo-European, has undergone significant shift-induced interference in phonology, syntax, and to a lesser extent morphology as a result of shift by speakers of Uralic languages, especially Livonian; among the interference features in the most-affected dialects are its fixed initial stress rule, nominal object construction, and loss of gender distinctions (see Comrie 1981, pp. 147, 149, 152, 154). Shift-induced interference comprises both features carried over from the native language (L1) and failure to learn some target language (TL) features. Whether the shifting group's version of the TL will ultimately cause any changes in the TL as a whole depends on the extent to which the learners are integrated into the larger TL community. Note that imperfect group learning cannot be predicted with any confidence, though such factors as the relative sizes of the shifting and TL communities permit tentative predictions.

If imperfect learning plays no role in an interference process, the prediction about transferred features differs sharply: in this case the first interference features to appear in the receiving languages are nonbasic lexical items; structural features and basic vocabulary may appear later, if contact is intense enough, but in all or almost all known cases, borrowed nonbasic vocabulary predominates. In these interference processes, which have been labeled 'borrowing' in a narrower sense than the traditional usage (Thomason and Kaufman 1988), the people responsible for the interference are fully fluent in relevant aspects of both the source language and the receiving language.

Unlike the prediction of shift-induced interference in cases of imperfect group learning, even the most intense contact does not guarantee that significant borrowing will occur: communities in various parts of the world refuse to borrow vocabulary (or, in some cases, anything at all) from the language of their neighbors, even when (for instance) all members of a subordinate community are fully bilingual in a dominant group's language. So, for instance, the Montana Salish language in northwestern USA has been in intimate contact with English for 150 years, and the 60

or so remaining fluent speakers of the language are fully bilingual in English; and yet Montana Salish has only a tiny handful of loanwords from English, and no detectable structural interference of any kind.

Still, examples of extensive lexical and even structural borrowing are very easy to find in contact situations all over the world. A typical case is borrowing by Ossetic (Iranian, Indo-Iranian subgroup of Indo-European) from languages of the Caucasus, e.g., the Kartvelian language Georgian: much lexicon, glottalized ejective phonemes even in native vocabulary, several added cases in noun declension, agglutination in noun declension, and sentence structure that is more typically SOV (subject–object–verb) than in other Iranian languages of the former Soviet Union and that has a 'highly developed system of postpositions' (Comrie 1981, pp. 167, 171, 179).

Two-language contact situations, complex as they can be both socially and linguistically, are nevertheless easier to understand, in a historical sense, than multilingual contact situations, in particular regions called linguistic areas or *Sprachbünde*. Although the processes by which a Sprachbund arises are the same as those by which interference occurs in a two-language contact situation, establishing the sources of many areal features in a Sprachbund is difficult and often impossible, at least with our present knowledge of such diverse linguistic areas as the Balkans, South Asia, and the Pacific Northwest of North America.

2.2 Mechanisms of Interference

The only two mechanisms of interference that have received much attention in the literature are code-switching (especially as a mechanism of borrowing) and second-language acquisition strategies (as a mechanism of shift-induced interference). Code-switching becomes a route to interference when a code-switched element, such as a noun inserted into a sentence that is otherwise in a different language, turns up more and more frequently in the other language's sentences until it is fixed as a part of that language, with or without phonological and morphosyntactic adaptation to the receiving language's structure. One strategy used by second-language learners is the employment of L1 lexicon and structure to fill gaps in their knowledge of the L2, as when L1 English speakers use an English pronunciation of /r/ in speaking L2 German, or when they use English SVO word order in a German subordinate clause instead of the native German SOV order. A related strategy is guessing what patterns the L2 has on the basis of a perception that the L2 differs from the L1, as when Hungarian learners of a Serbo-Croatian dialect ended up with fixed penultimate stress—different both from fixed initial Hungarian stress and from free (other) Serbo-Croatian stress. These strategies lead to shift-induced interference if and when the learners' errors become a permanent part of a community's language. (The type of guessing that is done in such cases may be subsumable under a separate mechanism, called 'negotiation'; see Thomason 2001).

But although these are by far the best known mechanisms, there are others as well. One is code alternation, in which a bilingual speaker uses one language with some people and the other with different people—but never both languages with the same person, so that no code-switching is involved. In contrast to code-switching, this mechanism seems likely to be responsible for the importation of more structure than lexicon into one of a bilingual's languages; but as it has not yet been studied in any systematic way, it's hard to be sure of its typical effects. An example would be the borrowing of phonological features (e.g., aspiration of initial voiceless stops) and lexical semantic changes in the Italian of an Italian/English bilingual (M. Shigley-Giusti, personal communication, 1993). This example doesn't necessarily point to permanent interference even in this one speaker's idiolect; but it isn't hard to see how such local effects could eventually snowball into permanent community-wide interference.

A fourth mechanism of interference is passive familiarity, in which the language of a person or group is altered through contact with a language or dialect that the relevant speakers understand but do not ever speak. An obvious example is the borrowing of numerous words into whites' American English from African-American vernacular English, e.g., *Drop a dime* (on someone) 'to inform (on)' (as in *That dude'll drop a dime on ya in a heartbeat*), *boogie* 'go, leave,' and *chill* 'relax, calm down.' But structural features are also transferred by this mechanism. In fact, it is presumably part of the complex process through which shift-induced interference features make their way into the language of an integrated community consisting of L2 learners and original L1 speakers of the TL: the eventual community's language will contain a subset, but not all, of the shifting group's version of the TL—and those features were in effect borrowed by the original TL speakers, even though they are very unlikely to have spoken the shifting group's TL version.

A fifth mechanism of interference is bilingual first-language acquisition. Again, however, L1 acquisition as a mechanism of interference has not been studied systematically, so it is hard to know just how widespread its effects are. The clearest examples in the literature to date concern either syntactic features like word order or nonsalient phonological features such as intonation patterns, as in Queen's (1996) discovery that young Turkish/German bilinguals kept two phrase-final intonation patterns that are isofunctional in the two adult languages, and introduced a functional distinction between the two patterns in each of their L1's.

A sixth mechanism of interference, finally, is speakers' deliberate decision to alter their languages. This mechanism is best attested for changes in a whole language if the community is quite small, but examples like that of the eighteenth-century grammarians who introduced the Latin-inspired ban against split infinitives into Standard English at least show that the phenomenon isn't confined to hunter–gatherer societies.

2.3 Contact Languages and Language Death

The field of language contact is vast, and in a limited space only a few of its aspects can be touched on. To round out the picture a bit, this survey will conclude with very brief comments on two other aspects of great importance, contact languages and language death. Contact languages can (in my opinion) only be adequately defined by reference to their histories; there are no promising approaches that would permit them to be identified by their linguistic features alone. The one thing that all contact languages have in common is the fact that their structures and lexicons cannot all be traced back primarily to a single source language. Given the historical linguist's standard criterion for membership in a language family—descent with modification from a single parent language—this means that a contact language does not belong to any language family.

There are two basic kinds of contact languages: pidgins and creoles (see, for example, Arends et al. 1994), on the one hand, and bilingual mixed languages on the other (see e.g., Bakker and Mous 1994). The genesis of pidgins and creoles involves imperfect group learning and also a negotiation mechanism; but often there is no true target language in the sense of a language that the creators of the contact language try to learn. A creole, more or less by definition (although, as with most issues in this subfield, the claim is controversial), serves as the main language of some speech community. Prototypical pidgins serve a variety of functions: they permit communication among linguistically diverse groups that share no common language but need to communicate with each other about a limited range of topics; but many pidgins also serve to keep outsiders at a distance. Hiri Motu in New Guinea, for instance, probably developed as a means of fulfilling both purposes. It was a means of intergroup communication, but it also ensured that outsiders would not learn the true Motu language (Dutton 1997).

In sharp contrast to pidgins and creoles, bilingual mixed languages show no effects of imperfect learning: they are clearly created by bilinguals. They also serve a very different function from pidgins and creoles, because they are in-group languages, not intergroup languages.

Some contact languages arise abruptly, probably crystallizing into a language that has to be learned as such within a few years or at most one or two generations; others appear to be gradual developments. Abruptly created contact languages almost certainly include many pidgins and the creole Pitcairnese (which developed after 1790 among the Bounty mutineers, their Tahitian-speaking partners, and the offspring of those unions); they also include such bilingual mixed languages as Michif, a language created by mixed-blood Cree/French bilinguals (French noun phrases, Cree verb phrases and sentential syntax), and Mednyj Aleut, the language of mixed-blood Aleut/Russian bilinguals (Russian finite verbal inflection, otherwise mostly Aleut). In all such abrupt cases of language genesis there is a sharp break in transmission; the resulting mixed language is not the product of normal language transmission, which involves the learning of a whole language from speakers of that language (see Thomason and Kaufman 1988). It is not the product of ordinary bilingual L1 acquisition, either, because bilingual L1 learners keep their languages separated from a very early age.

Other contact languages, however, seem to be best understood as the product of gradual development: at every stage in the process, a whole language is passed down from one generation to the next, but so many interference features are accumulated over a long period of time that, ultimately, too little is left of the original language for it to be classifiable as belonging to its original family. Contact languages of this type comprise at least some creole languages born of the slave trade, where successive waves of imported slaves learned versions of a European TL that was increasingly distant from the original TL as spoken by Frenchmen (see Arends 1993, Chaudenson 1989), and also bilingual mixed languages which developed through long-term intensive borrowing that ultimately replaced most of the inherited structure and much of the inherited lexicon. A prime example is Ma'a (northeastern Tanzania), which started as a non-Bantu language (perhaps originally an ordinary Cushitic language, though the evidence is unclear—Mous 1993) but, over a period of three hundred years or so, incorporated so much lexicon and structure from neighboring Bantu languages that by the 1980s its lexicon was about half Bantu and its structure almost entirely Bantu, including a full set of Bantu inflectional affixes (Thomason 1997, but see Mous 1994 for a different historical scenario).

Finally, the saddest outcome of language contact, often for the speakers and always for linguists' hope of understanding human language in all its immense diversity, is language death. This outcome is becoming increasingly common in our modern world, and in spite of intensive language preservation efforts in many places, the process is probably irreversible for a shockingly high percentage of the languages currently alive (Hale et al. 1992). The linguistic study of language death has focused on attrition, though other aspects of

the topic have also received a considerable amount of attention; for a representative sampling, see Dressler and Wodak-Leodolter (1977) and Dorian (1989).

Language, Continental Philosophy of

Although philosophical interest in language is as old as philosophy itself, during the twentieth century this interest flourished to such an extent that the analysis of language has now become one of the most productive philosophical fields. Besides the general interest in language present in virtually all different philosophical traditions of the past century, it is possible to distinguish at least two very different ways of approaching linguistic analysis, namely, the so-called 'Anglo-American' and 'continental' philosophies of language. The first (also called 'analytic' philosophy) usually refers to the kind of analysis of language initiated at the end of the nineteenth and the beginning of the twentieth century by authors such as G. Frege, B. Russell, L. Wittgenstein, the logic positivists, etc. The second, continental philosophy of language, refers to the conception of language that finds its roots in the eighteenth century, in the works of authors such as J. G. Hamann and J. G. Herder, and was further developed in the nineteenth century by W. v. Humboldt. Through the work of M. Heidegger, it has extended its influence to contemporary hermeneutic philosophy (H.-G. Gadamer, K.-O. Apel, J. Habermas, etc.). In this article the specific features of the continental conception of language are examined.

In general terms, one of the crucial differences between the Anglo-American and the continental philosophies of language is the explicit attempt found in all the authors of the continental tradition to break with what Humboldt termed the 'primacy of logic over grammar,' that is, the predominance given from the very beginnings of Greek philosophy to the cognitive function of language at the expense of its communicative function. As a consequence of conceiving language less as a vehicle of knowledge and more as a means of understanding, this tradition analyzes the role that language plays not only in our relationship with the objective world (by allowing us to have propositional knowledge about it) but also in our relationship with the social world (which is constituted through communicative interaction) and with our

own subjective worlds (which are expressible through linguistic articulation). In this way, language is considered in its multidimensional world-disclosing function. In keeping with this focus, continental philosophy of language has always concentrated on the analysis of natural languages, developed through contingent historical processes, and has considered these as *constitutive* of our experience of the world.

In order to understand the roots of the distinctive features of the continental conception of language, it is important to keep in mind that this conception was developed against the background of an explicit confrontation with Kant's philosophy. This is important because, in spite of all criticisms of Kant, continental philosophy of language remains to this day under the decisive influence of transcendental philosophy. This influence explains two of its most characteristic features: its idealist tendencies (which in some cases lead to a clear hypostatization of language, most remarkably in the work of the late Heidegger) as well as one of the crucial problems that have concerned the authors of this tradition from the very beginning, namely the problem of linguistic relativism. The connection between these features can be understood best through an analysis of the different historical phases of development within this tradition.

1. *The Hamann–Herder–Humboldt Tradition*

As already suggested above, most of the reflections on language found in the works of the authors of this tradition take place in more or less explicit confrontation with Kant's philosophy. In the cases of Hamann and Herder this confrontation takes the specific form of a metacritique of Kant's critique of pure reason (see Hamann 1784/1988, Herder 1799/1960). One important target of both metacritiques is Kant's attempt to purify reason from its internal connection with language. The constant reference that Hamann and Herder make to the common origin of both expressions 'language' and 'reason' in the Greek word *logos* is by no means a merely etymological remark. With the explicit identification of language and reason (i.e., the claim that 'reason is language, *logos*' or 'without the word, neither reason nor world'), these authors initiate a way of thinking about both language and reason that moves constantly between the extremes of universalism and relativism, rationalism and irrationalism. On the one hand, the identification of language and reason supports the attempt to transform Kant's idea of a critique of reason into the romantic idea of the essential limitations of reason (due to the limits of the natural languages that contingently developed in history). This is a powerful motive behind the critique of the Enlightment in which many authors of this tradition participate (from Hamann to Heidegger and Gadamer). On the other hand, however, the identification of language and reason also supports the attempt to preserve the universalism of Kant's conception of reason in an equally universalist conception of communicative rationality (from Humboldt to Apel and Habermas). But beyond the remarkable differences in the philosophical programs among the authors of this tradition, the common presupposition behind their identification of language and reason is the view of language as constitutive of our experience in the strict sense given by transcendental philosophy. Accordingly, language is conceived as having the transcendental power to constitute experience that Kant erroneously ascribed to an abstract, transcendental ego.

Hamann's critique of Kant can be seen in retrospect as the initiator of such a view. Hamann identifies language as the common root of sensibility and understanding, which was sought by Kant without success. In this way, he considers language as both empirical and transcendental at the same time. By conceding to language such a quasi-transcendental status, Hamann certainly disagrees with Kant's view of language. However, he does not disagree with the most basic assumptions of transcendental philosophy. Hamann is actually taking for granted Kant's transcendental idealism, namely, the idea that the conditions of possibility of experience are at the same time the conditions of possibility of the objects of experience. As a consequence of Hamann's critique, this idea is now understood to mean that the conditions of possibility of our linguistically mediated experience of the world are, at the same time, the conditions of possibility of that which is experienced in the world. Now, the claim that language does not merely mirror but actually shapes our experience of the world faces a problem completely foreign to transcendental philosophy. For the various historical languages do not seem to offer an equivalent for the Kantian transcendental ego. First of all, these languages are plural. Second, they do not allow for a sharp distinction between the empirical and the transcendental, between that which is supposed to count as valid in them *a priori* (knowledge of the language) and that which is valid *a posteriori* (knowledge of the world). Thus if languages shape our experience of the world, they do so in merely contingent and plural ways. As Hamann points out, the meaning and use of words of different languages is *a priori* arbitrary and indifferent, but *a posteriori* necessary and indispensable. Seen in this light, Hamann's critique of Kant seems to force the relativist conclusion that Humboldt will express later in one of his most famous theses, namely, that 'every language contains a peculiar world-view.'

Hamann never addressed the problem of linguistic relativism entailed in his transformation of transcendental philosophy. Moreover, given the decisively antisystematic impulse behind his critique of Kant's philosophical system, he never attempted to work out this new view of language into a systematic conception. His reflections on language are limited to more or less

isolated remarks spread throughout his writings. A much more elaborate account of this new conception of language can be found in Humboldt's work. Although Humboldt's general reflections about language do not amount to a philosophical theory of language—they are mostly confined to the introductions to empirical works in comparative linguistics—one of their specific aims is to bring about a radical break with the traditional conception of language. Humboldt is convinced that without such a break a science of language is not possible at all. Thus his writings contain a very articulated account of the essential features that distinguish the new conception of language from the received view.

In the context of criticizing the traditional conception of language in his work *Ueber den Nationalcharakter der Sprachen*, Humboldt enumerates the basic features of his own conception of language when he remarks 'that the diversity of languages is more than a mere diversity of signs, that words and their syntax simultaneously shape and determine our concepts and that, given their systematicity and their influence on knowledge and sensibility, different languages are in fact different world-views' (Humboldt 1903–36, IV, p. 420). In this brief summary, we can see the three fundamental claims that separate Humboldt's position from the received view: (a) the rejection of the view of language as a mere system of signs, as a tool for the transmission of prelinguistic thoughts or the designation of objects that exist independently of language, (b) the thesis of the identity of thought and language that justifies the critique of the instrumental conception of language, and as a consequence (c) the claim that different languages are in fact different world-views. The problem of linguistic relativism implicit in this consequence can be traced back to the very core of Humboldt's critique of the instrumental conception of language.

The traditional view of language as a mere instrument for the designation of entities independent of language is based on an assimilation of two relations that are actually irreducible to one another: the relation of *designation* between a name and an object and the relation of *satisfaction* between a predicate and the objects to which the predicate applies. From this assimilation there arises the problem of determining what the predicates actually 'designate,' a problem encountered already in the Middle Ages; the ensuing dispute over the universals offers clear testimony as to its depth. Nonetheless, this highly problematic conception of language can be considered as the ruling view from Aristotle to Kant. Humboldt seeks a decisive break with this reduction of the powers of language to their designating function, advocating a more stratified analysis of language. In contemporary terms, such an analysis would have to deal not only with the name/object distinction, but also with the distinction between concept (or class) and object. By the same token, concerning the interpretation of signs, this analysis would have to differentiate between their meaning and reference. Humboldt states this last distinction as follows: 'The word acts in such a way that the object given in it is represented by the soul. This representation must be distinguished from the object; … along with the objective part *that relates to the object*, it has a subjective part that *lies in its manner of conceiving*. … In turn, we scarcely need to mention that this division rests upon [an] abstraction; [further,] that the word can have no place outside of thought, and neither can its object, if it is non-physical.… This remains so even in the case of material objects, *since it is never the objects directly, but always only the representation of them provided by the word, that is made present in the soul*' (Humboldt 1903–36, V, p. 418).

It is important to note that by introducing the useful distinction between the referent of the word and its meaning, Humboldt also excludes *every* possibility of a pure designating relation between a name and its object, which was the paradigm for the traditional explanation of the functioning of language. He generalizes the meaning/reference distinction as applicable to all linguistic signs. Accordingly, Humboldt extends this distinction even into the realm of names, including proper names. He continues: 'The word conceives of *every concept as general*, always designating, strictly speaking, classes of reality, *even if it is a proper name*; for thus it comprehends … all the various states, with respect to time and space, of that which it designates' (Humboldt 1903–36, V, p. 419).

Thus, Humboldt counteracts the problematic reduction of predicates to mere names in the traditional view with the inverse reduction, namely, the assimilation of names to predicates. This move can be considered the systematic point from which the problem of linguistic relativism arises. If this is not immediately evident, it soon becomes clear by analyzing its implications. According to this assumption, names are actually general concepts. Instead of designating an object, they too, by strict analogy with predicates, can relate only in a mediated fashion to their referent, as if to an object falling under a concept. Humboldt explains: 'the picture of language as merely designating *objects*, already perceived in themselves, is also not sustained by examination of what language engenders as its product.… Just as no concept is possible *without language*, so also *there can be no object for the mind*, since it is only through the concept, of course, that anything external acquires full being for consciousness. But the whole *mode of percieving* things *subjectively* necessarily passes over into cultivation and the use of language. For the word arises from this very perceiving; it is a copy, not of the object in itself, but of the image thereof produced in consciousness' (Humboldt 1903–36, VII, p. 60). Seen in this light, the idealistic conclusion that Humboldt draws from this assumption seems entirely consistent: namely, that

'man [lives] with the objects … *exclusively* in the way that they are conveyed to him by language' (Humboldt 1903–36, VII, p. 60). This in turn explains why different languages are in fact different world-views. As Humboldt remarks in a similar context: 'In this way, in words of identical meaning that are found in a number of languages, there arise diverse representations of the same object, and this characteristic of the word contributes chiefly to the fact that *every language yields a particular world-view*' (Humboldt 1903–36, V, p. 420).

However, once the diversity of conceptual systems or world-views contained in the different languages is recognized, it is no longer clear how speakers of different linguistic communities can talk about the same things and thus communicate successfully. Humboldt has to admit that 'every language places *definite boundaries* upon the spirits of those who speak it, and insofar as it provides a determinate orientation, excludes others' (Humboldt 1903–36, VII, p. 621). The commensurability of different linguistic world-views does not become a problem for Humboldt because he has skeptical doubts about the possibility of translation between languages. Actually Humboldt remarks repeatedly that 'experience with translation of the most diverse languages … shows that *it is possible to express every concatenation of ideas in every language*' (Humboldt 1903–36, IV, p. 17). Instead, the problem of linguistic relativism originates in the fact that through his criticism of the traditional conception of language Humboldt has destroyed the plausibility of the traditional answer to this problem. His conception of language as world-disclosing precludes the possibility of explaining interlinguistic understanding by appealing to a world-in-itself accessible to all human beings in the same way and to which all speakers refer through the different conventions of their languages.

Humboldt is aware of this challenge and indeed tries to articulate an alternative answer to the question of interlinguistic understanding. His answer is also based on a criticism of the traditional view of language, but this time from a different angle. Humboldt opposes the reduction of language to a mere system of signs entailed in the traditional view. In the introduction to his work on the Kawi language, Humboldt expresses this opposition with the help of one of his most famous claims, namely that language is not a product (*ergon*) but an activity (*energeia*). To take this claim seriously implies transforming the traditional conception in two important respects.

First, in the sense already mentioned, Humboldt's view of language as an *activity* underscores the fact that language does not passively mirror the world but it is actually world disclosing. Language is what makes the world appear as an ordered whole. For it is through the web of linguistic concepts that what would otherwise be a disconnected flux of perceptions is transformed into an order of objects properly so called. In this sense Humboldt claims that 'the generation of language is, from the beginning, a *synthetic process* in the most genuine sense of the term, *where the synthesis creates something that did not exist before in any constituent part*' (Humboldt 1903–36, VII, p. 95). Humboldt terms this genuine synthesis 'articulation' and regards it as 'the authentic essence of language, the lever *through which language and thought are produced*, the culmination of their intimate mutual connection' (Humboldt 1903–36, VI, p. 153).

However, there is a second, more radical sense in which Humboldt sees language as an activity. According to Humboldt, the synthetic process through which both language and thought are produced is not something given once and for all, i.e., fixed through the grammar and lexicon of a language. It is rather the result of a praxis, namely the process of communication between speakers. As he remarks repeatedly: 'Language only exists in ongoing speech; grammar and lexicon are hardly comparable to their dead skeleton' (Humboldt 1903–36, VI, p. 148). Humboldt opposes the reduction of language to a mere vehicle of thought that underlies the analysis of language in logic. In this context language is considered in abstraction from the use of language in speech for the purposes of analyzing the general structure of thoughts. But Humboldt's opposition to this abstraction is not based on the obvious fact that language, in addition to being a vehicle of thought, is also a means of communication. His view is rather that language can only be a vehicle of (intersubjective) thought to the extent that it makes communication and understanding between speakers possible. Thus a proper analysis of the cognitive function of language is impossible if language is considered in isolation from its communicative function. Behind Humboldt's claim is the idea that the different communicative perspectives, generated through the system of personal pronouns present in all languages, are the condition of possibility of any intersubjectively valid thought. For these different perspectives make it possible that speakers both express their views in their irreducible singularity and achieve a common understanding through conversation as well. Thus the commesurability of linguistic world-views is not guaranteed in advance by a unique syntax or lexicon; it is actually the result of a different feature of all languages, namely its dialogical structure. It is in virtue of the pragmatic structure of speech that a free synthesis of perspectives among speakers can come about in conversation.

Humboldt is fascinated by the double nature of language as the *source* of both *generality* and *individuality*. Due to its general character language makes it possible that different speakers share identical concepts (and in this way fulfills a socializing function). But due to its expressive potential it also allows speakers to maintain their genuine individuality (i.e., it makes individualization possible). Humboldt explains: 'in language the *individualization* within a

general conformity is so wonderful, that we may say with equal correctness that the whole of mankind has but one language, and that every man has one of his own' (Humboldt 1903–36, VII, p. 51). However, there is an obvious tension in this view. On the one hand, Humboldt claims that in virtue of its intrinsic generality (the fact that we can share it), language entails the condition of possibility of understanding among speakers. It guarantees, in Humboldt's words, that: 'nobody may speak differently to another from the way in which the latter, under similar circumstances, would have spoken to him' (Humboldt 1903–36, VII, p. 47). But on the other hand, the possibility of understanding among speakers is not a mere function of a shared grammar or lexicon. Given that the only reality of language is speech, genuine understanding can only be the lucky outcome of the process of communication itself, in which different individuals express their individuality or particular world-view. For 'only in the individual does language get its last determination.... A nation as a whole has indeed the same language, but not all the individuals in it have ... exactly the same one, and if one looks more carefully, every person actually has his own' (Humboldt 1903–36, VI, p. 183). But given that speakers' linguistic differences are actually differences in world-view, it is not clear within Humboldt's account how speakers can talk about the same things despite their genuinely different linguistic world-views. Without such an explanation the possibility of understanding in dialogue remains puzzling. Humboldt has to recognize that 'nobody means by a word precisely the same as his neighbor does, and the difference, be it ever so small, vibrates, like a ripple in water, throughout the entire language. Thus all understanding is always at the same time a not-understanding, all agreement in thought and feeling at the same time a divergence' (Humboldt 1903–36, VI, p. 183). The tension present in Humboldt's writings between the roles ascribed to language in its world-disclosing and in its communicative dimensions remains a characteristic feature of the works of most of the authors of this tradition.

2. *Further Developments in the Twentieth Century*

M. Heidegger is undoubtedly the most influential defender of Humboldt's conception of language as world-disclosing in twentieth century philosophy. However, despite the deep similarities between the conceptions of language developed by both authors, Heidegger was rather critical of Humboldt's approach to language at different times during his philosophical development and for different reasons (see Heidegger 1927, 1986). The view of language as responsible for world disclosure is not articulated explicitly in Heidegger's early writings, although some features of what would be his later conception of language already appear in them, including in *Being and Time* (see Lafont 2000). Most of Heidegger's reflections on language are contained in a collection of articles that appeared in English under the title *On the Way to Language*.

As is characteristic of all the authors in this tradition, Heidegger articulates his view of language as world-disclosing in direct opposition to the traditional conception of language as a mere tool for the designation of objects that exist independently of language. He argues that the linguistic activity of naming something with a word cannot be understood as a pure relation of designation between a name and an entity. It does not consist of the fact 'that something already familiar to us is provided with a name, rather ... through this naming, the entity is first nominated as that which it is. It is in this way that it is known as an entity' (Heidegger 1944). In *The Origin of the Work of Art*, Heidegger explains: 'When language names the entity for the first time, such naming alone brings the entities to word and to appearance. This naming nominates the entity to its being from out of this being. Such saying is a projecting of the clearing, in which it is announced as what the entity comes into the open' (Heidegger 1986, pp. 59–60). In *On the Way to Language* he expresses the same idea in a much more provocative way using a line of Stefan George's poem, namely, that 'there is no thing where the word is lacking.' Heidegger explains: 'The thing is a thing only where the word is found for the thing. Only in this way *is* it.... The word alone supplies being to the thing, [for] ... something only *is*, where the appropriate word names something as existing and in this way *institutes* the particular entity *as such*.... The being of that which is resides in the word. For this reason, the following phrase holds good: language is the house of being' (Heidegger 1986, pp. 164–6).

As Humboldt had already argued before, entities can only be identified as such once they are linguistically categorized. It is in this sense that language is responsible for world-disclosure: language determines our possible experience with entities and thus determines in advance what kind of world is disclosed to us. With regard to the world-disclosing power of language, Heidegger basically agrees with Humboldt. However, on this very same basis he criticizes Humboldt's view of language as an activity. As mentioned above, Humboldt tried to conceive the production of a linguistic world-view as a result of the human activity of speech. This would explain how speakers can synthesize their different world-views and revise them through dialogue. However, as Heidegger argues, in order for a dialogue to be possible at all, it is first necessary that one and the same world be disclosed to all speakers. As he had already claimed in *Being and Time*, 'only he who already understands can listen.' Heidegger interprets Humboldt's emphasis on the communicative dimension of language as just a remi-

niscence of the instrumental conception of language. Heidegger directs one of his most provocative claims against any attempt to transfer language's power of world disclosure to the human activity of speech. He writes: 'Man acts as though he were the shaper and master of language, while in fact language remains the mistress of man … For strictly, it is language that speaks. Man first speaks when, and only when, he responds to language by listening to its appeal' (Heidegger 1954, p. 184).

As a result of this extremely idealistic conception of language, Heidegger sees world disclosure, which is anchored in the language of a specific people or culture, as the most significant event of their historical development (see Heidegger 1980). Based on this idea, Heidegger interprets the history of Western culture as the fateful development of the understanding of being as presence, which is disclosed in Western languages and may bring this culture towards its own destruction. From a Humboldtian point of view, the reification of language implicit in Heidegger's view seems just a consequence of ignoring that language is not a product but an activity, i.e., that language is nothing other than the communicative activity between human beings. However, it is hard to question Heidegger's criticism of this Humboldtian claim, given that for both authors language has the power to constitute our experience in the strict sense set by transcendental philosophy. So long as this presupposition is not questioned, achieving the balance sought by Humboldt between the world disclosing and the communicative dimensions of language remains an unresolved task in this tradition.

H.-G. Gadamer, Heidegger's most influential student in contemporary German philosophy, tries to achieve this balance in his main work *Truth and Method*. In this work Gadamer articulates the essential features of the approach to philosophy that he calls 'philosophical hermeneutics.' At the core of this approach is an analysis of hermeneutic experience, i.e., of the interpretative relationship that human beings entertain with each other and with their symbolic products (e.g., texts, works of art, and the like). To support his account of hermeneutic experience he appeals to the conception of language developed in the Hamann–Herder–Humboldt tradition, to which he wishes to contribute with his own reflections on language. He uses the Humboldtian model of dialogue between speakers who try to reach agreement about something in the world and generalizes it as the appropriate model for describing any hermeneutic experience whatsoever (e.g., the understanding of canonical texts, works of art, and any other symbolic products by an interpreter, most significantly in the context of the human sciences). In this respect, Gadamer explicitly focuses on the communicative dimension of language. However, he looks at the Humboldtian model of dialogue with Heideggerian eyes.

Gadamer emphasizes that a genuine dialogue by its very nature is not just the product of the speakers' activity. First of all, as Gadamer remarks, 'no one knows in advance what will come out of a conversation. Understanding or its failure is like an event that happens to us' (Gadamer 1960, p. 383). But more importantly, a conversation is only possible if the participants share a linguistically disclosed world. Thus, a shared world disclosure, i.e., a common tradition, is the precondition for any understanding or agreement that speakers try to bring about in conversation. Although Gadamer opposes, as much as did Humboldt, the thesis of the incommensurability of different linguistic world disclosures, he has never seriously confronted the challenge of explaining how intercultural understanding is possible, that is, how a dialogue between participants who do not belong to the same tradition and thus do not share the same linguistic world disclosure is possible at all.

More recently, K.-O. Apel and J. Habermas have tried to work out Humboldt's and Gadamer's model of dialogue into a systematic theory of communication (see Apel 1994, Habermas 1981). Both authors identify in the communicative function of language a specific kind of rationality (communicative rationality) that allows participants in communication to reach a rational agreement about something in the world. Although they share the view of language as world disclosing that characterizes the continental tradition, their approaches introduce a strong dichotomy between form and content that aims to conceive rational understanding as a universal possibility (and thus to avoid the problem of incommensurability between different linguistic world disclosures). In clear opposition to Heidegger and Gadamer's claim that understanding is only possible on the basis of a factual agreement among speakers with a shared linguistic world disclosure, Apel and Habermas claim that understanding depends only on a 'counterfactual agreement' that all speakers share just in virtue of their communicative competence. This agreement is based on *formal* presuppositions and thus it does not depend on a shared content or shared world disclosure among the participants in conversation. A rational reconstruction of these formal presuppositions of communication is the core of the analysis of language that these authors offer in their respective approaches. Apel understands this analysis as a transformation of transcendental philosophy within the linguistic paradigm and thus calls it 'transcendental semiotics.' Habermas disagrees with Apel's claim that the formal presuppositions of communication have a transcendental status in the strict Kantian sense; thus he prefers the designation of 'formal pragmatics' for his approach. But beyond these methodological differences their reconstructions of the formal presuppositions of communication are very similar.

According to both approaches, speakers who want to reach an agreement about something in the world

have to presuppose the truth of what they are saying, the normative rightness of the interaction they are establishing with the hearer through their speech acts, and the sincerity or truthfulness of their speech acts. Complementary to these three validity claims (truth, normative rightness, and truthfulness), speakers share the notion of a single objective world that is identical for all possible observers. This is just a *formal* notion that is freed of all specific content. It is important to note that this presupposition does not correspond to the naïve belief in a world-in-itself accessible to all speakers that characterizes the traditional conception of language. As Habermas argues, if speakers had such a naïve belief they would identify the *contents* of their respective linguistic world-views with the assumed world-order itself. But with such a dogmatic attitude they would not admit the possibility that in case of disagreement the claims raised by other speakers may turn out to be right about the way the world is. In order for a rational discussion to be possible at all, speakers have to be able to adopt a hypothetical attitude vis-à-vis their own beliefs about the world. This is only possible if they distinguish, however counterfactually, between the assumed world-order itself and their respective claims about how the world is. Seen in this light, the formal presupposition of a single objective world is just a consequence of the universal claim to validity built into the speakers' speech acts. It is just an expression of the communicative constraint that makes rational criticism and mutual learning possible, namely, that from two opposed claims only one can be right. Thus the formal notion of world and the three universal validity claims build a system of coordinates that guides the interpretative efforts of the participants in communication towards a common understanding, despite their differences in beliefs or world-views.

It is an open question whether this proposal is actually successful in explaining the possibility of interlinguistic understanding, as much as it is open whether any current theory within contemporary philosophy of language is so successful. However, Apel's and Habermas' approaches are intentionally designed to meet this challenge in a way unprecedented in prior continental philosophy of language. Equally unprecedented is the scope and sophistication of the philosophical analysis of language and communication that these authors offer. This is in part due to the reception and creative integration in their own work of most of the approaches developed within contemporary philosophy of language across the borders of the different philosophical traditions.

Language: Dependency

1. Notion of Linguistic Dependency

A sentence is organized by syntagmatic relations holding between its words; these relations are involved in arranging words into strings, supplying them with appropriate prosody and giving them a necessary form. (Syntagmatic relations can be contrasted with paradigmatic relations holding between words in the language and involved in choosing semantically/syntactically appropriate words.)

The main type of syntagmatic relations is dependency: *B depends on A* if *A* controls *B*, i.e., determines *B*'s presence, position or form; we also say that *A governs B*. ('Depend on' and 'govern' are converse relations, as 'be a parent of' ~ 'be a child of.') In sentence (1)

(1) *The boy cares for his mother*.

boy depends on *care*: as the Subject, *boy* must precede the Main Verb [MV], i.e., *cares*; *for* also depends on *cares*: (if MV were *thinks* or *likes*, the preposition should be *of* or *nothing*), and *for* must follow *care*; *mother* depends on *for*, since *mother* follows *for*; etc. Dependency is symbolized with an arrow pointing from the governor to the dependent: *boy* ← *cares*, *care* → *for*, *for* → *mother*. It is an anti-reflexive and anti-symmetrical binary relation $\mathscr{D}$ ['depend on']; $\mathscr{D}$ holds between *A* and *B* such that:

no *A* can depend on itself: $\neg A\mathscr{D}A$, i.e., $A\mathscr{D}A$ is always false [anti-reflexivity];

if *B* depends on *A*, then *A* cannot depend on *B*: $B\mathscr{D}A$ entails $\neg A\mathscr{D}B$ [anti-symmetry].

Some syntagmatic relations are not dependencies, for instance, coreferentiality relation: in sentence (1), *boy* and *his* have the same referent; this relation is reflexive and symmetrical.

In what follows, only dependencies are considered.

2. Three Major Types of Linguistic Dependency

Speaking about dependency, people often mean just syntactic dependency. However, this is not the only dependency between wordforms of a sentence. Three types of linguistic dependency are distinguished: semantic, syntactic, and morphological (Mel'čuk 1981, 1988, p. 105).

Figure 1
The SemS of the sentence
I ordered him to go

Figure 2
The SemS of the sentence
The boy cares for his mother

2.1 Semantic Dependency [Sem-$\mathscr{D}$]

2.1.1 Definition of semantic dependency The wordform $\mathbf{w}_2$ semantically depends on the wordform $\mathbf{w}_1$ in the given sentence ($\mathbf{w}_1$–**sem** → $\mathbf{w}_2$), if the meaning of $\mathbf{w}_1$ is a predicate and the meaning of $\mathbf{w}_2$ is an argument of it: '$\mathbf{w}_1$' ('$\mathbf{w}_2$').

A Sem-dependent of a wordform is called its Sem-Actant.

2.1.2 Properties of semantic dependency: As all $\mathscr{D}$s, Sem-$\mathscr{D}$ is anti-reflexive and anti-symmetrical. As for transitivity, Sem-$\mathscr{D}$ is neither transitive nor anti-transitive: in most cases, $\mathbf{w}_1$–**sem** → $\mathbf{w}_2$ and $\mathbf{w}_2$–**sem** → $\mathbf{w}_3$ entail neither $\mathbf{w}_1$–**sem** → $\mathbf{w}_3$, nor ⌜($\mathbf{w}_1$–**sem** → $\mathbf{w}_3$). Thus, from *I saw* [$\mathbf{w}_1$] *Alan's* [$\mathbf{w}_3$] *wife* [$\mathbf{w}_2$] it does not follow that I saw Alan, but it does not follow, either, that I did not. However, for some predicates, Sem-$\mathscr{D}$ is transitive: $\mathbf{w}_1$–**sem** → $\mathbf{w}_2$ and $\mathbf{w}_2$–**sem** → $\mathbf{w}_3$ entail $\mathbf{w}_1$–**sem** → $\mathbf{w}_3$, e.g., '[to] order' in *I order* [$\mathbf{w}_1$] *him* [$\mathbf{w}_3$] *to go* [$\mathbf{w}_2$] (see the Sem(antic) S(tructure) in Fig. 1). In other cases, Sem-$\mathscr{D}$ is anti-transitive: in *I wrote* [$\mathbf{w}_1$] *down Alan's* [$\mathbf{w}_3$] *address* [$\mathbf{w}_2$], $\mathbf{w}_1$–**sem** → $\mathbf{w}_2$ and $\mathbf{w}_2$–**sem** → $\mathbf{w}_3$ entail ⌜($\mathbf{w}_1$–**sem** → $\mathbf{w}_3$).

Sem-$\mathscr{D}$s are *labeled*: a Sem-$\mathscr{D}$ arc carries a symbol identifying the corresponding Sem-Actant.

Sem-$\mathscr{D}$ does not presuppose the uniqueness of the governor: a wordform can semantically depend simultaneously on several other wordforms, as shown by Figs. 1 and 2.

Sem-$\mathscr{D}$ is universal: it is present in all languages, appears in all sentences of a language, and embraces all full wordforms of a sentence. In a sentence, Sem-$\mathscr{D}$s form a connected structure (there is a Sem-'path' between any wordform and any other wordform): a network (see Figs. 1 and 2).

2.2 *Syntactic Dependency* [Synt-$\mathscr{D}$]

Sem-$\mathscr{D}$ is mentally perceived by the speakers, and Morph-$\mathscr{D}$ is perceived physically; but Synt-$\mathscr{D}$, which mediates between them, is not directly perceivable. It is an abstract construct that must be specified by some formal criteria.

2.2.1 Criteria for Synt-$\mathscr{D}$: To establish a Synt-$\mathscr{D}$ relation between wordforms $\mathbf{w}_1$ and $\mathbf{w}_2$ in a sentence three groups of criteria are needed: (a) criteria for Synt-connectedness (= for the presence of a Synt-$\mathscr{D}$); (b) criteria for Synt-dominance (= for the orientation of the Synt-$\mathscr{D}$); and (c) criteria for the specific type of the Synt-$\mathscr{D}$.

(a) *Criteria A: Synt-Connectedness*

For $\mathbf{w}_1$ and $\mathbf{w}_2$ to be syntactically directly linked ($\mathbf{w}_1$–**synt**–$\mathbf{w}_2$), both Criteria A1 and A2 must be satisfied.

Criterion A1: Linear arrangement of wordforms

Wordforms $\mathbf{w}_1$ and $\mathbf{w}_2$ have a direct Synt-$\mathscr{D}$ link only if the linear position of one must be specified with respect to the other.

'The position of $\mathbf{w}_1$ is specified with respect to $\mathbf{w}_2$' means that $\mathbf{w}_1$ precedes $\mathbf{w}_2$, follows it, or else can precede or follow it (optionally or under some conditions). If the manner adverbial can precede or follow the verb it modifies, the possible positions of the adverbial are still specified with respect to the verb, rather than the other way around.

Criterion A2: Potential prosodic unity

Wordforms $\mathbf{w}_1$ and $\mathbf{w}_2$ can have a direct Synt-$\mathscr{D}$ link only if:

(1) Either $\mathbf{w}_1$ and $\mathbf{w}_2$ can form a phrase in $\mathscr{L}$ [general case]:

e.g., N + V, N + ADJ, V + N, PREP + N, ADV + ADJ, NUM + N, etc.

(2) Or the $\mathbf{w}_1$ and $\mathbf{w}_2$ cannot form a phrase, but $\mathbf{w}_1$, $\mathbf{w}_2$ and a set of wordforms $\{\mathbf{w}_i\}$ can, such that in this phrase, $\mathbf{w}_1$ is the Synt-head and $\mathbf{w}_2$ and $\{\mathbf{w}_i\}$ also form a phrase in which $\mathbf{w}_2$ is the Synt-head [special case]:

e.g., *escape* [$\mathbf{w}_1$] *from* [$\mathbf{w}_2$] *many problems* [the set $\{\mathbf{w}_i\}$], where *escape from many problems* is a phrase, with *escape* as the Synt-head; *from many problems* is also a phrase in which *from* is the Synt-head; therefore, *escape*–**synt** → *from*.

(b) *Criteria B: Synt-Dominance*

In a phrase $\mathbf{w}_1$–**synt**–$\mathbf{w}_2$, one wordform is the Synt-governor of the other (and the Synt-head of the phrase). The Synt-governor is the wordform that determines to a greater extent than the other wordform (its Synt-dependent) properties of the phrase: syntactic, morphological, and semantic.

Criterion B1: The Synt-valency of the phrase

The passive (Synt-)valency of a phrase is the set of syntactic constructions of $\mathscr{L}$ in which this phrase can appear.

In the phrase $\mathbf{w}_1$–**synt**–$\mathbf{w}_2$, the wordform $\mathbf{w}_1$ is the Synt-governor of $\mathbf{w}_2$ if the passive valency of the whole phrase is determined to a greater extent by the valency of $\mathbf{w}_1$ than by that of $\mathbf{w}_2$.

The Synt-head of a phrase determines the possible external syntactic links of the phrase more than any other of its wordforms.

(i) The passive valency of the phrase *for decades* is fully determined by the preposition; therefore, *for*–**synt** → *decades*.

(ii) A phrase like *has escaped* or *does not escape* plays the same Synt-role as *has/does* rather than that of *escaped* or *escape*; therefore, *has*–**synt** → *escaped*, does–**synt** → *escape*.

Criterion B2: Morphological links between the wordforms of the phrase and its external context

In the phrase $\mathbf{w}_1$–**synt**–$\mathbf{w}_2$ in which the passive valency does not allow us to establish the Synt-governor (because the valencies of $\mathbf{w}_1$ and $\mathbf{w}_2$ are identical) $\mathbf{w}_1$ is the Synt-governor of $\mathbf{w}_2$ if $\mathbf{w}_1$ controls the inflection of wordforms external to the phrase or if $\mathbf{w}_1$'s inflection is controlled by such wordforms.

The Russian phrase *jubka-štany* (literally, 'skirt-pants') does not allow for the application of Criterion B1 (both wordforms have the same passive valency); but Criterion B2 singles out *jubka* as the Synt-governor: *èt**a*** [FEM.SG] *jubka-štany byl**a*** [FEM.SG] … 'this skirt-pants was …', where the external agreement is with *jubka* [FEM.SG], and not with *štany* [PL] ⟨**èt**i*** *jubka-štany byl**i*** …⟩; therefore, *jubka*–**synt** → *štany*.

Criterion B3: The semantic content of the phrase

In the phrase $\mathbf{w}_1$–**synt**–$\mathbf{w}_2$ in which neither the Synt-valency nor the morphology allows us to establish the Synt-governor $\mathbf{w}_1$ is the Synt-governor of $\mathbf{w}_2$ if $\mathbf{w}_1$–**synt**–$\mathbf{w}_2$ means 'a kind/instance of $\mathbf{w}_1$' rather than 'a kind/instance of $\mathbf{w}_2$.'

(i) In *jam sandwich*, the Synt-governor is *sandwich*, because 'jam sandwich refers to a kind of sandwich, rather than to a kind of jam' (Hudson 1990).

(ii) In Chinese *shí bàng ròu* 'ten pounds [of] meat', *ròu* 'meat' is the Synt-governor: *shí bàng ròu* refers to meat, not to pounds; therefore, *shí* ← **synt**–*bàng* ← **synt**–*ròu* [both wordforms *bàng* and *ròu* are nouns, and Chinese has no inflection].

The Synt-governor is thus the syntactic category determinant, or (if there is no syntactic determinant) the morphological behavior determinant, or (if both syntactic and morphological determinants are absent) the semantic content determinant (Zwicky 1993, p. 4).

Most approaches dealing with Synt-$\mathscr{D}$s require concord between these three properties, i.e., between Criteria B1–B3. In sharp contrast, we do not expect such a concord. Only Criterion B1 is genuinely syntactic; B2 is morphological, and B3 semantic. And it is known that the orientations of Sem-$\mathscr{D}$, Synt-$\mathscr{D}$ and Morph-$\mathscr{D}$ between two wordforms can differ (as shown in Sect. 3); therefore, these criteria must be expected often to be in conflict. Criteria B1–B3 form a hierarchy: B1 > B2 > B3. If B1 is applicable, its indication is sufficient. Only if it is not applicable, B2 applies, but only in $\mathscr{L}$ having inflection and only for $\mathbf{w}_1$ and $\mathbf{w}_2$ with different morphological properties. Otherwise, B3 applies. Therefore, Criteria B are never applied simultaneously and thus cannot contradict each other. For Criteria B to be satisfied, at least one of Criteria B1–B3 must be satisfied.

The criteria for the orientation of Synt-$\mathscr{D}$ ('Head-vs.-Dependent' problem) are discussed in Zwicky 1985, 1993, Hudson 1987, 1990, pp. 106–7, Mel'čuk 1988, and in Corbett et al. 1993.

(c) *Criteria C: Labeled Synt-Dependencies*

For each pair of wordforms $\mathbf{w}_1$–**synt** → $\mathbf{w}_2$ which are syntactically linked in a particular direction, the type of the Synt-$\mathscr{D}$ relation that links them must be established. In order to represent the SyntS of utterances, different types of Synt-$\mathscr{D}$ are needed. Thus, I ← **synt**–LOVE–**synt** → YOU does not distinguish between 'I love you' and 'You love me'; [JOHN] I ← **synt**–SEND–**synt** → YOU can be implemented as 'John sends me to you' or 'John sends you to me'; etc. In all such cases, different types of Synt-$\mathscr{D}$s, or different Syntactic Relations [SyntRels], are needed:

I ← $\mathbf{r}_1$–LOVE–$\mathbf{r}_2$ → YOU, [JOHN] I ← $\mathbf{r}_2$–SEND–$\mathbf{r}_3$ → YOU, …

SyntRels are *labeled*, and the label **r** of a SyntRel refers to a family of syntactic constructions that implement the SyntRel **r**. Thus, consider the label '**subj(ectival**' of the SyntRel that appears in Russian phrases V_{fin} [$\mathbf{w}_1$]–**subj** → N [$\mathbf{w}_2$] (*Mal'čik prixodit/ prišël* vs. *Devočka prixodit/prišla* 'The boy/girl comes/ came'). This label identifies a set of Synt-rules that make the verb $\mathbf{w}_1$ agree with the noun $\mathbf{w}_2$ in person and number (in the present/future) and in number and gender (in the past/subjunctive); these rules also position $\mathbf{w}_2$ with respect to $\mathbf{w}_1$.

In phrases $\mathbf{w}_1$–**r[?]** → $\mathbf{w}_2$, the Synt-$\mathscr{D}$ that links the two wordforms can be labeled **r** only if it satisfies the following three criteria C; if one of them is not satisfied, the presumed SyntRel **r[?]** must be split in different SyntRels.

Criterion C1: Absence of semantic contrast [**w**(L) is a wordform of lexeme L]

A SyntRel must not describe two phrases

$\mathbf{w}_i(L_1)$–**synt** → $\mathbf{w}_j(L_2)$ and $\mathbf{w}_m(L_1)$–**synt** → $\mathbf{w}_n(L_2)$ which contrast semantically ['$\mathbf{w}_i(L_1) \rightarrow \mathbf{w}_j(L_2)$' ≠ '$\mathbf{w}_m(L_1) \rightarrow \mathbf{w}_n(L_2)$'] and differ formally by purely syntactic means of expression (i.e., by word order, syntactic prosody, or syntactic grammemes).

The construction Rus. DESJAT′ ← **r[?]**–DOLLAR has two different implementations with different meanings:

desjat′ dollarov '10 dollars' vs. *dollarov desjat′* 'approximately 10 dollars';

the formal difference here is purely syntactic: word order; therefore, the presumed SyntRel **r** must be split in two different SyntRels:

DESJAT′ ← **quantitative**–DOLLAR ⇔ *desjat′ dollarov*

DESJAT′ ← **approx-quantit**– DOLLAR ⇔ *dollarov desjat′*

Criterion C1 corresponds to the '*minimal pair test*,' widely used in linguistics.

Criterion C2: Syntactic substitutability

Substitutability of syntactic subtrees for establishing SyntRels was proposed by Kunze (1975, p. 235) and is known as the *Kunze property*. Here, a weaker version of it is used: the *quasi-Kunze property*.

The quasi-Kunze property [$\Delta_{(\Xi)}$ is a subtree with the top node of the class Ξ]

A SyntRel **r** has the quasi-Kunze property if, and only if, there exists in $\mathscr{L}$ a part of speech X such that for any Synt-configuration L–**r** → $\Delta_{(Y)}$, replacing $\Delta_{(Y)}$ by $\Delta_{(x)}$ (but not necessarily vice versa!) in any Synt-structure does not affect its syntactic well-formedness.

Any SyntRel **r** must possess the quasi-Kunze property.

In phrases *have*–**r[?]** → *been* and *be*–**r[?]** → *going* the presumed SyntRel **r** does not possess the quasi-Kunze property: **have*–**r[?]** → *going* and **be*–**r[?]** → *been*; therefore, there are two different SyntRels:

HAVE–**perfect-auxiliary** → BEEN and BE–**progressive-auxiliary** → GOING

Criterion C2 is a particular case of what is known as the '*substitution test*:' it deals with the substitution of subtrees that hang on the same SyntRel **r**.

Criterion C3: Repeatability with the same Synt-governor

Any **r** of language $\mathscr{L}$ can be either non-repeatable or unlimitedly repeatable.

Non-repeatable SyntRels

A SyntRel **r** is non-repeatable if, and only if, no more than one branch labeled **r** can start from any governor.

Actantial SyntRels, which describe the Subjects, the Objects and the Complements, are non-repeatable. (In some languages, an actant can be duplicated by a resumptive pronoun, but such duplication is not considered as repeatability: it has a completely grammaticalized character.)

(Unlimitedly) Repeatable SyntRels

A SyntRel **r** is (unlimitedly) repeatable if, and only if, several branches labeled **r** can start from a governor.

The **modificative** and **circumstantial** SyntRels in English are unlimitedly repeatable; so is the **obl(ique)-**

obj(ectival) SyntRel. For a repeatable SyntRel **r** the number of branches labeled **r** starting from a governor is theoretically unlimited, although practically it is limited by pragmatic considerations or the properties of governors (e.g., by their Government Pattern, with the **obl-obj** SyntRel).

Criterion C3

Any SyntRel **r** must be unlimitedly repeatable or non-repeatable.

In Persian, expressions of the following type are extremely widespread:

Rāmin + rā ← **r[?]**–*kard*–**r[?]** → *bedār*,

Ramin DirO made awakening [Noun]

'[He] awoke Ramin.'

They include verbal collocations like *bedār kard* 'awakening make' = 'awake' or *dars dad*, (literally, 'lesson give' = 'teach') and seem to contain a DirO (*bedār* or *dars*), but behave as transitive verbs and take a 'genuine' DirO (with the suffix **-rā**). The presumed SyntRel **r[?]** in such expressions would be limitedly repeatable—just twice. Therefore, there are two different SyntRels:

RĀMIN ← **dir-obj**–KARD–**quasi-dir-obj** → BEDĀR.

Criterion C3 corresponds to the '*co-occurrence test*:' in morphology, an element of a morphological category is either non-repeatable (tense or number in English or French) or unlimitedly repeatable (the causative in Turkish).

The SyntRels of a language form a systematic inventory, just like phonemes or grammemes; Criteria C1–C3 are part of a methodology for establishing SyntRels' inventories.

Now the definition of Synt-$\mathscr{D}$ can be formulated:

The wordform $\mathbf{w}_2$ *syntactically depends* on the wordform $\mathbf{w}_1$ via SyntRel **r** ($\mathbf{w}_1$–**r** → $\mathbf{w}_2$) if Criteria A, B and C are satisfied for this pair of wordforms and **r**.

2.2.2 Properties of syntactic dependency: Like Sem-$\mathscr{D}$, Synt-$\mathscr{D}$ is anti-reflexive and anti-symmetrical: ⌜($\mathbf{w}_1$–**synt** → $\mathbf{w}_1$); $\mathbf{w}_1$–**synt** → $\mathbf{w}_2$ entails ⌜ ($\mathbf{w}_1$ ← **synt**–$\mathbf{w}_2$). Anti-symmetry means that $\mathbf{w}_1$ cannot be the Synt-governor of $\mathbf{w}_2$ and simultaneously have $\mathbf{w}_2$ as its own Synt-governor. In addition, Synt-$\mathscr{D}$ is anti-transitive: $\mathbf{w}_1$–**synt** → $\mathbf{w}_2$ and $\mathbf{w}_2$–**synt** → $\mathbf{w}_3$ (in one sentence) entail ⌜ ($\mathbf{w}_1$–**synt** → $\mathbf{w}_3$). This fact underlies the principle of unique Synt-governor, see below.

Synt-$\mathscr{D}$ is labeled: to properly represent *Mary loves John*, in the phrases *Mary* ← $\mathbf{r}_1$–*loves* and *John* ← $\mathbf{r}_2$–*loves* the SyntRels $\mathbf{r}_1$ and $\mathbf{r}_2$ must be different; otherwise, the semantic contrast will not be preserved in the Syntactic Structure [SyntS].

Synt-$\mathscr{D}$ presupposes the uniqueness of the governor: a wordform can syntactically depend only on one other wordform (or it can be independent, as is the top node of a SyntS).

Synt-$\mathscr{D}$ is universal: it is present in all languages, appears in all sentences of a language, and embraces all wordforms of a sentence. In a sentence, Synt-$\mathscr{D}$s form a connected structure: a (dependency) tree.

Figure 3
SyntS of sentence (1)

A dependency tree is a connected graph in which each node but one depends on only one node (= the uniqueness of the Synt-governor), while one and only one node does not depend on anything—the top node, or the root, of the SyntS. The linear order of the nodes in a SyntS is not defined; the $\mathscr{D}$-description consistently separates the Synt-links between wordforms and their linear order. (During sentence production, word order is computed by syntactic rules of $\mathscr{L}$ on the basis of Synt-$\mathscr{D}$s.) See the SyntS of sentence (1) in Fig. 3.

2.3. *Morphological Dependency* [*Morph–$\mathscr{D}$*]

2.3.1 A definition of morphological dependency: The wordform $\mathbf{w}_2$ morphologically depends on the wordform $\mathbf{w}_1$ according to the inflectional category C ($\mathbf{w}_1$–**morph/C** → $\mathbf{w}_2$) if at least one grammeme **g** of $\mathbf{w}_2$, such that $\mathbf{g} \in$ C, is determined by $\mathbf{w}_1$.

2.3.2 Properties of morphological dependency: Like Sem-$\mathscr{D}$ and Synt-$\mathscr{D}$, Morph-$\mathscr{D}$ is anti-reflexive: the inflection of a wordform cannot be determined by the wordform itself. But in contrast to Sem-$\mathscr{D}$ and Synt-$\mathscr{D}$, Morph-$\mathscr{D}$ is neither symmetrical, nor anti-symmetrical. (This does not contradict the notion of dependency because the anti-symmetry of Morph-$\mathscr{D}$ is violated only for different categories $C_1 \neq C_2$.) For agreement of ADJ with an N or for government of the case of N by V/PREP, Morph-$\mathscr{D}$ is anti-symmetrical: $\mathbf{w}_1$–**morph** → $\mathbf{w}_2$ entails ⌜ ($\mathbf{w}_1$ ← **morph**-$\mathbf{w}_2$). However, in some cases Morph-$\mathscr{D}$ is symmetrical (i.e., reciprocal): $\mathbf{w}_2$ is inflected, for the category C_1, as a function of $\mathbf{w}_1$, and, at the same time, $\mathbf{w}_1$ is inflected, for a different category C_2, as a function of $\mathbf{w}_2$, so that $\mathbf{w}_1$–**morph** → $\mathbf{w}_2$ entails $\mathbf{w}_1$ ← **morph**–$\mathbf{w}_2$; as a result $\mathbf{w}_1$ ← **morph** → $\mathbf{w}_2$ obtains, with $C_1 \neq C_2$.

In Russian:
dv + ***a*** *stol* + ***a*** 'two tables'
two MASC.NOM table(MASC) SG.GEN
The noun *stola* morphologically depends for its singular and genitive case on *dva*, while *dva* depends on *stola* for its masculine gender; for example, *pjat′ stol* + ***ov*** [PL.GEN] 'five tables' or *dvadcat′ odin stol* + ∅ [SG.NOM] (literally, 'twenty-one table'), but *dv* + ***e*** [FEM.NOM] *krovati* 'two beds'.

Like Sem-$\mathscr{D}$ and Synt-$\mathscr{D}$, Morph-$\mathscr{D}$ must be *labeled*: to fully specify a Morph-$\mathscr{D}$, we have to indicate the inflectional category C of $\mathbf{w}_2$ whose grammeme is imposed by $\mathbf{w}_1$.

Morph-$\mathscr{D}$ does not presuppose the uniqueness of the governor: a wordform can morphologically depend simultaneously on several wordforms—for different inflectional categories.

Morph-$\mathscr{D}$ is not universal: it is completely absent from many languages (e.g., Vietnamese); in a language where it exists it is not present in all sentences; and in a sentence where it is present it does not necessarily embrace all wordforms. Morph-$\mathscr{D}$s do not form, generally speaking, a connected structure in a sentence.

3. *Possible Combinations of the Three Types of Linguistic Dependency*

The semantic, syntactic, and morphological dependencies are logically autonomous and can co-occur in fourteen logically possible combinations (Mel'čuk 1981, 1988, pp. 118–28, Nichols 1986).

CASE 1: $\mathbf{w}_1$ $\mathbf{w}_2$, i.e., no syntagmatic dependency between two wordforms. Example: *the* and *mother* in sentence (1).

CASE 2: $\mathbf{w}_1$**–sem→** $\mathbf{w}_2$, i.e., Sem-$\mathscr{D}$, unsupported by any Synt-$\mathscr{D}$ or Morph-$\mathscr{D}$.

Example: In *Alan had a drink* the wordforms *Alan* and *drink* are semantically directly related, ['drink'–**sem→** 'Alan'], yet there is no Synt-$\mathscr{D}$ or Morph-$\mathscr{D}$ between them.

CASE 3: $\mathbf{w}_1$**–synt→** $\mathbf{w}_2$, i.e., Synt-$\mathscr{D}$ without any Sem-$\mathscr{D}$ or Morph-$\mathscr{D}$.

(a) In Japanese, a quantifier, while bearing semantically on the Subject as in '**Five** people were injured', depends syntactically on the verb, with which it has neither semantic nor morphological links:
Sono ziko + *de* *keganin* + *ga*
this accident LOC injured.people SUBJ(ective)
GO + NIN *deta*
five CLASS(ifier) emerged
'In this accident, five people were injured.'

(b) In English, a measure noun used as a DirO depends syntactically on the verb, but has no semantic or morphological link with it (semantically, the verb dominates the noun quantified):
John bought–**synt** → [*five*] ***kilos*** [*of potatoes*].

CASE 4: $\mathbf{w}_1$**–morph→** $\mathbf{w}_2$, i.e., Morph-$\mathscr{D}$, without any Sem-$\mathscr{D}$ or Synt-$\mathscr{D}$.

In Alutor, a verb of perception that governs a DirO clause can show object agreement either with the Subject or with the DirO of this clause (depending on their communicative roles):
(a) *Qəmavə* + *nak* *na* + *laʕu* + *tkəni* + *γət*
Qamav SG.LOC 3 SG.SUB see PRES 2SG.OBJ
γən + *annə*
you.SG INSTR
∅ + *kəlγatətkə* + *na* + *wwi* *qura* + WWI
2SG.SUB harness 3.OBJ PL reindeer PL
'Qamav sees that YÓU are harnessing the reindeer.'
(b) *Qəmavə* + *nak* *π* + *laʕu* + *tkəni*
Qamav SG.LOC 3 SG.SUB see PRES
+ NINA + WWI
3.OBJPL
γən + *annə* ∅ + *kəlγatətkə* + *na*
you.SG INSTR 2SG.SUB harness 3.OBJ
+ *wwi* *qura* + WWI
PL reindeerPL
'Qamav sees that YÓU are harnessing the REINDEER'.

CASE 5: $\mathbf{W_1} \xrightarrow{\textbf{Sem}} \mathbf{W_2}$, $\mathbf{W_1} \xrightarrow{\textbf{Synt}} \mathbf{W_2}$ i.e., Sem-$\mathscr{D}$ and Synt-$\mathscr{D}$ oriented the same way, with no Morph-$\mathscr{D}$.

Example: objects/complements in caseless languages, cf. *for* and *mother* in (1).

CASE 6: $\mathbf{W_1} \xrightarrow{\textbf{Sem}} \mathbf{W_2}$, $\mathbf{W_1} \xleftarrow{\textbf{Synt}} \mathbf{W_2}$ i.e., Sem-$\mathscr{D}$ and Synt-$\mathscr{D}$ oriented the opposite ways, again with no Morph-$\mathscr{D}$.

Example: an adjective and the modified noun in ADJ + N phrase in a language with invariable adjectives, as in *new* and *areas* in *new areas*.

CASE 7: $\mathbf{W_1} \xrightarrow{\textbf{Sem}} \mathbf{W_2}$, $\mathbf{W_1} \xrightarrow{\textbf{Morph}} \mathbf{W_2}$ i.e., Sem-$\mathscr{D}$ and Morph-$\mathscr{D}$, oriented the same way, with no Synt-$\mathscr{D}$.

Example: a pronominal clitic which semantically and morphologically depends on an infinitive, while syntactically it depends on a higher verb, which 'hosts' it cf.:

Sp. ***Le*** ← **synt**–*quisiera poder enviar este libro*, [literally, 'To-him [I] would-like to-be-able to-send this book.'

CASE 8: $\mathbf{W_1} \xrightarrow{\textbf{Sem}} \mathbf{W_2}$, $\mathbf{W_1} \xleftarrow{\textbf{Morph}} \mathbf{W_2}$ i.e., Sem-$\mathscr{D}$ and Morph-$\mathscr{D}$, oriented the opposite ways, with no direct Synt-$\mathscr{D}$.

Example: an attributive adjective as in French, cf.:
Elle semblait ***fatiguée*** 'She seemed tired';

here, semantically *elle* depends on *fatiguée* ['fatigué'–**sem** → 'elle'], but morphologically *fatiguée* depends on *elle* for its singular and feminine; syntactically, the two are not directly linked.

CASE 9: 
i.e., Synt-$\mathscr{D}$ and Morph-$\mathscr{D}$ oriented the same way, with no Sem-$\mathscr{D}$.

(13) A measure noun as a DirO in a language with cases depends syntactically and morphologically on the verb, but does not have a semantic link with it.

Example: in Russian: *Ivan kupil* ***tonnu*** *kirpičej* 'Ivan bought a ton of bricks'.

CASE 10: 
i.e., Synt-$\mathscr{D}$ and Morph-$\mathscr{D}$ oriented the opposite ways, again with no Sem-$\mathscr{D}$.

Example: a phasal verb syntactically dominates its Subject, but morphologically depends on it (= agrees with it in person and number), while there is no Sem-$\mathscr{D}$ between them, because the Subject semantically depends on the lexical verb, as in *Alan* ***begins*** *to read.*

CASE 11: 
i.e., all three types of dependency oriented the same way.

Example: a verb and its nominal object in a language with cases, as in the Russian *ljubit Mašu* '[He] loves Mary'.

CASE 12: 
i.e. Sem-$\mathscr{D}$ and Morph-$\mathscr{D}$ oriented the same way, while Synt-$\mathscr{D}$ goes in the opposite direction.

Example: a negative particle and the verb in Arabic, cf.:

	ya+ktub+u	'writes'

vs.

la	*ya+ktub+u*	'does not write'
	INDICATIVE	
	katab+a	'wrote'

vs.

lam	*ya+ktub+∅*	'did not write'
	JUSSIVE	
	sa+ya+ktub+u	'will write'
lan	*ya+ktub+**a***	'will not write'
	SUBJUNCTIVE	

Semantically, the negative particle bears on the verb and morphologically controls its form (*lam* requires the jussive and *lan*, the subjunctive; *la* is neutral); syntactically, it depends on the verb.

CASE 13: 
i.e., Sem-$\mathscr{D}$ and Synt-$\mathscr{D}$ oriented the same way, while Morph-$\mathscr{D}$ is opposite.

Example: a verb and its nominal actants in a caseless language with polypersonal agreement of the MV; cf. e.g., Abkhaz:

Sara Nadš'a ***i+l+əs+teiť*** *aš^w q'^w ə*
I Nadsha it her I gave book
'I gave Nadsha [a] book.'

CASE 14: 
i.e., Synt-$\mathscr{D}$ and Morph-$\mathscr{D}$ are oriented the same way, while Sem-$\mathscr{D}$ is opposite.

Example: an adjective and the modified noun in a language with adjectival agreement, where the adjective bears semantically on the noun, but syntactically and morphologically depends on it.

4. *Syntactic Dependency and Syntactic Constituency*

A systematic comparison of the $\mathscr{D}$-approach with the constituency, or $\mathscr{C}$-, approach is impossible here (see Vennemann 1977, Hudson 1980a, 1980b, Dahl 1980, Matthews 1981, pp. 71–95, Mel'čuk 1988, pp. 13–17, Sgall and Panevova 1988–89, Rambow and Joshi 1997). Only two points will be touched upon.

4.1 *Syntactic Dependency and Word Order*

There are several linguistic phenomena for whose description Synt-$\mathscr{D}$ is crucial: valency, voice, restricted lexical cooccurrence, ellipses, etc. However, Synt-$\mathscr{D}$ is especially convenient for the description of word order: it forces strict separation of the hierarchical (= genuinely syntactic) 'order' from the linear order, the latter being a surface means for the expression of the former. The main task of syntax—linearizing a two-dimensional Synt-structure (Tesnière 1959, pp. 19–20)—can be solved more easily with Synt-$\mathscr{D}$s than in any other way:

(a) Word order rules can be naturally formulated in terms of positioning a Synt-dependent with respect to its Synt-governor (before or after it).

(b) Synt-$\mathscr{D}$ has allowed for the discovery (Lecerf 1960, Iordanskaja 1963, Hays 1964, Robinson 1970) of an important property of word order: projectivity. If a sentence is supplied with its $\mathscr{D}$-SyntS and a perpendicular is drawn from each wordform to the

Figure 4
Sentence (1) supplied with its Synt-Structure

node that represents it, then no branch of the SyntS intersects with another branch or with a projection perpendicular. Sentence (1) is projective:

A sentence appears as a 'projection' of its SyntS; hence the name 'projectivity.'

The majority of sentences in any language are projective. This fact ensures a more elegant formulation of word-order rules and facilitates computer processing of texts: except for particular cases, only projective sentences must be produced from a given SyntS, and only SyntSs that guarantee projectivity must be associated with a given sentence.

However, projectivity can be systematically violated in many special cases, for instance:

All non-projective constructions (optional or obligatory) of ℓ must be specified in the syntactic description. Within the $\mathscr{D}$-approach this poses no problem whatsoever (while the $\mathscr{C}$-approach is unable to represent non-projective constructions without some additional machinery—e.g., transformations).

The $\mathscr{D}$-approach has the inherent ability to accommodate long-range links. The perturbations introduced into the word order of a sentence by its communicative structure—frontings, extractions, postponings, etc., in such languages as German or Russian—can wreak havoc on a $\mathscr{C}$-structure, since even the closest-knit phrases can be torn apart and permuted. But a $\mathscr{D}$-structure, completely free of linearity and contiguity, is insensitive to such permutations. As a result, the $\mathscr{D}$-approach does not face problems in representing discontinuities, which, in the literal sense of the word, simply do not exist in a $\mathscr{D}$-structure.

Dealing with the above phenomena is related to the trend in modern linguistics that Hudson (1990) aptly dubbed *lexicalism*: putting at the center of the description facts about lexical units rather than facts about syntactic constructions, so that the lexicon is given a place of honor. Stressing the importance of the lexicon goes quite well with the $\mathscr{D}$-approach in syntax, because in this approach all the links are established between wordforms and based, in the final analysis, on their lexicographic properties.

4.2 Crossing Syntactic Dependency with Syntactic Constituency

For years, linguists have been looking for a hybrid between $\mathscr{D}$- and $\mathscr{C}$-representations (e.g., Vennemann 1977). The incentive for integration comes primarily from such phenomena as coordination (see Sect. 5), extractions (*I know* ***which girl*** *you told my wife Alan*

Figure 5
Non-Projective Synt-Structures

was going out with); analytical forms (*has been detected*; *the book*); collocations (*make headway, pay a visit, launch an attack*); and the like. The main idea is to introduce for any of these constructions a special type of subtree that is allowed to occupy—as a whole—one node of a $\mathscr{D}$-tree.

The first formal proposal for a 'mixed' $\mathscr{D}$-/$\mathscr{C}$-representation—by means of syntactic groups—was advanced by Gladkij (1966). The most recent one was made by Kahane (1997), in which he introduces the concept of bubble: a subset of nodes of a $\mathscr{D}$-tree which is treated as a node, while having inside a completely specified $\mathscr{D}$-structure of its own, including other bubbles.

5. *Insufficiency of Syntactic Dependency: Coordination*

If we agree to use two levels of representation for syntactic structures (Deep-SyntS and Surface-SyntS) plus communicative structures on each level, then a pure $\mathscr{D}$-representation in syntax seems to be sufficient for all syntactic phenomena, except for some types of coordination (see Hudson 1990, p. 97). A wordform **w** may 'relate' either to a whole conjoined phrase or to its Synt-head alone, such that the two constructions are formally distinct and have different meanings; however, within the strict $\mathscr{D}$-approach, both types of structure can be represented only by the direct Synt-$\mathscr{D}$ of **w** on the Synt-head of the conjoined phrase (the pure $\mathscr{D}$-formalism does not allow for the dependency on a phrase as a whole). Consequently, one SyntS corresponds in such cases to two different meanings:

The SyntS *old* ← *men* → *and* → *women* has:
—either a joint reading [the adjective bears on both nouns]:
'old {men + women}' = '{old men} and {old women}';
—or a disjoint reading [the adjective bears on one noun only]:
'{old men} and women [who are not necessarily old]'.

Different implementations that formally distinguish intended meanings are in principle available, depending on the language and particular lexical means used; for instance ('‖' stands for a pause): *old men and women* [without a pause] vs. *old men* ‖ *and women*. The semantic contrast accompanied by a formal contrast requires that the semantic distinction be maintained in the SyntS (Criterion C1). The only way to do so is to complement the $\mathscr{D}$-approach with groupings—specification, within the SyntS, of $\mathscr{D}$-subtrees relevant in such cases (Mel'čuk 1974, pp. 214–16, 1988, pp. 28–33): *old* ← ***modif***–*men* → *and* → *women* (without grouping) stands for the disjoint reading ('{old men} and women'), but old ← ***modif***–[–men → and → women] (with a grouping indicated by square brackets) for the joint reading ('old men and old women'). A grouping is not a constituent: there is no higher node to represent it as a whole (it is not a projection of a complete subtree), and it does not participate in $\mathscr{D}$-links as such (in a consistent $\mathscr{D}$-approach, only single nodes do). The use of groupings makes the $\mathscr{D}$-formalism sufficient for all syntactic purposes.

For a general view of the main topics related to Synt-$\mathscr{D}$, see Heringer 1993, Hudson 1993a, 1993b; a description of German syntax in terms of Synt-$\mathscr{D}$ is offered in Engel 1977 and Heringer 1996, and of English syntax in Mel'čuk and Pertsov 1987.

Language Development, Neural Basis of

1. *The Neurobiology of Language Processing in Adults*

The classic theory of the neural basis of language function was based on observations of adults with acquired brain injuries. Approximately 95 percent of adults who develop aphasia after stroke have damage to the left hemisphere (LH). The LH was, therefore, assumed to play a crucial role in mediating expressive and receptive language. Within the LH, Broca's area (the inferior frontal operculum) was thought to be the neural substrate for speech production and Wernicke's area (the posterior superior temporal area and supramarginal gyrus of the parietal lobe) the neural substrate for speech comprehension (Caplan 1987).

New experimental methods that assess the neural substrate of language in awake and processing individuals have revolutionized the classic theory. Language areas are not well circumscribed and are not homogeneous. Researchers have proposed that Wernicke's area is involved in phonological processing (Petersen and Fiez 1993) and may include the neurocognitive network for the written and spoken word lexicon (Howard et al. 1992). Posterior inferior temporal cortex has also been implicated in lexical and semantic aspects of language comprehension and production (Alexander 1997). Broca's area has been implicated in syntactic processing (Zurif and Swinney 1994), in verbal short-term memory (Braver et al. 1997), and in phonological processing (Demonet et al. 1992, Zatorre et al. 1992). Other areas of the brain seem to participate in language functioning. The middle-superior temporal region has been implicated in semantic processing and anterior-superior temporal area in syntactic processing (Mazoyer et al. 1993, Price et al. 1996). Moreover, the dorso-lateral prefrontal cortex (DLPFC) is active during language and reading tasks. The DLPFC may be responsible for modulation of processing in posterior semantic regions, such as Wernicke's area (Frith et al. 1991, Raichle et al. 1994) or for maintaining verbal information in memory during comprehension of complex sentences (Jonides et al. 1997).

Three lines of evidence suggest that language processing in the normal state may involve bilateral representation, at least under some circumstances. The superior temporal areas in both the LH and right hemisphere (RH) are specialized for processing auditory information (Heffner and Heffner 1984). Adult stroke patients undergo a period of recovery that leads to increased activation bilaterally during auditory and language tasks (Weiller et al. 1995, Engelien et al. 1995). Finally, fMRI studies with normal adults show that increasing task difficulty increases the magnitude of bilateral activation. Homologous areas of the RH become active as the intensity and volume of the neural response within the LH increases. This pattern has been documented for language and working memory (Braver et al. 1997, Just et al. 1996). If bilateral activation emerges during difficult cognitive tasks, these findings suggest that the relevant neural wiring for language processing may be in place in both hemispheres and utilized when a single hemisphere is unable to complete the task or complete it in a timely manner.

Though research over the last several years has documented the neural systems involved in language processing, very little is known about the processing at more molecular levels of analysis. Obviously, animal models cannot be used to consider these questions. New methods such as Magnetic Resonance Spectroscopy may provide information into energy metabolism in language processing and expand our current knowledge.

2. *Challenges in Studying the Neural Basis of Language Development*

The main question that researchers have focused on regarding the neural basis of language development has been to what extent are neural systems organized in advance of language learning? Are the involved

areas of brain, even if they are widespread and nonhomogeneous, nonetheless committed prior to language development? Or is the system organized by the very act of learning language? A secondary issue of interest has been whether the dramatic changes in language during the first few years of life are stimulated by changes in brain development, such as myelination, or whether the behavioral changes can be accounted for as the outcome of learning. At the present time this second question is addressed only by correlational studies of brain and behavioral developments and is thus highly speculative in terms of causality. This article will not address that issue.

Currently, our knowledge about the neural basis of language development is extremely limited. A major impediment to the development of the field is the paucity of methods appropriate for use in human infants and young children. In adults, neural mechanisms are investigated through a variety of different noninvasive functional imaging techniques, such as event-related potentials (ERP), positron emissions tomography (PET), and functional magnetic resonance imaging (fMRI). Each of these methods has advantages and limitations; considering them together assists in piecing together a full account of the neural basis of language function. In children, PET scanning has been avoided—except in children with clinical indications for its use—because the tests require exposure to ionizing radiation. Functional MRI involves no exposure to ionizing radiation but requires an awake and responding subject to hold still. Even minimal movement by a young child renders it impossible to detect the minimal differences in activation between baseline and experimental conditions. Children less than 7 years of age cannot usually comply with the stringent requirements of the scanning. Therefore, for infants and young children, the only direct method of functional imaging that has been used successfully is ERP.

An indirect method for addressing the neural underpinnings of language development has been to study children with early lesions impinging on classical language areas of the cortex. If, the argument goes, children with damage to the usual language areas have serious delays and disabilities in aspects of language functioning, then the implication is that the neural mechanisms for those aspects of language development were probably present prior to the injury. If the damage occurred around the time of birth and language performance is impaired, then the inference is that specialization is congenital, and possibly determined or initiated by genetic mechanisms. If children with early brain injuries successfully master language, then the implication is that, at least under extreme circumstances, alternative organizations within the human brain for language are possible.

This experimental strategy also has serious limitations. Early focal brain injury in childhood is rare and, unlike the situation in adults, the causes are diverse. Studies in the 1970s and 1980s enrolled children with hemidecortication for intractable seizures in Sturge–Weber syndrome, a vascular malformation of the brain and overlying skin (Dennis and Kohn 1975, Dennis and Whitaker 1976), and children with embolic strokes sustained during cardiac procedures to treat congenital cardiac disorders (Aram et al. 1986, Aram and Ekelman 1987). In these populations, the age of onset and extent of injury both vary. More recently, studies have enrolled children with strokes that occurred *in utero* or in the perinatal period. Though the age of onset of this population is narrow and the injury preceded any language development, the locations of injury still vary substantially. Furthermore, the study of children with early focal lesions is challenging because the language capabilities of the young infant had no injury occurred are uncertain, whereas the capacities of adults can be inferred from their previous functioning and occupation. Other variables and coexisting conditions such as seizure disorder and use of anticonvulsant medications appear to mediate outcome (Dall'Oglio et al. 1994).

3. *Evidence from Behavioral Data*

Behavioral data suggest that language development has a strong biological basis. Language development begins when a child approaches one year of age and reaches almost adult levels of competence by the time that the child enters school. The rapidity of that development, at a time when other skills—basic adding and substracting, playing chess or riding bikes—are rudimentary suggests a strong biological predisposition or preparedness. Prelinguistic infants demonstrate processing biases before they have had much exposure to language. For example, they categorically discriminate phonetic contrasts, even those that are not found in the native language and therefore not part of the linguistic environment (Eimas et al. 1971, Best et al. 1988). They become tuned to the phonetic contrasts in their native language in the second half of the first year, as their babbling approaches the sound patterns of the adult language (Best et al. 1988). These processing biases may provide the mechanisms that infants use to begin to segment and organize the sound stream to which they are exposed. Though it is tempting to assume that the mechanisms are innate, neonates also show preferences for their mother's voice, though they do not recognize their mother's face (Burnham 1993). Thus, prenatal exposure to the mother's voice *in utero*, rather than some innate bias, is likely responsible for the early preference. Interestingly, when infants start learning to map words to meaning, they confuse similar sounding words, suggesting that they are not able to capitalize immediately on their speech discrimination skills when they begin to acquire verbal language. The neural basis of language development

may involve forming connections between the neural substrates involved in speech perception and language production.

Behavioral data also suggests a strong environmental component to language development. In the area of vocabulary development, the rate of vocabulary growth is a function of the amount of maternal input the child hears (Huttenlocher et al. 1991). In the realm of syntax, children first learn features that are highly regular and prosodically prominent. Differences in the features of the adult language seem to explain some differences in the order of acquisition across languages.

4. *Evidence from ERP and fMRI*

Using ERP techniques on normal children learning language, a picture emerges that initial development of language requires a wide and bilateral neural network and that progressive neural specialization and lateralization occurs in association with language experience rather than strictly with age. Specific ERP components in toddlers 13 to 20 months of age demonstrate differences between words that the child understands and words that are incomprehensible. Word comprehension shows both age and experience components. At 13 months of age, the comprehension effects can be found over both the right and left hemisphere and over anterior and posterior regions. By 20 months of age, the effects are detectable only over the posterior left hemisphere. However, younger toddlers who are more advanced in language development show this laterality effect at a younger age than do less advanced children (Mills et al. 1997).

Data from children with early focal brain injury corroborate the view of initial bilateral involvement in language development. Children with focal injury to either hemisphere experience developmental delays in prelinguistic skills, including the onset of babbling and communicative gestures (Marchman et al. 1991) and in the onset of vocabulary development and use of word combinations in parent–child conversations (Feldman et al. 1992, Thal et al. 1991). Once the children with focal injury begin to acquire functional vocabulary and syntactic skills, their rate of developmental progress as measured by vocabulary use and mean length of utterance is comparable to each other and to children developing typically (Feldman et al. 1992). By age 4, children with focal LH damage can even master the complex morphosyntactic structures of a language like Hebrew (Levy et al. 1994). However, at school age, children with damage to either the LH or RH show delays compared with children developing typically in the creation of narrative discourse (Reilly et al. 1998). These findings are suggestive that both hemispheres participate in advanced language skills such as narrative discourse in school aged children.

Research also indicates that individual differences in developmental rate relate to the location of injury. Children ages 10 to 17 months of age with RH damage have been shown to have greater initial delays in word comprehension and production than do children with LH damage. However, at the point of word and syntax development children with LH temporal lobe injury demonstrate slower development than do those with damage to other areas of the RH or LH (Thal et al. 1991). These data are compatible with a view of increasing specialization during language development. However, it is important to note that individual differences also relate to other variables besides the size and site of the lesion, such as the presence of seizures and the use of anticonvulsant medications (Dall'Oglio et al. 1994).

Studies using fMRI in children developing typically demonstrate that predominant LH activation during language tasks is present by about age 7 to 9 years, and as with adults, bilateral activation occurs under some circumstances. The activation of neural networks on fMRI was studied during sentence processing in adults, normal school aged children and also children with perinatal focal brain injury (Booth et al. 1999, 2000). In a relatively natural linguistic task, children listened to sentences and then responded true or false to a statement about each sentence. Adults and children show lower accuracy levels to difficult object-relative sentences, such as 'The pig that the dog jumped ate the trash in the street,' intermediate accuracy to moderate subject-relative sentences, such as 'The principal that tripped the janitor used the phone to call home,' and highest accuracy levels to relatively easy conjoined-verb-phrase sentences, such as 'The cat chased the rabbit and enjoyed the hunt in the yard.' However, children are less accurate than are adults. Children, as well as adults, are more accurate when true–false statements test for the subject of the first verb, for example, 'The dog jumped the pig,' than for the subject of the second verb, for example, 'The principal used the phone.'

In adults, the fMRI showed that the sentence comprehension task produced more activation in the LH than in the RH. The greatest activation was found in the superior temporal, middle temporal, and inferior frontal areas, the traditional language areas but also in prefrontal areas, the brain region associated with working memory. Healthy children activated similar neurocognitive networks as did the adults with LH predominance. However, the distribution of activity across these networks was related to response accuracy, strategy use, and task difficulty. Greater activation was associated with higher response accuracy and with consistent use of a comprehension strategy, whether correct or incorrect. Improved performance was also associated with more activation in the anterior middle temporal area suggesting that this area was important in the syntactic processing demanded by the task. Activation of occipital regions

was greater in children who were less accurate in the task. These findings suggest that some children may have been using a different and immature strategy in complex sentence processing, possibly trying to visualize the sentence as an aid to comprehension. In both normal adults and children, the number of areas activated correlated with the difficulty of the sentences. The RH was recruited for difficult sentences (Booth et al. 2000).

Children with LH damage showed patterns of activation consistent with organization of cognitive processing into homologous areas of the contralateral hemisphere. The size of their lesion was associated with the degree of their cognitive deficit. These results confirmed earlier findings of RH language in many individuals with left hemisphere damage undergoing a carotid amytal infusion (Rasmussen and Milner 1977).

Studies of children with LH damage indicate that though the RH can participate in language processing, the LH has a more central role in language tasks at school age. Dennis and co-workers found that despite comparable intelligence, children with LH hemidecortication were inferior to children with RH hemidecortication on the ease and speed of syntactic discrimination, interpretation of passive negative sentences, and repetition of syntactically complex sentences (Dennis and Kohn 1975, Dennis and Whitaker 1976, Dennis 1987). Aram and co-workers similarly found expressive and receptive syntactic difficulties in children with LH focal damage from embolic events (Aram et al. 1986, Aram and Ekelman 1987). However, it is important to note that children with LH damage acquired in early infancy or childhood have only subtle deficits, and are not frankly aphasic as are adults with comparable lesions.

It is difficult to assess if syntax is particularly vulnerable in children with these lesions acquired later in life. An alternative hypothesis is that subjects with LH damage had greatest difficulty with the most developmentally advanced items on the assessment (Bishop 1983). Children with LH injuries and LH perinatal damage also show difficulty in tests of comprehension of difficult verbal material, formulating sentences, and lexical retrieval (MacWhinney et al. 2000).

To determine the specificity of underlying information-processing deficits after early injury, MacWhinney et al. (2000) used on-line reaction time methodology. School-aged children underwent visual and auditory tasks of signal detection, recognition, and choice as well as rapid naming to visual and auditory stimuli. The results showed that children with LH, RH, and with mixed lesions generally were as accurate as age-matched controls but consistently had slower reaction times. The reaction times of normal learners lawfully decreased as the children went from 5 to 10 years of age. Similarly, in the subjects with early lesions, the reaction times became shorter as the children got older and the slopes suggested that by adulthood the reaction times might converge. The two tasks that best distinguished children with LH injuries from children with other lesions were verbally repeating numbers presented in the auditory mode and naming numbers presented in the visual mode, though there was considerable overlap across groups. Interestingly, both these tasks required phonological access and verbal output.

Taken together, these findings on school-aged children suggest that despite adequate functional communication skills, children with LH injuries may have more difficulty than do children with other lesions performing precise, constrained, high-level language tasks, particularly in tasks that require speed. The areas of greatest difficulty seem to be developmentally challenging syntactic skills, comprehension of difficult oral directions, and formulating sentences with a constrained vocabulary. Phonological access, as evidenced in naming and repeating verbal items, also differentiates subjects with damage to the LH from other children without injuries.

5. *Summary*

Study of the neural basis of language function is advancing rapidly in the era of neural imaging and related methods. Study of the neural basis of language development is lagging behind because many of the techniques are not appropriate for children. The early emerging picture is that sensory processing mechanisms that are called on for initial segmentation and organization of the linguistic stream are present at or even before birth. However, these processing biases are not immediately available to true verbal development. Language development seems to use a broad and bilateral neural network at each stage. That network becomes more constrained and specialized to the LH as a function of language experience. However, bilateral activation remains possible in normal functioning, for example, when tasks are difficult and in circumstances of brain injury. Adult patterns of neural activation are present by school age and show LH predominance. However, children with LH damage may use homologous regions of the RH for sentence processing. Hopefully, in the near future new experimental techniques will allow greater detail and understanding of these processes and will begin to explain individual differences in children developing typically and children with a variety of developmental disorders.

Language Endangerment

About 6000 languages are spoken in the world. Major languages, such as English, French, Spanish, Portuguese, German, Russian, Arabic, Hindi, and Chinese, which have millions of speakers, constitute a tiny fraction of them (less than 1 percent). More than 95 percent of the world's languages are spoken by minority peoples (Krauss 1992, pp. 5, 7), and many of these minority languages have just a few remaining speakers. In every part of the world, minority languages are disappearing at an alarming speed, being replaced by major languages such as those listed above. This article examines this language crisis.

1. *Degree of Language Endangerment*

In terms of the degree of their viability, languages of the world constitute a continuum, with fully thriving ones at one end and extinct ones at the other. Various terms—both adjectival and nominal—have been proposed to characterize this continuum. Some of the terms may be arranged as in Fig. 1.

Figure 1
Degree of language endangerment, intensifying left to right

Consider Schmidt's (1990, p. 54) terms and their characterizations.

(a) Healthy languages: all generations actively use the language in a wide range of activities.

(b) Weakening languages: usually spoken by old people, but not fully transmitted to the younger generation.

(c) Dying languages: only a few speakers remain.

(d) Extinct languages: no speakers remain.

The use of the terms as proposed in Fig. 1 is as follows. Endangered languages comprise weakening/ailing and dying/moribund languages. Language decline and language obsolescence concern both groups of endangered languages, while language death and language loss refer to dead/extinct languages. The term 'language endangerment' is for the general subject.

2. *Current State of Language Endangerment*

The gravity of the current state of language endangerment can be seen from the following reports of selected areas.

In Australia, of the 250 languages spoken at the time of the first British colonization in 1788, about 100 are alive, mainly spoken by old people, and only about 20 are being passed on to children (Dixon 1991, pp. 235–36). In the USA and Canada, there must have been many hundreds of languages at the beginning of the sixteenth century, but only 187 have survived, and 149 of 187 are moribund (Zepeda and Hill 1991, p. 135, Kinkade 1991, p. 158, Krauss 1992, p. 5). In Russia, 45 of 65 indigenous languages are moribund (Krauss 1992, p. 5). In Africa, nearly 200 languages are endangered (Sasse 1992, p. 7).

To sum up, Krauss (1998, p. 103) estimates that, of 6000 languages of the world, only 5–10 percent are 'safe,' and 40 percent up to 75 percent are weakening, and at least 20 percent to perhaps 50 percent are moribund. Krauss (1998, p. 105) then forecasts that, if current trends are not reversed, during the next 150 years the number of languages is likely to be reduced to as few as 300.

3. *Two Approaches to Language Endangerment*

One approach is to document endangered languages. This is the most important thing to be done about them, and it is the most urgent task of linguists. Ideally, such documentation should include grammars, vocabularies, and texts/stories, employing audio and video recording. The other approach examines the process of language endangerment, in terms of (a) its causes, (b) its sociolinguistic aspects, and (c) structural changes (Sasse 1992). These three

Table 1
Functional differentiation

Minority language	Dominant language
Traditional life	Modern life
Within the community	With the outside world
Inside families	Outside families (inside the community)
Private, domestic	Public
Informal	Formal
Intimate	Nonintimate
Solidarity	Power
Secrecy	Nonsecrecy

aspects of language endangerment will be considered in the following three sections.

4. *Causes of Language Endangerment*

Language endangerment is caused by multiple factors, such as those listed below. They are all closely interrelated, and are often difficult to separate from one another.

(a) Dispossession of the land by invaders for settlement, farming, etc.

(b) Decline or loss of the population, caused by (i) natural catastrophes, e.g., volcanic eruption, earthquakes, (ii) diseases imported by invaders, e.g., venereal disease, smallpox, measles, influenza, and (iii) violent acts, e.g., massacres, genocide.

(c) Relocation of the people away from their traditional land.

(d) Socioeconomic oppression, by economic deprivation, discrimination, etc.

(e) Low status of the language, accompanied by ridicule, stigma, shame, etc.

(f) Assimilation policy, language policy by the government, e.g., (i) ban on the use of the indigenous language at schools, and (ii) placing children in boarding schools, which separates the children from their home environment and interrupts the transmission of the language.

(g) Switch to modern life, e.g. (i) schooling where the dominant language is used to the exclusion of the minority language, (ii) introduction of mass media, such as TV, and (iii) improvement of transport.

(h) Religion. For example, with the spread of Islam, Arabic replaced many languages of the Middle East and north Africa.

(i) Mixture of speakers of different languages, e.g., in boarding schools and reservations, where people were often forced to speak the dominant language, such as English, as a lingua franca.

(j) Language attitude. For example, if old speakers consider their language as an invaluable treasure, they may prefer not to transmit it to the younger generation for fear that the latter, who have often been westernized and 'modernized,' may not treat it with due care and respect (Schmidt 1990, p. 20).

5. *Sociolinguistic Aspects of Language Endangerment*

If a minority language and a dominant language coexist in one community, often they are used in different functional domains. Such functional differentiation is shown in Table 1. Needless to say, these domains are all closely inter-related; most of them are self-obvious. Consider the following examples.

(a) In Paraguay, Paraguayan Guarani and Spanish show a functional split, roughly as follows (Rubin 1972). If the location is rural, then Guarani will be used. If the location is nonrural, then Spanish will be used in a formal setting. In a nonformal setting, Spanish will be used if the speakers are not intimate. Between intimates, Guarani will be used if the discourse is not serious. If the discourse is serious, then the speaker may use, for instance, his/her first language or the language the hearer is estimated to be the more proficient in. Paraguayan Guarani has secured its position in this stable bilingualism, and consequently it is not endangered. It is the only native language of South America that is not endangered (Adelaar 1991, p. 73).

(b) Nahuatl of Mexico was used as an 'inside' language, and Spanish as an 'outside' language. This functional split has then developed into the 'solidarity–power' split: Nahuatl functioning as a marker of ethnicity and as a language of solidarity, as against Spanish, which is now a language of power, used to express ambition and mobility (Hill 1983, pp. 265–66).

(c) A minority language is often used as a secret language, for talking about something secret or private in the presence of outsiders.

Now, if the bilingualism in a given community is stable, with the two languages exhibiting a functional differentiation, then the minority language has a chance of survival, as is the case with Paraguayan Guarani. However, in most cases the functional range of the minority language diminishes, while that of the dominant language increases, with the result that the people shift from the minority language to the dominant language. (This phenomenon is called language shift.) When the language shift is completed, the minority language is extinct.

6. Structural Changes in Language Endangerment

6.1 Dyirbal of Australia

As a language is endangered and nears its demise, it undergoes structural changes, in phonology, morphology, syntax, semantics, lexicon, and speech styles, among other features. See *Language obsolescence*. Most such changes appear to be in the nature of simplification and reduction. Opinions differ, however, as to whether it is possible to generalize about structural changes in language endangerment. In the following, just one case study will be presented, namely, Schmidt (1985) on Dyirbal of northeast Australia. Due to the space limitation, only a very small portion of Schmidt's brilliant work can be cited. (TD refers to the traditional Dyirbal, and YD (young Dyirbal) refers to varieties of Dyirbal that deviate from the traditional norm.)

6.2 Phonology

One of the interesting changes concerns *r*-sounds. TD has an opposition of retroflex *r* and trill *rr*; consider the minimal pair of *yara* 'man' and *yarra* 'fishing line.' English has no such opposition. Now, in YD, this opposition is maintained, but it is maintained only in minimal pairs; elsewhere this opposition is not adhered to consistently, and speakers are not certain whether to use *r* or *rr*.

6.3 Morphology

One of the issues Schmidt examines is the ergative case, and it will be useful to provide a brief introduction to the phenomenon of ergativity.

Ergativity is a phenomenon in which the intransitive subject (S) and the transitive object (O), are treated alike, in distinction from the transitive subject (A). This pattern is called an ergative–absolutive pattern. It contrasts with, for example, a nominative–accusative pattern, in which the S and the A are grouped together, separately from the O. Ergativity may be manifested at various levels in grammar, e.g., morphology and syntax.

In TD, in terms of case-marking morphology, nouns, adjectives, etc. have an ergative–absolutive pattern, with the S and the O in the absolutive case and the A in the ergative case, e.g., (a), (b), while first- and second-person pronouns have a nominative–accusative pattern, see Table 2. (The ergative case does not occur in 'familiar' languages, such as English.)

(a) *nguma-Ø* *banaga-nyu.*
father-ABS(S) return-NONFUT
'Father (S) returned.'

(b) *nguma-Ø* *yabu-nggu* *bura-n.*
father-ABS (O) mother-ERG (A) see-NONFUT
'Mother (A) saw Father (O).'

In TD, the ergative suffix has six allomorphs, including *-nggu* for disyllabic vowel-final stems, e.g., *yabu-nggu* 'mother-ERG,' cf. (b); *-gu* for trisyllabic or longer vowel-final stems, e.g., *girimu-gu* 'snake-ERG'; *-ju* for *y*-final and *ny*-final stems, e.g., *walguy-ju* 'taipan (snake species)-ERG' and *binyjirriny-ju* 'lizard-ERG'; and, *-du* for *n*-final stems, e.g., *midin-du* 'possum-ERG.'

Schmidt shows that, among YD speakers, this morphological complexity was gradually reduced as a given speaker's proficiency in TD diminished, to the point where one single suffix, *-gu*, was used for all stems, irrespective of their stem-final phoneme. There were even less proficient speakers, who did not use an ergative suffix at all, and instead relied on word order, more specifically, on the English-type word order in a nominative–accusative pattern, in which the S and the A occur before the verb, and the O after the verb. (In TD, word order is free; syntactic function is indicated by case affixes of NPs.)

(c) *gugar* *buga-bi-n.*
goanna dead-INTR.VERBALIZER NONFUT
S V
'The goanna is dead.'

(d) *gugar* *baja-n* *ban* *jugumbil.*
goanna bite-NONFUT her woman
A V O
'The goanna bit the woman.'

6.4 Syntax

TD exhibits a rare phenomenon called syntactic ergativity. Due to the space limitation, a highly simplified account will be given below (for details, see Dixon 1994, pp. 160–72). Consider:

Table 2

	A (transitive subject)	S (intransitive subject)	O (transitive object)
Nominative–accusative pattern	nominative case	nominative case	accusative case
Ergative–absolutive pattern	ergative case	absolutive case	absolutive case

(e) *nguma-Ø* *yabu-nggu*
father-ABS (O) mother-ERG (A)
bura-n *banaga-nyu.*
see-NONFUT return-NONFUT
'Mother (A) saw Father (O) and [Father (S), not Mother] returned.'

It is important to stress that (e) does NOT have the meaning of the English sentence (f):

(f) Mother (A) saw Father (O) and [Mother (S), not Father] returned.

That is, in English, the understood S refers to the A and not the O; the S and the A are treated alike, in distinction from the O. In contrast, in Dyirbal, the understood S refers to the O and not the A. That is, in Dyirbal, the S and the O are grouped together, separately from the A, in complex sentences as well. This phenomenon—the grouping of the S and the O, separately from the A, in complex sentences—is called syntactic ergativity. It is rare among the world's languages.

Now, Schmidt shows that the use of syntactic ergativity, too, was on the decline among YD speakers.

6.5 Lexicon

Schmidt's study indicates that certain areas of the vocabulary were prone to loss. They include (a) types of animals and trees, e.g., 'ironbark,' 'bottlebrush,' (b) culture-specific items, e.g., 'yamstick,' 'fighting ground,' and (c) kinship terms for which there is no corresponding term in English. However, there were also areas of the vocabulary that were resistant to borrowing, such as (d) human body, e.g., 'hair,' 'tooth,' 'eye,' (e) human classification, e.g., 'man,' 'woman,' 'child,' and (f) well-known animates, e.g., 'carpet snake,' 'black bream.'

7. Language Maintenance and Revival

There are many attempts to maintain or even revive languages (see Fishman 1991). The types of these programs include the following.

(a) Language classes. For example, more than a dozen Ainu language classes for Ainu people are conducted in Japan.

(b) Bilingual education. In Australia, for instance, a number of schools are conducted using the local Aboriginal language and English.

(c) Language immersion program. An environment, e.g., preschool, is provided in which children will only hear and speak the language. The most successful and best-known is 'the language nest' program for the Maori language of New Zealand.

(d) 'Neighborhood method.' A most drastic example is a group of eleven families in Belfast, who—in order to create a cohesive community—bought houses in the same neighborhood in the middle of an English-speaking community in Belfast, and raised their children as bilinguals (in Irish and English) (Maguire 1991).

Factors that contribute to the success of a language maintenance program include the following. (i) Determination and often even sacrifice on the part of the community (cf. (d)). (ii) Government support, e.g., funding. (iii) Good documentation of the language. (iv) Availability of human resources, e.g., teachers, and advice from experts. (v) Land/area where the people concerned can live together (cf. (d)), preferably away from speakers of the dominant language. (vi) Existence of just one language for maintenance, as is the case with Maori of New Zealand. In contrast, language maintenance is much more difficult in Australian Aboriginal communities, where often several languages are spoken. (vii) Existence of a sufficiently large number of speakers. (viii) Inclusion of cultural activities, e.g., music, dance, handcraft. (ix) Tolerance of language change, as against linguistic purism. Attempts to preserve a 'pure' language may hinder the language's maintenance by discouraging non fluent speakers from speaking it.

8. Value of Linguistic Heritage

As seen above, a large number of people are making efforts, with dedication and determination, to revitalize languages in danger. Why is it important to do so? What appear to be three representative and interrelated views are cited below.

(a) 'Community view': ethnic identity. In this view, language is one of the most central components of a given group's culture. Their language is the symbol of their ethnic identity, expressing their culture in terms of worldview, ceremonies, songs, kinship terms, etc.

(b) 'Global view': linguistic diversity. This view maintains that linguistic diversity is important to human intellectual life. Minority languages often exhibit phenomena quite unimaginable if our attention were limited to, say, English. An example is syntactic ergativity of Dyirbal. With the death of minority languages, these aspects of rich cultural heritage of mankind die.

(c) Language rights. In June 1996, the draft of the Universal Declaration of Linguistic Rights was proclaimed at the World Conference on Linguistic Rights in Barcelona. The declaration is based on the principle of the equality of all peoples and all languages, and considers the following, among others, to be an inalienable human right:

(i) the right to use one's own language, and

(ii) the right for one's own language and culture to be taught.

The concept of language rights is no doubt one factor that motivates the community view, cited above, although the members of the community may not always be conscious of it.

9. Organizations

There is now an increasing number of organizations devoted to endangered languages, e.g., Endangered Language Fund (elf@haskins.yale.edu, http://www.ling.yale.edu/~elf); Foundation for Endangered Languages (nostler@chibcha.demon.co.uk, http://www.bris.ac.uk/Depts/Philosophy/CTLL/FEL/); Society for Endangered Languages (GBS@uni-koeln.de, http://www.unikoeln.de/gbs); and Terralingua (gws@mail.portup.com, http://cougar.ucdavis.edu/-nas/terralin/home.html). The following mailing list is available: endangered-languages-l@cleo.murdoch.edu.au, http://cleo.murdoch.edu.au.lists/endangered-languages-l. The following website is useful: http://www.tooyoo.ac.jp/ichel.html.

Language Learning Impairment

Early reports of children who failed to learn language at or near the expected age, but with no history or evidence of acquired brain lesions, began to emerge only in the mid 1960s. Such children were first diagnosed as 'developmentally aphasic.' The diagnosis of 'developmental aphasia' emphasized the congenital or developmental, rather than acquired, nature of the language learning impairment. Similarly, it was emphasized that the specificity of the deficit must lie in the linguistic domain. Language learning problems secondary to other developmental disabilities such as hearing loss or deafness, mental retardation, evidence of frank neurological problems (such as seizure disorder or hemiplegia), or structural or motor deficits effecting the oral musculature (such as cleft palate or cerebral palsy), were traditionally excluded from the classification of developmental aphasia. One exception to this diagnosis by exclusion was notable deficits, not only in speech and language, but also in higher order central auditory processing.

Over the years the term 'developmental aphasia' has been replaced by other terms such as 'congenital aphasia,' 'specific language impairment' and, most recently 'language learning impairment.' The most recent classification, 'language learning impairment,' acknowledges the frequent continuum between oral and written language learning impairments in children. More recently, research has moved away from a focus on exclusionary definitions of specific language impairments to a broader perspective that focuses on better elucidating the linguistic, cognitive, and neurobiological concomitants of developmental language learning impairments.

Developmental language learning impairments (LLI) can occur in children for a wide variety of reasons, and are one of the most prevalent of all

developmental disabilities. It has been estimated that approximately 20 percent of all children have some form of language learning impairment. The most common known causes of developmental language learning impairments are hearing loss (including intermittent hearing loss resulting from chronic otitis media), general mental retardation, and motor or structural defects affecting the oral musculature. Approximately 7.5 percent of children have developmental language impairments of unknown origin.

1. Diagnosis

The differential diagnosis of developmental language learning impairments is based on behavioral evaluations that include audiological, neurological, psychological, educational, speech, and language assessments. Developmental oral language learning impairments are divided into two basic categories; Expressive Language Disorder, affecting language production, and Mixed Receptive–Expressive Language Disorder, a disorder encompassing both language comprehension and production deficits. Comprehension and/or production problems may occur within one or more of the components of language; including phonology, morphology, semantics and/or syntax. Problems with pragmatics (interactive conversational skills) also occur frequently. A high proportion of children with developmental language learning impairments also have difficulty with speech articulation; that is, difficulty clearly and correctly producing one or more of the speech sounds of their language. However, speech articulation defects and developmental language learning impairments can occur independently of each other.

Many developmental cognitive disorders, such as mental retardation, pervasive developmental disability (including autism), attention deficit disorder, central auditory processing disorder, or specific syndromes such as Down's Syndrome, Fragile X Syndrome, Klinefelter's Syndrome, etc., may include delay in language development. In addition to these known concomitants of developmental language impairment, a recent epidemiological study of monolingual English-speaking kindergarten children in the US found that approximately 8 percent of boys and 6 percent of girls have a specific developmental language impairment of unknown origin. This epidemiological study also showed that the clinical identification of developmental language impairments remains low. Over 70 percent of the parents or teachers of children identified in this epidemiological study as language impaired had previously been unaware that their child had a speech or language problem (Tomblin et al. 1997). These data emphasize the importance of early referral for differential diagnosis for children failing to meet language milestones.

Children with developmental language learning impairments also have been shown to be at risk for childhood behavioral disorders. For example, clinical research studies showed that children referred to child guidance clinics for a variety of behavioral and emotional problems were found to have a higher than expected incidence of developmental language learning disorders. Conversely, children diagnosed with developmental language disorders also have been found, upon examination, to have a preponderance of behavioral and emotional disorders. Over 80 percent of juvenile delinquents were found, upon testing, to be language learning impaired (Beitchman et al. 1986, Hall and Moats 1999).

Longitudinal research studies that have followed children with early developmental language impairments, from the preschool though elementary school years, consistently have demonstrated a striking link between early developmental oral language impairments and subsequent academic achievement problems, especially dyslexia, which is characterized by reading, writing, and spelling deficits. Research that has compared children classified as 'language impaired' with those classified as 'reading impaired' has shown that both groups are characterized by a variety of oral language deficits, specifically phonological and memory problems, as well as language comprehension deficits (Snow et al. 1998). Whether these common deficits derive from speech-specific mechanisms, or from more basic neural processing deficits, has been the focus of considerable research and theoretical debate (see Tallal et al. 1993, Farmer and Klein 1995, Leonard 1998 for review).

2. Etiology

Considerable research attention has been focused on trying to understand the causes of developmental language learning impairments. Given the lack of homogeneity amongst children showing delayed language development, and the diversity of symptomatologies that can accompany developmental language learning impairments, it is unlikely that a single etiology is responsible. Etiological research to date has focused on linguistic, cognitive, and neurobiological studies.

2.1 Linguistic Studies

There have been considerable advances made in understanding the specific linguistic deficits of children with language impairments. Research has demonstrated particular patterns of difficulty within the linguistic components of phonology, syntax, and morphology. Specifically, deficits in both receptive and expressive grammatical morphology have been dem-

onstrated (Leonard 1998, Bishop 1997). However, results of longitudinal studies have shown that children with developmental language impairments develop the linguistic structures of language along a similar linguistic trajectory to that observed in normally developing younger children, albeit considerably more slowly. To date, there is little evidence that these children make linguistic errors that are deviant or substantially different from younger children at the same stage of language development. Rather, children with language learning impairments take much longer to progress through the stages of normal language development. A similar pattern of delay, rather than deviance, occurs across most populations of children with developmental language impairment, regardless of clinical diagnosis.

Looking cross-linguistically at children with developmental language impairments learning different languages in different countries, it has been shown that whichever linguistic structures are brief, unstressed, or of weak phonetic substance, and occur less frequently in a particular language, are the most difficult for children to learn, and also the most delayed in children with language learning impairments (Leonard 1998). That the same order of development occurs across populations and language environments gives strong support that there is a potent metric of sheer difficulty (whether representational or perceptual) that is imposed on the learning of linguistic structures and contents.

2.2 Cognitive Studies

The most extensive etiological studies to date have utilized behavioral methodologies and have resulted in the formulation of two prominent hypotheses: the 'linguistic specific' hypothesis and the 'rate processing constraint' hypothesis. The rate processing constraint hypothesis assumes a direct impact on the learning of the linguistic system, specifically on learning phonology and grammatical morphology. This hypothesis claims that central auditory processing constraints, particularly in the areas of auditory attention and serial memory, may result from a more basic impairment in the rate of neural information processing (Tallal et al. 1993). Tallal and colleagues have shown that many children with phonologically based speech, language, and reading disorders need significantly more neural processing time (hundreds of milliseconds instead of tens of milliseconds) to process dynamic (rapidly changing) sensory stimuli. They have hypothesized that this dynamic sensory processing rate constraint has a particularly detrimental effect on phonological processing, as many acoustic changes occurring in rapid succession within syllables and words, necessary to distinguish the individual phonological elements (speech sounds), occur within the tens of milliseconds time window. Research has demonstrated that perception of those speech syllables that incorporate brief, rapidly successive acoustic cues is most problematic for these children.

There is growing evidence from family and twin studies that developmental language learning impairments may aggregate in families and may be genetically transmitted. Twin studies have shown a particularly high concordance rate (heritability) for measures of phonological analysis (Bishop 1997). Family studies show that, as a group, infants born into families with a positive history of developmental language learning impairment demonstrate longer processing times for both nonverbal and verbal acoustic stimuli than matched infants born into families with a negative family history. When followed prospectively, nonverbal acoustic processing rates established at six months of age have been shown to predict the rate of language development, with infants showing the slowest processing rates subsequently being most likely to be delayed in language learning (see Tallal et al. 1993 for review).

In older children and adults, highly significant positive correlations between nonverbal auditory and visual dynamic sensory sensitivity and reading decoding (phonological and orthographic, respectively) also have been found across a number of studies (see Farmer & Klein 1995, Stein & Talcott 1999 for reviews). Importantly, highly significant correlations between dynamic auditory and visual sensitivity and literacy skills has been reported in normally developing children as well (Talcott et al. 2000). These recent findings provide strong evidence that individual differences in dynamic sensory sensitivity play an important role in the development of both oral and written language, across the entire range of development. As such, children with LLI may fall at the disadvantageous end of a normal distribution, rather than representing a distinct impairment.

The proponents of the 'linguistic-specific' hypothesis strongly dispute these data. They exclude any role for nonlinguistic processing constraints as a possible etiology for language learning impairments. Rather, they support a modular view of language processing and propose that language learning impairments are caused by failure of innate, 'language specific,' modules to function normally (see Leonard 1998 for review).

2.3 Neurobiological Studies

With the recent advent of *in vivo* brain imaging technologies, these powerful new methods have been applied to the study of the neurobiological basis of developmental language impairments. Electrophysiological studies support the results of behavioral studies showing specific deficits in phonological processing as well as acoustic analysis (Leppanen & Lyytinen 1997). Results from structural magnetic

resonance imaging (MRI) show that pars triangularis (Broca's area) is significantly smaller in the left hemisphere of children with language learning impairments and that these children are also more likely to have rightward asymmetry of language structures. The opposite pattern is seen in children developing language normally (Gauger et al. 1997).

Studies using functional neuroimaging such as magnetoenchephalography (MEG), have the advantage of providing both the spatial and temporal resolution most compatible with studying *in vivo* the real time neural processing involved in language. Recently, MEG has been used in an attempt to help resolve the hotly debated 'linguistic-specific' vs. 'rate processing constraint' hypotheses. These MEG studies have uniformly demonstrated significant physiological processing rate differences in individuals with a history of language learning disability, compatible with the rate processing constraint hypothesis (see Tallal et al. 1998 for review). However, the precise neural mechanisms that link these physiological rate processing constraints and the phonological and other linguistic deficits that characterize individuals with language learning disabilities, remain to be determined.

New evidence from neuropathological studies as well as functional magnetic resonance imaging (fMRI) studies has suggested that reduced cell size and density in magnocellular regions of the thalamus, leading to aberrant cortico-thalamic transmission, may underlie both the rate processing constraints and phonological processing problems of individuals with language learning impairments (see Stein and Talcott 1999 for review). Furthermore, differential cortical axonal myelination thickness has recently been postulated to underlie left hemisphere specialization for language function in general (Anderson et al. 1999), as well as for language learning impairments in particular (Klingberg et al. 2000).

3. *Remediation*

Remediation of language learning impairments is generally provided by speech language pathologists, psychologists, or special education teachers. Traditionally, speech and language therapy has been guided by a detailed linguistic assessment of the pattern of receptive as well as expressive errors made by an individual child using both standardized testing instruments and language sampling methodologies. Remediation has focused on helping the child to use age-appropriate linguistic structures in a variety of contexts. Reading remediation has focused on explicitly training children to recognize and manipulate phonemes within words (called phonological awareness) in an attempt to improve reading decoding skills, as well as on methods aimed at improving fluency and reading comprehension. Longitudinal outcomes research has shown that children with developmental language learning impairments generally require approximately two years of traditional intervention to acquire the equivalent of one year of gain in oral and written language development (see Leonard 1998, Lyon & Moats 1997 for reviews).

Electrophysiological studies of sensory fields in the cortex of primates have shown that the underlying neural circuitry can be altered after specific, temporally cohesive training regimens, leading to 'remapping.' These mapping studies demonstrate the dynamic plasticity of the brain (Jenkins et al. 1990). These studies recently have led to the development of new approaches to treating language learning impairments that incorporate temporally cohesive computerized training programs. Remediation studies, incorporating for the first time explicit dynamic auditory training, have been coupled with language training using speech that has been computer-modified to enhance and extend dynamic changes within the ongoing acoustic waveform. These studies demonstrated that explicit training, aimed at enhancing dynamic auditory sensitivity, results in highly significant improvement in temporal processing thresholds, speech discrimination, and listening comprehension (Merzenich et al. 1996, Tallal et al. 1996). These new remediation studies, together with those that have focused attention on phonological awareness training (see Lyon and Moats 1997 for review), have stimulated remediation research that aims to develop more scientifically validated approaches for the treatment of oral and written language learning impairments.

4. *Goals for Future Research*

Future research will need to continue to focus on etiology, specifically understanding the neurobiological, genetic, and environmental influences that contribute interactively to developmental language learning disabilities. It will be particularly important to better understand how nonlinguistic neural processing mechanisms (attention, dynamic processing, memory, and other executive functions) interact developmentally with linguistic systems in the brain during both typical and atypical language development. Integrating new data from advanced imaging technologies, genetics, and cognitive methodologies should lead to a better understanding of the causes and determinants of developmental language learning impairments. Determining whether language learning impairments represent a distinct impairment or rather lie at the disadvantageous end of individual differences along a normal distribution will also remain an important focus of research. The ultimate goal will be to understanding better the multiple factors affecting the broad array of individual differences that characterize the language learning process, which should in turn lead to the development of more effective methods for accelerating oral as well as written language

learning in all individuals, specifically those with developmental language learning impairments.

Language Obsolescence

Languages passing out of vernacular use are said to be obsolescent. As one of the possible outcomes of language contact, obsolescence may emerge both in conditions of universal multilingualism, as in the case of Tariana in the Brazilian Amazon (Aikhenvald 1996), and where a substantial part of an ethnic population has previously been monolingual, as in the case of the Gaelic-speaking fisherfolk of East Sutherland, Scotland (Dorian 1981).

The obsolescent phase of a language accompanies speech community members' shift to the use of some other language. Such a shift often comes about as a response to changes in political conditions (e.g., introduction of state-controlled schooling, transfer of territory to the control of a different state) or in economic conditions (e.g., heightened contact with outsiders through decline of traditional livelihoods or through new exploitation of local resources), or both. Language shift may also be prompted primarily by ideological factors, as in the case of Taiap, a language spoken only in Gapun village, Papua New Guinea. Despite physical isolation, limited school exposure, and continued pursuit of largely traditional subsistence activities, shift to the geographically expanding creole Tok Pisin (see *Pidgin and Creole Languages*) proceeds apace among Taiap-speaking villagers, chiefly because ideology links language, gender, and affect in ways that have steadily devalued the local vernacular as indexical of women (Kulick 1992).

1. The Emergence of a Proficiency Continuum

Except where a physical calamity (volcanic eruption, infectious disease, genocidal attack, etc.) brings about the death of most speakers within a short period, obsolescence advances gradually, accompanied by the development of a proficiency continuum. The oldest members of a speech community typically speak the ancestral language with high proficiency and some other language(s) equally or less well, while younger

members speak the ancestral language with diminishing proficiency and some other language(s) with higher proficiency.

1.1 Segmenting the Proficiency Continuum

While such continua are prominent in accounts of the structural effects of gradual obsolescence, no general consensus prevails on the levels of proficiency that should be recognized across the continuum. In one model, speakers of obsolescent languages are characterized as strong, with full or nearly full competence; imperfect, with less than full competence; weak, with restricted speaking competence; and at the low end as rememberers, capable of producing only words and isolated phrases (Campbell and Muntzel 1989). In another model, fully fluent speakers are divided into older and younger fluent speakers, according to age-related degrees of retention of conservative grammatical features; those who make grammatical mistakes recognized as such by the fully fluent are considered semispeakers and are again subdivided according to level of control of conservative grammatical features (Dorian 1981). The existence of age-atypical individuals can complicate the segmentation of a proficiency continuum. While there is normally an overall correlation with age, individuals within any age cohort may by reason of personal history be atypical; childhood residence with grandparents sometimes produces age-exceptional proficiency in the receding language, for example, whereas periods of residence away from the linguistic heartland may have the opposite effect.

1.2 Assessing Structural Changes by Sampling along the Proficiency Continuum

By sampling the usage of speakers at various points along the proficiency continuum, ongoing changes in phonological and grammatical structure can be identified in an obsolescent language. Caution is necessary both in identifying and in interpreting evidence of change, however. In assessing change, the norms against which any deviation is measured must be established strictly in terms of the most conservative local usage. Local norms are essential, since any standardized or official form of the language may be historically irrelevant to the local form, based mainly on quite different dialects, for example, or relatively recently devised. Furthermore, structural changes found to be in progress are not necessarily the unequivocal result of obsolescence as such since intensive contact with another language often promotes structural change, whether language shift is underway or not. Reports of structural convergence appear, for example, both where a language long in contact with others has become obsolescent (as with Tariana, cited above) and where languages long in contact with one another all continue to be maintained (as in the Urdu, Marathi, and Kannada case discussed by Gumperz and Wilson 1971). Generally speaking, the broader the age-range encompassed by the proficiency continuum and the larger the number of speakers sampled at various points along it, the greater the likelihood that changes to which obsolescence contributes substantially can be identified. Where circumstances permit, longitudinal sampling can offer important additional evidence, by determining the degree to which innovative structural features once absent or rare among the oldest and most conservative speakers establish themselves subsequently among those who were previously the younger speakers.

2. The Rise of Interest in Language Obsolescence

Interest in language obsolescence arises in large part from the very structural deviation that generally accompanies reduction in use and incomplete transmission. This is a striking reversal of earlier attitudes and preoccupations. Until the last few decades of the twentieth century researchers were intent on describing a language in the most intact form available and avoided working with speakers who controlled an ancestral language imperfectly. But insights from the study of language acquisition (see *First Language Acquisition: Cross-linguistic*), pidginization, and speech disorders suggested that language obsolescence, as another arena in which structural shortfall appeared, might make a similarly useful contribution to a growing body of knowledge about the nature of human language capacities. Interest grew, therefore, in exploring such questions as whether grammatical features acquired late would also be lost early, whether morphological complexity would be any more sustainable in obsolescence than it was in pidginization, whether obsolescent-language features without parallel in the language to which speakers were shifting would be maintained, and so forth.

2.1 Focus on Reduction and Loss

Because rising interest in obsolescence stemmed from questions such as these, early research focused strongly on reduction and loss in obsolescent forms of a given language. Dressler (1972) looked at phonological rule loss in Breton, Hill (1973) at decreasing subordinate clause density in Luiseño and Cupeño, Dorian (1973) at loss and merger in nominal case and passive voice in Scottish Gaelic, and Dorian (1978) at decreasing morphological complexity in plural and gerund formation in Scottish Gaelic. The first two larger-scale studies of obsolescent languages were similar in focus. Dorian (1981) reported weakening and loss of grammatical gender in pronoun replacements, weakening of case in the noun phrase, progressive loss in verbal inflection, reduction of allomorphy in the formation of

noun plural and gerund, and substitution of analytical constructions for synthetic ones among imperfect speakers of an obsolescent variety of Scottish Gaelic. Schmidt (1985), investigating obsolescent Dyirbal in Queensland, Australia, noted similarity of reductive and replacive phenomena on the morphological and syntactic levels: replacement of ergative structure by nominative/accusative structure; allomorphic reduction in the nominal case system; loss of a distinction between alienable and inalienable possession; generalization of a single case affix over various case functions; English prepositions used in place of certain suffixes, or marking simply lost; substitution of free-standing words for tense-marking verbal affixes; regularization of an irregular verb inflection and of certain complex noun-marker paradigms; breakdown in agreement rules in the noun phrase and verb complex; rigidification of word order; and simplification of the noun classification system.

In these and subsequent accounts of the structural phenomena that accompany increased language contact and ongoing language shift (e.g., Silva Corvalán 1994, Holloway 1997), certain processes are conspicuous by their recurrence, e.g., outright loss of certain morphological markers, allomorphic reduction, paradigmatic and syntactic regularization, substitution of analytic structures for synthetic structures, and convergence with the phonological and grammatical structure of an expanding language in the contact setting. These are changes long familiar from the study of language history, including cases in which obsolescence was not at issue. In consequence, obsolescence researchers have generally favored the position that the changes characteristic of obsolescence are well recognized historical processes appearing with higher incidence in conditions of obsolescence and advancing more rapidly (Dorian 1981, Schmidt 1985, Silva Corvalán 1994).

2.2 *Focus on Retention of Complexity*

Early research on language obsolescence brought to light anticipated reduction and loss but produced at the same time considerable evidence of retained complexity. Despite increased favoring of a single suffix in imperfect Scottish Gaelic speakers' plural and gerund formations, for example, suffixation did not become the sole formation process and allomorphy remained diverse. Despite reductions in inflectional morphology among young Dyirbal speakers, the same speakers preserved notable complexity in derivational morphology. Particularly contrary to expectations was the finding that grammatical structures without parallel in the expanding language could survive in the usage of speakers toward the lower end of the proficiency continuum. With no reinforcement of grammatical gender available from English, for example, and despite the disappearance of gender-differentiated pronoun replacement in their Gaelic, gender differentiation in high-frequency diminutive formation remained relatively strong among imperfect English-dominant Gaelic speakers in East Sutherland. Young Dyirbal speakers maintained two verb conjugations surprisingly well in some structures, even though English has only one productive verb conjugation.

These findings have been important in establishing the structural phenomena of language obsolescence as distinct from those of pidginization or creolization and from those of first-language acquisition. Imperfect adult speakers of obsolescent languages are by definition bilingual at least. They have the cognitive equipment of adulthood as well as extensive experience with at least one other language to draw on at communicative need. Borrowing and code-switching are available to them, of course, and they have the inventive capacity of adults to extend in potentially novel ways the structural or semantic reach of whatever ancestral-language elements they have available. A weak semispeaker proved for example to have developed her own system for keeping grammatical genders distinct to some extent, in the nominal case system of East Sutherland Gaelic, despite the fact that she lacked one of the central morphophonemic devices used for that purpose by fully fluent speakers (Dorian 1986).

3. *Evidence of Linguistic Creativity in Obsolescence*

Apart from such individual cases of creativity as this last, more generalized instances have been noted. Imperfect younger speakers from a Hungarian population in a predominantly German-speaking region of Austria demonstrated the ability to use a structural property of Hungarian, expression of one grammatical or derivational category per morpheme in concatenative word-formation, to create grammatically regular constructions that substituted intelligibly for irregular formations which they lacked (Gal 1989). More strikingly, recent research has demonstrated that obsolescence is not a barrier to the development of new grammatical structures, even for speakers whose proficiency in an expanding language exceeds their proficiency in the recessive language. Ongoing potential for grammatical elaboration therefore joins retention of grammatical complexity in establishing that the phenomena associated with language obsolescence are not solely those of progressive reduction and loss.

3.1. *Development of New Grammatical Structures in Obsolescent Languages*

When certain grammatical distinctions cease to be made by speakers of an obsolescent language, grammatical elements (particles, nominal or verbal affixes,

functionally distinct forms of adverbs, etc.) may be emptied of their original grammatical content, after which they become subject to loss or to reinterpretation. While loss is certainly commonplace and reinterpretation sometimes amounts to no more than the development of variant forms, reinterpretation can also give rise to novel grammatical structures. Morphemes which formerly served as nominal case markers have emerged as focus-markers in Jingulu, for example; prominent now in this obsolescent Australian language, the focus-markers can be shown to have developed during the past four decades (Pensalfini 1999). New verbal morphology has similarly appeared in obsolescent Tariana, via grammaticalization of elements derived from compounded verbal roots and serial verb constructions (Aikhenvald 2000). Speakers of an obsolescent Walser German dialect in northern Italy have developed a complete set of verbal inflections for person via the familiar process of reanalysis of postverbal clitic pronouns as personal endings (Dal Negro 1998). As these instances demonstrate, the linguistic processes involved are once again not unique to obsolescent languages.

4. *Methodological Problems in the Study of Obsolescence*

4.1 *Inherent Difficulties in Assessing Imperfect Speakers' Linguistic Competence*

Some of the difficulty in establishing parameters of obsolescence stems from methodological obstacles to assessing low-proficiency speakers' competence. Even where the least proficient speakers willingly undertake assessment exercises such as translating set sentences or supplying a story-line to accompany a series of pictures, their performances may be affected by psychological or cultural factors: degree of acquaintance and compatibility with the researcher, anxiety about the adequacy of ancestral-language knowledge, uncongeniality of question-and-answer interactions, and so forth. Since failure to produce particular material on request can by no means be equated with inability to produce it, this remains a serious methodological shortcoming. Certain types of social encounter can evoke previously unavailable evidence of imperfect-speaker skills, as a chance encounter with a lonely Gaelic-dominant hospital patient did in the case of an East Sutherland Gaelic semispeaker; but by their very nature such encounters can seldom be staged or recorded. In Gapun village the attractiveness of Kulick's recording machinery allowed him to coax from a young child who routinely used Tok Pisin for extended speech an unexpectedly intact short narrative in Taiap (Kulick 1992). Receptive bilingualism in near-passive bilinguals uncomfortable with testing can sometimes be evaluated via macaronic interviews, with the researcher speaking only the receding language and the interviewee responding in the expanding language (Dorian 1999).

4.2 *Cultural Differences as Obstacles to Assessing Imperfect Speakers' Linguistic Competence*

In some settings the cultural norms for transmission of knowledge disfavor the question-and-answer approaches researchers have often used to isolate the individual elements of complex grammatical systems. Speakers may resist answering strings of questions, preferring to offer instruction by companionable activity or by story-telling. Recording narratives from speakers willing to go over them in detail with the researcher subsequently is a more successful and productive technique for phonological and grammatical analysis in some settings (Dixon 1984), although it may preclude direct comparison across the proficiency continuum unless a number of different speakers can offer versions of the same narrative.

There appear also to be differences in the degree to which imperfect speakers in late-stage obsolescence settings are willing to make spontaneous use of what active skills they have. In some Arvanitika-speaking districts of Greece, extremely low-proficiency individuals willingly produce this Albanian speech variety at a structural level that one researcher characterizes as 'pathologically' malformed (Sasse 1992). Spontaneous speech at this low a proficiency level, independently confirmed for Arvanitika (Tsitsipis 1989), would be highly unusual in some settings and therefore unavailable for study; Arvanitika currently stands as an extreme case for spontaneous low-proficiency speech production in an obsolescent language.

5. *Lacunae in Obsolescence Studies to Date*

In an important attempt to distinguish the effects of language obsolescence from those of language contact more generally, Sasse (1992) has pointed to acquisition by exposure alone (hearing the language spoken in one's vicinity) rather than by active transmission (being addressed in the language and expected to reply in it) as the crucial factor in giving rise to the low-proficiency producers of 'pathological' Arvanitika. One well-studied individual who had an exposure-only acquisition history for East Sutherland Gaelic produces far less malformed spontaneous speech than do the weakest Arvanitika semispeakers (Dorian 1999), but the effect of acquisition history merits closer study, especially in incipient obsolescence settings where families differ in the extent to which they use the ancestral language with their children. Studies of whole communities which share an ancestral language, but differ in degree of contact with a particular expanding language, and hence in the degree of shift,

are needed for what they may reveal of progressive stages in convergence, reduction, and loss of specific structural features. Again to illuminate the effects of contact, studies of a single language in contact with a variety of expanding languages would be useful.

Language Policy: Linguistic Perspectives

The planned allocation of resources to language is but one of many instances of organized and purposive intervention into areas of social usage and social change. Although the discussion here will be restricted to governmental policy in connection with language, given that such governmental interventions affect the largest numbers, language policies are also adopted and implemented by nongovernmental organizations and interest groups. Indeed, even individuals frequently implement their own language policies of the various kind described below, and/or advocate such policies for more general adoption. Language policies are of two major types: (a) language status policies, pertaining to the desired or permitted public societal functions of particular languages, and (b) language corpus policies, pertaining to the desired or permitted features of languages themselves, whether in connection with their writing systems, orthographies, pronunciations, lexicons, and/or grammars. Language policy is both an applied and a theoretical field of endeavor and the influence of the one on the other has been both substantive and productive (Kaplan and Baldauf 1997).

1. Language Status Policy

Language status policies are either prohibitory, permissive, or facilitative. If policies are prohibitory they oppose and penalize the public use of particular languages for particular societal functions. Thus, the 'English Only' movement in the United States opposes any requirement that American governments (federal,

state, or local) use any language other than English in the discharge of their governmental functions (including direct services to the public, whether or not its members have a command of English). During the years of the fascist Franco regime in Spain, the regional Iberian languages (primarily Catalan, Basque, and Gallego) were prohibited in public, whether spoken or written. The Communist regime of the Soviet Union prohibited publication in, or the teaching of, Hebrew (thereby effectively rendering inoperative religious Jewish services or traditional schooling) due to that language's perceived theological and bourgeois (i.e., antirevolutionary) associations. One of the earliest examples of modern prohibitive language policy is the 'abolition' of the regional languages (pejoratively referred to as 'patois' or 'dialects') by the French Revolution toward the very end of the eighteenth century (Schiffman 1996, Tabouret-Keller 1999).

Permissive language policies are presumably 'neutral.' While they permit nongovernmental efforts on behalf of, or in opposition to, particular languages (or in conjunction with all languages other than the national or official languages which are, naturally, supportively treated), they neither obligate the government positively nor negatively with respect to such languages. During most of its history, the USA has had a permissive language policy, making it possible for citizens of various non-English mother tongues to advocate on behalf of these languages publicly, seeking for them recognized functions above and beyond any religious functions which some of them may have and which are separately protected by the Constitution. The search for additional functions may aim at and utilize both print and nonprint media, and may aspire to functions such as becoming the medium of instruction in the public education of their young, or advocacy of governmental use of these languages in discharging various official services to speakers of these languages (e.g., in the courts, in the fire, police, and health services, as well as in social services more generally).

However, the absence of supportive policies has meant that when the mother-tongue speakers of non-English languages finally learn English (as all of them have done within a generation, or at most two), the Government has permitted these languages to fade away in public as well as in private life, and has in no way been committed to their functional continuation as a potential resource for American diplomatic, commercial, or intellectual/cultural growth. Because of such passively permissive policies, even major world languages such as German, French, and Spanish have thus far failed to be intergenerationally continuous in the US, even though all of them predate the establishment of the United States on American shores. The unwritten nature of permissive policies has also meant that little if any prior supportive legislation has had to be annulled on the few occasions when prohibitive policies have been implemented (e.g., the post-World War I, anti-German or anti-foreign language legislation in Nebraska and in several other mid-Western states—later overturned as unconstitutional by the Supreme Court decision *Meyer vs. Nebraska*, 262 US 390, 1923).

Since to post-World War II sensibilities prohibitive policies smack of anti-minority discrimination, such policies have often been replaced by purportedly permissive ones. The effective differences are often minor or totally absent, since the lack of outright supportive policies usually leaves demographically, functionally, and attitudinally threatened languages bereft of tangible opportunity to reverse their deteriorating fortunes.

Supportive policies are either across the board (multifunctional), or functionally specific in their focus. The Swiss government's support of Romansh has been multifunctional, spanning support for nursery schools, elementary and secondary schools, courses for adults, the preparation of visual and auditory media, periodical publications, and book publications. The Canadian government's Ministry of Multicultural Affairs supports cultural programs, publications, creative artists and curricular materials preparation for the immigrant languages (termed 'heritage languages' to differentiate them from the founding languages—English and French—or the indigenous languages of Canada), although the latter alone are still responsible for providing most of the basic funding for the schools, theaters, and media that utilize their languages. During most of the 1980s and 1990s, Australia's language policy with respect to immigrant languages has gone beyond that of Canada by also providing funds for teacher training and certification, as well as for student competence certification, in connection with ethnic community supplementary schools—for LOTEs (languages other than English).

In addition, many of these very same community languages have been added to the foreign language programs of elementary and secondary schools servicing ethnic neighborhoods in large urban centers. Australia has also had an unusually effective program of supporting radio and television in many of the LOTEs. However, toward the end of the 1990s many of the above supportive policies have been curtailed or phased out entirely, as the Liberal Party has assumed the leadership previously in Labor Party hands. In the US, Title VII Bilingual Education remains the most obvious example of supportive policy toward other languages, even though this policy has had transitional purposes (subtractive bilingualism leading to English alone) as part of its avowed purpose. Since all three policies (those of the US, Canada, and Australia) obtain in English-mainstream and immigrant-based societies, the differences between their policies is indicative that the omnipresence of English (or any other language of wider communication) need not

necessarily lead only to prohibitory or permissive policies vis-à-vis sidestream or less powerful languages.

2. Reversing Language Shift

One of the most demanding (and, often, most disappointing) areas of language status policy-efforts deals with the attitudinal, demographic, and functional recovery of languages that have become seriously weakened by virtue of competition with their neighbors. Prolonged and debilitating reverses often lead to language death, on the one hand; and to re-ethnification, on the other hand. Indeed, both these outcomes may themselves be the conscious or unconscious consequences of prior, or even still ongoing, language policies, at the very same time that permissive or even supportive efforts are underway for one or more threatened or weakened languages within the very same polity. When the lost or weakened functions are narrowly specific (e.g., press, media, curricular recognition as subjects of instruction), similarly specific and delimited efforts can be undertaken to reverse or, at least, more nearly balance the social forces that are at play. This is not the case when intergenerational mother-tongue continuity (rather than mere language reproduction) is in question. Mother tongues (taken as the most frequent language of early home, family, neighborhood and community life) are, by definition, acquired early, quickly and intimately (i.e., affectively). As a result, it is difficult, for formal and authoritative policies to rationally determine either their acquisition, or their retention through the period from one generation's mother-tongue acquisition and the time some 20 years off when the next intergenerational transition occurs (Fishman 1991).

The difficulties encountered in the long-term planning of intimate and informal interactions (or even in the reinforcement of such interactions via formal institutions such as schools, governments, economies, and media) has resulted in very few successes along the lines of reversing language shift in twentieth-century historical perspective. The more recent partial successes along such lines by efforts on behalf of French in Quebec, Catalan in Spain, and the clearly unusual case of Hebrew in Palestine/Israel (where prestigeful, formal [written/read], and theological functions predated the language's revernacularization) have encouraged renewed and better informed efforts on behalf of Basque, Frisian, Maori, and even Irish. (The last named suffering from approximately 80 years of unsuccessful efforts to foster widespread intergenerational mother-tongue transmission, notwithstanding an array of supportive policies.) In order to achieve the desired results, the realm of intimacy-and-infancy must be successfully ideologized as to its consequences for language transmission, but even the institutions that are not normally effective within, nor focused upon, the infancy/intimacy realm (school, media, worksphere, and government) must be focused upon language interaction with home, family, and neighborhood processes; and the threatened language must be explicitly related to the rewards to which these institutions can lead. This difficult and long-term intergenerational feedback process—(a) within, and (b) upon the informal nexus of language transmission—has been conceptualized in terms of a Graded Intergenerational Dislocation Scale (Fishman 1991). This scale highlights the priority of re-establishing informal and intergenerational interactions, the interruption or attenuation of which is viewed as particularly mother-tongue dislocative (just as the higher numbers on the Richter earthquake scale indicate greater damage and threat to life), in contrast to dislocations of formal functions normally distant and compartmentalized from the mother-tongue transmission nexus, and not normally directly related thereto.

All in all, whether in connection with reversing language shift, or in connection with other policies pertaining to the authoritative recognition of particular languages in particular societal functions, the policy culture in connection to language issues closely corresponds to the policy culture that local authorities are accustomed to, or are obliged to, utilize more generally. Democratic authorities generally begin with open policy debate (including the exchange of promises and commitments, 'bargaining,' related to forthcoming other-than-language decisions and resource allocations). This is followed by policy adoption ('decision making'), codification (the formal wording of the law), and elaboration (the law as interpreted in practical terms of 'regulations') of the decisions reached; implementation of the foregoing; ultimate evaluation by other authorities or specialists than those entrusted with formulation and implementation of the adopted language policies (wherever such separation of formulation, implementation, and evaluation are built into the political culture); and, finally, iteration of language policy debate in subsequent areas highlighted for attention.

The culture of policy formulation and implementation in the language field is clearly an instance of the more general policy culture that is locally and contemporaneously in place. Where political stability is lacking, newly elected or empowered language policy authorities may counteract those that have been previously enforced and may undertake policy replanning along different and even quite contrary lines. Such replanning commonly has both status consequences and corpus consequences for the languages to which they pertain (Clyne 1997).

3. Language Corpus Policy

Languages that are not customarily used to discharge certain societal functions commonly lack the corpus features that are required for such functions, all the

more so if they have never (or not for prolonged periods) been associated with the implementation of these functions. Accordingly, language policies may be called upon to devise writing systems, establish spelling norms, promulgate standardized grammatical conventions (particularly for nonfiction prose), foster different styles for different kinds of writing (e.g., popular newspaper style vs. serious adult reading style for languages that have exercised neither function before), create or recover terminologies (e.g., for the natural sciences), or repair lexical gaps (e.g., in revising the pronoun system in order to reflect and foster democratic and egalitarian interpersonal address and interaction). Such corpus policies may be enacted by the very same governmental or quasi-governmental authorities that are involved in status policy formulation and implementation; but, because of their more technical nature, more commonly, they are entrusted or delegated by the latter to special boards, committees, or 'academies' of linguistic specialists. On occasion, various illustrious leaders and exemplary writers and intellectuals have been instrumental in propelling corpus planning in particular directions closely allied to their own preferred usage (e.g., Luther for High German, Pushkin for Russian, Bialik for Modern Hebrew, Perets for Yiddish, Cervantes for Castilian). This frequent prominence of individual 'influentials,' particularly in early corpus planning stages, is the reason why such planning efforts often precede those undertaken by governments, or even precede the establishment of governments and governmental corpus planning authorities (Rubin et al. 1977).

Although linguistically technical, the corpus planning of academies is commonly exposed to two different and possibly contradictory sources of influence. The first is the acceptability of corpus recommendations insofar as the intended target group is involved. In this connection, considerations of euphony, transparency, simplicity, absence or presence of cognates, or other esthetic and 'least effort' notions may prevail (Fishman 1997). Another powerful (and even a more powerful) direction of influence upon the efforts of corpus planning and corpus policy is the ideological interpretation given to such efforts by the political authorities who are engaged simultaneously in culture planning (i.e., in national identity planning) more broadly. Accordingly, corpus policy is regulated in accord with bipolar considerations such as uniqueness, authenticity, purity, and classicization, on the one hand, and modernization, regionalization, vernacularization, and internationalization, on the other hand. These emphases all differ to some degree, but they may all be subsumed under the general bipolar rubric of independence vs. interdependence. Since the facilitation of economic and political interaction within the modern world is generally a prime underlying motive in all modern corpus planning, the need to maximize linguistically both the interactive advantages and the independent challenges of modern life provide language policy, particularly with respect to its corpus concerns, with a built-in tension which can often be very anguished in those language-policy settings where the rejection of internal or external colonialism and the liberation from other foreign influences come to be of primary concern.

The 'authenticity' pressure upon late-modernizing languages that are faced either by confrontation with 'genetically related' Big Brothers (i.e., with long-established and well-modernized languages of similar lexical and structural characteristics to those of the late-modernizing language), or even faced by other, genetically similar, recent arrivals at the gates of modernity have long been studied. Languages in interaction and ethnicities in interaction are both dependent on considerable constructivist effort—namely policy interventions *per se*—in order to render them recognizably and consensually 'separate,' at least within their own authoritative frameworks. The policy and planning effort on behalf of authenticity-motivated distancing has been termed 'Ausbau' i.e., the building away of one language from another, by emphasizing the real, imagined or preferred differences between them. Endlessly exploitable sources of such differences may be found in older (archaic) periods of the language, in the varieties of the rural countryside that have suffered from fewer foreign/urban influences, or in a favored classical language of particularly acceptable historical, religious, or cultural significance. Ausbau efforts have been engaged in as part of the corpus policy of Hindi and Urdu relative to each other, of Macedonian vis-à-vis Bulgarian, of Yiddish vis-à-vis German, of Ukrainian vis-à-vis Russian, of Belorussian vis-à-vis both Russian and Ukrainian, of Moldavian (under Soviet influence) vis-à-vis Romanian, of Slovak vis-à-vis Czech, of Rusyn vis-à-vis Ukrainian, etc. More general 'purification' movements exist, e.g., for French (vis-à-vis English), for North Korean (vis-à-vis Mandarin borrowings), for Catalan vis-à-vis Castilian, for Czech vis-à-vis German, for the newly independent Baltic languages vis-à-vis Russian, for Navaho vis-à-vis English, for Hebrew vis-à-vis Yiddish and English, for Yiddish vis-à-vis Russian, etc.

Of course, all languages whose communities are engaged in interactive modernization with the Western World are exposed to linguistic influences as a result thereof. Since the material and intellectual gains attributed to the general interactive stance often seem incontrovertible, the corpus policies that attempt to limit or counteract the lexical and structural borrowings that are rooted in, and that derive from, interaction with and exposure to the West are faced by a dilemma from which there is no simple or easy escape. Indeed, one school of linguistics (the so-called 'Prague School') explicitly recognizes this tension but regards the 'national language' to be the supradialectal and generally written variety of the local linguistic rep-

ertoire which is most consistently monitored by nationally oriented linguists with the goal of keeping it as authentically pure as possible. In North India this process takes the approach of Sanscritization, in South India: of Classical Tamilization, i.e., of genuinely local classicals which can both intellectualize and de-Americanize or de-Westernize the corpuses of their modernizing local national languages. Language corpus authenticity (usually experienced as primordial) and language status Westernization (usually as a result of constructivist experiences) are often pursued simultaneously (or seriatim), eliciting tensions in either case.

4. *Linguistic Culture*

Obviously, status planning and corpus planning policies are also pragmatically (rather than only ideologically) closely interdependent. What would be the good of achieving the status goals of any given language policy if the corpus remained as inadequate to discharge or implement those statuses as it had, perforce, been before the status goals had been pursued? Conversely, what would be the good of endless corpus refinement if there were no societally recognized and protected functions in which the new lexicons, grammars, spellers, and writing systems could be put to use? Indeed, when one policy emphasis (whether status or corpus) is too far in advance of the other, then this lack of synchronization is itself a major policy problem. Accordingly, all language policy efforts, even in advance of any governmental recognition, require both linguistic expertise and political expertise in order to move ahead productively in connection with their language goals.

The diversity of talents required to bring language policies into operational rather than merely theoretical existence is well illustrated by the 'first congresses' that have been organized all over the world on behalf of different late-modernizing languages (Fishman 1993). Those organized primarily under academic auspices have least commonly attained their stated status goals (e.g., re the Mayan languages or Yiddish). Those convened by jubiliant nationalist movements have often found themselves without technical linguistic expertise or consensus, even when they were triumphantly swept into power (e.g., re Macedonian). Those organized by pre-existing cultural or political organizations have most frequently combined both the political constituencies and the technical scholarly expertise needed to attain their goals (e.g., re Catalan, Hindi, or Hebrew).

In any case, the goals and means employed in conjunction with linguistic policy reflect the historically deeply ingrained linguistic culture of its sponsoring power base. Language policies are expressions of a long-lasting 'linguistic culture—i.e., of the cultural myths and cultural values pertaining to the types of linguistic accommodations, programs, and efforts that are in accord with the brunt of local historical experience and aspiration (Schiffman 1996). Rather than being expressions of conscious or unconscious linguistic determinism, language policies are generally expressions of widespread convictions that the furtherance of crucial national policies more generally also require language status policies and language corpus policies that can contribute to national policies as a whole.

Language Policy: Public Policy Perspectives

Language policy involves the governance of diversity arising from historical configurations, recent immigration, or both. Whereas it is possible for a state to adopt a neutral stance with regard to a variety of religions, or to make itself blind to ancestry, it cannot choose to become mute or deaf. Because of the widespread belief that language differences are a source of political instability and societal conflict, as well as that they constitute an economic liability, policies are commonly designed to reduce the actual diversity encountered among the population and to minimize its potential growth. This reductive tendency is reinforced by the costs of multilingual services and

institutions. Consequently, over three-quarters of the world's countries have central governments that are officially or effectively monolingual; but half of them contain linguistic minorities of 10 percent or more; and in about one-third of the cases, a majority of the inhabitants do not use the official language as their everyday speech. Even where central governments are officially multilingual, the languages recognized rarely encompass the full range of everyday speeches used by the population (Laponce 1987, pp. 95–102).

The development of languages, especially in written form, has been closely interrelated with state formation. For example, Chinese ideographic writing, elaborated over 4,000 years ago into a system for ruling a vast empire that encompassed a wide variety of spoken tongues, contributed to the unique resiliency of China as a polity despite many upheavals and regime transformations and still serves as an instrument of communication between groups whose spoken languages are not mutually intelligible. By contrast, the European pattern, which was set when the Athenian and Roman empires elaborated the vernaculars of their respective territorial centers into onomatopoeic written languages, rendered these polities more vulnerable to disaggregation into territorial entities constituted around other vernaculars (Diamond 1999 pp. 215–38, 322–33). Vastly facilitated by the advent of printing in the late fifteenth century, linguistic unification within territories moved to the fore as Europe's rival states sought to transform their populations into 'nations' sharing a distinctive identity (Anderson 1983, Gellner 1983). In both France and the United Kingdom, state expansion by way of the incorporation of peripheries or of adjoining foreign territories, the advent of mass armies, democratization, and industrialization, rendered linguistic unification ever more urgent (Nordman 1998, de Certeau et al. 1975, Weber 1976, Dillard 1985, Colley 1992). Both states imposed strikingly similar repressive language policies on their respective Celtic peripheries, and both also adopted analogous language policies in their colonies with regard to central administration and the education of indigenous elites.

By virtue of the hegemonic position the states of Western Europe achieved in the modern world system, linguistic unity came to be equated with modernity and emerged as a global norm that shaped policy among the states arising from European settlement in the Americas and Oceania, notably the United States, where the founders expressed concern over the persistence of German-speaking communities, as well as among the modernizing empires of the European periphery and, later on, the postcolonial states of Asia and Africa. But the fact that most of the latecomers had more heterogeneous linguistic configurations than Western Europe during the equivalent period of state formation rendered the pursuit of uniformity illusory. Paradoxically, Europe's equation of state with nation also fostered a contradictory norm, whereby distinct linguistic groups were entitled to political autonomy. The tensions between these two norms, as well as the discrepancies between them and socio-linguistic realities, are at the root of the wide variety of language policies observable in the world at large today and of the contentions they evoke.

Although language has long been of concern to states because of its instrumental and symbolic functions, issues of language policy have recently achieved unprecedented prominence as a concomitant of the expansion of governmental activity and of citizen participation, as well as of the advent of postindustrial conditions that enhance the value of linguistic skills (Bell 1973). Among older self-acknowledged multilingual countries such as Belgium, Switzerland, and Canada, historical arrangements reflecting earlier power relationships between the groups have been called into question. This is true also of situations involving surviving indigenous minorities such as the Saami in Norway and Native Americans in Canada, the United States, or the Amazon basin. Concurrently, the decolonization of imperial possessions in Asia and Africa has resulted in the emergence of a large number of new states with heterogeneous and complex configurations involving both indigenous and imperial languages. Previously established arrangements have been called into question also among the new states of the post-Communist world. The quantitative growth and expanding scope of international migrations has produced additional diversity in both old and new states, while changing attitudes toward the incorporation of immigrants have broadened the range of policy responses, notably with regard to the education of immigrant children. Beyond the state level, entirely new language questions are being raised by the formation of international organizations engaged in governance, notably the European Union. Finally, policy makers throughout the world must deal with the implications of the ascent of English as the first global language.

A basic policy choice is whether or not to declare one or more languages 'official.' Among older states in which one language was clearly dominant, as in the Netherlands, the United Kingdom, Italy, Thailand, or the United States at the time of the founding, the default stance was silence, reflecting the fact that the language's hegemonic status was taken for granted. In relation to this baseline, the specification of an official language expresses determination to maintain or reinstate the status quo in the face of changing practices or perceived challenges. In this vein, in the last two decades of the twentieth century, approximately half the states of the United States adopted laws or constitutional amendments declaring English their official language, and there were efforts to enact a constitutional amendment to that effect at the national level as well. In 1992 the French government also initiated a constitutional amendment establishing French as the national language. Among multilingual

states, 'officialization,' which usually involves an invidious distinction between privileged languages and others, signifies the establishment of a language regime providing general rules for policy making.

Whether or not a regime has been formally established, language policy involves at the minimum a determination of the language(s) in which public services are provided, ranging from the posting of street signs to the educational system and law enforcement; of the linguistic qualifications of the appropriate officials and government employees; of the language(s) in which citizens can exercise their rights, notably voting, contacting representatives, or officials, or defending themselves against charges; and of the language(s) in which citizens are expected to exercise their obligations, such as military service, paying taxes, or maintaining business records subject to inspection. Language policy usually extends also to the specification of criteria for membership in the society, as expressed in linguistic requirements for naturalization and occasionally for immigration itself. Beyond this, the advent of the welfare state has drawn government deeply into the private sector, notably to monitor the appropriateness of language requirements for various types of employment and to insure the availability of consumer information, such as labels, to the several language communities. State intervention may extend to the regulation of language use in printed and electronic media, and even in private speech. The persecution of human beings merely for speaking their mother tongue is an extreme but unfortunately not uncommon manifestation of language policy.

In all types of states and at all levels of governance, language policy is often acutely controversial because almost any institutional arrangement entails an uneven distribution of costs to the individuals affected, considered as members of distinct language groups (Pool 1991, De Swaan 1991). The costs are both economic and psychological because language not only carries considerable weight as capital in the determination of socioeconomic status (Bourdieu 1979), but also is intimately linked to the formation of personal and collective identities. Overall, language institutions reflect prevailing class and majority-minority relations. The development of policy in this as in other spheres tends to be path-dependent. Established conceptualizations, power relationships, and institutional arrangements, set a course from which it is difficult to depart; consequently, there is likely to be a considerable discrepancy between political and social conditions at the time these institutions were established and the present. Understandably, challenges to the status quo tend to arise from efforts by the disadvantaged to lessen the costs they bear. Characteristically, the resulting confrontations take on the features of a constant-sum game, even if the proposed policies do not impose very great economic costs on the larger community, because those who hold the upper hand perceive the change as a decline of hegemony. The relatively modest costs imposed on the majority tend to be inflated, and the new arrangements magnified into a threat to the community's integrity.

The agenda of language policy arises in the first instance from a population's actual socio-linguistic configuration, itself shaped by past policies. Relevant aspects include not only the number of languages and the size of the groups, but also their spatial distribution (territorially concentrated vs. dispersed); their sociopolitical power (languages that have achieved written form and are used in government, business, and science, vs. others); and whether the relevant groups are native or immigrant. Other significant elements of the sociolinguistic configuration include the language groups' location in relation to the poles of political and economic development (center vs. periphery), as well as the relationship of language differentiation to the overall stratification system and other cultural signifiers, notably religion and physical appearance or ancestry (Laponce 1987, pp. 120–35).

Another weighty factor is linguistic culture, the set of behaviors and beliefs a speech community has about its own language and the others with which it comes into contact, whose explicitly political aspects may be termed linguistic ideology (Schiffman 1996, p. 5, Stevens 1999). The culture or ideology of the dominant group(s) naturally carries extensive weight in the determination of policy. Of special import in the contemporary period are the cognitive elements of linguistic culture, notably scientific discourse. For example, in the early twentieth century, British psychologists reported, on the basis of studies of Welsh children, that bilingualism interfered with the development of intelligence. Their findings supported the maintenance of an educational system that brutally suppressed Celtic speech on behalf of total immersion in English. The harmfulness of bilingualism was subsequently confirmed by American psychologists investigating Japanese children in California and immigrant European children in New York. This theory prevailed until the 1960s, when Canadian research, undertaken in the context of a reformist national administration more responsive to French-speakers' grievances, not only exposed the studies on which it had been based as deeply flawed, but suggested instead that bilingualism produced beneficial effects (Hakuta 1986, pp. 14–27). The new theory was then quickly invoked by Hispanic advocates of bilingual education in the emerging US debate on the subject. Of special relevance in the Third World is the ambiguous cultural loading of the colonial language in postcolonial countries: on the one hand it is resented as a language of subjection, but on the other admired as a language of prestige, which is also instrumental for accessing the world at large. The resulting ambivalence is often manifested in the educational sphere. For example, Algeria has undertaken to replace French with Arabic in its elementary schools—without concessions to the country's large Berber-speaking

minority—but is maintaining French as the language of instruction at higher levels.

Language policy varies also as a function of the general political regime. The historical expansion of political participation to encompass the more modest strata of the population imparted to language minorities greater weight in the political arena, fostering demands to lower what they perceived as an unduly large share of language costs by providing public services in additional languages as well as reducing or eliminating linguistic obstacles to upward mobility by way of education. Similar challenges tend to arise among hitherto authoritarian countries in the course of democratization. Another important regime variable is its degree of centralization. By virtue of the prevailing normative equation 'language = nation,' where linguistic minorities are territorially concentrated, demands for greater linguistic equity tend to engender, sooner or later, aspirations to greater political autonomy, which are much easier to fulfill within a federalist framework (Switzerland, Canada) than a unitary one (e.g., pre-1970 Belgium). Indeed, democratization tends to propel hitherto centralized multilingual societies with spatially concentrated groups toward federalism (Belgium, post-Franco Spain). Devolution of authority to the regional level with concomitant control over linguistic policy generally satisfies demands for autonomy (Fishman 1986), but separatist aspirations may persist (e.g., Quebec), and occasionally result in the breakup of existing states (Czechoslovakia, Yugoslavia).

The combined effect of these factors in determining policy variation can be highlighted by way of cases illustrating characteristic situations encountered in the world today.

1. One-language Dominant 'First World' Democracies

1.1 United States

Despite the absence of a formal national policy, English reigned unchallenged at the federal level from the founding onward and was imposed as a matter of course on non-English-speaking dependencies such as Indian reservations, Hawaii, and Puerto Rico (Fishman 1986). However, in the course of the nineteenth century states and local bodies often diverged from this norm in response to local conditions: Spanish was recognized in New Mexico's constitution; numerous school boards provided a modicum of bilingual public education to their immigrant communities; the use of foreign languages in the press and private education was unquestioned; language requirements for naturalization were minimal, if they existed at all; and foreign language ballots occasionally appeared as well. German was particularly widespread among public institutions throughout the Midwest. However, hostility to the 'new immigration' from eastern and southern Europe of the late nineteenth century triggered demands to restrict admissions and to Americanize newcomers forcefully. The movement achieved considerable success in the wake of World War I, when German was in effect eradicated from the public sphere, including education. However, its triumph was limited by the *Meyer v. Nebraska* decision (1924), in which the US Supreme Court ruled on due process grounds that states did not have the authority to prevent the teaching of foreign languages (Wexler 1996, p. 346). Nevertheless, as noted earlier, the educational community overwhelmingly supported monolingualism on pedagogic grounds. Notwithstanding acceptance of cultural pluralism in other spheres, an English-only regime prevailed throughout the country for the next half century, except for the recognition of Spanish as the language of Puerto Rico in the New Deal era.

Policy changes, amounting to the elaboration of a mildly multilingual regime, were brought about by distinct developments in the post-World War II era: the civil rights movement; the massive importation of Mexican workers under the 'Bracero' program (1942–65); the enactment of a less restrictive immigration law in 1965; and the adoption of a generous policy toward refugees from the Communist world. The turning point was the Bilingual Education Act of 1968, introduced on behalf of Spanish-speaking pupils in the Southwest, which added a Title VII to the first large-scale federal program in support of local schools enacted three years earlier. This provided a small demonstration program that was vastly expanded following the *Lau v. Nichols* decision (1974), in which the US Supreme Court held the Civil Rights Act to mean that the failure to provide instruction in a language students can understand constitutes unlawful discrimination (Foster 1982, p. 293). Advocates of bilingual education seized upon the case to press for the expansion of their programs, and a task force subsequently convened by the US Office of Education to prescribe 'Lau Remedies' placed bilingual education in a preferred position (Leibowitz 1971, 1982, Schmidt 2000, p. 13). In the wake of these actions, as well as the continued flow of federal funding, bilingual education programs proliferated in a variety of forms, mostly designed to facilitate transition to English instruction, but with a minority dedicated to the maintenance of non-English mother tongues. Additional federal programs were launched in the 1990s to overcome the deficiencies of earlier ones.

Concurrently, a lobbying campaign initiated by the Mexican-American Legal Defense and Education Fund (MALDEF) to obtain coverage for language minorities under the Voting Rights Act of 1965 led to the addition in 1975 of Titles II and III, requiring that registration forms, ballots, and other election materials be provided in a language other than English if more than five percent of the voters in a given district

spoke the same non-English language, and if the district's English illiteracy rate surpassed the national average. Applicable to American Indians, Asian Americans, Alaskan Natives, and citizens of Spanish heritage, the legislation covered 384 counties. Titles II and III were reauthorized in 1992 in strengthened form. Parallel developments occurred with regard to the language rights of defendants, as well as of employees in both the public and private sectors. In a dramatic reversal of past policy, in 1990 the Congress adopted the Native American Languages Act, which committed the United States to preserve and enhance its indigenous languages. The development of foreign language media, especially Spanish, in response to market opportunities has also contributed to the institutionalization of a more multilingual configuration.

Contrary to contentions that the new policies reduce incentives to learn English, research indicates that recent newcomers rapidly learn English and that, as with past waves, use of the country of origin's language declines sharply in the second generation and almost disappears in the third (Stevens 1994, Espenshade & Fu 1997, Portes and Hao 1998). The steady shift to English is somewhat hidden from view because the number of American residents who used a language other than English at home rose by virtue of continuing immigration from 23 million in 1980 to nearly 32 million in 1990, with Spanish accounting for slightly over half of the total.

Not surprisingly, the dawning regime change provoked widespread opposition, often invoking the specter of conflict ridden multilingual countries (Petrovic 1997), and triggered moves to counteract the trend by officializing English at the state and national levels, as well as eliminating bilingual education. Hostility was especially high in California, which enacted several referenda to that effect, including Proposition 227 (1998) eliminating nearly all bilingual education; Arizona followed suit two years later. As against this, the rapid transformation of immigrants into electoral clienteles fostered support for the new regime. On balance, multilingualism of services is likely to persist, so long as substantial replenishment of foreign-language speakers by way of new immigration continues; however, the future of bilingual education is less certain. As of 1997, the United States had approximately 3.5 million students with limited English proficiency (LEP), a 57 percent increase since the beginning of the decade; but they had higher rates of repetition and dropped out of school four times more frequently than their English-fluent peers (United States General Accounting Office 1999). Research findings regarding the effectiveness of various approaches to the education of LEP children, including the effects of the elimination of bilingual education in California in favor of 'immersion,' were indecisive; but run of the mill transitional programs, many of which lacked qualified staff, were widely criticized for their ineffectiveness and possible perverse effects, notably fostering within-school segregation of newcomers.

1.2 France

Markedly different from American concerns, the issues driving French language policy focus on the changing role of regional languages such as Breton, Alsatian, Occitan, Basque, and Corsican; the protection of the national hegemony of French against the intrusion of English; and the promotion of the national language abroad as an instrument for enhancing France's international standing. Nevertheless, overall movement has also been toward a softening of the traditional strict monolingual regime.

Notwithstanding the Jacobin centralist tradition, successive republics have also cultivated the image of a nation consisting of 'small fatherlands' and embraced a domesticated version of regionalism in the form of folklore, often expressed in the regional languages. The Loi Deixonne (1951) provided for the limited teaching of these languages as optional subjects in public secondary schools. The identity quests of the 1970s fostered demands for the expansion of such programs. Endorsed by a new leadership generation within the Socialist Party, they were translated into policy when it gained power in the 1980s and again in the 1990s. As of 1997, about three percent of pre-university students in both public and private education were enrolled in regional language classes (Le Monde 1999, p. 12). However, in reaction to this, in 1992 a Gaullist government enacted a constitutional amendment declaring French the national language and invoked the amendment four years later as grounds for refusing to sign the European Charter of Minority Languages, on the grounds that this would undermine the hegemony of French (Wexler 1996). Language policy was made into an electoral issue the following year, when Socialist leader Lionel Jospin expressed support for linguistic and cultural pluralism. After his victory, France signed the Charter, albeit with some reservations. The Socialist government also granted an unprecedented degree of autonomy to Corsica and announced a plan to offer bilingual education to the island's population.

Initiated on a personal basis by Charles de Gaulle after he returned to power in 1958, the promotion of special ties with French speakers abroad constitutes a counterthrust to the ascent of English as a world language, itself denounced early on by de Gaulle and prominent literary intellectuals. The francophone policy, which encompasses France's former colonies, Belgium, Switzerland, and overseas communities of French descent, notably in Canada and the United States (Louisiana, New England), was endowed with a permanent administrative apparatus in 1966, entrusted to a distinct Secretariat of State in 1986, and

elevated to cabinet level in 1993 as one of the responsibilities of the Minister of Culture. Protection of French within France was institutionalized in 1975 by way of a law requiring its use throughout the public and private sectors, including contracts, marketing, and advertising. However, the measure proved difficult to enforce, and the courts insisted on a narrow interpretation of its authority. The Loi Toubon, enacted by a Gaullist government in 1994, further imposed the use of French by private citizens in all aspects of public discourse (Wexler 1996, p. 311). But although these actions have evoked considerable attention in France and abroad, English has continued to gain ground in many spheres of society, notably within the scientific and financial communities and at the level of popular culture.

The fact that France is as much of an immigration country as the United States, with a similar proportion of foreign-born residents, has had little or no impact with regard to language in the public sphere. Albeit attributable in part to the fact that a majority of the immigrants originate in the Maghreb, where French is widespread both as a language of instruction and as a lingua franca, the absence of change largely reflects the lasting power of France's assimilationist stance. No provisions have been made for public services in languages other than French, except to a limited extent with regard to court translators for the benefit of the accused. Bilingual education, even of a transitional sort, does not exist; the only concession made to immigrant communities at the elementary level is to allow the teaching of 'languages and cultures of origin' as an elective subject outside of regular school hours. In 1989–90, attendance ranged from 13 percent for children of Algerian origin to 35 percent for Turks (Tribalat et al. 1996, pp. 188–213).

2. *Multilingual 'First World' Democracies with Large Spatially Concentrated Groups*

2.1 *Belgium*

Issued from the vagaries of Europe's dynastic tribulations and united by the Roman Catholic religion, the kingdom of Belgium straddles the long-established boundary zone between Germanic and Romance languages. Around the time of the state's founding in 1830, approximately 60 percent of Belgians, concentrated in the north, spoke varieties of Flemish, closely related to Dutch; and another 30 percent, concentrated in the south, used mostly varieties of Walloon, a group of Romance speeches with more Germanic root words than standard French. However, following the introduction of French as a language of state by their Austrian Habsburg rulers in the eighteenth century and the subsequent annexation of the Belgian provinces by revolutionary France, the traditional elites of both regions, amounting to perhaps 10 percent of the population altogether, had by then mostly adopted French as their usual language. It is therefore hardly surprising that they unhesitatingly imposed French as the country's sole official language. French exclusively was used in government as well as secondary and higher education, limiting Flemish to local administration and terminal elementary education in the north, and relegating Walloon to the margin. The capital city, situated within the Flemish region, functioned as a French-speaking transmission center. The resulting linguistic inequality was compounded by uneven economic development, centering on the Walloon coalmining region. Hence until well into the twentieth century, Flemings striving for upward mobility had no choice but to learn French, and in time many of them abandoned their ancestral language altogether (Zolberg 1974).

Demands for change arose in the second half of the nineteenth century from the ranks of the Flemish region's expanding middle class, severely disadvantaged by the burden of having to function in French rather than in their mother tongue. Initially demanding recognition of Flanders itself as a bilingual region, they subsequently shifted to the establishment of official bilingualism at the national level. This was formally achieved in 1897. Nevertheless, Flemish retained in effect second-class status; most notably, university education continued to be conducted exclusively in French, and French remained the language of command in the army. In the early decades of the twentieth century, the more radical wing of the Flemish movement took on a nationalist cast, demanding the establishment of a federal system; a few even advocated secession, possibly followed by reunion with the Netherlands. However, Flemish nationalism was tarnished by its association with German occupation in the two world wars. In the mid-1930s, a language settlement was achieved whereby the country was divided into two monolingual regions, with a bilingual capital district and national administration; as part of this, the state university at Ghent was converted into a Flemish-language institution. However, language conflict returned to the fore in the post-World War II period, and Flemish power increased as the economic standing of the regions was reversed. After a lengthy period of perennial low-level conflict, in the 1970s Belgium finally transformed itself into a complex federal system, with a language regime founded on 'dual monolingualism' rather than bilingualism. The country was divided into two regions and Brussels with regard to economic decision making, as well as into linguistic/cultural communities (Flemish, French, and a small German one) with regard to educational and cultural policy. Parity prevailed at the center, with a mandatory equal number of cabinet posts allocated to each of the two major communities and parallel administrative services in the two languages (Zolberg 1976, Witte and Craeybeckx 1987, pp. 423–518).

2.2 Canada

Paralleling the status of Flemish in Belgium, Quebec French was long associated with backwardness in the eyes of Canadian officials and English-speaking businessmen, as well as their US neighbors, despite the near identity of its written form with standard French. Paradoxically, however, the conquered French Canadians fared better under Protestant British imperial authorities than the Flemings at the hands of their own countrymen. As part of the post-conquest settlement, in an attempt to secure French Canadian loyalties in the impending conflict with the unruly American colonies, the British granted the Roman Catholic Church and the Province of Quebec a considerable degree of autonomy. This enabled French Canadians to create from the very outset institutions of secondary and higher education that fostered the formation of a French-speaking professional middle class. Although many educated Quebecois learned English, outright language shift occurred only among those who left the province. After a period of repressive direct rule imposed in the wake of proto-nationalist agitation, the creation of the Canadian Confederation in 1867 accorded Quebec along with the other provinces a degree of self-government long unthinkable in centralized Belgium (Latouche and Poliquin–Bourassa 1977). Consequently, around the turn of the twentieth century French Canada possessed many more of the elements of a distinct society than did Belgian Flanders. Nevertheless, in the 1960s, lingering insecurity concerning the survival of Quebec's distinctive culture within the Anglophonic North American environment stimulated a movement for outright independence, which experienced electoral ups and downs in the last three decades of the twentieth century. This prompted in turn reforms to implement full linguistic and cultural parity at the federal level, as well as perennial negotiations to provide Quebec with yet greater autonomy within the Canadian framework (Burnaby and Ricento 1998).

3. Postcolonial Multilingual Countries

The array of former colonial countries in Asia and Africa that achieved independence in the second half of the twentieth century display a policy pattern that has been formulated in game-theoretical terms as a '3 + / − 1 language outcome' (Laitin 1992, 1993). The basic model is drawn from India. Britain's adoption of Urdu as the official language of colonial administration for the South Asian subcontinent in the early nineteenth century fostered a movement among Hindi-speaking provinces on behalf of parity for their own language. The resulting alignment prefigured the partition of India and Pakistan in 1947. However, within the Hindi-speaking zone, other languages such as Tamil emerged concurrently as rallying points for distinct regional nationalities. From the 1920s onward, the Indian National Congress adopted Hindi as the language of national business, but allowed its provincial committees to use regional languages at their own level. The arrangement anticipated India's post-independence policy; but because of widespread English bilingualism within the bureaucracy, English was maintained also as a 'temporary' accommodation. However, the growth of regionalism after 1947 challenged the status of Hindi as India's national language and concomitantly fostered support on behalf of English as a 'neutral' alternative. Hence, although the 1950 constitution provided for switching to Hindi as the exclusive national language after 15 years, opposition rendered this politically impossible and the status quo was maintained indefinitely (Dua 1993). The outcome was thus Hindi-English bilingualism at the national level, plus the appropriate Indian vernacular at the regional level (i.e., a total of three languages); but where Hindi was the vernacular, the outcome was 3 − 1, whereas for minorities whose mother tongue differs from the official regional language, the repertoire extends to 3 + 1 (Laitin 1992, p. 45).

Similar policies prevail among the postcolonial states of sub-Saharan Africa as well, notably in Nigeria, which has a federal structure similar to India's, as well as in Congo, to the extent that any policy may be said to exist, Senegal, and Ghana. Ivory Coast might have followed the '3 + / − 1' pattern as well, thanks to the widespread use of Dyula as a lingua franca; however, in the first four decades of independence the country's leadership insisted on maintaining French exclusively as part of a general policy of close association with the former colonial power, and their choice was reinforced by the association of Dyula with a widely resented trading minority, constructed as 'foreign.' Where there is no obvious vernacular, lingua franca, or pidgin that could serve to symbolize national values, remain politically neutral, and be widely understood, the European colonial language tends to remain the interregional link language, while vernaculars tend to prevail regionally, thus resulting in a two-language outcome. Examples include Zimbabwe, Mozambique, Namibia, and possibly South Africa, with Afrikaans figuring as a 'regional' or 'group' language. A major exception is Tanzania, which thanks to the prevalence of Swahili as a lingua franca for most and as a vernacular for many has been able to pursue a traditional European-type monolingual policy; as against this, neighboring Kenya is leaning toward Swahili-English bilingualism (Laitin 1992, pp. 119, 132, 141, Mazrui and Mazrui 1993, Sure 1999).

4. Language Policy at the International Level

Despite the absence of comprehensive authority at the international or global level, the imperatives of communication have fostered voluntary arrangements

regarding language and within international organizations such arrangements have achieved more formal status. French emerged as the international diplomatic language at the time of that country's European hegemony in the late seventeenth century; but English gained ground after the Napoleonic Wars in keeping with Britain's leading role within the Concert of Europe, and its standing was reinforced by the emergence of the United States as a major international actor in the twentieth century. Accordingly, the League of Nations used French and English as its official languages; however, reflecting the waning of European hegemony and aspirations to globalize the international community, the United Nations subsequently added Spanish, Russian, and Chinese (Wexler 1996, pp. 305–6).

Arrangements involving a greater exercise of authority amounting to 'international language policy' have been evolving since the launching of the European Economic Community in 1957. The original Treaty of Rome limited itself to declaring that language matters regarding the organs of the Community shall be resolved unanimously by the Council, which declared in 1958 that the official languages of the six original members would serve as its 'official' as well as 'working' languages. This served as a guiding principle for the organization's subsequent development. With the accession of Finland and Sweden, the number of official languages reached 11, but the combinations to be covered by the translation and interpreting services reached 110, and the likelihood of a substantial number of additional East European members affords the prospect of another quantum jump in complexity and cost. However, for purposes of internal communications, de facto pragmatic arrangements prevail: Irish and Luxemburgian have official status but do not serve as working languages, whereas Catalan—with more speakers than Danish—is recognized symbolically, but not officially. In practice, Eurocrats operate largely in French, German, and English, with the latter steadily moving to the fore (De Swaan 1993b, Kraus 2000, Wright 1999).

The emergence of English as a lingua franca is a worldwide and unprecedented development, fostered by globalization. However, the latter process is also promoting certain regional languages to international status, notably Spanish, so that the hegemony of English may be limited. The wave of the future may well be widespread multilingualism, where each language is assigned its own distinctive societal function; and this will probably be facilitated by the concomitant development of electronic translation programs. A likely pattern in practice and in policy will be '2 + / − 1,' with an increasing incidence of individual-level bilingualism involving a national language and one of a small number of world languages (English and Spanish, as well as possibly Arabic and Chinese). Whereas speakers of regional languages will use 2 + 1, those whose national language ranks also as a world language will have little incentive to learn another, and hence are likely to remain monolingual (2 − 1). Although these trends have stimulated the development of nongovernmental organizations urging the enactment of national and international policies dedicated to the preservation of 'threatened' minority languages, it is unlikely that they will succeed in arresting their decline (Fishman 1998–9, Laitin 1993, De Swaan 1998).

Languages: Genetic Classification

The genetic classification of languages is a method by which language families can be identified, that is, a group of languages can be shown to have evolved from a single earlier language. A simple example is the Romance family, which includes Romanian, Italian, French, Catalan, Spanish, and Portuguese, all of which are later changed versions of the Latin language spoken in Rome two millennia ago.

1. Methodological Preliminaries

Genetic classification is based on the fundamental property of language: the arbitrary relationship between sound and meaning. Each word (or grammatical ending) may be thought of as a coin with meaning on one side and the sounds that represent that meaning on the other. With a few exceptions there is no intrinsic connection between the two sides. Any series of sounds can represent any meaning just as well as any other; and there are hundreds, if not thousands, of possible sequences for each meaning. It is therefore unlikely that two languages will independently pick the same (or similar) sequence of sounds to represent the same meaning.

If, then, one finds similar words (that is, words that are similar in both sound and meaning) in different languages there are four possible explanations: (a) common origin, (b) borrowing, (c) chance, (d) onomatopoeia. In classifying languages one seeks to use only those similarities due to common origin, weeding out those resemblances due to the other explanations. Borrowings may be identified by a number of linguistic techniques, the most basic of which is that fundamental vocabulary—pronouns, body parts, and natural phenomena—is rarely borrowed. Borrowings may also be detected by outgroup comparison; the Romance words in English always resemble French, never Spanish or Rumanian. Accidental resemblances will of course crop up once in a while, but numerous similar words, shared by the same set of languages, cannot be accidental. Finally, onomatopoeia is quite

marginal in language precisely because it violates the arbitrary sound–meaning relationship.

In classifying languages in this manner, using only resemblances due to common origin, one arrives at families (or taxa) each of which is defined by a unique set of exclusively shared innovations (synapomorphies in biological terminology). It is important to emphasize that this requirement of exclusively shared innovations applies to all families at all levels; the Romance, Indo-European, and Eurasiatic families are all defined by a unique set of such innovations.

2. History

The first evolutionary explanation for linguistic diversity is usually attributed to Sir William Jones, an English judge stationed in India, who observed in 1786 that similarities shared by Sanskrit, Greek, and Latin could only reasonably be explained by the assumption that all three 'have sprung from some common source, which, perhaps, no longer exists.' The kinds of resemblances that led Jones to this conclusion were the similar roots and grammatical endings shared by these languages. Jones also noted that Gothic, Celtic, and Persian probably belonged to the same group, or family, which is today known as Indo-European. It includes almost all the languages of Europe (excluding Basque, Hungarian, Finnish, and Estonian) as well as languages in Iran, Afghanistan, Pakistan, and India. Extinct languages such as Hittite (Turkey) and Tocharian (western China) also belong to this family.

There were in fact many precursors to Jones' genetic hypothesis; even before he identified the Indo-European family in 1786, other families—Romance, Celtic, Finno-Ugric, Austronesian, Bantu, Iroquoian, and Algonquian—had been recognized by others. During the nineteenth century additional families were discovered in various parts of the world, and historical work on those families already identified, especially Indo-European, was carried out. Of prime concern to scholars during the latter part of the century was the reconstruction of the original Proto-Indo-European language and the discovery of the regular sound correspondences that connected the various branches of Indo-European.

Other families discovered by the nineteenth century included Uralic (Samoyed, Hungarian, Finnish), Altaic (Turkic, Mongolian, Tungus), and Dravidian (Telugu, Tamil, Malayalam). In fact, even a genetic connection between Uralic and Altaic was widely accepted, and as early as 1817 Rask had pointed out similarities shared by Eskimo-Aleut and Uralic.

During the twentieth century taxonomic work at the higher levels of classification largely came to a standstill as historical linguists, who were almost always Indo-Europeanists, decided that Indo-European represented the temporal limit of the comparative method. They believed that classification could not proceed beyond Indo-European, because language changes so rapidly that after around 6,000 years (the putative age of Indo-European) there is nothing left to compare. Also required, according to this view, is a complete reconstruction of the proto-language, as well as reconstructions of all the intermediate languages between the original proto-language and the modern languages. It is this view that has dominated historical linguistics in the twentieth century, and still prevails at the start of the twenty-first century.

Yet there have always been, from the beginning of the century to the present day, a number of scholars who argued against the supposed isolation of Indo-European, pointing out that Indo-European did indeed share a significant number of roots with certain other families spread across Eurasia. At the start of the century Pedersen called this larger family Nostratic and this name is still used today, though the precise membership of Nostratic has changed during the century. Recent works on Nostratic include Dolgopolsky (1964, 1998), Illich-Svitych (1971–84), and Bomhard and Kerns (1994). In addition, Greenberg (2000) presents evidence for a family that he calls Eurasiatic which is similar to, but not identical with, Nostratic. Greenberg's Eurasiatic includes Indo-European, Uralic, Altaic, Korean, Japanese, Ainu, Gilyak, Chukchi-Kamchatkan, and Eskimo-Aleut. One of the most salient traits of the Indo-European family is a pronoun system in which the first-person pronoun is based on M and the second-person pronoun on T (e.g. English 'me/thee,' French *moi/toi*, Russian *menya/tebya*). As early as 1905 Trombetti pointed out that this same pronominal pattern was shared by other families spread across Eurasia and he maintained that the explanation could only be genetic. Also characteristic of Eurasiatic is a system of plurality in which K represents the dual (i.e., exactly two) and T the plural (i.e., more than two); this was the similarity that Rask noted in 1817. The Nostraticists have discovered hundreds of lexical roots characterizing this family and Greenberg (2000) presents 72 Eurasiatic grammatical elements. There are thus numerous grammatical and lexical items that are found in Eurasiatic languages, but not elsewhere; these are the exclusively shared innovations that define the family.

Without doubt the most important contribution to linguistic taxonomy in the twentieth century has been the work of Greenberg. Beginning with his classification of African languages (1963), followed by a classification of New Guinea languages (1971), and then Native American languages (1987), Greenberg provided an overall classification where none previously existed. In his African classification Greenberg proposed four families: Khoisan, Niger-Kordofanian, Nilo-Saharan, and Afro-Asiatic. While this classification was initially controversial (Greenberg provided neither the reconstructions nor sound correspondences demanded by the traditionalists), subsequent research showed it to be correct in all but a few details.

It is today the general framework for all African historical research.

Greenberg's classification of New World languages into just three families—Eskimo-Aleut, Na-Dene, and Amerind—has been the subject of intense debate during the past decade, with traditional historical linguists defending their belief that there are not three, but over 200 independent families in the Americas, with no hint of genetic connections among any of them. While the Eskimo-Aleut and Na-Dene families have long been accepted as valid taxa by virtually everyone the Amerind family provoked considerable controversy. Yet Greenberg (1987) provided over 300 lexical and grammatical comparisons among various Amerind languages. In contrast to the Eurasiatic pronoun pattern, M/T 'I/you,' the most common pattern in Amerind languages is N/M 'I/you.' Elsewhere in the world an N/M pattern is virtually nonexistent, yet in the Americas it runs through Amerind languages of both North and South America. Indeed, as early as 1905, Trombetti (1905) devoted an entire appendix of his book to the evidence for this pattern in the Americas; a decade later Sapir also noted the same pattern.

While this distinctive pronominal pattern is, by itself, a powerful indicator of the validity of Amerind, there is a lexical item that provides even more compelling evidence in support of Amerind (Greenberg 1987, Ruhlen 1994). Throughout the (Amerind) languages of the Americas one finds traces of a root T–N whose meaning is some kind of child: son, daughter, child, brother, sister, sibling, etc. The vowel connecting the two consonants seemed at first to vary haphazardly; subsequent research revealed that the particular vowel was correlated—originally at least—with the gender of the child: *t'ina* 'son, brother,' *t'ana* 'child, sibling,' *t'una* 'daughter, sister.' (The apostrophe after the *t-* indicates that this consonant was originally glottalized.) Such an idiosyncratic lexical item—involving the arbitrary association of a particular vowel with a particular gender—can hardly be explained by anything other than common origin. This single innovation, by itself, defines the Amerind family.

While the controversies concerning Amerind and Nostratic/Eurasiatic were swirling around over the past 15 years, yet another large and ancient family was proposed uniting languages and families that had hitherto been considered isolates like Indo-European. As always, there were precursors, including Trombetti, to the discovery of this family, but its modern conception began with the work of Starostin (1984), who proposed that the Caucasian, Sino-Tibetan, and Yeniseian families constituted a higher-level family that he named Sino-Caucasian. Around the same time Starostin's colleague, Nikoleav, argued that Caucasian was also related to Na-Dene, thus making Na-Dene a member of Sino-Caucasian, a name that was replaced by Dene-Caucasian. In the late 1980s Bengtson provided evidence that two language isolates—Basque (Spain) and Burushaski (Pakistan)—should also be included in Dene-Caucasian. The most recent articles on this new family may be found in Shevoroshkin (1991). Like Eurasiatic and Amerind, Dene-Caucasian remains controversial and the Basque affiliation has been attacked by several scholars.

Yet another controversy that has surfaced in the past decade has been the very question of monogenesis, that is, whether all extant (and historically attested) languages share a common origin. For traditional historical linguists, who believe that even a family as shallow as Indo-European has no recognizable relatives, the question of monogenesis cannot even be approached. But for taxonomists such as Greenberg the question can be investigated simply by asking whether such large and ancient families—Eurasiatic, Australian, Dene-Caucasian, Amerind—themselves have certain words in common. In other words, have some of the putative exclusively shared innovations that define these families really been inherited from an even earlier language? If so, they are not really innovations, but derived traits. Bengtson and Ruhlen (1994), again with Trombetti as the main precursor, discuss 27 roots that are attested around the world, in language families from Africa to the Americas. Two of the most striking examples are the roots TIK 'finger, one' and PAL 'two.'

A final controversy that has involved linguistic taxonomy in the last decade has been the discovery by Cavalli-Sforza et al. (1994) that the taxonomic structure of the human populaton, based on gene frequencies, correlates to a remarkable degree with the linguistic taxonomy outlined by Greenberg and others, including such heavily criticized groups as Amerind. In fact, Cavalli-Sforza arrived at precisely the same three families that Greenberg found using language, and similar correlations have been noted for the African families. These recent findings recall Darwin's (1871) observation that 'the formation of different languages and of distinct species, and the proofs that both have been developed through a gradual process, are curiously parallel.'

The foregoing is but a brief summary of the history of genetic classification; for a complete history of linguistic taxonomy, as well as a complete classification of the world's languages, see Ruhlen (1991).

3. *Current Status*

Though traditional historical linguists estimate there are over 250 unrelated language families in the world (Campbell 1999), Greenberg posits only a dozen. Figure 1 presents a map of these 12 families. The following sections will address, in the main, outstanding unresolved issues. It should be noted, from the outset, that what is currently most lacking is the higher-level subgrouping of these 12 families. Conse-

Figure 1
Map of the world's language families

quently, there is, as yet, no strong linguistic support for the 'Out of Africa' theory of human origins; the linguistic evidence, however, is certainly compatible with such a theory. On the other hand, global roots such as TIK 'finger' and PAL 'two' would appear to be incompatible with the multiregional theory of human evolution.

3.1 Khoisan

The presence of clicks in this family, but no others (except for borrowings such as in Zulu), complicates the comparison of this family with others. Internally there is a large southern group and two outliers in Tanzania (Hadza and Sandawe) that are quite different both from each other and from the southern group.

3.2 Niger-Kordofanian

It has been suggested that this family and Nilo-Saharan form a higher-level family that has been called Congo-Saharan. This possibility, which would unite most Black Africans in a single family, merits further study. Internally the highest levels of the family remain in some dispute. Greenberg posited a primary division into Kordofanian and Niger-Congo, with the latter divided into Mande vs. all the rest. Other scholars believe, however, that Kordofanian may well be closer to non-Mande Niger-Congo than is Mande; yet others consider Kordofanian, Mande, and Niger-Congo to be coordinate branches.

3.3 Nilo-Saharan

The proposed connection with Niger-Kordofanian was mentioned above. Internally Nilo-Saharan consists of around ten subgroups whose relationship to one another remains unclear.

3.4 Afro-Asiatic

Originally the Nostraticists included Afro-Asiatic in Nostratic, but, with the exception of Dolgopolsky, today most Nostraticists consider it a sister of Nostratic, rather than a daughter, which is essentially Greenberg's position. The internal subgrouping of Afro-Asiatic remains a focus of investigation, but the

divergent position of the Omotic branch seems favored. It is also possible that Semitic, Berber, and Chadic form a higher-level subgroup.

3.5 Eurasiatic

Ruhlen (1994) offers evidence connecting Eurasiatic with both Afro-Asiatic and Amerind; Starostin, however, has presented evidence linking Nostratic and Dene-Caucasian (Starostin 1989). The internal structure of Eurasiatic is unclear, but Greenberg posits a subgroup consisting of Korean, Japanese, and Ainu. The Nostraticists exclude Ainu from their family and consider Korean and Japanese as part of Altaic, rather than coordinate to it.

3.6 Kartvelian

The Nostraticists include Kartvelian in Nostratic; Greenberg considers it related to Eurasiatic but not part of it, pointing especially to similarities with Afro-Asiatic.

3.7 Dravidian

Most Nostraticists include Dravidian in Nostratic, whereas Greenberg considers it, like Kartvelian, to be related to Eurasiatic but not a member. Starostin considers Dravidian to be the most divergent member of Nostratic. The precise external relationships of both Kartvelian and Dravidian require further study.

3.8 Dene-Caucasian

Starostin's proposal for an external connection with Nostratic was noted above. Internally, Bengtson has proposed a subgroup composed of Basque, Caucasian, and Burushaski, and I have suggested that Yeniseian and Na-Dene also form a subgroup. The precise position of Sino-Tibetan in the family is unclear.

3.9 Austric

There are few proposed external connections. Internally, Daic and Austronesian seem to form a subgroup coordinate with the other two branches, Austroasiatic and Miao-Yao.

3.10 Indo-Pacific

Greenberg (1971) is the only comprehensive attempt to classify these languages. All other historical work on this very diverse family has been at a low taxonomic level. Essentially everything remains to be done. External connections with Australian have been suspected, but to date little evidence supporting this idea has appeared.

3.11 Australian

Possible external connections with Indo-Pacific were mentioned above. Internally Australian consists of some 15 subgroups, one of which—Pama-Nyungan—covers most of Australia; the 14 other subgroups are all found together in the extreme north. The reason for this peculiar distribution is not known. Internal subgrouping is unclear.

3.12 Amerind

Suggested links with Euroasiatic and Afro-Asiatic were mentioned above. Greenberg (1987) proposed 11 subgroups and suggested that three of them (Almosan-Keresiouan, Penutian, Hokan) formed a higher-level subgroup he called Northern Amerind. In South America he suggested that three branches (Macro-Carib, Macro-Panoan, Macro-Ge) form a Ge-Pano-Carib subgroup. The internal structure of the family as a whole requires further study.

Laplace, Pierre-Simon, Marquis de (1749–1827)

Pierre-Simon de Laplace was born on 23 March 1749 in Beaumont-en-Auge into a well-to-do family of the Norman landed gentry which occasionally married into the nobility. Destined for the priesthood, he studied first at the College de Beaumont under the direction of the Benedictines of Saint-Maur. Endowed with an excellent memory and a keen intellect, Laplace seems to have excelled at the College, where he received the classical education of the time—the great Latin and French authors, in particular Virgil, Cicero, and Racine, whom he liked to cite and who are perhaps the origin of his obvious liking for well-turned phrases and his passion for physical astronomy. At the age of sixteen, he entered the College of Arts at the University of Caen for the two years of philosophy prior to the Degree in Theology. Here he discovered mathematical analysis in his dealings with natural philosophy, Euler, Clairaut, d'Alembert, and Daniel Bernoulli, and at the same time discovered his astonishing aptitude for handling formulae. On the advice of his tutors, he abandoned theology and moved to Paris in 1769, where he was very quickly noticed by d'Alembert. From then on, he was never to leave either Paris or analysis.

1. *Programme of Studies*

As Professor of Mathematics at the Ecole Royale Militaire, Laplace was literally to inundate the Académie des Sciences with mathematical papers, some fifteen in four years, certain ones of which ran to well over one hundred pages in quarto. On 24 April 1773, he was elected *adjoint mécanicien* at the Académie des Sciences in Paris. The subjects which he tackled were those which he would continue to explore for the whole of his scientific life, a life which was to prove exceptionally long, especially as he would continue publishing original and fundamental papers right up to his death in Paris on 5 March 1827.

Becoming very quickly aware of his intellectual superiority, Laplace set about tackling all the problems of his day in the three principal academies where exact sciences were fostered—Paris, Berlin, and St Petersburg. Indeed, one need only read the titles of his first papers to get a good idea of the state of mathematical sciences in the last quarter of the eighteenth century. First and foremost came differential and integral calculus, and in particular the study of differential equations and partial differential equations which governed the mechanics of solids as well as fluids and the stars. In a paper presented in 1773 Laplace 1912, Vol. 9, pp. 5–68), it was Laplace who was the first to demonstrate that in very general cases one could determine the whole integral of linear partial differential equations, and that in exceptional cases it was still possible to obtain from them particular solutions in the form of *defined integrals* that is, *integral transforms* which fitted with the initial data. This method would allow him, for example, in 1809, to solve the equation of heat in more general cases than those envisaged by Fourier.

The second subject tackled by Laplace equally concerns the solutions of differential systems, but in those cases where whole integrability is beyond reach, such as in the theory of the Moon or the large planets. These theories had not only eluded Newton, who had not used the infinitesimal algorithm in its full extension, but had also eluded Euler, Clairaut, d'Alembert, and Lagrange who were ingenious rivals in their use of it. Laplace, right from the outset, was to demonstrate his extraordinary faculty—often spoken of in terms of intuition—for reducing by approximation the irreducible difficulties present in equations dealing with the problems of multiple bodies. In March 1773, Laplace presented a paper (Laplace 1912, Vol. 8, pp. 201–75) on the 'principle of universal gravitation' in which he showed that Euler and Lagrange had been wrong in their planetary theory and that he, Laplace, at the age of twenty-four, through Newton's single principle that 'the planets gravitate against each other,' could show the absence of secular inequalities in planetary mean motions, so that the planets could not accelerate their motion around the sun irreversibly by themselves. Furthermore, they only deviated from their perfectly elliptical trajectories through periodic and temporary inequalities, thus assuring a stability in the 'system of the world' which Laplace would encounter again in all areas of his work. The mechanics of the planets is quasi-stable, and the God of Newton played no useful role in maintaining them within rational limits. The foundations for Laplace's astronomical work were established, a work which he never once doubted and which he would pursue from then on, right up to his death.

The third subject, the 'theory of chance,' is more surprising coming from a protégé of d'Alembert, but it

was of great topical interest in 1770. It was in fact in this year that the great academies suddenly resumed this subject, which had to some extent been abandoned for fifty years, and which was now brought back into fashion by works in political arithmetic—notably those of Süssmilch—and at the same time by the requirements of astronomy. Lambert, Euler, Daniel Bernoulli, Lagrange, and Condorcet simultaneously published important papers on *probability calculus*. It was therefore inevitable that the young Laplace would turn his efforts to it, and his first contributions were magnificent, notably the great paper 'on the probability of causes' published in 1774 (Laplace 1912 Vol. 8 pp. 27–65), which marked the beginning of Laplacian mathematical statistics. In this paper, one of the classic works of the theory, Laplace developed the analytical results of the proportionality principle from the probability of causes to that of effects, and, for the first time, proposed, as a criterion for estimation, a quantity known only from observations subject to unavoidable errors, this criterion serving to minimize the sum of potential errors through their respective probability. This method, which Laplace called the *method of situation* and which appeared to him to be the result of the nature of things, should, he believed, be applied to research in astronomical fields. In fact, it led to formidable mathematical difficulties which Laplace would, in the next fifty years, work on breaking down into a series of fundamental works which would culminate in 1812 in the publication of the *Analytical Theory of Probability* (Laplace 1820).

Analysis, *celestial mechanics*, and the *theory of probability* were three overlapping subjects which Laplace did not invent and which he already found in the academic papers of his time, but which he grappled with and never abandoned, to such an extent that he was to change the view scholars had formed of the world which surrounded them, a physical world, of course, but also a moral world from the moment when it could be converted into numbers.

2. *Celestial Mechanics*

The years which were to follow were a long succession of scientific triumphs. One after another, Laplace solved the most difficult problems in celestial mechanics posed since Newton, problems which had foiled the attempts of the most eminent scholars of the eighteenth century to such an extent that it was sometimes doubted whether the single principle of attraction could really account for the inequalities of motion—such as the secular inequality of the Moon, the inequalities of Jupiter and Saturn, the theory of the satellites of Jupiter, and so on—which were being brought to light by the increasingly precise observations of modern astronomy. Laplace's works as a whole—which were spread over twenty years—were brought together in a vast treatise, *Celestial Mechanics* (Laplace 1825), the publication of which began in 1799, and which Laplace would continue to expand and amend up to the end of his life. Concurrently, in 1796 he published *Exposition of the System of the World* (Laplace 1984), which was aimed at a wider readership and presented, in layman's terms, the principal results which demonstrated with the utmost clarity that Newton's law of universal gravity 'represents all celestial phenomena, right down to their smallest details' and that 'through this, empiricism has been entirely removed from Astronomy, which is now a major problem of mechanics.'

However, Laplace was well aware of the fact that whole areas of the system of the world existed where empiricism seemed difficult to exclude entirely, such as the theory of oceanic or atmospheric tides; in other words, the areas where 'irregular causes' occurred in an anarchic fashion which could, if one did not bear them in mind, conceal the true causes of phenomena and their fixed order. Laplace encountered this problem from the beginning of the 1770s to the moment when the theory of errors began to take shape. Observations of all parts of nature, even the most precise, were affected by 'unavoidable errors' which could prove themselves predominant if left to accumulate by chance, and remove all scientific value from the apparent objectivity. According to Laplace, it was therefore necessary to multiply the observations, adjust the value of the uncertain elements progressively, and reveal gradually the phenomena which were 'until this point shrouded in the errors of observations.' This progressive revealing could not be done without a method, and this is precisely the purpose of Laplace's probability calculus.

3. *The Analytical Theory of Probability*

For Laplace, probability theory was first conceived as a means of critically analysing data from observation, a critical analysis which gradually became more refined and revealed the true system of the world. Two periods in Laplace's development are usually distinguished. The first, which runs from 1774 to 1785, saw the development of Laplace's first method. In the spirit of Bayes, but essentially asymptotic in that it was independent of the special nature of *a priori* laws, it did not allow Laplace to deal with the major problem of the theory of errors, that is, to determine in the best possible way the elements known from a large number of indirect observations. It did, however, allow him to solve the population theory problems posed by Daniel Bernoulli and Condorcet by giving political arithmetic the scientific rigor it lacked, left open as it was to the most trivial empirical digressions; for example, in deciding whether in truth more boys were born in London than in Paris for the same number of births, or even whether the population of France was increasing or decreasing.

The second Laplacian asymptotic theory, this time non-Bayesian, began in 1810 after its author had solved one of the major problems of probability theory, the *central limit problem* as it is called today, where under very general conditions the total sum of errors is asymptotically normal, which allows the calculation of probability even if the particular law of errors is unknown. This remarkable theorem and its applications in the *method of least squares*, published the following year, makes up Chapter IV of Book II of the *Analytical Theory of Probability*, published by Laplace in 1812 (Laplace 1820), and bringing together his work on probability as a whole. This second great treatise from Laplace would be expanded with various different chapters until 1825. From 1816, Laplace gradually extended the applications of probability calculus into increasingly wider fields, anticipating a large number of the applications which the twentieth century would develop. The theory of probability, therefore, became for Laplace 'the most felicitous addition to the ignorance and weakness of the human spirit' as he asserts in conclusion to his *Philosophical Essay on Probability* (Laplace 1986), the first edition of which dates back to 1814 and the last to 1825.

Laplace did not limit the possibilities for the application of probability calculus to traditional fields such as games, the theory of errors, and annuities. From the moment when a shred of calculation seemed to him possible, whatever the field and however tenuous it may be, he got to grips with it and generally exceeded previous results by a great deal. For example, inspired by the works of Daniel Bernoulli, Laplace moved from population theory to a general reflection on the chance series of draws from a ballot box which, at first, only display disorder and chaos and gradually adjust and give way to the simplest and most admirable order, the irregular causes cancelling each other out to display the eternal action of constant causes. These reflections on order in chaos anticipate the work on statistical physics at the beginning of the twentieth century. What is more, Laplace, inspired by Condorcet, proposed a theory of decisions in majority voting where the basic concepts of modern test theory can be seen. Further still, inspired once again by Daniel Bernoulli, Laplace established a general result for the concave utility functions, and applied it to questions of maritime insurance and so on. One can also see many more things in the *Analytical Theory* (Laplace 1820), which make this work a monument of science for all time. (See Bibliography for complete studies on this subject.)

4. *Career*

After the flamboyant beginnings we have seen, Laplace was very quickly recognised by his peers, and if his arrogance had caused him some trouble at the beginning, he had an exceptional career. Elected in 1783 to the position of Associate Academician, he became a member of the Académie des Sciences in Paris in 1785. During the French Revolution, Laplace retired to a property near Paris to draft out *Celestial Mechanics* and kept himself at a distance from events. But with the fall of Robespierre, he returned to Paris and took an active part in the creation of three great scholarly institutions emerging out of the Revolution—the Institut de France, the Bureau de Longitudes, and the Ecole Polytechnique. Bonaparte, who was concerned about his image and the scientific glory of France, was to make Laplace, albeit short-lived, his First Minister of the Interior and soon one of the highest dignitaries of the Empire, the Chancellor of the Senate and Count of the Empire.

In 1814 Laplace voted with the majority of the Senate for the forfeiture of the Emperor. He was immediately made a peer of France, then marquis, by King Louis XVIII. In the numerous positions he held, Laplace made himself the herald and the defender of exact sciences. He involved himself little in politics, and when he did, only with questions he could reduce to numbers.

In his lifetime, Laplace enjoyed an immense scientific prestige. As founder of the Société d'Arcueil in 1807, he addressed all the scientific debates of his time, and created a brilliant school which would make his mark on part of his century, up to the point at which Laplacian physics of corpuscular fluids was superseded by positive mathematical physics and experimental physics (on this subject, see Gillispie 1997).

In 1788, Laplace married Charlotte de Courty (1769–1862) with whom he had two children, Charles (1789–1874), general and peer of France who died without descendants, and Sophie (1792–1813) who died in childbirth. Angelique (1813–1889), the only daughter of Sophie, was brought up by her grandparents and married the marquis de Colbert Chabanais and had three children, through whom the family line was established.

5. *Influence*

Laplace was one of the most influential men of science of all time, as much through his scientific work as through his two expository works which met with considerable success. There was no public or private library which did not possess them, and Laplace remains among the most cited scholars in present-day literature. His contribution to the formal assertion of mechanical determinism is sometimes summarized thus: 'All events, even those which by their insignificance do not seem to be due to the great laws of nature, are a consequence of them which is as necessary as the revolutions of the sun.' This introductory sentence from the *Philosophical Essay* (Laplace 1986) of 1814 which can already be found in one of Laplace's first philosophical texts written in 1773, is without doubt the most frequently occurring scholarly quotations in the whole of world literature.

In fact, as is well known, the assertion of determinism is a recurrent theme in the history of human thought, and countless authors in the eighteenth century in particular could be credited with it. Laplace's originality lies in producing a brilliant proof; that the tiniest disturbances in the system of the world—for example the slow acceleration of the Moon—are a necessary consequence of the single best established law of nature, that of universal gravity. It was because such a deduction was possible, as Laplace demonstrated, that determinism could be asserted and, even more, that it was then a question of one of the highest scholarly ambitions of humanity. Science in the nineteenth century became a race for precision made possible by the local determinism of phenomena in the whole of nature.

However, Laplace's influence extends well beyond that, particularly in the social and moral sciences of the nineteenth century, most notably in the work of Quetelet. Indeed, 'Laplacian determinism' was not limited to determinist phenomena. In the system of the world, there are numerous phenomena which are subject to irregular accidental causes which constantly alter the course of these phenomena. Necessity, order, and determinism are nevertheless not absent from them. For example—and it is an example dear to Pastor Süssmilch which Daniel Bernoulli took up again—the sex at birth does not seem to be subject to any determinism, yet one observes that always or almost always slightly more boys are born than girls as soon as one considers quite a large number of births. Laplace concludes that the invariability involved here is 'a result of regular causes which override the anomalies due to the chance' of irregular causes Laplace 1912, Vol. 7, p. xlviii. Chance is thus furnished with a special meaning; it is the combination of irregular causes which take effect in all directions, without favouring any one in particular. Regular causes, on the other hand, compel nature along enforced paths which become apparent in the long term. This is Laplace's *theory of constant causes* which one can clearly see in the works of other authors, for example Buffon, Moivre, and the Bernoullis, but also in the works of the ancient Stoics. It is Laplace, however, who, just as in the case of determinism in minor astronomical perturbations, provides this theory with a mathematical provision which justifies its implementation. This is the full import of his theorem of 1810; the variations due to *irregular causes* are enclosed in narrow limits determined by the Laplace formula, which gradually move closer to genuine elements in such a way that the constant causes determine them. The analysis of causes which Adolphe Quetelet undertook of the 'phenomena which organised beings present us with' is no different, except in that it integrates into the Laplacian constant causes–accidental causes schema a third type of causes, *variable causes* which, for example, produce seasonal effects, causes which Poisson, Cournot, and Bienaymé had envisaged in order to account for irregularly periodic statistical data. Quetelet's 'average man,' and the 'tendencies to crime,' can only be understood in the perspective of the constant causes in Laplace's *Essay*. In a still more obvious way, Poisson's 'law of large numbers' is a triumphant metaphor for Laplacian theory, or at least for certain aspects of it—showing as it does the order of constant causes within the apparent chaos of accidental causes.

The decision-making aspect of Laplace's work—the theory of probability seen as 'common sense reduced to calculation'—experienced a less glorious fate. After the Laplace school—Poisson, Cournot, and Bienaymé—had attempted to give it a more acceptable form in the first half of the nineteenth century, it was for a long time rejected, and with this rejection went an increasingly significant part of Laplace's work on probability. Causes were multiple and, moreover, 'variable' since this aspect a century later was reinstated at the highest level in the way that it is best known today—the theory of games, the theory of decisions, the theory of tests, and judgments based on samples. For Laplace, chance was also the name for our ignorance, an ignorance which was often incurable owing to those multiple accidental causes which distort the natural order of things and of our reason, so that the eminent role of the theory of chance, of probability calculus, is to 'criticise' the statistical data from all parts of nature; and even in the absence of data, by analogy, image, model, and calculation when possible, the theory still allowed one to find one's way more confidently through the maze of social and economic life. In France one would have to wait for Borel and his theory of games before one considered afresh along with Laplace that the theory of probability 'leaves nothing arbitrary in the choice of opinions and in the choice of decisions to make, every time one can determine, in one's way, the most advantageous choice.' Laplace's legacy—to perfect everything through the powerful means that mathematical analysis places at the scholar's disposal—is in no danger of being forgotten.

Large Data Sets in Statistical Computing

Statistics can be viewed as the scientific process of building a stochastic model which 'explains' a dataset. Data analysis is an inherently iterative (and preferably interactive) process with the similar goal of understanding a dataset; this process is not restricted to purely statistical (inferential) methods. Data mining is the process of searching a large dataset to find nuggets (interesting subsets or patterns). Because data mining is such a new field its precise aims are still changing (see *Exploratory Data Analysis: Multivariate Approaches (Nonparametric Regression)*). Unlike statistics or data analysis, data mining seems to require a large dataset. And, there is an emphasis on computer science issues such as algorithm design and database organization. As more statisticians become involved in this field it is changing to look more and more like data (or statistical) analysis for large datasets. Because our interest here is in large datasets, the distance among statistics, data analysis, and data mining is small. When datasets could be written by hand on a single piece of paper, one could reasonably contemplate 'all' possible models or at least a very large family of models for a dataset. As datasets have grown we can no long consider such a possibility.

Table 1
Units of measurement (SI prefixes) for large and small sizes with equivalent powers of 2 and 10

Decreasing	Increasing
10^{-3}–2^{-10} = milli- (m)	10^{3}–2^{10} = kilo- (K)
10^{-6}–2^{-20} = micro- (μ)	10^{6}–2^{20} = mega- (M)
10^{-9}–2^{-30} = nano- (n)	10^{9}–2^{30} = giga- (G)
10^{-12}–2^{-40} = pico- (p)	10^{12}–2^{40} = tera- (T)
10^{-15}–2^{-50} = femto- (f)	10^{15}–2^{50} = peta- (P)
10^{-18}–2^{-60} = atto- (a)	10^{18}–2^{60} = exa- (E)
10^{-21}–2^{-70} = zepto- (z)	10^{21}–2^{70} = zetta- (Z)
10^{-24}–2^{-80} = yocto- (y)	10^{24}–2^{80} = yotta- (Y)

In 1980, perhaps the largest dataset in the social sciences was the US Census; in 1990 it was still one of the biggest. The official 1990 Census dataset (the Public Law 94-171 dataset known as the 'PL94 data') consists of ten CD-ROMs, each containing roughly 600 megabytes of data for a total of 6 gigabytes; these are the block level counts for every Census block, plus higher level aggregations. The Summary Tape File 3A (STF3A) containing the long form data is larger; for example, the STF3A for the Commonwealth of Pennsylvania totals over 1 gigabyte itself. (Table 1; discussed in Sect. 2, gives the various units of size.) The 2000 US Census dataset is dwarfed by any number of other datasets and a few are mentioned here. An important factor influencing the recent rapid growth in the size of datasets is the automated collection of data. This process was begun in the physical sciences (think of high energy physicists collecting data on every nuclear event detected in one of their large atomic accelerators), spilled over into the commercial world (think of AT&T, the phone company, collecting data on every single phone call passing through their system), and is now pervasive, even in the social sciences.

For example, a market researcher collects point-of-scale (POS) data in a large retail chain (think of Wal-Mart or your favorite grocery store); it can easily produce a hierarchical dataset with tens or hundreds of millions of transactions per week, each containing tens of individual items. Allowing only 100 bytes per item, yields a dataset which grows (!) at the rate of 100 gigabytes per week.

As another example, a student of anthropometry obtains three-dimensional mesh images of human bodies (3D People) using an automated imaging system. An actual study in which each such image is more than 10 megabytes is described at http://www.sae.org/technicalcommittees/caesar.htm and indicates there will be a total of 24,000 images totaling over 300 gigabytes.

As a third example, a cognitive scientist studies human brain function using magnetic resonance imaging (MRI). The raw data collected on one subject in an hour or two exceeds four gigabytes. An active research center might collect several terabytes of raw data in one year.

As a final example, the World Wide Web (WWW) is, without question, the single largest social science dataset. Various estimates of its size exist; the variation in the size of those estimates is very large. As a working value let's assume it contains many tens of terabytes.

The methods by which one can study and learn about datasets of such sizes are simply not the same ones that were learned in Statistics 101. Many of the issues relevant to this point are discussed in this entry.

The next section gives definitions of the various terms of size and discusses them briefly. Sect. 3

describes why the speed of computation and the speed of data access (probably the more important for large datasets) matter. In Sect. 4 data types and methods of analysis also matter. Visualization as a primary tool for analysis is considered in Sect. 5.

1. Size Does Matter

First, a few words on words. In order to talk about the size of large datasets we need a vocabulary of sizes. An important fact in the computer world of today is that ten raised to the power of three, which equals one thousand ($10^3 = 1000$) is approximately equal to two raised to the power of ten which equals one thousand and twenty-four ($2^{10} = 1024$). The metric system uses prefixes to denote each three powers of ten (or roughly equivalently, each ten powers of two) as given in Table 1. The table also includes the standard abbreviation for each unit. As a specific example of a metric weight, one yottagram equals 10^{24} grams; it can be written as 1 Yg and is very heavy. In the other direction, one hydrogen atom, for example, has a mass of almost two yoctograms. By way of history, yotta and yocto (along with zetta and zepto) were adopted by the *Conférence Générale des Poids et Mesures* in 1991 as permissible prefixes used to modify SI units. (SI is an abbreviation for *Système International d'Unités*.) In the metric system, the seven base SI units are: the ampere, candela, kelvin, kilogram, meter, mole, and second. Other SI units are derived from these base units.

Here we are going to talk about bits and bytes. A bit (a term created by the late statistician John Tukey) is a binary integer, either a zero or a one. Eight bits in a group is a byte, the standard unit of measurement in the computer world. A half of a byte is a nibble (although this term is not used much anymore).

Table 2 gives some common descriptive terms to describe sizes of datasets together with some example storage devices with that size. This choice of names for sizes above the horizontal line was first given by Huber (1992). Four names have been added below the horizontal line for ease of reference; the reader will note that common language does not ordinarily distinguish among these four additional names so their order is somewhat arbitrary. Throughout the remainder of this article the word 'large' is used in its generic sense and not in the sense implied by this table.

Thinking back to the examples mentioned in the introduction, we see that each falls below the horizontal line in Table 2. The Census itself is roughly 'enormous,' although one can always quibble about double counting and data compression. For the POS data we can usefully refer to one year of such data as being 'enormous' and note that there are interesting things to be learned from multiple years of such data. For the 3D People data we see that the experiment cited there is 'enormous' and the potential obviously exists for larger such datasets. The fMRI data is also 'enormous,' again with the potential for growth as the engineers and physicists increase the capability of MRI technology. The WWW data seems to clearly fall between 'gigantic' and 'immense' and it continues to grow daily.

Table 2
Descriptive names and typical storage devices for datasets of various sizes (in bytes). (The terms ZIP and JAZ are trademarks of Iomega Corporation)

Descriptive name	Size	Storage device
	10^1	Fingers
Tiny	10^2	Blackboard
	10^3	Sheet of paper
Small	10^4	
	10^5	
Medium	10^6	Floppy disk
	10^7	Printed book
Large	10^8	ZIP drive
	10^9	JAZ drive
Huge	10^{10}	Hard disk
	10^{11}	
Enormous	10^{12}	Jukebox
	10^{13}	
Gigantic	10^{14}	100 terabytes
	10^{15}	
Immense	10^{16}	World Wide Web
	10^{17}	
Colossal	10^{18}	One exabyte

Note that physical scientists currently discuss even larger datasets; a number of groups are planning the collection and analysis of datasets that would be characterized as 'immense' or larger. There is no end in sight to this growth; technology provides continual downward pressure on the cost of data collection and storage, and upward pressure on the size of possible datasets that can be collected.

Current commercial statistical software cannot handle enormous data sets, and there is no particular reason that it should be able to. First, much of this software is designed to be interactive; this means that an entire data set must be held in the random access memory of the computer and immediately limits the size of possible data set to merely large. Second, all of this software has a history which typically began with one individual writing a small program to perform some specific analysis on a particular data set; size was of no concern. When the software became commercial, it was 'ruggedized' and a language was invented but no special concern was given to the size of data sets. The net result is that little attention is paid to the speed of algorithms.

2. Speed Also Matters But Not Too Much

Building on tools developed to process smaller datasets, Huber (1994) has identified five possible appro-

Table 3
Computing time as a function of problem size and algorithm speed (assuming 1 problem is solved in a microsecond). Time units are second (s), day (d), and year (y). The last column gives the multiplicative factor or additive term showing the speedup that would be achieved by a thousand-fold increase in computer speed. The entries marked by *** are extremely large and were not computed exactly

Rate	10	100	1,000	10,000	100,000	1,000,000	Speed up
N	10^{-5}s	10^{-4}s	10^{-3}s	10^{-2}s	10^{-1}s	1s	*1,000
N^2	10^{-4}s	10^{-2}s	1s	10^2s	10^4s	10^6s	*33
N^4	10^{-2}s	10^2s	12d	300y	***	***	*6
N^6	1s	12d	300y	***	***	***	*3
2^N	10^{-3}s	10^{22}y	***	***	***	***	+10
3^N	10^{-2}s	10^{40}y	***	***	***	***	+6

aches to the computational problems engendered by the statistical analysis of large datasets.

Use existing algorithms
Select smaller subsets
Process summaries
Derive smaller datasets
Develop new methods

Each of these approaches is discussed further.

Table 3 gives the running time required by various algorithm speeds on datasets of various sizes assuming that one million problem instances can be solved each second. The lesson to be learned is that lots of things are essentially impossible. Despite the sophisticated algorithms developed by computer scientists, and despite the tremendous speeds achieved by current computer hardware there are many problem-size/algorithm-speed combinations that simply cannot be realized in practice. Using the equivalence of one thousand and 2^{10}, and Moore's law, which predicts a doubling of computer speed every 18 months, the last column of Table 3 shows what one can expect from 15 years of continued technological improvement. Obviously and sadly, technology is not the answer.

Turning back to Huber's five approaches we can ask, 'What is possible?' Thinking about the first approach and restricting our attention to data which are contained in a rectangular array (a data matrix), the short answer is that we can essentially perform any algorithm that is linear in the larger dimension (usually the rows or 'cases.' This means that simple summary statistics can be computed, tables of counts, regressions (conditional expectations). Beyond that essentially nothing is possible on datasets of the size we are contemplating.

To think about this more carefully, suppose that we have a matrix with r rows and c columns with a total of $n = r \times c$ entries. Today a fast workstation can achieve 1 billion operations per second. We can ask for column sums and expect an answer in a few seconds if $n = 10^9$, no matter what the value of c. On the other hand, a regression calculation takes $r \times c^2$ calculations. If $r = 10^6$ and $c = 10^3$ then this requires 10^{12} calculations and will take several minutes. If $r = 10^5$ and $c = 10^4$ then it might take several hours. Repeating this arithmetic with $n = 10^{12}$ suggests that for $r = 10^9$ and $c = 10^3$ the regression calculation will take a week. The reader can consider other combinations of r and c. Of course, CPU speed is not the only constraint. With datasets of this size one needs to worry about the speed of data transfers from disk and the details of operating system performance such as memory paging and swapping.

This latter point is very important. Currently, the fastest data transfer speed from a hard disk drive into the main memory of a computer is no larger than 10 MB/s. More than one day will be required in order to read in an 'enormous' dataset. A 'gigantic' dataset could take a year without special tricks (simple tricks such as multiple disks, or multiple disks and multiple CPUs).

The second approach is 'select smaller subsets.' The beauty of this approach is that it can handle any size dataset no matter how large; simply take a random subsample and proceed. The drawback is that for large datasets this subset will contain a vanishingly small fraction of the data. If the subset happens to not contain some interesting part of the data, the analysis will obviously miss it too. On the other hand, if the subset happens to contain some really unusual feature the analysis can be easily misled. And, for data miners, any fairly rare combination is very likely to be overlooked because it won't appear in the subset; they won't find the nuggets.

Working with selected summaries of the data, Huber's third approach, has the great advantage that the analyst has a lot of control over the procedures used to produce the summaries, and hence the number of summaries produced. It also has the advantage that the lack of homogeneity in large datasets can be dealt with by using the subset identifier as a covariate (see Section 5). For the POS data set, it is natural to study shopping baskets. Consider simply the number of items in a basket. I am currently working with a POS dataset in which there will be roughly 10^7 summaries

generated from a dataset containing over 200 GB of data; analysis of these summaries will be a serious task in itself.

One example of Huber's fourth approach occurs when studying migration from census data. In the USA the census divides the country into roughly 5 million 'blocks.' These are amalgamated into 'block groups' and larger collections. The migration study needs to construct a table counting the number of individuals who have moved from location i to location j. Constructing this table is a daunting task; it requires processing records on the hundreds of millions of people appearing in each of two censuses. The size of the resulting table is determined by the analyst; for state-to-state migration studies it is only 50 by 50; for block-to-block studies it would be 7,000,000 by 7,000,000. Constructing the table could take massive quantities of computer time; analyzing it will take much less.

Devising new procedures, Huber's fifth suggestion, is a job for the statistical and computational scientists and will not be discussed further here.

3. Types of Data

The single most important type of data is the data matrix. We normally think of it as being organized with the columns being 'variables' and the rows being 'cases.' The discussion in Sect. 3 focused on the $r \times c$ data matrix as the basic unit. It is very often the case that large datasets have an intrinsically more complex structure. Mutli-media datasets are the most common example. Here we discuss a few of the more common types.

The generalized data matrix is a hierarchical dataset where some variables are only reported (observed) if other variables take on certain values. Often, for purposes of analysis hierarchical datasets are 'unrolled' into a data matrix. This has the unfortunate property of making them substantially larger to go along with the motivating property that processing a matrix is often a straightforward task that can be performed with pre-existing software.

With the variety of digital data collection devices currently available, ranging from television cameras, to digital audio recorders, to POS terminals, the kinds of datasets collected has an equally wide range. Television and other digital cameras can produce two-dimensional color images with a high spatial, temporal, and color resolution. Complex systems of cameras can produce three-dimensional surface mesh images (this was most recently demonstrated during the football game, Superbowl XXXV, when multiple cameras allowed the game analysts to replay full three-dimensional video and interactively change the point of view) and medical imaging devices such as computed tomography (CT) or magnetic resonance imagers (MRI) can produce fully three-dimensional volume images. The combination of sound with pictures can produce multimedia data.

4. Methods of Analysis

Small datasets are often homogenous. Large datasets are never homogenous. The major task in the analysis of a large dataset is finding homogenous subsets.

Raw data is raw. A fundamental and very time-consuming part of any analysis of a large dataset is getting it cleaned up and organized so that it can be analyzed.

At its heart, statistical data analysis is not simply a procedure which is applied to data but rather it is an iterative process involving repeated attacks on a dataset to tease out the message. For large datasets this creates a compound problem. The dataset is large but each step of the process produces additional datasets which are typically the same size as the original or larger.

Large datasets almost always, as a corollary of their inhomogeneity, are best explained by complicated models. Complicated models are hard to understand. The human visual system is ideally adapted to make sense of complex inputs and this leads naturally to the consideration of visualization methods for the analysis of large datasets. There are many points of view, many different technologies, and a wide variety of methods available for use. A quick review of traditional graphical methods is given by Jacoby (1998). An interesting collection of papers which sketches the history of dynamic methods is given by Cleveland and McGill (1988). A wonderful coffee-table book on graphical methods is Tufte (1983). (See also: *Graphical Methods: Presentation*; *Graphical Methods: Analysis*.)

5. Discussion

The problems of statistical analysis of large data sets are myriad. Here we have tried first to give a few examples of the very largest data sets. We have considered the limitations of computers and computer programs in providing analyses for these data sets. In particular we have looked at five methods for dealing with such large data sets and tried to clarify the costs and benefits of each.

There is little statistical literature to which one can turn, beyond that already cited, to learn more about statistical analysis of very large data sets. The proceedings of the *Annual Interface Symposium*, now in its thirty-third year, is one place to begin; the proceedings of the *Knowledge Discovery and Data Mining* conference, now in its seventh year, is another. Also, the annual Conference on Very Large Databases has

much that is relevant. Sadly, those readers who want to do something as conceptually simple as compute least squares linear regression estimates for a data set with 500,000 regressors, are on their own at present. Perhaps the situation will change before too long.

Large-scale Social Survey, Analysis of

Large-scale social surveys provide an inexpensive and easily accessible source of information on a wide range of topics including education, health, economics, demography, politics, and criminal justice. These surveys may serve as a primary data source, a preliminary data source to be analyzed prior to conducting a more tailored survey, or in combination with smaller, more specific data sources. After summarizing the advantages of using large-scale social surveys, we discuss how to confront the challenges they present.

There are many advantages to analyzing data from large-scale social surveys. The data are usually extensive in content and coverage of the target population. Sample sizes are often very large and the data are often easily obtained from the sponsoring agency on CD-ROM or from the internet, in many cases at no cost to the researcher. Moreover, these surveys are typically conducted by large government agencies or private survey organizations that have experienced interviewers, well-designed and tested survey instruments, and the expertise to design efficient sampling plans. As a result, the response rates are typically high (e.g., 75 percent–90 percent) and sophisticated nonresponse adjustments are often incorporated into the data to try to reduce nonresponse bias that results from systematic differences between respondents and nonrespondents. The sample data are also often reweighted, using poststratification, to agree with known population distributions of characteristics such as age, sex, and race. Finally, many surveys contain panel (longitudinal) components in which the same sample units are interviewed repeatedly over time, allowing researchers to follow individual changes over time.

The analysis of large-scale social survey data also presents several difficulties. One of the greatest technical challenges arises because sampling in these surveys is usually carried out according to complex multistage designs that combine stratification, cluster sampling, and unequal probability sampling. Many surveys that are repeated on a regular basis also rotate respondents in and out of the sample. Often point estimates of simple estimands such as population means and proportions can be calculated using a minimal amount of information about the sampling design, but standard error calculations must incorporate the key sampling design elements explicitly. Survey weights, provided along with the survey data, contain important sampling design information. Correct interpretation and use of these weights is key to the analysis of large-scale social survey data, and particularly key to standard error estimation. Analysts must also be aware of the impact of nonresponse adjustments—such as weighting class adjustments for unit nonresponse and imputation for item nonresponse—on standard error estimates. Complex multistage sampling must also be taken into consideration when calculating confidence intervals for population parameters. In particular, the degrees of freedom used when calculating confidence intervals using a t-distribution depends on the sampling design, not solely on the sample size. Methods of incorporating survey weights into estimates of simple population parameters such as means, totals, and proportions are well established; however the appropriate approach is less obvious when fitting more complex statistical models such as linear regression models and loglinear models. We address each of these issues in the following sections.

1. Complex Sample Designs

Although simple random samples are the easiest to design and analyze, large-scale social surveys often take advantage of complex multistage sampling designs to increase the precision of the resulting estimates. These designs typically involve multiple stages of sampling. For example, the first stage of sampling may select a sample of counties; the second stage may select a sample of subregions within each

sampled county; the third stage may select a certain number of sample units (e.g., individuals, households, or hospitals) within each sampled subregion. Units selected at the first stage of sampling are called primary sampling units (PSUs). Units selected at the final stage are called ultimate sampling units. One reason for multistage sampling is to minimize the travel costs of interviewers in face-to-face surveys. Another reason is that a sampling frame (a list of all the ultimate sampling units in the population) may not exist for the target population, but may be constructed sequentially as needed. For example, a list of all school-age children in a state may not be readily available, but a list of all school districts in a state may be available; then for a sample of school districts, a list of all the schools in those districts may be obtained; then for a sample of schools, a list of children may be obtained.

Multistage designs often involve cluster sampling in which groups of sampling units are selected, rather than individual units. Examples of cluster sampling include selecting several students in a class, several households in a city block, or several patients in a hospital. Cluster sampling tends to increase the variability of survey estimates compared with a simple random sample of the same size. This occurs because units in the same cluster tend to be correlated and, as a result, each additional unit sampled within the same cluster provides less additional information about the overall population parameters than an element selected at random from the population. However, due to travel costs, frame construction costs, and other overhead costs associated with each sampled cluster, a simple random sample may be much more expensive than a cluster sample of the same size. Therefore, given a fixed budget, a cluster sample may provide the most efficient estimates.

Another common design element used in large-scale multistage surveys is stratification, which involves dividing the population into nonoverlapping segments, called strata, and sampling independently within each stratum. Typical stratifying factors include region of the country and urbanicity (urban, suburban, rural). If the variable of interest tends to take on different values, on average, in each stratum, then stratified sampling can lead to more efficient estimates. In particular, the sample can be optimally allocated so that a larger sample is obtained in strata where there is larger variability in the variable of interest. Another reason for stratification is to ensure adequate representation of all segments of the population, avoiding the possibility of a simple random sample that, by chance, omits part of the population. Often certain strata, such as those containing a large proportion of racial minorities or elderly people, are sampled at a disproportionately greater rate (oversampled) in order to ensure an adequate sample size for research hypotheses that involve these groups. For example the British Crime Survey oversamples inner city areas by a factor of two (Mirrlees-Black et al. 1998). Sometimes a census is conducted in some strata, called self-representing or take-all strata. This type of stratification is particularly useful for very skewed populations that contain a few large units and many small units (e.g., Hidiroglou 1986). Stratification can also be combined with cluster sampling. For example, neighborhoods may be stratified by geographic region and then a sample of households within neighborhoods may be selected; or schools may be stratified by size and then a sample of classes may be selected from each school.

Unequal probability sampling is often used when sampling clusters. In particular, clusters are usually selected with probabilities proportional to their size (PPS sampling), with larger clusters having greater probabilities of selection. The size measure used will depend on the survey, but, as examples, a school can be measured in terms of the number of students enrolled, a company can be measured in terms of the numbers of employees, a farm can be measured in terms of acreage, and a city block can be measured in terms of the number of households. PPS sampling will lead to more efficient estimates whenever cluster totals are proportional to the size of the cluster, which is often the case. For example, larger schools tend to have more students with learning disabilities, larger companies tend to have larger revenue, larger farms tend to have a larger crop yield, larger city blocks tend to have more single parents. Unequal probability sampling is also sometimes used for convenience. For example, random-digit-dial telephone surveys actually select households with probabilities proportional to the number of voice telephone lines in the household. Selecting a simple random sample of households would require a list of the individual households, rather than a list of telephone-numbers, and this may be much more difficult to obtain or construct than a list of telephone numbers,

Finally, many large surveys that are repeated on an ongoing basis (e.g., monthly) use rotation groups. Rather than select new nonoverlapping samples each month, rotation groups remain in the sample for several months in a row (Fienberg and Tanur 1983, Iachan and Jones 1987). Every month a new rotation group enters the survey and an old one drops out so that each month only a fraction of the sample units are new. This reduces costs by not having to draw a new sample each month (there are administrative costs with drawing a new sample, locating the new sample members, explaining the survey to them, etc.) and also provides some longitudinal information. Rotation groups present no complication to cross-sectional analysis of a single wave of data but can complicate analyses that combine several months of data since the same sample units may appear multiple times in these combined datasets. Analysis should then account for correlations between repeated measurements on some sample units. In contrast, some surveys, called rolling surveys (Kish 1998) are specifically designed with

nonoverlapping samples each month so that the resulting data can be analyzed for a single month or combined over several months to form larger datasets.

2. Survey Weights

The simplest analysis of survey data assumes that all elements in the population are equally likely to be included in the sample, Unfortunately, this is not generally true for two reasons. First, complex sampling designs often lead to unequal selection probabilities, as discussed in the previous section. Second, even if units are equally likely to be selected, they generally have different probabilities of response; for example, in household surveys, women are usually easier to reach and more likely to cooperate than men.

Survey weights are used for correcting for known or expected differences between sample and population: each unit i is given a weight, w_i, and the population mean $\bar{Y}$ of any variable y is estimated by the weighted sample average,

$$\hat{\bar{Y}} = \frac{\sum_{i=1}^{n} w_i y_i}{\sum_{i=1}^{n} w_i}$$

As the formula indicates, only the relative values of the weights are relevant. The weights are usually calculated by the survey producers and provided along with the survey data. An informal interpretation of these weights is that w_i is proportional to the number of units in the population represented by respondent i. Estimates of population proportions are calculated using the same formula, where y_i is a variable taking on values of 0 and 1.

Survey weights in large-scale surveys are often constructed so that sample estimates agree with current census estimates of key variables such as age, sex, and race, through a process called poststratification and raking (Oh and Scheuren 1983, Gelman and Carlin 2001).Voss, Gelman, and King (1995) detail the various design and weightings strategies used by various national polling organizations for pre-election surveys. Survey weights are also often adjusted to account for nonresponse, through a process called weighting class adjustment (Oh and Scheuren 1983, Kalton and Kasprzyk 1986, Bethlehem 2001).

In most complex multistage samples, sampled units have different survey weights. However, it is possible to design these samples so that all sampled units have the same weight. These designs are called self-weighting (Cochran 1977, p. 91) because the usual unweighted estimators, the same ones used for simple random samples, will produce unbiased estimates of population parameters such as means and proportions. However, the usual unweighted standard error estimation formulas are not necessarily appropriate in these designs. Therefore, although self-weighting designs may simplify point estimation calculations, they do not simplify standard error estimation calculations.

Finally, many surveys produce separate sets of weights for different types of analyses. For example, the US General Social Survey (GSS) (Davis and Smith 1992) provides separate weights for household-level estimates and for individual-level estimates. The GSS is designed to give each household an equal probability of inclusion in the sample so that the sample is self-weighting for household-level variables. However, since only one individual in each household is interviewed, people living in large households are less likely to be interviewed than people in smaller households. Therefore, even though each household has an equal chance of being selected, individuals have different chances of being selected depending on the size of their households, with these inclusion probabilities varying by the type of survey (Gelman and Little 1998). Longitudinal studies may also have separate cross-sectional and longitudinal weights. For example, the 1993 US Panel Study on Income Dynamics (PSID) provides both 'cross-sectional analysis weights' and 'longitudinal analysis weights' (Hill 1992). Cross-sectional analysis weights can be used to obtain unbiased estimates of population statistics for a given year. Longitudinal analysis weights, on the other hand, can be used to estimate models of changes over time. In particular, the 1993 PSID longitudinal analysis weights assign non-zero weights only to individuals who were respondents during each of the preceding five years. The Canadian Survey of Income and Labour Dynamics also provides both longitudinal and cross-sectional weights (Statistics Canada 1997). When using surveys with multiple sets of weights, consult survey documentation for advice on appropriate choice of survey weight.

3. Standard Errors

Although estimates of simple population parameters such as means and proportions can easily be constructed as weighted averages using survey weights, the corresponding standard error estimation procedures are not included in most standard statistical packages. When the data have been collected from a survey with a complex sample design, standard error estimates of survey statistics derived under simple random sampling assumptions generally underestimate the true standard error, resulting in confidence intervals that are too narrow and hypothesis tests that are too likely to reject the null hypothesis. In particular, most standard statistical packages can handle 'analytic' weights that are used in regression estimation when the data values themselves each have different (known) variances, and 'frequency' weights that are used to store data concisely by recording the number of times an observation is duplicated in the dataset rather than recording each observation individually, but these weights should not be confused

with survey weights. Incorrectly treating survey weights as analytic weights or frequency weights will generally result in unbiased point estimates but underestimated standard errors. Moreover, ignoring the weights altogether and using a standard statistical package to perform an unweighted analysis of complex survey data will generally yield biased estimates of population parameters and underestimated standard errors. Furthermore, standard statistical packages do not account for stratification, cluster sampling, or adjustments such as post-stratification and raking. Brogan (1998) and Wang et al. (1997) illustrate some of the potential consequences of incorrectly analyzing survey data using standard statistical packages.

As a measure of the effect of the sampling design on the variance of survey estimates some surveys report design effect estimates. The design effect (deff) (Kish 1965, p. 162, Lohr 1999, p. 239) measures the increase (or decrease) in variance obtained using the given sample design relative to the variance that would have been obtained if a simple random sample of the same size had been used. For example, Davis and Smith (1992, p. 41) report that the average design effect for 60 variables in the GSS is 1.76, with slightly larger design effects on average for demographic variables which tend to have more clustering and smaller design effects, on average, for attitude variables. Similarly, Hill (1992, p. 67) reports design effects for estimates from the PSID ranging from 0.95 to 2.53, with most in the range 1.1 to 2.2. A design effect of 1.76 indicates that the variance of an estimate from the current design is 1.76 times greater than the variance that would have been obtained using a simple random sample of the same size. The design effect can be used to determine the 'effective sample size' by dividing the actual sample size by the design effect. The effective sample size is the number of observations that would yield the same level of precision from a simple random sample. For example, a design effect of 1.5 implies that the precision obtained by sampling 1500 units under the current complex sampling design could be obtained by sampling only 1000 in a simple random sample design. The design effect does not, however, account for differential costs of the two sampling designs.

Several software packages are available to analyze data from complex multistage surveys. Summaries and reviews of these packages are provided by Lepkowski and Bowles (1996), Cohen (1997), Carlson (1998), and Zaslavsky (2000). Stata (StataCorp 1999) and the latest release of SAS (An and Watts 1998) are multipurpose statistical packages that include procedures for analyzing complex survey data. Because variance estimation calculations for sampling designs that use without-replacement unequal probability sampling are complex, most survey software packages approximate these variances using formulae appropriate for unequal with-replacement sampling. This approximation is usually acceptable since, for these survey designs, the resulting variance estimates will slightly overestimate the true variance, resulting in slightly conservative confidence intervals and hypothesis tests. Finally, survey software packages generally use variance formulae that are technically only appropriate when the survey weights represent only the sampling design and do not incorporate nonresponse or poststratification adjustments. A few packages (WesVarPC and VPLX, see Lepkowski and Bowles 1996) use a variance estimation method call replication or resampling (Wolter 1985, Chap. 2, Korn and Graubard 1999, p. 29) that can incorporate the impact of nonresponse weighting adjustments and post-stratification adjustments. To take advantage of these capabilities, data users must be provided with 'replicate weights' (e.g., Korn and Graubard 1999, p. 34) by the data producers. For example, the US Census Bureau releases replicate weights for the Survey of Income and Program Participation.

Finally, many large-scale surveys provide generalized variance functions (Korn and Graubard 1999, p. 218, Lohr 1999, pp. 308–10) in summary reports of the survey data. To reduce publication costs and calculation effort, these surveys do not publish standard errors for every estimate in the summary report. Instead, generalized variance functions are provided to enable data users to calculate standard errors for their estimates of interest. These functions estimate the standard error of an estimate as a function of the estimate. These standard error estimates are very approximate and their results should be interpreted with caution. Direct calculation of standard error estimates, using the raw data, survey weights, and other sampling design information is always preferable to using generalized variance functions. However, generalized variance functions permit standard error estimation when either the raw data or the sampling design information cannot be released for confidentiality reasons.

4. *Confidence Intervals*

When constructing confidence intervals for population parameters using survey data, it is usually assumed that survey estimates of means and proportions are approximately normally distributed, so that the usual normal confidence intervals or, for small sample sizes n, t-distribution intervals with $n-1$ degrees of freedom are appropriate (Cochran 1977, p. 27). For complex multistage sampling, the degrees of freedom for t-intervals is typically equal to the number of sampled primary sampling units minus a correction, c, where $c = 1$ for unstratified cluster sampling and c equals the number of strata for stratified cluster sampling (Korn and Graubard 1999, p. 62). The normality approximation may break down for estimates of proportions that are very close to 0 or 1. In these situations, Korn and Graubard (1999, p. 65)

provide approximations to exact binomial confidence intervals that can be used with data from complex multistage sampling schemes.

5. Statistical Modeling with Survey Data

Much has been written on the use of the sample design and weights when fitting statistical models such as linear regression, logistic regression, loglinear models, and survival models to survey data (Fienberg 1980, Groves 1989, Sect. 6.7, Little 1991, Pfeffermann 1993, Lohr and Liu 1994, Winship and Radbill 1994, Korn and Graubard 1995, Lemeshow et al. 1998). In general, it is recommended to include, as explanatory variables in any regression-type analysis, all variables that are used in the design or the weighting of the survey. These variables include stratum indicators, cluster indicators, and demographics (such as age, sex, ethnicity, and education) that are used to construct the weights. It is thus important in such an analysis to know how the weights were constructed, not just their numerical values. If all these variables are included, one can fit the model without survey weights (see DuMouchel and Duncan 1983, Korn and Graubard 1999, p. 177). It may then be necessary to put the weighting information back into the model—after having estimated the parameters—to estimate population quantities of interest. For example, Gelman and Little (1997) present an example in which estimates are obtained for each of the states in the US, summing over demographic categories, which requires the use of census demographic breakdowns for each state. Difficulties can arise when the number of clusters or strata is large relative to the sample size or when stratum or cluster indicators are not released in public-use data for confidentiality reasons. It can also make sense to perform both weighted and unweighted analyses (DuMouchel and Duncan 1983, Groves 1989, p. 290, Lohr 1999, p. 365; see also *Sample Surveys: Model-based Approaches*). Large differences between the two analyses may indicate model misspecification.

Modeling is also used for 'small-area estimation' in which inferences are made about subsets of the population (e.g., small geographic regions or demographic segments) whose sample sizes are so small that simple weighted mean estimates are too variable to be useful. Hierarchical Bayes and related methods have been useful here (Fay and Herriot 1979, Dempster and Raghunathan 1987), and one area of ongoing research is combining these methods with classical weighting adjustments (Gelman and Carlin 2001).

6. Missing Data

In a sense, all sampling is about missing data, since the goal is to learn about the entire population from a subset. Usually, however, missing data in sample surveys refers to unit nonresponse, which occurs when some sampled units do not participate at all in the survey, either because they refuse or cannot be reached for interview, and item nonresponse, which occurs when a sampled unit responds to some but not all questions in the survey. Survey organizations usually adjust for unit nonresponse by weighting, as discussed earlier in this article.

Item nonresponse is typically handled in one of three ways (Little and Rubin 1987). In 'complete-case' analysis, one works only with the data from respondents who provided responses to all questions of interest. 'Available-case' analysis is the other extreme, where, for each question, one uses all the responses in the data. Both these approaches have the serious problem that item nonresponses do not generally occur completely at random, so it can be misleading to simply ignore them (Rubin 1976). A more flexible approach to item nonresponse is 'imputation': filling in values for missing responses.

Imputation can be done in a number of ways, and for large-scale surveys, it is often performed by the survey organization itself. Missing values may be imputed using single or multiple imputation. In single imputation (Kalton and Kasprzyk 1986 Little and Rubin 1987, Sect. 4.5), a single value is imputed for each missing value. In multiple imputation (Rubin 1987), m plausible values are imputed for each missing value to reflect the uncertainty about the missing data (usually m is between 5 and 10). These plausible values create m completed datasets that can each be analyzed seperately as if they had complete response. Simple combining rules (Rubin 1987, p. 76) can be used to combine results from each of these m separate analyses into one overall estimate along with its standard error. If data have been imputed using single imputation, special variance formulae (e.g., Rao 1996) are needed to account for the extra variability introduced into survey estimates due to the uncertainty in the missing values. Most large-scale surveys are currently singly imputed, but multiple imputation is becoming more popular because of the relative ease of analyzing multiply imputed datasets compared to singly imputed data. For example, the US National Health and Nutritional Examination Survey plans to release a multiply-imputed dataset (Schafer et al. 1993, 1996).

Related to imputation are various data-adjustment and correction procedures. For example, survey questions such as income that have occasional very high, unreliable responses can be 'topcoded'—that is, truncated at threshold values. Difficulties with analyzing topcoded data can sometimes be avoided by working with medians or quantiles (e.g., upper fifth, second fifth, etc.), as these are less sensitive than averages to extreme values.

7. Summary

Large-scale social surveys are an important source of information for a wide range of topics. In analyzing such surveys, it is important to be aware of the

complexity of the sampling design and the data adjustments that are used by survey organizations, including weighting to adjust for differences between sample and population and imputation to fill in missing responses. For estimating population means and proportions, the analyst should calculate weighted averages, using survey weights. In regression analysis, it is best to include, among the predictors, the variables that are used in the design and the weighting. Hierarchical models can be used to obtain inferences for small subpopulations.

In general, simple standard error estimates, which assume simple random sampling, are too small because of stratification, clustering, and weighting. These calculations can often be adjusted reasonably well by using design effects reported in the survey documentation or in previous analyses. For more involved analysis, it is advisable to use statistical packages that are specifically designed to correctly handle complex survey data.

Lashley, Karl Spencer (1890–1958)

It is probably fair to say that Karl Lashley was the most important and influential American scientist in the first half of the twentieth century in the development of modern biological (and even experimental) psychology. His work and writings had a profound influence on such fields as brain substrates of learning and memory, the study of serial behaviors, complex cognitive processes, and our understanding of basic brain organization, particularly of the cerebral cortex.

Karl Lashley was born in Davis, West Virginia on June 7, 1890. His parents were themselves successful—his father was variously a storekeeper, postmaster, banker, and mayor of Davis and his mother, energetic and intellectual with literary and artistic interests. Lashley grew up in Davis, except for a rather extraordinary trek; the family took to the gold rush in the Klondike in 1898–1899.

Lashley was an only child and acknowledged a great debt to his mother for nurturing his intellectual interests. He had learned to read well by the age of four. His mother taught in a country school until Karl was born but maintained a center for adult education in her home where women (and Karl) came for instruction in such subjects as civics, Greek poetry, and drama.

As a boy Karl read widely from the extensive family library but also displayed great interest in plant and animal life, wandering through the local fields and woods, collecting butterflies, snakes, frogs and snails, and keeping pet mice and raccoons.

Karl entered a private school at the age of four and later attended public schools in Davis, where he graduated from high school at the age of fourteen. He entered the University of West Virginia but did not qualify as a freshman because his high school was not accredited. He spent a preparatory year which he felt was wasted. He initially planned to study Latin but was instead assigned English as a major. To fill a vacancy in his schedule he enrolled in a course in Zoology taught by John Black Johnston, a neurologist and the only teacher of zoology at the university. This course and Johnston had a profound influence on Karl. He later wrote that 'within a few weeks in his class I knew that I had found my life's work.'

Lashley received his BA at West Virginia in 1910. He then entered the master's degree program at the University of Pittsburgh as a teaching fellow. During his year there in biology, he attended a course in experimental psychology by Karl Dallenbach, a teaching fellow in psychology. To quote Dallenbach: 'Lashley's laboratory was on the floor above mine. Though he had never taken a course in psychology, he was permitted, because he was a fellow, to elect my laboratory course in experimental psychology. The class was small and we worked intimately together upon the various experiments. Lashley was intensely interested and was the outstanding student in the class—as one might expect being a graduate student in an undergraduate class, but he was more than a run-of-the-mine graduate student. He showed in that course the promise that he later fulfilled.' (Beach 1961, p. 170).

The following summer Lashley worked at the Carnegie Laboratories at Cold Spring Harbor, where he conducted basic studies on a ciliate. A very distinguished zoologist at Johns Hopkins, H. S. Jennings, was so impressed with this work that he offered Lashley a fellowship. At Hopkins, Lashley worked with Jennings on paramecia and completed a Ph.D. thesis on inheritance in the asexual reproduction of Hydra (1914). Lashley took a minor in psychiatry with Adolf Meyer, a pioneering figure in biological psychiatry and another minor (in psychology) with John B. Watson. The influence of Watson on Lashley was profound.

In a letter written much later to Ernest Hilgard at Stanford, Lashley described taking a seminar with Watson in 1914. Watson called their attention in the seminar to the writings of Bechterev on conditioned reflexes, which they translated. 'In the spring I served as an unpaid assistant and we constructed apparatus and did experiments, repeating a number of their

experiments. Our whole program was then disrupted by the move to the lab in Meyer's Clinic. There were no adequate animal quarters there. Watson started work with infants as the next best material available. I tagged along for awhile but disliked the babies and found me a rat lab in another building. We accumulated a considerable amount of experimental material on the conditioned reflex that was never published. Watson sought the basis of a systemic psychology and was not greatly concerned with the reaction itself.' (Hilgard, personal communication, 1984).

The conditioned reflex thus came to form the basis of Watson's behaviorism. Lashley, on the other hand, had become interested in the physiology of the reaction and the attempt to trace conditioned reflex paths through the central nervous system. At the end of his career, Lashley was reputed to have said that anyone who knows American psychology today (Circa 1958) knows that its value derives from biology and from Watson.

During the period at Hopkins, Lashley worked with Shepherd Ivory Franz at St. Elizabeth's Hospital in Washington. Together, they developed a new approach to the study of brain mechanisms of learning and memory and published landmark papers on the effect of cortical lesions on learning in rats. From this time (1916) until 1929 Lashley systematically used the lesion method in the attempt to localize memory traces in the brain. Following Watson (and Pavlov), Lashley conceived of the brain as a massive reflex switchboard, with sequential chaining of input-output circuitries via the cerebral cortex as the basis of memory. This work culminated in his classic monograph *Brain Mechanisms of Intelligence* (1929). He was also President of the American Psychological Association that year. His presidential address, and his 1929 monograph, destroyed the switchboard reflexology theory of the brain function and learning as it existed at that time.

In complex mazes, rats were impaired in learning and memory in proportion to the degree of cerebral cortex destroyed, independent of locus. Lashley employed the terms 'mass action' and 'equipotentiality' more to describe his results than as a major theory. He did not deny localization of function in the neocortex; indeed, his work on visual discriminations strongly supported localization (see Lashley 1942). Using anatomical and physiological methods, he was perhaps the first to demonstrate the point-to-point projection from the lateral geniculate nucleus to the visual cortex. Rather, he argued that the neural substrate for higher order memorial functions, he often used the term 'intelligence', as in complex maze learning in rats, was widely distributed in the cerebral cortex. He did attempt to develop a theory of cortical field-like interference patterns as a mechanism to account for equipotentiality in perception and learning, but he found it wanting. 'He remarked that he had destroyed all theories of behavior, including his own' (Hebb 1959, p. 149). Lashley was perhaps the most formidable critical thinker of his time, successfully demolishing all major theories of brain-behavior extant at the time, from Pavlov to the Gestalt psychologists, to his own views.

Lashley's influence was such that the field concerned with brain substrates of learning and memory went into decline for a period of years. The studies by Lashley had critics. Walter Hunter, for example, noted that the more cortex destroyed, the more sensory areas are destroyed and the fewer sensory cues are available to the animal. Part of the problem is that maze learning is a very complex task; the notion that a simple localized engram or memory trace could serve to code the memory for a maze, seems unrealistic today. In fact, simple memories do appear to have engrams that are quite localized in the brain: conditioning of discrete responses like eyeblink in the cerebellum and conditioned fear in the amygdala. The brain structure most involved in spatial learning and memory is not the neocortex but rather the hippocampus, at least in rats. However, Lashley's view is still held today in the sense that some cognitive scientists argue that complex memories are widely distributed in the brain. The jury is still out on this matter, no distributed memories having been found.

Near the end of his career, looking over his lifetime of research on memory, Lashley (1950) concluded that: 'This series of experiments yielded a good bit of information about what and where the memory trace is not. It has discovered nothing directly of the real nature of the memory trace. I sometimes feel, in reviewing the evidence of the localization of the memory trace, that the necessary conclusion is that learning is just not possible. It is difficult to conceive of a mechanism that can satisfy the conditions set for it. Nevertheless, in spite of such evidence against it, learning sometimes does occur.' (pp. 477–8).

Lashley's positive contributions were extraordinary, including an insightful analysis of 'instinctive' behaviors, analysis of sexual behaviors, characterization of the patterns of thalamocortical projections, a rethinking of cortical cytoarchitectonics, etc. Lashley's first professional position was as instructor of psychology at the University of Minnesota (1917). Robert Yerkes was to become the chair of the psychology department there and arranged Lashley's hire. However, Yerkes became much involved in the organization of the National Research Council in Washington and did not move to Minnesota. Lashley left after one year, returning to Baltimore where he resumed his work with John Watson. Lashley returned to Minnesota in 1920, where he was promoted from instructor to full professor in three years. Lashley remained at Minnesota until 1926, when he moved to the University of Chicago.

In 1936 James B. Conant, then the new president of Harvard, appointed an ad hoc committee to find the best psychologist in the world. Lashley, then at the University of Chicago, was chosen and hired in 1937.

He became Director of the Yerkes Laboratory of Primate Biology in Florida but maintained his Chair at Harvard, traveling to Cambridge once each year to give his two week graduate seminar. The roster of eminent psychologists and neuroscientists who worked with Lashley is without parallel.

Lashley was an extraordinary teacher, albeit most of his teaching was individual. He was of the view that those who need to be taught can't learn and those who can learn don't need to be taught. Following is a description of his teaching at Minnesota by a former student: 'I saw Karl for the first time when I was taking a General Psychology course. An assembly lecture was given to all psychology classes once every two weeks, with different professors giving one lecture to about 200 students. Karl, tall, lean, sardonic held up a frog, made the muscles jump, grinned at us and talked informally in his rather precise voice. We learned more in 40 minutes from him than we had from the other eight professors and we all filed out of the hall wanting to know when we could take a course from this thin, splendid lecturer, with the pince-nez on a black string. We quickly learned that we couldn't. He hated teaching formally and was available for only a few graduate students.' (Beach 1961, p. 182).

Although Lashley is not widely recognized as one of the sources for the development of the current field of cognitive neuroscience, his extraordinary paper on the problem of serial order in behavior clearly anticipated this field (see Bruce 1994).

'This is the essential problem of serial order: the existence of generalized schemata of action which determine the sequence of specific acts, acts which in themselves or in their associations have no temporal valence' (Lashley 1951, p. 122).

Lashley never wrote directly about the nature of consciousness. According to his student Roger Sperry (personal communication) he was interested in the problem of consciousness but refused to write about it, considering it to be perhaps something of an epiphenomenon. He did, however, speculate about the nature of mind: 'Mind is a complex organization, held together by interaction processes and by time scales of memory, centered about the body image. It has no distinguishing features other than its organization… there is no logical or empirical reason for denying the possibility that the correlation (between mental and neural activities) may eventually show a complete identity of the two organizations' (Lashley 1958, p. 542).

Lashley received essentially all the honors available to a psychologist: President of the American Psychological Association; election to membership in the Society of Experimental Psychologists; British Psychological Association; Harvey Society; US National Academy of Sciences; Royal Society, London (Foreign Member); American Philosophical Society; American Academy of Arts and Sciences; granted the Howard Crosby Warren Medal by the Society of Experimental Psychologists for outstanding scientific contributions to psychology; the Daniel Girard Elliot Medal in Zoology by the National Academy of Sciences and the William Baly Medal in Physiology from the Royal College of Physicians. About the only honor he did not receive is the Nobel Prize, and many felt he should have done so. Sir Francis Walshe, a most distinguished neurologist, gave the following tribute: '… one of the most brilliant exponents of those problems that include psychology and physiology of the brain. He moved in this difficult territory with an experimental flair, an intellectual poise, and a competence he shared with few. His contributions to science were of a major order, and lesser men than he have been Nobel Prize men' (Beach 1961, p. 191).

Frank Beach (1961) offered a favored tribute: 'Eminent psychologist with no earned degree in psychology. Famous theorist who specialized in disproving theories, including his own. Inspiring teacher who described all teaching as useless' (Beach 1961, p. 163).

Karl Lashley died in Poitiers, France on August 7, 1958.

Latent Structure and Causal Variables

A 'latent variable' in a statistical model is unmeasured, although not necessarily unmeasurable. Many types of statistical models contain latent variables, including factor analytic models, item response models, some structural equation models, Rasch models, and finite mixture models. Section 1 describes latent structural equation models, which are representative examples of latent variable models. (Latent structural equation models include factor analytic models as a special case. See *Factor Analysis and Latent Structure: Overview*, and *Factor Analysis and Latent Structure, Confirmatory*.) Section 2 describes the purpose of introducing latent variables into a model. Section 3 describes methods of constructing latent variable models, and problems that arise with the introduction of latent variables. Section 4 is a brief summary, and Section 5 gives pointers to the literature.

1. Linear Structural Equation Models

There are several different methods of parameterizing structural equation models. The one described here is essentially the same as the one used in Bentler (1985). The variables in a linear structural equation model (SEM) can be divided into two sets, the 'error variables' or 'error terms,' and the substantive variables. The error terms are latent, and some of the substantive variables may be latent as well. A structural equation model consists of a set of structural equations, one for each substantive variable, and the distributions of the error terms; together these determine the joint distribution of the substantative variables. The structural equation for a substantive variable X_i is a linear equation with X_i on the left-hand side of the equation, and the direct causes of X_i plus an error term ε_i on the right-hand side of the equation. (In some representations, some substantive variables occur only on the right-hand side of structural equations and do not have a corresponding error variable.) A SEM contains information about both the joint probability distribution over the substantive variables, and about the causal relations between the substantive variables.

Figure 1 contains an example of a latent variable SEM that is a model of mathematical test scores discussed in Spirtes et al. (2001). The original data set came from Mardia et al. (1979). The test scores for 88 students in five subjects (Mechanics, Vector Algebra, Algebra, Analysis and Statistics) are the measured variables. The latent substantive variables are Algebra Skill, Vector Algebra Skill, and Real Analysis Skill. The distribution of the test scores is approximately normal. In Model M of Fig. 1, the free parameters are the linear coefficient a , b, c, and d, and the variances and means of the error terms ε_M, ε_V, ε_{Al}, ε_{An}, ε_S, δ_{Al}, δ_{An} and δ_V. (The coefficients in the structural equations for Mechanics, Algebra, and Statistics have been fixed at 1 to ensure identifiability, which is explained below.)

Structural equation models are a subset of graphical models (see *Graphical Models: Overview*). Each SEM is associated with a graph (known as a path diagram) that represents the causal structure of the model and the form of the linear equations, where there is a directed edge from X to Y ($X \rightarrow Y$) if the coefficient of X in the structural equation for Y is nonzero (i.e., X is a direct cause of Y), and there is a bi-directed edge between the error terms ε_X and ε_Y if and only if the covariance between the error terms is nonzero. In path diagrams, latent substantive variables are enclosed in ovals, and measured variables are enclosed in rectangles.

1.1 SEMs and Probability Distributions

Let θ be a set of parameter values for SEM N that contains just the parameter values for the linear coefficients that have not been fixed, and the covariances of the error terms (i.e., the means of the error terms are not included in θ). In a SEM N, θ determines a covariance matrix over the substantive variables which will be denoted by $\Sigma(\theta)$ (Bollen, 1989). A covariance matrix Σ is represented by a SEM N if there is a set of parameter values θ for the parameters in N such that $\Sigma(\theta) = \Sigma$. From the joint distribution over the variables, it is also possible to calculate conditional distributions, e.g., the conditional covariance matrix is just the partial covariance matrix if the error terms are normally distributed.

If there are no two distinct sets of parameter values θ and θ' for a model N such that $\Sigma(\theta) = \Sigma(\theta')$ then the model is *identified*. If a model is identified then there are a variety of methods for estimating the parameters, and a number of programs that perform the estimation (Bentler 1985, Jöreskog and Sörbom 1998). Also, if a model is identified, it is possible to evaluate it by testing it against a nested model using a χ^2 test with the appropriate degrees of freedom, or by assigning one of a variety of kinds of scores to the model (Bentler 1985, Jöreskog and Sörbom 1998).

In addition to implying a distribution over the substantive variables in the model, a SEM implies the total effect of each variable on each other variable (Bollen, 1989). A SEM is *acyclic* when its path diagram contains no directed path from a variable to itself. For acyclic SEMs, there is a simple rule for calculating the total effect of A on B. Suppose that the edge $X \rightarrow Y$ in the path diagram is labeled by the linear coefficient of Y in the structural equation for X (e.g., the edge from *Real Analysis Skill* to *Analysis* is labeled by b.) Then the total effect of A on B is the sum over all directed paths from A to B, of the product of the edge labels along each path (e.g., the total effect of *Algebra Skill* on *Real Analysis* is $b \times d$).

$$\textit{Mechanics} = 1 \times \textit{Vector Algebra Skill} + \varepsilon_M$$
$$\textit{Vector} = a \times \textit{Vector Algebra Skill} + \varepsilon_V$$
$$\textit{Algebra} = 1 \times \textit{Algebra Skill} + \varepsilon_{Al}$$
$$\textit{Analysis} = b \times \textit{Real Analysis Skill} + \varepsilon_{An}$$
$$\textit{Statistics} = 1 \times \textit{Real Analysis Skill} + \varepsilon_S$$
$$\textit{Vector Algebra Skill} = c \times \textit{Algebra Skill} + \delta_V$$
$$\textit{Real Analysis Skill} = d \times \textit{Algebra Skill} + \delta_{An}$$
$$\textit{Algebra Skill} = \delta_{Al}$$

Figure 1
Model M

The meaning of the total effect of A on B can be described as follows. In contrast to conditioning, a manipulated probability distribution is not a distribution in a subpopulation of an existing population, but is a distribution in a (possibly hypothetical) population formed by externally forcing a value upon a variable in the system. For example, among the subgroup of students who scored above 65 on the *Analysis* test (which was quite a high score), the mean *Statistics* score was above the mean for the whole class. On the other hand it is possible to manipulate the scores of all of the students by teaching them the answers to the questions on the *Analysis* test before they take it. In that case the mean *Statistics* score would remain the same for the whole class. So the mean *Statistics* score conditional on the *Analysis* score being above 65 would not equal the mean *Statistics* score, given that the score of the *Analysis* test was manipulated to be above 65. The total effect of A on B is just the change in B resulting from a manipulation that forces a unit change in A.

Of course, how an actual manipulation would affect other variables would depend upon how the system is manipulated. If the *Analysis* test score were changed by practice and studying to improve *Real Analysis Skill*, then one might expect that the *Statistics* test score might change as well. In that case, the manipulation has changed *Statistics*, but not through the mechanism of changing the *Analysis* score. The total effect of *Analysis* on *Statistics* is the resulting change in *Statistics* due to a kind of ideal manipulation of *Analysis*, in which the only variable in the system directly affected by the manipulation of *Analysis* is *Analysis* itself. Strotz and Wold (1960) suggested that an ideal manipulation of a variable X to a fixed value x could be represented by replacing the structural equation for X with a new equation $X = x$. The manipulated distribution is then just the distribution for the new structural equation model. Figure 2 shows the model that results from the manipulation of *Analysis*. The path diagram of the manipulated population is formed by breaking all of the edges into the manipulated variable.

Unlike a conditional distribution which is completely determined by the population joint distribution, a manipulated distribution depends upon both the population joint distribution and the true path diagram (or structural equations). In particular, two models with different path diagrams can represent the same set of joint probability distributions, but differ in

$$Mechanics = 1 \times Vector\ Algebra\ Skill + \varepsilon_M$$
$$Vector = a \times Vector\ Algebra\ Skill + \varepsilon_V$$
$$Algebra = 1 \times Algebra\ Skill + \varepsilon_{Al}$$
$$Analysis = 100$$
$$Statistics = 1 \times Real\ Analysis\ Skill + \varepsilon_S$$
$$Vector\ Algebra\ Skill = c \times Algebra\ Skill + \delta_V$$
$$Real\ Analysis\ Skill = d \times Algebra\ Skill + \delta_{An}$$
$$Algebra\ Skill = \delta_{Al}$$

Figure 2

Figure 3
Model M

their predictions of the total effect of manipulating a variable. Figure 3 shows an alternative to Model M of Fig. 1, where the edge between *Real Analysis Skill* and *Algebra Skill* has been reversed. In Model M, the total effect of *Algebra Skill* on *Real Analysis* is nonzero, while in Model M′, the total effect of *Algebra Skill* on *Real Analysis* is zero. However, both M and M′ represent the same set of distributions over the substantive variables. If Model M′ were considered to be compatible with background knowledge, the fact

Figure 4
SEMs without latent variables

that M′ passes a statistical test or is assigned a high score is not sufficient evidence that M′ can be used for calculating total effects; it is also important to know whether there are any other plausible models compatible with background knowledge (such as M) that would also pass a statistical test or receive a high score, and predict a different total effect.

2. *Introducing Latent Variables*

There are three main reasons for introducing latent variables into a model. The first is that there may be variables of interest that either were not measured, or cannot be measured without error. The second is that a latent variable model may be necessary in order to represent correctly both the probability distribution over the measured variables, and the total effects that the measured variables have on each other. The third is that a latent variable model may be a more parsimonious representation of the distribution over the observed variables than any model without latent variables.

2.1 *Measurement Error*

Whenever there are measurement errors, the actual measurements are observed, but the quantity of interest that is being measured is a latent variable. For example, in Fig. 1, *Algebra Skill*, *Real Analysis Skill*, and *Vector Algebra Skill* are measured indirectly by test scores. The test scores are not perfect measures of the corresponding latent quantities, but are also dependent on the error terms, i.e., there is measurement error in this model. Hence *Algebra Skill*, *Real Analysis Skill*, and *Vector Algebra Skill* are latent variables. If the goal is to estimate the total effect of *Algebra Skill* on *Statistics*, and the variance of ε_{Al} is not zero, then regressing *Statistics* on the measured variable *Algebra*, instead of on the latent variable *Algebra Skill*, gives a biased estimate of the total effect. However, under the assumption that the latent variable Model M is correct, estimations of the parameters of M can be used to calculate an unbiased estimate of the effect of *Algebra Skill* on *Statistics*.

2.2 *Representing Causal Relationships Between Variables*

The second main reason for introducing latent variables into a model is to represent correctly the total effects of the variables upon each other. Suppose that Model M is the correct representation of the causal relations between the variables in the path diagram. In that case, the total effect of *Analysis* on *Statistics* is zero, the total effect of *Statistics* on *Analysis* is zero, but *Analysis* and *Statistics* are correlated. The possible SEMs (with no correlated errors) when there are no latent variable and only two measured variables *Analysis* and *Statistics*, are shown in Fig. 4. None of these nonlatent variable models correctly represents both the correlation between *Analysis* and *Statistics*, and the zero total effects of each variable on the other. So in this case, a latent variable model is needed for the correct representation.

Figure 5
A parsimonious latent variable model

A bi-directed edge between the ε_{Al} and ε_S also correctly models the probability distribution and the total effects and does not explicitly introduce a latent variable that is a direct cause of both *Analysis* and *Statistics*; however, it does introduce such a latent variable implicitly. Assuming that a correlation between ε_{Al} and ε_S is produced either by ε_{Al} causing ε_S, ε_S causing ε_{Al}, or some third latent variable causing both of them, a bi-directed edge between ε_{Al} and ε_S also implies that there is some latent variable (possibly ε_{Al} or ε_S) that is a direct cause of both *Analysis* and *Statistics*.

2.3 *Parsimonious Models*

In some cases a latent variable model provides a more parsimonious (i.e., fewer parameters and higher degrees of freedom) representation of a distribution than any nonlatent variable model that represents the same distribution. Consider the model in Fig. 5, where one latent variable (e.g., *IQ*) causes many measured indicators (e.g., various intellectual tasks.) It follows from results in Spirtes et al. (2001) that the latent variable model is more parsimonious than any other SEM nonlatent variable model that represents the same distribution (assuming all of the parameters of the

nonlatent variable model are not constrained). Other things being equal, from a small sample size, the more parsimonious latent variable model could be used to provide a prediction of x_n (e.g., grades in first year in college) from $x_1,\ldots, x_{n-1}$ (e.g., scores on many different kinds of tests) that has a smaller mean squared error than any nonlatent variable model.

3. Construction of Latent Variable Models

Construction of SEMs often proceeds through a combination of the application of background knowledge with either nonautomated or automated searches through the space of alternatives. The searches look for a model or a set of models with high posterior probabilities (see *Bayesian Statistics*), or high scores, or that pass a statistical test. Even without latent variables, the problem is a difficult one because the space of models to be searched grows exponentially with the number of variables. The search space may be constrained by background knowledge, but it is still typically enormously large.

Allowing latent variables into models makes the problem of constructing good models even more difficult. This is because estimating, testing, scoring, and searching for latent variable SEMs is fundamentally more difficult than the corresponding operations for acyclic directed graph SEMs (i.e., SEMs without latent variables, cycles, or correlated errors). The space of possible acyclic directed graph SEMs is finite, but the space of latent variable models is infinite. An acyclic directed graph SEM is always identified. A SEM with latent variables may not be identified, and the only known algorithm for determining if it is identified has a running time that grows exponentially with the number of variables. It is always easy to calculate the number of degrees of freedom for an acyclic directed graph SEM, but it is often difficult to calculate the number of degrees of freedom for a SEM with latent variables (Geiger and Meek 1999).

While the estimation, testing, and scoring problems with latent variable models have been solved for special cases, and there are heuristic rules for other cases (Bollen 1989), practical general solutions are not available.

4. Conclusion

There are three main reasons for introducing latent variables into models: using latent variables can lead to a more parsimonious model that improves prediction; when there is measurement error the natural representation of the quantities of interest is as latent variables; in some cases the only correct representation of the joint distribution of the observed variables and of the total effects of variables on each other is with models that contain latent variables (or bi-directed edges which imply the existence of latent variables).

While latent variable models have some advantages over nonlatent variable models, construction of a latent variable model is often more difficult than construction of nonlatent variable models. It is generally more difficult to estimate, test, score, and search for latent variable models than for nonlatent variable models.

5. Pointers to Literature

Sewell Wright (1921) introduced a form of structural equation model called path models. Bollen (1989) provides an overview and a brief history of linear structural equation models with latent variables, and Bartholomew and Knott (1999) describe a wide variety of latent variable models. Rubin (1977) discusses manipulations, which are also discussed in Spirtes et al. (2001), Pearl (1995), and Pearl (2000). Heckerman et al. (1999) and Spirtes et al. (2001) discuss the causal interpretation of latent variable models and describe a variety of automated search techniques. Acyclic directed graph structural equation models are special cases of Bayesian networks and graphical models (see *Graphical Models: Overview*).

Latin American Studies: Economics

The economics of Latin America and the Caribbean is a study of structure, performance, and policy. It is also a study in ideas, since these play a central part in the story. By convention, Latin America is defined as the 19 republics that gained their independence from Portugal or Spain together with Haiti (a former French colony). The Caribbean includes all other islands from the Bahamas southwards together with the mainland countries of Belize and the Guyanas. Although separated by history and geography, the barriers between Latin America and the Caribbean are breaking down and the region will be considered as a whole in this article.

1. Economic Structure

The countries of Latin America and the Caribbean (LAC), from the largest to the smallest, have all been shaped by their common experience of European imperialism. Starting with the revolution in Haiti in 1791, the independence movement gathered pace and by the end of the 1820s all mainland countries except Belize and the Guyanas had become separate states. Decolonization in the Caribbean was much more complicated and, indeed, has never been completed. Several countries remain overseas territories of either Holland or the United Kingdom, others are an integral part of mainland France, while the United States retains responsibility for defense and foreign affairs in Puerto Rico and the US Virgin Islands.

All the available evidence suggests that at the time the United States secured its independence, the difference in living standards between North America and the rest of the hemisphere was modest (see Coatsworth and Taylor 1998, Chap. 1). During the nineteenth century the gap, as measured by Gross Domestic Product (GDP) per head, steadily widened and by the end of the century GDP per head in Latin America was only 12.5 percent of the comparable US figure (see Thorp 1998, p. 353). This differential did not increase in the twentieth century, but this is largely due to the rapid growth of Brazil—the largest country by far in LAC—from 1900 to 1980. If Brazil is excluded from the comparison, the gap has in fact widened over the last 100 years.

The LAC region has therefore lagged behind North America (the US and Canada) despite the fact that many countries have been independent for nearly 200 years. The region is (correctly) classified as 'less developed' by international agencies and a handful of countries (e.g., Haiti) are so poor that they are categorized as 'least developed.' Within each country poverty is widespread and the most recent estimates suggest that over one-third of households are poor; this amounts to some 200 million people (see CEPAL 1999, p. 36).

While poverty is generalized, there are also pockets of wealth for two separate reasons. First, a handful of countries in the Caribbean have enjoyed rapid economic growth and now have standards of living comparable to those in the less wealthy countries of the European Union. These include some (but not all) former British or Dutch colonies, such as the Bahamas and Aruba, the French *Départements d'Outre Mer*, and the territories linked to the United States. There are no rich Latin American states, but the regions around São Paulo in Brazil, Buenos Aires in Argentina, and Monterrey in Mexico have many of the characteristics of developed countries and a standard of living comparable to southern Italy or Portugal.

Second, income distribution is highly unequal in almost all LAC countries (the main exception is Cuba where socialist economics after 1958 narrowed wage differentials and eliminated private income from capital) and it is not uncommon for the top 10 percent to receive 40 to 50 percent of household income. This social group—nearly 20 million people in Brazil, for example—is almost a state within a state and is largely isolated from the rest of society through education, housing, transport, and international ties. The consumption pattern of this decile is similar to its counterpart in developed countries, while its propensity to save is much lower than the equivalent group in Asia. Thus, wealth—not just poverty—is an important component of the LAC region at the beginning of the twenty-first century.

Ideology has always played a central role in the LAC countries. Economists and policy-makers have by tradition identified explicitly with one or other school of economic thinking since the time of independence. There have been intense debates over the economic model considered most appropriate for each country; new ideas have also spread quickly, helped by an absence of cultural and linguistic barriers. The adoption of an apparently successful new policy in one country is invariably followed by a similar experiment in other parts of the region. It has been relatively rare for intellectuals to argue in favor of the uniqueness of their country's economy (as happens frequently in the United States and the United Kingdom). Part of the reason for this is the exposure (some would say vulnerability) of each country to similar external influences.

The role of ideas is illustrated by the enthusiasm with which LAC countries have adopted since the mid-1980s a new paradigm based on market-friendly policies and export-led growth. Based to some extent

on a false reading of the Asian miracle, the new paradigm also owes a great deal to the experience of Chile, widely recognized as the star performer in the LAC region from 1985–2000. Indeed, Chile could be said to have initiated many of the reformist policies—in social security, health, education, and environmental management—that are now being adopted not only in the rest of LAC, but also in many European countries.

2. *The Inward-looking Model*

The new paradigm has replaced the inward-looking model of development based on import-substituting industrialization (ISI), which became increasingly popular after the 1929 depression. The slump in commodity prices and the collapse in capital flows, after widespread bond defaults, hit LAC countries hard in the 1930s. The region's integration into the world economy based on the export of primary products and the import of manufactures, although it had contributed to the rapid rise in living standards in a few countries (notably Argentina), was criticized for its vulnerability to external shocks and its failure to take account of protectionism in developed countries.

The ISI model was slow to reach maturity. The political elite remained close to the pressure groups associated with export-led growth and policy reform in the 1930s was piecemeal rather than wholesale. World War II gave a strong boost to the region's incipient efforts at industrialization, spurred on by the absence of competing imports. In the late 1940s, and in some cases even later, tariffs and non-tariff barriers were set explicitly to favor the protection of industry. This process gathered pace and by the 1960s Latin American countries had some of the highest tariffs in the world coupled with a system of quotas and licenses that made the import of consumer goods almost impossible in the larger countries.

The shift to a fully-fledged model of import substitution after World War II owed much to the influence of the United Nations Economic Commission for Latin America and the Caribbean (usually known by its Spanish acronym, CEPAL) and especially its second Director (Raúl Prebisch). No doubt influenced by his experience at the Central Bank of Argentina in the 1930s, Prebisch was persuaded that specialization in primary products did not reflect Latin America's long-run dynamic comparative advantage. This idea, put forward by Prebisch for the first time in 1948, was also being developed independently by Hans Singer at the United Nations in New York and for that reason it has come to be known as the Prebisch-Singer Hypothesis (PSH).

The PSH claims—on both empirical and theoretical grounds—that there is a secular tendency for the price of primary product exports to fall in relation to the price of manufactured imports. Since LAC countries by tradition export primary products and import manufactures, this amounts to a claim that Latin America's Net Barter Terms of Trade (NBTT) are set to deteriorate over the long-term. The policy implication, according to the PSH, is to shift resources out of primary product exports and into manufacturing for the home market, i.e., ISI. Over time, both Prebisch and Singer recognized the need to adopt additional measures that would promote the export of manufactured goods and this was the rationale behind the move towards regional integration in LAC countries in the 1960s and 1970s.

The empirical basis for the PSH was always stronger than the theoretical. Prebisch in particular was forced to switch between different—not always consistent—theoretical explanations for the hypothesis, including the claim that different 'institutional arrangements' made it possible for factors of production to reap the benefits of technical change in the 'north' (i.e., developed countries) while forcing the 'south' to transfer the benefits to the rest of the world through lower prices for exports.

The PSH spawned a huge debate inside and outside the region and produced a series of theoretical innovations. One of these was dependency theory, popularized by Fernando Henrique Cardoso in the 1960s nearly three decades before he became President of Brazil (see Cardoso and Faletto 1979). Dependency theory went beyond the PSH by claiming that Latin America's links with the rest of the world had resulted in a distortion of development from which the region had derived only modest benefits. In its extreme form (the theory of unequal exchange), dependency theory provided a justification for almost any policy that promoted national autonomy through inward-looking development and discriminated against imports, multinational companies, and other forms of foreign investment.

The ISI model was not without its successes. The manufacturing sector grew rapidly and increased its share of GDP. Industrial activity became increasingly sophisticated, including capital goods production in the larger countries. Direct foreign investment by multinational companies was promoted by legislation offering tariff reductions on imported inputs and tax holidays on profits. Employment opportunities in the large industrial conurbations, where manufacturing was concentrated, encouraged rural–urban migration and by the end of the 1970s almost four out of five Latin Americans were living in cities.

However, the timing of the ISI model was most unfortunate. It reached its apogee just as the postwar secular boom in world trade was unfolding. With its anti-export bias and discrimination against imports, the model led to a rapid withdrawal of the LAC region from international trade. The share of world trade of the 20 Latin American republics, over 10 percent in 1950, had fallen to under five percent in 1980. The LAC region was in large part deprived of the stimulus

from foreign trade: so important for the transformation of much of South-East Asia after 1960.

Withdrawal from world trade did not reduce the region's vulnerability to external shocks, contrary to what had been claimed by the architects of the ISI model in CEPAL. ISI proved to be very import-intensive, while the profitability of the traditional export sector was undermined by overvalued exchange rates, tariffs on inputs, and (in many cases) taxes on exports. Manufactured goods, profitable to produce behind a tariff wall, were too high cost for the world market. Thus, many of the region's governments faced an uncomfortable balance of payments constraint that often required standby agreements with the International Monetary Fund (IMF).

The ISI model was also associated with high rates of inflation. Not all LAC countries suffered from high rates of inflation and some (smaller) countries used a nominal exchange rate anchor with great success to keep inflation at or below the US rate. However, all the larger countries (with the exception of Mexico) suffered from chronic inflation, which occasionally resulted in hyperinflation. This inflationary experience led to a heated debate between monetarists, associated with the IMF, and structuralists linked to CEPAL. The monetarists, with their emphasis on the budget deficit rather than structural weaknesses such as an alleged food supply bottleneck, had the better of the intellectual argument, but they were no more successful than their rivals in eliminating inflation.

The ideological conflict between monetarists and structuralists led to an abrupt change of policy in the 1970s in the southern cone (Argentina, Chile, Uruguay) after military coups in each country. The southern cone model was a conscious attempt to reverse the inward-looking policies in each country that had brought low growth, high inflation, and successive balance of payments crises. The most extreme version of this model was adopted in Chile under General Pinochet, where it was led by a group of technocrats dubbed the 'Chicago Boys' in honor of their association with the University of Chicago's Department of Economics where Milton Friedman had kept the flame of monetarism burning during the long period of Keynesian dominance.

The southern cone model was radical and excited much attention. Tariffs were lowered sharply, state-owned enterprises were privatized, and market forces were given free reign. However, the model was undermined by the application of inconsistent policies at the macroeconomic level and the excessive speed with which financial liberalization was adopted. This led to financial crises in all three countries at the beginning of the 1980s and the (temporary) abandonment of the model.

The exhaustion of the ISI model was apparent to many as early as the late 1960s. However, the move towards syndicated lending and flexible interest rates in the international capital market, coupled with the 1973/4 and 1978/9 oil crises, gave Latin American governments and state-owned enterprises access to commercial bank loans in almost unlimited quantities. This loosened the balance of payments constraint, but at the expense of a rapid build up of external public debt. The result was the Latin American debt crisis, triggered in August 1982 by a threatened Mexican default.

3. *The New Economic Model*

It took nearly 10 years to work out a solution to the debt crisis, culminating in many cases in the replacement of commercial bank loans with Brady bonds (named after Nicholas Brady, the US Treasury Secretary at the time) offering longer maturities and lower interest rates. By that time the ISI model was completely discredited and Latin America had begun its transition to the new paradigm. Labeled variously neo-orthodoxy, neo-liberalism, or the New Economic Model (NEM), the new paradigm revolved around a series of policies that were favored by international financial institutions. For that reason, it was also known as the Washington Consensus.

3.1 *Trade Liberalization*

The first step towards the new paradigm was trade liberalization. Those—numerous—countries that were not yet members of the General Agreement on Tariffs and Trade (replaced in 1995 by the World Trade Organization, WTO) applied to join and tariff and non-tariff barriers were reduced unilaterally. For those countries doing so in the mid-1980s (e.g., Mexico), this was a bold step, as the balance of payments had once again become a major constraint on growth. The consequence was a sharp depreciation of the nominal exchange rate, leading in some cases to an increase in inflation.

Trade liberalization was eventually adopted all over the LAC region; in many cases (e.g., Argentina and Brazil) it coincided with the renewal of net capital inflows at the start of the 1990s. This eased the adjustment problem of unilateral trade liberalization, but made it more difficult to promote nontraditional exports. One result was a revival of interest in regional integration schemes. These had been launched in the region in the 1960s as part of the ISI model, but had collapsed with the debt crisis. The new schemes were less concerned with the promotion of industry and more concerned with providing a platform for reducing costs of production and thereby gaining access to the world market for a broad range of goods and services. It was therefore named 'open regionalism' by CEPAL in order to distinguish it from the 'closed regionalism' of the 1960s and 1970s.

Regional integration has been a mixed success. The efforts to revive previously moribund schemes—the Caribbean Community (CARICOM), the Central American Common Market (CACM), and the Andean Pact (now known as the Andean Community)—have been disappointing with many of the old problems surfacing again. The new schemes—the North American Free Trade Agreement (NAFTA) and the *Mercado Común del Sur* (MERCOSUR)—have been much more promising. Mexico's membership of NAFTA has given economic policy a credibility it lacked before and has contributed to a rapid increase in exports to the US and Canada. MERCOSUR, made up of Argentina, Brazil, Paraguay, and Uruguay together with Bolivia and Chile as associate members, has not only brought about a major increase in intra-regional trade since its launch in 1991, but has also stimulated direct foreign investment and the overhaul of the region's antiquated infrastructure.

3.2 Fiscal Reform and Financial Liberalization

The increase in imports made possible by trade liberalization and the renewal of capital inflows forced governments to address seriously the problem of inflation stabilization. At the center of these efforts has been the reform of fiscal policy, including an overhaul of the tax system, a revision of spending plans, and the privatization of state-owned assets. This process is far from complete in most countries, but budget deficits have been reduced and monetary policy has become more responsible. Argentina, under the *Ley de Convertibilidad* in 1991, established an extreme version of the new orthodoxy, which succeeded in bringing the rate of inflation below that in the United States.

The renewal of capital inflows to the LAC region since 1990 has been a mixed blessing. While it has allowed countries to raise their investment rates above what would have otherwise been possible, it has been subject to great volatility and generated considerable uncertainty. It has also led in many cases to an appreciation of the real effective exchange rate (i.e., the nominal rate adjusted for inflation), undermining the efforts to promote nontraditional exports. Some countries, notably Chile, have tried to reduce the inflow of short-term capital through the system of taxation, but none have resorted to capital or foreign exchange controls. It is fair to say that LAC countries are still searching for policies that will maximize the benefits of capital inflows while minimizing the costs.

The other elements of the NEM have all involved microeconomic reforms: health, education, social security, and the labor market to name but a few. There has been a learning-by-doing process with Chile in many cases as the pioneer. The privatization of the pension system in Chile has been adapted, rather than copied, in many parts of the region while the reform of the health system in Colombia has been much admired. The reform program in general has benefited from the priority given to it by international funding agencies: notably the Inter-American Development Bank and the World Bank. Inevitably, political constraints have slowed down or distorted the process of reform in some countries, but the overall picture is impressive with very few sacred cows left untouched.

4. The Performance of the LAC Economies

It will be many years—perhaps decades—before the new paradigm can be judged satisfactorily. The rate of growth of GDP per head in the 1990s was certainly faster than in the 'lost decade' of the 1980s, but it has not yet returned to the rate achieved during the golden age of the ISI model in the 1950s and 1960s. A small number of countries appear to have achieved a structural break with their past, leading to a realistic prospect of sustainable long-run growth rates of GDP per head faster than those in the United States and other developed countries. Chile and Mexico are the most important cases, but some of the smaller countries—Costa Rica, for example—may also be included in this list.

The disappointing rate of growth of the LAC region in the first decade of the NEM is in part due to the sheer weight of Brazil. With over 30 percent of the population and over 35 percent of GDP, the performance of Brazil is crucial for any regional indicator. While Brazil has succeeded since the launch of the 1994 *Plano Real* in eliminating chronic inflation, it has been only partially able to implement other elements of the NEM. As a result, exports remain less than 10 percent of GDP and the country has yet to enjoy export-led growth. There is no doubting the commitment of successive administrations in Brazil to the need for reform, but the size of the country, the complexity of decision-making, and the depth of the inherited problems have made the application of the new model particularly difficult.

The new paradigm emphasizes the need for LAC countries to promote nontraditional exports. There has been some progress in this area. Mexico has rapidly expanded its exports of manufactures and oil now accounts for only a small proportion of the total. Chile has developed new markets for agro-industrial products and non-oil mineral exports are emerging in Argentina for the first time since the collapse of the Spanish empire. Even Cuba, a reluctant reformer denied access to the US market, has been able to diversify exports with tourism replacing sugar as the major source of foreign exchange. However, traditional primary products continue to account for almost half of all exports and a much higher proportion in the smaller countries. Prices remain volatile for these products and the reforms to world trade in agricultural products under the WTO have not been able to eliminate the many obstacles that exporters face.

Diversification of products has not been matched by diversification of markets. Despite the revival of regional integration, the United States is still the main market and absorbs almost 50 percent of all LAC exports (this proportion tends to fall as one goes south so that for MERCOSUR the European Union is the principal trade partner). The United States is also the leading source of direct foreign investment in most countries and provides much of the equity flows to the region. The bulk of new bond issues are placed in New York and the commercial bank links through financial centers in the US (now including Miami) are very strong. However, far from being resented, US economic influence is generally welcomed. This is partly because of the cultural changes associated with the NEM in the LAC region, but also because international economic relations have become more rule-based with arbitration (in the WTO, for example) occasionally favoring LAC countries. Furthermore, the proposal by President Bush in 1990 for a Free Trade Area of the Americas (FTAA) was taken up enthusiastically by the rest of the continent and negotiations involving all countries except Cuba were formally launched in 1998.

The NEM has yet to make much impact on equity in the LAC region. The proportion of households classified as poor has fallen in the 1990s, but it is still no lower than before the debt crisis. Income distribution remains stubbornly unequal; indeed, inequality has increased in many countries from 1990–2000 despite the fall in inflation (widely seen as a tax on the poor). This is partly due to the widening of wage differentials as firms compete for the skilled labor needed to meet the quality thresholds demanded by foreign buyers. It is also due to downsizing by companies in the private and public sector looking for cost reductions; this has swelled the numbers seeking work in the informal sector where wages and hours of work are flexible. The drop in household income has also forced many women and children to seek work, further adding to the supply of labor and putting downward pressure on unskilled or semi-skilled wage rates.

The launch of the NEM has coincided with a rise in concern for the impact of economic growth on the environment both inside and outside the region. Some of these concerns are focused on pollution in cities, where inadequate legislation and lax regulation have combined to produce environmental hazards and health problems. The northern border of Mexico, home to most of the country's *maquiladoras*, is a good example of this problem and this was one of the main reasons for the introduction of a side agreement in NAFTA obliging Mexico to enforce its environmental laws. However, the LAC region is also home to some of the most sensitive rural environments, notably the Amazon basin, where damage can have spillover effects on the whole planet. International agencies now insist on Environmental Impact Assessments before approving loans in these areas, but the region is still far from achieving a pattern of growth that does not involve some deterioration of the environment.

None of the LAC countries, with the possible exception of a handful of small island states in the Caribbean, has yet fulfilled the potential that has been promised for so long. On the world stage, the LAC region occupies an intermediate position between developed countries and the poorest countries of Asia and Africa. Narrowing the gap with the rich countries has proved both difficult and frustrating. Neither orthodoxy nor heterodoxy has yielded the benefits claimed by their proponents. There have been some successes, but no major LAC country has been able to sustain a strong performance over a long enough period to break out of the straitjacket of underdevelopment. Now that equity and the environment are part of any definition of development, the task has become even harder since these are areas where LAC countries are seriously deficient. The sense of frustration will therefore remain and the current consensus on economic management is therefore likely to prove fragile.

That consensus owes much to the belief among Latin American elites that globalization will remain the dominant external influence on the region and that the task of policymakers is to help the private and public sectors adapt to the new reality. The economic theory underpinning globalization is generally accepted among the elites (President Chavez in Venezuela and Fidel Castro in Cuba are the main exceptions), leaving little or no room for a specifically Latin American theory of development. This is partly a reaction to the failures of inward-looking development, but is also a reflection of the influence of higher education institutions in North America and Europe where so many of the Latin American elites have been trained. Among mass organizations, however, including many trade unions, political parties, and churches, there is much greater willingness to think in terms of a specific Latin American reality that demands a different approach. Thus, the balance of power between mass and elite organizations—a critical part of any democracy—is likely to have a strong influence in the future on the extent to which LAC countries reassert the specificity of their region.

Latin American Studies: Education

Major trends in Latin American education research reflect wider developments in academia, including its increased responsiveness to the concerns of powerful actors. The eclectic present includes echoes from once-dominant modernization and dependency perspectives on education's role in society. Substantive interests continue to encompass such matters as expansion, inequality, identity, quality, and efficiency. Despite this continuity, the past overarching political emphasis on education for social transformation has yielded ground to research that aspires to more modest improvements through education policy. In these newer approaches, while social science methods and theories are widely invoked, most work is written by and for those interested in advocacy and reform rather than in social scientific theory *per se*. Several tendencies have been evident in research on compulsory primary, noncompulsory secondary, and higher education. While these levels are usually discussed separately, their investigations have much in common.

1. Major Trends and Tendencies

Three key tendencies in research on Latin American education are internationalism, intra-national localism, and a humbled but hopeful sense of progress through the application of research to practice.

There has been a widening international exchange of scholarship among those concerned with the *commonality* of educational problems in Latin America and beyond. In the early 1970s, Ernesto Schiefelbein and his colleagues established the REDUC database (now available on the worldwide web), summarizing country-specific projects (Schiefelbein 1982). Numerous applications of research from one area of Latin America have become available to other nations, although there is doubt about how faithfully researchers read one another's work (see Briones 1993 for a critical review). The Inter-American Dialogue projects and the Program to Promote Educational Reform in Latin America (PREAL) illustrate how cosmopolitan educational research has become. So does the impact of women's movements in Latin America. United Nations conferences on population and women's status have led to evidence for gender as an independent dimension of educational stratification (Bourque and Conway 1993). The new internationalization has blurred boundaries between research concerns and methods across countries of Latin America and other areas of the world, where common questions are posed and pursued. Nor does Latin American research today serve only to illuminate problems in other lower- or middle-income countries. For example, both advocates and critics of vouchers in England and the USA read evaluations of Chilean school vouchers (see Gauri 1998). Alongside the *expansionist* tendency of internationalization, however, is a tendency to localism, at least at the compulsory education level. With the end of the Cold War and decline of socialist–capitalist debate, many commentators have noted a resurgence of intra-national tensions. In education research, this has been accompanied by the emergence of research questions that were long left on the back burner. Often shifting the focus from the national and legal to the postmodern construction of the group, this research has legitimated a new emphasis on grassroots change agents who, though formally without authority, use education to pursue their ends. One growing view (at least for the compulsory level) is that not only individuals but groups have rights, and this view has advanced research into the status of linguistic and other ethnic minorities (see Stavenhagen 1990 for examples in English).

The third research tendency holds that even the best social scientific research usually has limited utility for policy-makers. Some (Farrell 1995) argue that North American researchers offer little guidance for Latin America, given the intractability of Canadian and US problems, and the disagreement among academicians in wealthy countries about how to improve education. The new humility among researchers is exemplified by the work of Harbison and Hanushek (1992), in one of the most sustained and rigorous social science experiments with interventions to promote achievement, student flows, and access among the poor (in north-

eastern Brazil). These researchers concluded that they were unable to say definitively whether their interventions worked as intended, though their findings suggested some positive impact. Nonetheless, the tenacity of educational problems has not led researchers to abandon explorations of how schools and universities promote progress in students or society. Rather, one narrowed focus aims to improve students' learning, and as a consequence, to transform the societies in which they live. Nor does all contemporary reform research aspire only to incremental change or increased efficiency (though much does). Whether or not it is related to a neoliberal agenda, such research pays considerable attention to such matters as policies to promote private institutional growth, private funding of public institutions (including tuition), vouchers, and substantial decentralization of public-sector activity (on higher education, see Balán 1999, Levy 1986). One underlying impetus for policy-oriented research is the near consensus that educational performance is poor. While negativism is exaggerated in many comparisons, international tests do show Latin American countries trailing counterparts at similar levels of economic development.

2. *Theory and Practice in Social Science Research*

A major wave of study on Latin American education came with the modernization school that dominated social research in developing countries after World War II. Central to modernization theory was the idea that significant positive change was possible. This change could be promoted, indeed directed and accelerated, through research. Most of all, it could be accelerated through education itself. Education was often taken as the key to shaping development. Such beliefs encouraged inquiry into education in the developing world (Coleman 1965.) The main social process studied was expansion. To bring rapid and broad development, education needed to achieve greater coverage. 'More' generally meant 'better.' Primary schooling needed to achieve universal coverage and literacy; higher education needed to move from a few percent of the cohort group to 15 percent and more. Expansion at all levels was considered crucial to social mobility and decreased inequality. Another concern was education's effect on spreading modern outlooks and norms, building identity beyond the narrower social units of village and family. Education was to contribute both to the productivity of individual students and their societies' growth through increased skills and knowledge. Human capital and 'rates of return' were considered important, if crude, indicators of this growth. Politically, education was expected to promote democratic values, participation, tolerance, and national identity. A policy concern to expand schooling to the masses guided much research into the reasons why schooling was slow to take off, and how much culture and poverty impeded access. A structural–functionalist assumption in much of this work was that, properly constituted, schools and universities would naturally prepare members of society for enhanced production and creativity. However, neo-Marxists and conflict theorists emphasized the competing interests that underlay the expansion of schooling. By definition, they concluded, state actors could not play a disinterested role in providing schooling to their citizens. Dependency theory argued that the interests of the elites and governments were too often subjugated to the interests of powerful extranational forces. Some on both sides attacked extremes or stereotypes of the other side. But, over time, contributions in certain perspectives and findings from each side gained acceptance with the other.

Today, economists and sociologists continue to be concerned with the importance of schooling for national progress or national dependency. However, if the goal of education is not certification but learning, then growth needs to be accompanied by quality. One emergent agenda for researchers has been how to measure quality. Educational psychologists have developed several international applications of student achievement tests for this purpose, building on the experience of Chile, which has long included mandatory testing as a measure of school quality. Earlier optimism that 'alternatives' to the school could work to the interests of the poor gave way in the 1970s to the unenthusiastic understanding that formal education is here to stay. The question is whether the system can be reformed by the state (as in Colombia's 'New School') or perhaps devolved to the constituencies (as in Chile) in order to increase the participation of stakeholders. The 1980s have commonly been depicted as a 'lost decade' for educational as well as other socioeconomic progress. Some researchers portray declining quality as the outcome of decreased per pupil spending (as percentages of GDP) at both basic and higher education levels, lamenting such matters as larger class size, and lower teacher salaries and professionalism. In this context, social psychologists have explored the subjective meaning of education to children and families, while anthropologists have looked at the integrating function of these beliefs in fragmented societies (Ansión et al. 1997). Others put more emphasis on public policies that fail to promote professional and competitive incentives for improved performance; in higher education studies this includes the deleterious consequences for quality, equality, and efficiency of overly standardized subsidization, inadequate cost recovery, and insufficient functional and inter-institutional differentiation, autonomy, and accountability (Tyler et al. 1997, Castro and Levy 2000).

A related stream of research into reform investigates the distribution of publicly financed benefits across the levels of education. Some argue that massive public

universities direct resources away from primary schools, where the returns to education are greater, and where there is also greater participation by the poor. Debates over the means of higher education finance have borrowed fruitfully from a North American concern with the equality of opportunity. Will decentralized or devolved responsibilities for education tend to promote or to close off the opportunities for upward mobility? Will public universities become more accountable to business, elected government, and the general public (Brunner 1995)? How do efforts to decentralize or even privatize schools and universities expand 'voice' as well as 'exit' opportunities? Is there greater citizen participation and ownership in local or private institutions?

With regard to curricular reform, vocational training, and adult education, there is no possibility for the 'manpower planning' exercises seen in the early 1960s, when central government sought, and accepted, all responsibility for education. Some researchers may wish that an international market for skills and goods did not govern the educational decisions made by families and nations; but even these researchers now acknowledge the reality. Consequent questions include how foreign investment opens or closes educational possibilities, and whether technology transfer to Latin America creates in any predictable way a greater demand for science and math skills and expanded technological higher education and research. This does not mean that government planning is unconcerned with longer-term consequences. Today, how do planners and parents train children and young adults for a future that is impossible to foresee, much less to control? What types of public or private investments will prove most beneficial in the future?

3. *Quality and Modes of Production*

The balance of this article focuses on the relationship between the substantive concerns considered above and the modes through which they are explored: how well, by whom, and within what institutional structures?

The quantity of research on Latin American education has increased notably in recent decades. Most of that which reaches an international readership comes from the larger countries led by Brazil and Mexico. More US scholars contribute research on primary–secondary levels than on higher education in Latin America. Research quality has also improved and there is a substantial tier, as noted throughout this article, of solid work. At the same time, too much investigation documents problems that have already been established (such as inequality in access, treatment, or results in the educational system). Too much still relies on limited data, and too little offers fresh empirical analysis. Much is based on the work of colleagues in the same unit or school of thought. Such weaknesses in educational research are hardly confined to Latin America. Further improvement could come where leading work would simultaneously consider the basic and higher education levels, where subject matter or policy reform is overlapping (as in social stratification or pressures for evaluation and accountability).

There is an increasing tendency for consultancy, contract research, and project evaluation, financed directly or indirectly through international agencies, led by the Inter-American Bank and the World Bank, as well as UNESCO. The results produced under these arrangements contrast with literature that concentrates on social critique. There is less often an assumption that central states must finance education at every level or for every individual. The efficacy of a strong state role is considered an empirical question rather than an article of faith; there is a suspicion that states are naturally poor agents of progress. National scholars sometimes react to perceived dictamens in policy or research agendas by denying the general applicability of positivism to the needs of the region, seeing structural adjustment as a dogma aimed at weakening the state, and seeing 'North American' approaches as neo-imperialism.

Today, however, most striking is how far these 'alien' assumptions have penetrated the curriculum and the national funding agencies. Even severe critics of penetration recognize its local appeal and institutionalization, sometimes even its pertinence, no longer associating empiricism with imperialism. For example, *Imperialism and Education in Latin America*, the 1980 classic by Argentine writer Adriana Puiggrós, appeared translated and revised in 1999 as *Neoliberalism and Education in the Americas*, with a postscript not attributing the neoliberal movement to the interests of any particular nation.

Sociological perspectives continue to remain prominent in Latin American education research, but economics is ascendant, given the current concern with both finance and feasible change within the system more than with social transformation. Although there are many policy pieces by practitioners, political science *per se* remains limited (despite the fact that Latin American research seldom assumes that education is apolitical). Exceptions include the spurt of work on university student activism in the 1960s, on the state later on, or on the similarities and differences in educational policy when regimes change, as in Chile, Cuba, and Nicaragua. Historical works have treated such matters as the development of national systems and universities, but much more common are historical sketches within works primarily about the present, and history has often been marginalized in today's preoccupation with policy study. (On disciplinary mixes and other matters of research production, see Myers 1981.)

For many, the policy preoccupation also comes from the conviction that analysis can lead to im-

provement. This obviously contrasts to most dependency, neo-Marxist, and other grand theory in that it concentrates not on blaming broad contextual realities but on education factors that can be manipulated. Yet it also differs from modernization's earlier optimism in that the current 'can-do' approach concentrates on feasible change within an accepted (if lamented) reality of the prevailing social structure and political balance of power nationally and internationally. The poor will always be with us, girls will long continue disadvantaged, but progress can nonetheless be made if researchers improve financial efficiency, incentives, teacher qualifications, curriculum, textbook distribution, and the like. These policy trends substantiate this article's theme of internationalization. Educational agendas (for policy and research both) come largely from abroad. Much of Latin Americans' best work becomes like others' best work. Along with the influence of funding for educational research is the influence of advanced academic training in US graduate schools, as well as increased collaboration between Latin American and US scholars. Moreover, as in the wider worlds of both policy and scholarship, internationalization has been led by the USA at the higher education level, notwithstanding growing regional contact, and numerous accords with European-based NGOs and universities. Although there is still little empirical scholarship that directly compares Latin American education with that of other countries, increasingly Latin American cases enter broad international volumes and conferences (Kempner et al. 1998).

The policy and international emphases have meant major changes in who does what types of educational research within Latin America. It also could be interpreted as part of the general decline of Latin America's left. Although a large body of work attacks international neo-liberal research-policy trends, this work appears defensive because neo-liberal projects have achieved greater currency, and funding, for their preparation and dissemination. Criticisms notwithstanding, there is a new age of interaction and even integration with US scholarship in orientation, norms, methods, and substance. Much of the internationally recognized and contract work is done in special research centers (Levy 1996). This contrasts to work done where the greatest number of the region's professors remain: in the administrative faculties of universities, which try to combine professional training and teaching with research. In research centers, by contrast, investigators need do little teaching and are buffered from the mass student movements, labor conflicts, and political ferment common in public university faculties. Centers have usually been receptive to international ideas, money, and networks. This is true especially of freestanding private centers, but also of certain public centers or government agencies, as well as many centers inside universities. Some longstanding centers are devoted to education, whereas other work on education comes from centers more widely engaged in social analysis; respective and prominent Chilean examples have included CIDE (Center for Educational Research and Development) and FLACSO (Latin American Faculty of Social Science). Downplaying basic and theoretical research in favor of projects aimed at policy, centers often combine research and action on education. Government funding, including that from research councils, tends to be allocated in ways supportive of internationalized orientations. The combination of governmental and international funding for educational research and graduate study abroad is hardly counterbalanced by research spending in university faculties or through teachers unions. In sum, the centers illustrate many of the tendencies identified in this article about both the substance and the modes of production of educational research in Latin America.

Several patterns can be identified in the expanding studies of Latin American education. These include internationalism, intra-national localism, and a reconceptualization of the relationship of scholarship to practice. The patterns reflect wider tendencies in social science research, in both substantive and methodological focuses. Notwithstanding considerable appropriate debate about these focuses, and about research purposes and quality, a fair overall assessment is that the field offers more abundant, sophisticated, and practical findings today than in the past.

Latin American Studies: Gender

Scholarship on women and gender in Latin America contributes much to global gender studies. It has long been informed by attention to social structures, world systems, and the hierarchy of economic class privilege within countries. Scholar activists have strategically moved their work into the Women in Development (WID) and Gender and Development (GAD) areas. WID and GAD work has also informed and enriched Latin American gender studies. The current challenge to Latin American gender studies comes from border analysis: both borders constructed around nation-states and metaphorical borders of cultural and linguistic lines. As such, borders challenge the very scope of 'area' in Latin America. Does the Latin American border end at the northern Mexican border, the old Mexican border before the 1848 Treaty of Guadalupe in which Mexico lost half its land to the USA, or as far as the Mexican diaspora to the north?

This essay incorporates studies from the traditional Latin American region: South America (including the Southern Cone of Argentina, Chile, and Uruguay and the largely Portuguese-speaking Brazil; Central America and Mexico; and the south-to-north diasporas in the Americas). The area is largely a Spanish-speaking one, which overlays indigenous populations who undergo assimilation into the dominant language regimes. The Caribbean English-, Creole-, Dutch- and French-speaking populations fall outside the geographic space addressed in this essay.

1. *Gender: Grounded in Area Studies Approaches*

The study of women and gender in Latin America is informed by the history of the region, its nation-states, especially their centralized (often Spanish) colonial experience and incorporation into the capitalist world system. Gender scholars are firmly grounded in analyses of countries with firmly defined class systems and economic 'dependency' on the global economy (Safa 1976, Latin American Perspectives 1977). Compared to other world regions, the study of women and gender has been more fully accepted and legitimized in Latin American area studies, thus transforming regional studies as a whole (Staudt and Weaver 1997, p. 84). Why has this happened? Gender scholars acquired legitimacy from their firm grounding in the social structural, class, and dependency/global perspectives. Besides that, though, leadership of the Latin American Studies Association has been in women's hands not just once, but several times, including the hands of strong women/gender scholars such as Carmen Diana Deere, Helen Safa, and Jane Jaquette.

2. *Global and Social Structural Perspectives*

Beginning with the global and connecting it with the national and local, Latin Americanists have analyzed public policy agendas imposed by foreign investment, dependency on outside capital, and specific state downsizing strategies from international banks in the name of 'structural adjustment' (Léon 1982, Deere and Léon 1987, Benería and Feldmann 1992, Bose and Acosta-Belén 1995). Gender scholars have influenced WID and GAD with respect to the need to contextualize analysis in the global economic context.

This structural approach, in both Latin American studies and women/gender scholarship, created an early scholarly climate of attention to the social construction of male and female, the power relations between men and women, and the complex intersection of economic class. Thus, we might say 'gender analysis' was pioneered in Latin America, even before this once uncommon term became the millennial codeword for what was once known as women's studies. Latin Americanists analyzed the social construction of men and women, even though they, too, titled their studies with the word 'women.' With the strength of social constructionism, an essentialist or biologically determinist approach never took hold among Latin Americanists. The analytic breakthroughs and predominance of social constructionism

preceded those of other world regions, including the USA (often regarded as a region unto itself).

Despite an overwhelming scholarly approach to the social construction of male and female, popular widespread perceptions until recently projected a deep and essential difference between men and women. Such internal cultural constructions are at odds with scholarly interpretations and worthy of study in themselves. These male–female differences were viewed as both temperamental and behavioral, and the expectation of difference deeply permeated the economic, political, and religious institutions imposed upon people in their everyday lives. The counterpart to the (now contested) *machismo*, or ideology of virulent men, is *marianismo*, a parallel ideology that idealizes women in terms of saintly mothers who sacrifice themselves for family. This Madonna image offers a dichotomous polar-opposite outcast female ('whore'), unworthy of protection/reverence. Perceptions, inaccurate or blurred as they may be, are used to justify interpersonal violence against women in homes and on streets. The *marianismo* writings (Stephens 1973) gave rise to insightful analyses of women in politics, from formal governance to everyday politics that crossed the public–private borders which historically defined female as apolitical. *Marianismo* also aids in understanding interpersonal relations within households.

Supermadre is the title of a pathbreaking book that draws on interviews with Peruvian and Chilean women in government (Chaney 1979). These 'super mothers' worked in institutions with deeply differentiated expectations for female and male civil servants and politicians. Idealized images of women as uncorrupted, honest, caretakers of the household allowance and the public purse led to some interesting female niches in government: accounting, personnel, and budgets. Deep prejudice persisted even into these *marianismo*-legitimized roles, as women described their work with the saying: whereas a man may be made of silver, a woman must be made of gold (Chaney 1979, p. 110).

3. *Political Structural Perspectives*

As Latin American countries moved toward revolution or military regimes, so also would analyses move to women's actions therein. Under military dictatorships in many Central American and Southern Cone countries, women took the risk of moving politically in the streets with the motherhood mantle as (semi-) protective cover. Mothers of disappeared children and husbands circled central city squares with pictures of their loved ones hanging around their necks. *Las Madres de la Plaza de Mayo*, the mothers in Buenos Aires, Argentina, symbolized to the country, region, and world, their grief, anguish, and willingness to seek accountability on life and death from dictatorships.

'[T]he concept of politics expanded to include the daily universe that had been invaded by the dictatorship. The dividing line between the public and the private became increasingly hazy as the repressive policies of the regime affected domestic unity and as its economic policies pushed women into the workforce' (Schmukler et al. 1998, p. 628).

In Argentina, Chile, and elsewhere, scholars analyzed 'social motherhood' and the ways it extended women's activism, participatory process, and public space itself. But women also assumed militant, revolutionary actions in civil wars throughout the hemisphere and in revolutions that triumphed. Many scholars have analyzed women's involvement in the Cuban and Nicaraguan revolutions especially, as well as the consequences of revolution for women and gender equality. The social imposition of motherhood on women, coupled with economic desperation for the majority of the population, usually casts shadows on women's ability to gain more power in and from formal politics and policies.

Under the Sandinista regime in Nicaragua, a revolution in which women participated in critical-mass numbers, the social differentiation of male and female continued to diminish women's ability to gain from real gender equality. Economic crisis also challenged the regime's ability to respond to people's wage and employment demands.

Women's everyday responsibilities for children, plus their significant numbers as heads of households, lead to social activism to push for 'practical' versus 'strategic' gender interests (Molyneux 1985). If and when women gained successes, their practical needs were met, but the social and legal differentiators that institutionalized male privilege remained in place. Molyneux's language would soon be popularized and spread globally with the prolific WID and GAD scholarly-activist writings.

Cuban women also confronted the deep hierarchy of gender privilege and hierarchy after the 1959 revolution. Women never gained hold in formal power exercised from the top; however, more than half of adult women belonged to the *Federacíon de Mujeres Cubanas* by 1970, and official policy legitimized 'strategic' gender claims. Cuba's Family Code of 1975, its pioneering feature on interpersonal relations that became famous worldwide, called for equality within marriage, establishing equal responsibility between husbands and wives for household work and childcare. Although the policy is not enforced (as governments generally retreat from policies that affect 'private' space), judges incorporate the Family Code language in civil marriage ceremonies (Hernández and Esperanza 1998, pp. 623–4).

4. *Toward Democracies?*

Despite attention to revolutions, 'transition' was the norm, with the common claim of transition to democracy. By democracy, claimants meant civilian rule, with people's participation in elections and civil

organizations, known as nongovernmental organizations (NGOs). Would women be part of this transition or its eventual consolidation, and might their participation create a new way of doing politics (*una nueva manera de hacer política*) or more gender-equal policy outcomes? These are the questions that inform edited collections on Latin America (Jaquette 1994, Jelin 1987) and comparative or global collections on movements and political institutions with chapters on Latin American countries (Nelson and Chowdhury 1994, Basu 1995). Statistical profiles paint a grim picture of gender equality in the region (Valdes and Gomariz 1993, UNDP 1990–2000), but women fare better in education and health indicators in Latin America than their counterparts in absolute and gender relative terms in Asia and Africa.

While women are gaining ground in the formal political process, their engagement with the state offers long-term challenges for achieving gender equality. One collection, with a section on *invadiendo las instituciones políticas* (invading political institutions) makes it clear that women must address the details of institutional mechanisms if they are to gain political space and use it for gender-equal outcomes (Tarrés 1998). Among institutions are the multiple political parties themselves, their policy platforms, and the electoral lists that privilege names at the top of lists in the common Latin American Proportional Representation electoral system. 'Women, Vote for Yourselves!' was a Peruvian feminist campaign, but the United Left listed women at the bottom (Vargas 1986). Yet women in Argentina have gained nearly a third of legislative seats (a level only reached in Western Europe) since early 1990s laws that required party quotas for women (Jones 1996). In Mexico, women's political work in multiple parties and civil organizations has begun to produce gender-equality gains (Rodríguez 1998).

Women's political advocacy work inside government institutions would also get attention. In Brazil, shortlived but influential women's commissions would engage women's NGOs and influence government budgets (Alvarez 1997). Their niche in the Chilean state did not go so far (Waylen 1997, Goetz 1998). Again, the Latin American experience would consolidate and inform knowledge about women's bureaus and gender in bureaucracy worldwide, predating the Australian-labeled 'femocrat' writing.

Once-autonomous radical feminist organizations struggle over the compromises they make with liberal feminist proposals that engage the still male-dominant legislatures (Staudt 1998, pp. 19–31). In Mexico, new policies to reduce interpersonal violence and sexual assault against women reflect these compromises (Lamas et al. 1995); the lingering shroud of death hovers over large Mexican cities like Juárez with its 200-women/girl murder record since 1993 (Benitez et al. 1999). Some women are reluctant to compromise, as with selected mothers' groups and their moral stance.

5. *Everyday Lives*

Yet does increased female space in political institutions, with occupants from economically privileged backgrounds on the whole, have consequence for working class women and those earning little or nothing in informal economies? And what about the women working the *doble jornada*, or double day of unpaid work inside the home and paid work outside the home? Although globalization and structural adjustment may have heightened women's work burdens (Moser 1997), even women less enveloped in the national political structure and global capitalism experience subordination in the indigenous gender hierarchy (Bourque and Warren 1981). Gender hierarchy is complex, with its double decked 'modern' subordination overlaying internal subordination. Cultural constructions of gender difference offer rationales for hierarchical continuity.

In the real economic options of the free-trade regimes of late-twentieth century Latin America, the majority of women work in export-processing factories (Fernández-Kelley 1983), home-based contracting (Benería and Roldan 1987), domestic service (Chaney and García Castro 1989), and informal labor (Berger and Buvinic 1989, Rakowski 1994, Staudt 1998a). Women's struggle to maintain economic livelihoods is constrained in a savage capitalism that provides little social support from political regimes, themselves constrained in the global economic contexts.

Women's efforts to reform or transform interpersonal inequality and violence have met only modest successes, as noted above. From multiple-country anti-violence measures to the Cuban Family Law, the cultural construction of gender difference, notably unequal difference, helps to sustain female subordination.

The borders of women's realities are moving northward, challenging the traditional northern border of Latin America: Mexico. These borders move just as the supposed 'free trade' sheds commercial borders.

6. *Borders: Moving North*

Border studies have been in place for a quarter century, but confined to the narrow zone of space around national territorial lines, particularly the USA and Mexico. Borders as metaphors for cultural lines and linguistic code switching (mixing two or more languages, especially Spanish and English) emerged in feminist literary work (Anzaldúa 1987, García 1992). Literary work has always expanded the intellectual borders of political economy to include the cultural and interpersonal relations of everyday life.

Economic crises in Latin America have prompted many to seek employment *en el norte*, to the north in the USA. With the US Bracero Program and the

amnesty provisions of the 1986 immigration law reforms, people of Mexico have become the largest category of 'foreign' residents and naturalized citizens. This Latin diaspora into the USA is redefining the boundaries of area studies in the western hemisphere. Informal economies, so common in Mexico and countries to the south, are alive and well on the US side of the border (Staudt 1998a). Perhaps informal economies flourish elsewhere, though the scholarly questions of Latin Americanists rarely emerged in US studies.

From international and comparative studies, scholars have coined terms like transnational, globalization, deterritorial, and debordering to understand people's movements that carry cultural, linguistic, and identity baggage in that migration (Staudt and Spener 1998). Through migration, both men and women bring experiences and expectations that are not gender neutral (Pessar and Grasmuck 1991). Latin Americanists should confront and engage the challenge to move from national-centered analyses (albeit in global contexts) to transnational attention to border spaces, regionalism, migration, and movements.

7. Conclusions

Latin American gender studies, which inform the study of women/gender worldwide, draw on the structural approach and particulars of this area. Gender is situated in the relations between women and men of different classes in the global capitalist economy. Yet gender studies necessarily draw on internal cultural constructions of everyday male–female relations that range from reverence to brutal violence, reflecting the *marianismo–machismo* constructs. Women's activism brings these agendas into political struggles toward policy change and democratic transition.

Latin American Studies: Geography

Geographers have made major contributions to the study of urban and regional development, environmental resource management, and cultural patterning in Latin America. Geographic research on Latin America during the 1970–2000 period was dynamic and innovative, but often marked by clear continuities with earlier research and indeed has shown a renewed interest in the collection of data (including the reading and interpretation of texts) from earlier periods. This is consistent with geography's nature as a discipline that combines methodologies from the sciences, social sciences, engineering, and the humanities, and that relies on both historical and contemporary data for its analyses, synthesis, and relevance to contemporary problems.

Before 1970, geography had established several strong traditions of research in Latin America, often focused on productive and charismatic scholars. Carl Sauer at Berkeley had trained numerous students in the 'Berkeley School,' emphasizing field work, the study of the cultural landscape, attention to long-term processes and native Americans, and a critique of modernization in cultural and ecological terms. Karl Troll in Germany had focused on mountain geoecology of the Andes, Preston James at Syracuse (among others) had developed regional geography, and Raymond Crist in Florida had focused on migration issues. There were many national schools of geography in Latin America, focused around such figures as Javier Pulgar Vidal in Peru, and Horacio De Frieri and Francisco de Aparacio in Argentina, for example.

The remainder of this article will consider more recent developments in regional geography and planning, political geography and ethnogeography, other varieties of human geography including human–environment relations, physical geography, and mapping. It will conclude with a discussion of recent institutionalization of geography within Latin America.

1. *Regional Geography, Planning, and Development*

By 1970, regional geography and planning were well represented in national geographic institutes in Latin America (often associated with the military), and were also stressed in the work of Latin Americanist regional geographers in the United States, Canada, the United Kingdom, and France. Much of this traditional regional geography was qualitative and oriented toward the needs of geographic education and journalism, as well as the needs of national administration and foreign policy.

The 'quantitative revolution' in Anglo–American geography between 1965 and 1978 absorbed theories and methods from other social sciences, and resulted in new approaches to the comparative study of migration, regional inequalities, innovation diffusion, urbanization, and regional development in Latin America. This emphasis resulted in work exploring the spatial patterns and processes of economic modernization. Large-scale projects such as the Trans-Amazon highway and the Ciudad Guyana growth pole created a sense of the importance of regional planning involving geographic analysis. A key Latin American center for development research was Santiago, Chile, where the United Nations had a think tank at

CEPAL/ILPES. Scholars included John Friedmann, who had studied geography as well as planning at the University of Chicago, and who published important works on development planning in Venezuela and Chile. Peter Odell (at the London School of Economics), Walter Stöhr, and Poul Ove Pedersen were other significant geographers working and publishing in this context. Much of the funding for geographic research on these themes came from the United Nations, Ford and Rockefeller Foundations, and United States programs such as the Alliance for Progress.

The 1973 Pinochet coup acted to disperse the Santiago group, while the 1973 Yom Kippur war in the Middle East led to the energy crisis and a period of economic problems in Latin America. Together, these events acted to slow and, at least temporarily, demoralize the integrated geographic study of development as modernization in Latin America. Key intellectual figures in Anglo-American Latin Americanist development geography either moved to the political left (Friedmann), to other regions of the world, or to other areas of geography, including urban studies. However Odell supervised British Latin Americanist dissertations by Alan Gilbert, David Slater, and Allen Lavell, all of whom were to continue to work on development issues. David Preston, Arthur Morris, Peter Ward, and Ray Bromley and Rosemary Bromley continued the British tradition of development geography into the 1980s and 1990s, while Christoph Stadel, Bromley and Ward moved to the United States, helping to support interest in the geography of development in that country. Ohio geographer, Lawrence Brown, and his students, among others, also supported the study of contemporary development from bases in the United States. All of these geographers have tended to emphasize the role of social factors and globalization in conditioning such spatial processes as migration, transportation development, and innovation diffusion.

Although over time the 'big project' focus of Latin American development came to be discredited intellectually and economically, somewhat less affordable, major government agencies such as ONERN in Peru and SIP in Mexico continued to dedicate funds to the production of planning documents, maps, and regional surveys for a variety of purposes. These provided employment for cartographers, remote sensers, and a variety of consultants, many of them geographers. French geographers such as Jean-Paul Deler not only helped support international research and development projects for mapping, resource analysis, and urban and regional planning, but also produced important original research on a variety of topics, including all branches of physical geography, agricultural and resource geography, and distinctive studies of the 'management of space' in various countries, regions, and time periods. Generous French support for geographic training (with funding from ORSTOM, now IRD—Institut de Recherche pour le Développement) has led to a growing base of French-trained geographers in many Latin American countries.

2. *Marxism, Political Ecology, and Ethnogeography*
